PREFACE

International Conference on Advanced Technology & Sciences (ICAT'16) has been organized in Konya, Turkey on 01-03 September, 2016.

The aim of International Conference on Advanced Technology & Sciences is to provide a platform for researchers and academics as well as practicing professionals from all over the world, to present their research and professional development activities in Computer, Electric and Electronics, Energy and Mechatronics. This conference provides opportunities for the different areas delegates to exchange new ideas and application experiences face to face, to establish business or research relations and to find global partners for future collaboration. We hope that the conference results constituted significant contribution to the knowledge in these up to date scientific fields.

All full paper submissions have been double blind and peer reviewed and evaluated based on originality, technical and/or research content/depth, correctness, relevance to conference, contributions, and readability. Selected papers presented in the conference that match with the topics of the journals will be published in the following journals:

- International Journal of Intelligent Systems and Applications in Engineering (IJISAE)
- International Journal of Applied Mathematics, Electronics and Computers (IJAMEC)
- International Journal of Energy Applications and technology (IJEAT)
- International Journal of Automotive Engineering and Technologies (IJAET)

At this conference, there are 700 paper submissions from 107 different universities. Each paper proposal was evaluated by two reviewers and 416 of these were accepted for presentation. And finally, 366 papers will be presented at our conference.

We are sure that, ICAT will be the flagship conference for researchers, students, and professionals in the areas of Electrical and Computer Engineering, Biomedical Engineering, Energy and Manufacturing Engineering and their applications from Turkey and around the world to disseminate their research advancements and discoveries, to network and exchange ideas in order to strengthen existing partnerships and foster new collaborations.

In particular we would like to thank Prof. Dr. Mustafa SAHIN, Rector of Selcuk University; Advanced Technology and Sciences, Academic Publisher; International Journal of Intelligent Systems and Applications in Engineering (IJISAE); International Journal of Applied Mathematics, Electronics and Computers (IJAMEC); Konya Metropolitan Municipality, Province of Konya Culture and Tourism Directorate, Konya Chamber of Industry, Konya Chamber of Commerce, Firdevs Patent and AYBIL Organization. They have made a crucial contribution towards the success of this conference. Our thanks also go to the colleagues in our conference office.

Looking forward to see you in next ICAT.

Ismail SARITAS - Omer Faruk BAY
Kemal TUTUNCU

PROGRAMME COMMITTEES

HONORARY CHAIR:
Mustafa Sahin, Turkey

GENERAL CHAIR:
Ismail Saritas, Turkey

CO-CHAIR:
Omer Faruk Bay, Turkey
Necmettin Tarakcioglu, Turkey
I Unal Sert, Turkey
Murat Ciniviz, Turkey
Silyan Sibinov Arsov, Bulgaria
Kemal Tutuncu, Turkey

PUBLICATION CHAIR:
Murat Koklu, Turkey
Mehmet Akif Sahman, Turkey
Ali Yasar, Turkey
Mustafa Buber, Turkey

INTERNATIONAL ADVISORY BOARD

A Engin Ozcelik, Turkey  Biagio Lenzitti, Hungary

An Efficient Resource Management in Cloud Computing

Bashir Yusuf Bichi*, TuncayErcan†, AnasMu’azuKademi‡
‡Yasar University, Department of Computer Engineering
Izmir, Turkey

Abstract— A cloud computing is gaining more recognition to the public, request for services to a given task within the virtual environment of the cloud also increases. This paper proposed a max-min algorithm like technique with the aim of developing a new framework that tends to balance the load that may be experienced due to the high demand of resources by a set of task within the virtual environment of the cloud computing ecosystem.

Keywords— Load balancing, Max-min algorithm, Makespan, Min-min algorithm, Task Scheduling, Resource Allocation.

I. INTRODUCTION

The fast development in the area of computing gives users of computer system the opportunity to have access as well as exploit the vast resources that are contained within the system. Cloud Computing is seen as a new technology that adopt the aspect of distributed computing and internet. The concept of cloud is to allow a client or a customer to have access to computing resources through the use of web services in a more efficient manner. Resources in the field of information and communication technology are more or less the fundamental elements that include some part of computer systems, computer networks, software application and so on. Managing these resources involve controlling and limiting access to the pool of resources that are been shared. This brings the concept of an agreement between the resource services providers and the clients otherwise known as Service Level Agreement (SLA). The idea behind the SLA is to restrict access to a given resources.

Cloud resource management may involve some policies such as admission control, Quality of Service (QoS) which involves specification from SLA. Other policy which is the main topic regarding this research is Load Balancing which involves balancing the work load evenly among the cloud servers. The cloud services are provided to customers through the use of virtual hardware, the services provided to the client such as IaaS, SaaS, and PaaS as shown in Fig. 1 can be scale up or down depending on the client’s level of usage and the SLA adopted.

Revolutionary increase of users and demand for various services parallel with the need for efficient resources usage reveal that load balancing should be done correctly and efficiently. The aimed of which is to optimize resources utilization, maximize throughput, minimize response time, and avoiding overload. Many load balancing algorithms have been designed so far, and the need for much more efficient algorithm that, with other things, also fairly allocate the loads across the system is high. Moreover, each developed algorithm has its own draw back and mostly performs better in one application than in others [12].

Load balancing, the absence of which negatively rises some issues (in performance, availability), is one of the primary challenges in cloud computing [12] [14]. For improvement upon the available solutions, of which min-max relatively performs well [13], a modified and extensively improved algorithm is formed.

The other part of this paper is organized as follows: Section 2 discussed on some previous studies related to task scheduling algorithms. In Section 3 and 4 we introduce some concept with regard to the technique for task scheduling and resource allocation in cloud computing, section 4 discuss on the issues pertaining load balancing, mathematical formulation, and the proposed algorithm. In section 5, mathematical simulation and results are discussed, and lastly concluding remarks are given in Section 7.

II. RELATED WORK

As research in cloud environment is increasing, task scheduling needs to be more scalable to the user demands. [1][2] Uses a technique known as improved max-min algorithm and enhance max-min algorithm respectively with the aim of distributing the load among the available resources. [1] is a modification of [2] in which both uses the max-min task scheduling algorithm. This paper employs the technique in [1] to propose another algorithm that will help in balancing load across the virtual resources and to allow for scalability when handing task with the aim of improving the performance of the system. Load balancing over resources in the cloud environment is used to achieve minimum load when using resources, different methods are use to achieved such balance as stated in [7, 8, and 9]. Based on these methods, we take interest in max-min algorithm and shows how load can be balanced across different resources in the cloud environment.

III. CLOUD COMPUTING AND TASK SCHEDULING

As the aspect of parallel and distributed computing involves Cloud computing which is a collection of computers that are interconnected and virtualized as one computing
resources, cloud client gets access to the resources through the SLA [11].

As mentioned previously, cloud computing offers software, platform, and infrastructure as a service respectively. The software as a service includes providing software such as Mail (e.g., Gmail, Yahoo mail), social network sites, Google drive, and so on, to the customers or clients. The infrastructure as a service deals with VM, storage, network, load balancer and so on as a service to the client and lastly the platform as a service deals with database like SQL, oracle, web services, runtime (e.g., Java) and so on as a service to the client. The clients get access to these services through various devices as shown in the figure below [3] [4].

Resource allocation in cloud computing is all about assigning available resources to a cloud application. Dynamic resource management is seen as a very active research area in the field of cloud computing. The cloud computing resources costs vary depending upon the type of configuration for using such resources. Therefore, an efficient use of these resources is considered as a prime interest for both the customer/client and the cloud provider. Resource allocation in cloud computing takes place in two levels [5]: firstly load is balanced within the physical machine whenever an application is uploaded and secondly, request are assigned to a specific application if there are multiple requests for the resource.

Resource allocation exhibits some benefits irrespective of the organization size or business market. It also has some limitations below are some set of advantages and limitations of resource allocation [6]; among the advantages is that users share their resources whenever there is a scarcity of resources. The limitation may arise in the aspect of security, which is a major challenge and another setback is that migration issues may arise whenever a client decides to switch service providers.

IV. LOAD BALANCING AND TASK SCHEDULING ALGORITHM

Load balancing is a technique used to distribute processing load (i.e., large processing load) to smaller processing nodes (i.e., resources) to enhance the overall performance within the system in a distributed environment as shown in fig. 2 above. The idea of load balancing is to avoid loading up a resource during task scheduling so that all the resources will be allocated with a task evenly across a given virtual environment. Various load balancing algorithms exist as stated in [7] with the aim of distributing the task’s load across resources. Some of these algorithms include:

- **Min-Min Algorithm**

  This algorithm has all the relevant information needed in advance. The algorithm uses some parameters to obtain the information it needs. Some of these parameters are: ETC (Expected Time Compute), MET (Minimum Execution Time), MTC (Minimum Completion Time) etc. The Min-Min algorithm selects a task with minimum completion time and maps it with a node with a minimum completion time [8].

- **Max-Min Algorithm**

  Max-min algorithm chooses large task to be executed first before executing small once [10]. This algorithm works almost the same way as the Min-Min algorithm except in Max-Min the task with maximum value is selected from the set of execution time of tasks and maps it to a node with
minimum completion time. The ready time of the node is updated by adding the execution time of the task \([7, 8]\).

As the cloud users send task to the cloud environment with different requirement to the cloud service providers. The requirement can be tasks with different set of data size and processing power, the task scheduler will then match the tasks with available resources (virtual resources) that are available. Some mathematical relations are given in \([9]\) to analyze resources scheduling in cloud computing which are employed and used in this paper are given below.

The set of VMs \(V\) with their respective processing power is given as:

\[
V = \{v_j(c_j) | j = 1, 2, ..., k\} \tag{1}
\]

The set of tasks is also given as

\[
T = \{t_i(a_i, b_i) | i = 1, 2, ..., y\} \tag{2}
\]

Where

\[
c_j = \text{processing speed (MIPS)}
\]

\[
t_i = \text{given task i}
\]

\[
a_i = \text{Data file size of a given task (Mb)}
\]

\[
b_i = \text{Processing power (MI) of a task t_i}
\]

With above equations (1) and (2) the expected execution time (EET) for a given task by a virtual resource can be obtained as:

\[
EET = \frac{\text{Size of task (MI)}}{\text{Computing Power of resource (MIP)}} \tag{3}
\]

Now with equation (3) above, another metric can be obtained, which is the completion time (CT) of task \(t_i\) by a given resource.

\[
CT_{(i,j)} = EET_{(i,j)} + r_i \tag{4}
\]

Where \(r_i\) indicate the starting time of the execution of task \(t_i\).

Using (4), another important metric can be obtained, which is called the makespan, define as a measure of the throughput of the heterogeneous computing system \([7]\).

\[
\text{makespan} = \max_{(w, j)}(CT_{i,j}) \tag{5}
\]

This paper employs a known scheduling algorithm called an improved max-min algorithm from \([1]\) and then based on this algorithm we propose another algorithm that will help in balancing load across the VMs’ resources to improve the performance of the system.

- Improved Max-Min Algorithm

The Max-min algorithm allocated task \(t_i\) to resource \(v_j\) such that large tasks have higher priority. For instance for a given large task, the max-min algorithm execute smaller task concurrently while running large tasks. Therefore, the largest task determines the total makespan for other resources. The improved max-min algorithm is given below \([2]\).

\[
\text{For all submitted tasks in Meta-task; } t_i \\
\quad \text{for all resources; } v_j \\
\quad C_{ij} = E_{ij} + t_i \\
\quad \text{Find task } t_i \text{ costs maximum execution time} \\
\quad \text{Assign task } t_i \text{ to resource } v_j \text{ which gives minimum completion time} \\
\quad \text{Remove task } t_i \text{ from Meta-tasks set.} \\
\quad \text{Update } t_i \text{ for selected } v_j. \\
\quad \text{Update } c_{ij} \text{ for all } j. \\
\quad \text{While Meta-task not Empty} \\
\quad \text{Find task } t_i \text{ costs maximum execution time.} \\
\quad \text{Assign task } t_i \text{ to resource } v_j \text{ which gives minimum completion time} \\
\quad \text{Remove Task } t_i \text{ from Meta-tasks set.} \\
\quad \text{Update } t_i \text{ for selected } v_j. \\
\quad \text{Update } c_{ij} \text{ for all } j.
\]

- Proposed Algorithm

The improved max-min algorithm is reliable and proved to be efficient in scheduling the set of tasks to the available resources. However to make effective and sufficient use of resource a proposed algorithm was introduced which is based on the improved max-min algorithm but small changes are made to make sure that all resources are used sufficiently and to minimize the use of these resources if few once can perform the task. The proposed algorithm is shown in the pseudo code below:

\[
\text{For all submitted tasks in Meta-task; } T_i \\
\quad \text{for all resources; } R_j \\
\quad C_{ij} = E_{ij} + t_i \\
\quad \text{Find task } T_i \text{ costs maximum execution time} \\
\quad \text{Assign task } T_i \text{ to its corresponding resources } R_j \\
\quad \text{Remove task } T_i \text{ from Meta-tasks set.} \\
\quad \text{Update } r_j \text{ for selected } R_j. \\
\quad \text{Update } C_{ij} \text{ for all } j. \\
\quad \text{Pivot= } 2\text{pivot}\text{- } t_i \\
\quad \text{For all updated task in Meta-task; } T_i \\
\quad \text{for all updated resources; } R_j \\
\quad \text{Find task } T_i \text{ costs maximum execution time} \\
\quad \text{Assign task } T_i \text{ to its corresponding resource } R_j \\
\quad \text{Remove task } T_i \text{ from Meta-tasks set.} \\
\quad \text{Update } r_j \text{ for selected } R_j. \\
\quad \text{Update } C_{ij} \text{ for all } j. \\
\quad \text{2pivot= } t_i \\
\quad \text{While Meta-task not Empty} \\
\quad \text{Find task } T_i \text{ costs maximum execution time.} \\
\quad \text{If 2\text{pivot}< } 2\text{pivot then} \\
\quad \quad \text{Assign task } T_i \text{ to previous resource } R_j \text{ which gives minimum completion time} \\
\quad \quad \text{Remove Task } T_i \text{ from Meta-tasks set.} \\
\quad \quad \text{Update } r_j \text{ for Selected } R_j. \\
\quad \quad \text{Update } 2\text{pivot.} \\
\quad \quad \text{Else} \\
\quad \quad \text{Assign task } T_i \text{ to resource its corresponding resource } R_j \\
\quad \quad \text{Remove Task } T_i \text{ form Meta-tasks set.} \\
\quad \quad \text{Update } r_j \text{ for Selected } R_j. \\
\quad \quad \text{Update } C_{ij} \text{ for all } j.
\]
In the algorithm the total makespan is made to be a pivot 1 value for the first step and another pivot 2 value is assigned during the second step of the execution. Then during the next execution step the second pivot value and the completion time of the current state are summed up together. If they are greater than the first pivot value, then a new resource is allocated to that task.

By given this criteria, the resources can be used in a balanced manner and fewer resources can be used, the remaining resources will not be involved to minimize the use of such resources. The aim of the above algorithm when compared to the improved Max-Min algorithm is to make effective used of the available resource during scheduling.

The flowchart for the above pseudo code is given in the figure (Fig. 3).

![Flowchart of Proposed Algorithm](image-url)
VI. PROPOSED ALGORITHM RESULT AND ANALYSIS

Scenario: A theoretical analysis of predefined meta-task values and resources are used to carry out the scheduling process as given below. The tables underneath shows the meta-task values and the resources used.

<table>
<thead>
<tr>
<th>Task</th>
<th>Size of task (MI)</th>
<th>Data volume (Mb)</th>
</tr>
</thead>
<tbody>
<tr>
<td>T1</td>
<td>522</td>
<td>200</td>
</tr>
<tr>
<td>T2</td>
<td>1128</td>
<td>500</td>
</tr>
<tr>
<td>T3</td>

<td>300</td>
</tr>
<tr>
<td>T4</td>
<td>340</td>
<td>410</td>
</tr>
<tr>
<td>T5</td>
<td>570</td>
<td>328</td>
</tr>
</tbody>
</table>

Table 1: Tasks values

<table>
<thead>
<tr>
<th>R</th>
<th>Processing speed (MIPS)</th>
<th>Bandwidth (MbPS)</th>
</tr>
</thead>
<tbody>
<tr>
<td>R1</td>
<td>130</td>
<td>100</td>
</tr>
<tr>
<td>R2</td>
<td>266</td>
<td>120</td>
</tr>
<tr>
<td>R3</td>
<td>294</td>
<td>150</td>
</tr>
</tbody>
</table>

Table 2: Resource processing speed and bandwidth

Given the above values, Matlab is employed to compute the expected execution time of each task and the results are tabulated and analyzed as given in Table 3 below:

<table>
<thead>
<tr>
<th>Task</th>
<th>R1</th>
<th>R2</th>
<th>R3</th>
</tr>
</thead>
<tbody>
<tr>
<td>T1</td>
<td>4.015</td>
<td>1.962</td>
<td>1.776</td>
</tr>
<tr>
<td>T2</td>
<td>8.677</td>
<td>4.241</td>
<td>3.837</td>
</tr>
<tr>
<td>T3</td>
<td>3.308</td>
<td>1.617</td>
<td>1.463</td>
</tr>
<tr>
<td>T4</td>
<td>2.615</td>
<td>1.278</td>
<td>1.156</td>
</tr>
<tr>
<td>T5</td>
<td>4.389</td>
<td>2.143</td>
<td>1.938</td>
</tr>
</tbody>
</table>

Table 3: Expected execution time of task

From the above tables, T1, with the maximum execution time is selected and then is assigned to the corresponding resource R1. Fig. 4 shows how the allocation was performed based on the max-min idea, the task are allocated to all the available resources within the scheduler, the processing time is measured in seconds.

In contrast to the proposed max-min scheduling algorithm, the figure fig. 4 below shows how the allocation is performed.

Fig. 4: Chart for Resource Allocation for Max-Min Algorithm

Fig. 5: Chart for Resource Allocation for proposed Max-Min Algorithm

From the chart (fig. 4), the largest task T1 (the blue colour) has a maximum makespan of 8.031 and it’s scheduled to resource R1. The maximum makespan, is considered as the maximum throughput for other resources the summation of the remaining task i.e. T4 (red), T3(green), T1 (purple) and T5 (dark purple) are not up to the maximum throughput therefore they are assigned to the second resource R2. This makes it possible to balance different smaller tasks to run concurrently on different resources across the system and also to use the resources wisely when needed. Another important factor which is based on the on-demand characteristics of cloud computing is that, the number of resources used is also minimized and a resource can be put into use when there is a demand for that resource. Based on the results obtained, instead of assigning the load to the three resources, it’s possible to assign the task to only two resources, thereby increasing the efficiency of the system, thus we can have many task running concurrently on some resources and other resources can be put in use only when the need arise.
VII. CONCLUSIONS

In conclusion Cloud Computing is an on-demand service, therefore, efficient on-demand allocation of VM is needed. In this paper technique to handle on-demand allocation is analysed and it proved to be effective. Allocation of resources can be performed efficiently within a cloud environment by balancing the load across the various virtual machine resources, by employing an efficient technique for load balancing such as the max-min algorithm that was used in this paper.

The usage of max-min technique made it possible to handle resources in an efficient and balanced manner. Thus, for a better service to be experienced in a field of cloud computing, a proper and efficient allocation techniques need to be adopted.

Abstract—Equitably reallocating of blocks among land owners has been one of the most important tasks in Land Consolidation studies. This task has to be fairly solved among landholdings for a land. This complicated problem is difficult to solve using linear methods. Therefore, a method is needed to solve this non-linear problem among land owners impartially. There are many applications employing optimization algorithms for solving the complicated and non-linear problems in literature. When we examine the literature, it is seen that Genetic Algorithm has been only used to overcome the block reallocation problem. Artificial Bee Colony (ABC) algorithm is one of the optimization algorithms that have been used to solve the non-linear and complicated problems in literature. Furthermore, this method has better performance when it is compared with the other optimization algorithms. In this study, we have aimed to fairly reallocate the landholding areas to blocks in a land by developing an algorithm using Artificial Bee Colony optimization method. When we develop the steps of the algorithm, we give priority to landholdings preferences and places of fixed installations. Data tables have been arranged by taking land consolidation data of DOT Village in Adiyaman, Turkey that into consideration. DOT Village land consolidation project includes 143 blocks and 225 landholders. Consequently, we have introduced the steps of an algorithm solving the block reallocation problem automatically using ABC for a sample land. Also, we have observed the applicability of the proposed method for automatic block reallocation problem in this study. This study is a preliminary study helping us to develop software providing to automatically solve complicated block reallocation problem in real time land consolidation process.

Keywords—Artificial Bee Colony Algorithm, Land Consolidation, Automatic Block Reallocation, Landholding, Optimization

I. INTRODUCTION

Land consolidation (LC) is an important component of determining the country farmland rational development utilizing and improving the sustainable use of land resources. Traditionally, LC is the most favourable land management approach for solving land fragmentation and it has been applied in many countries around the World [1]. Land consolidation aims to change land ownership by redistribution providing fewer, more compact, contiguous and larger land parcels for individual owners [2,3]. Land consolidation (LC) is a highly complex for spatial planning process because it involves many tasks, actors (landowners, rural engineers, local and regional administrations, consultants) [4]. Lands of landholdings in Turkey are jointly owned, fragmented, away from each other and in irregular geometric shapes. As a consequence of that, because of non-monolithic parcels, increasing in workforce demand, a great loss of time and uncultivated areas, agricultural landholdings can’t use modern farming methods. Therefore, agricultural productivity decreases constantly. Besides, agricultural parcels continue to be fragmented because of inheritance provisions, sale, newly opened roads and irrigation channels. This situation makes LC projects necessary on agricultural areas [5]. One of the important objectives of studies in agricultural LC is to increase agricultural cultivation and to eliminate the problems in the agricultural structure. Land reallocation is the most important stage of LC studies and a tool to rearrange proprietary rights. In reallocation of parcels and their emplacement on lands, there are some technical obligations such as farmer’s wishes, fixed installations, roads and irrigation network and the most suitable dimension, geometry, size and direction of parcels. These obligations can be easily overcame in the LC projects by using new computer technologies employing mathematical models [6].

LC projects consist of various steps. Within these steps, land reallocation is the most important and a time-consuming stage since high number of criteria are considered. Land reallocation is crucial for social peace to conduct land reallocation studies in such way to meet the demands of landowners and also the principles of equity and justice [7]. Many different solutions have been suggested for the land reallocation process. These are based on many mathematical models; model based on block priority [8–10], special-purpose interface program to perform land reallocation [11,12], a new model approach in reallocation [13], application of fuzzy logic in land reallocation [7], using the analytic hierarchy process in land consolidation [14], using the planning and decision support system in land consolidation [1], theoretical
framework and application of the land-redistribution modules [15], using genetic algorithm to land reallocation of land consolidation [16], a spatial genetic algorithm for automating land partitioning [17], a preliminary study for design of automatic block reallocation algorithm with genetic algorithm method [5], comparison of designed different land reallocation models [6].

Although Artificial Bee Colony (ABC) algorithm has been recently improved, there are lots of studies using ABC in literature. Karaboga and Basturk compared the Genetic Algorithm (GA), Particle Swarm Optimization (PSO), Particle Swarm Inspired Evolutionary Algorithm (PS-EA) and Artificial Bee Colony Algorithm (ABC) in the optimization of some numerical functions and they reported that ABC was better [18]. Aydin et al. were modified the ABC algorithm and they developed the Incremental ABC algorithm in which population size was grown over time and local search was applied [19].

Heuristic methods like swarm intelligence have been employed in complicated problems that are difficult to solve. These methods simulate the social behaviours of animals like bird flocking or fish schooling. Artificial bee colony (ABC) and genetic algorithm (GA) are examples of the heuristic methods. Solutions of automatic block reallocation problems in land consolidation studies are difficult and this problem has been solved by traditional methods such block priority based. However, as artificial intelligent systems like the heuristic methods develop, the solution of such complicated problems is getting easier. Genetic algorithm (GA) is one of optimization algorithms. This optimization method was firstly demonstrated for solving the automatic block reallocation problem in land consolidation projects in some studies [5,20]. Moreover, it was concluded that the optimization methods was more successful than traditional one to reallocate the blocks in a land consolidation project [20]. Artificial bee colony algorithm (ABC) is an optimization algorithm which can solve non-linear and complicated problems. This method was firstly proposed in 2005 by Derviş Karaboga [18,21]. When ABC is compared with the other optimization algorithms, it is seen to produce good results for complicated problems described in literature. [22]. In this study, we propose an algorithmic model that can automatically solve the block reallocation problem in consolidation of a land using ABC. The steps of this model are described in results.

In this paper, we described the steps of an algorithm to solve the block reallocation problem among landholders for the land found in DOT village, Adıyaman-Turkey using ABC. ABC algorithm is preferred because it is swarm intelligence and said to be better than the other optimization algorithms. In Sect. 2, the proposed ABC algorithm and some materials are described; in Sect. 3 results and discussion are presented; in Sect. 4 conclusion is given.

II. MATERIALS AND METHODS
A. Block Reallocation in Land Consolidation

The problem encountered in LC projects can be defined as reallocating “n” number of cadastral parcels to “m” number of blocks. To this end, optimization studies have been conducted for land reallocation process [7]. The remaining amount after deducting the share from the total land amounts of each landholding in land consolidation area is placed in blocks, if possible, in a single piece and as parcels in proper geometrical shapes. In this location process; preferences of farmers, fixed installations and provisions of related legislation must be taken into account. As for this situation, new parcels can be placed in blocks in many different ways. Therefore, multiple options and solutions emerge in this process. The aim is to find the most appropriate solution for our goals. For this reason, block reallocation problem can be defined as an ‘optimization’ process [5].

B. Application Area

The study area, Dot Village is located in the east of Adıyaman Province (Fig. 1). It is situated 12 km along from Kahta district and 35 km along from Adıyaman city centre. Its altitude is 660 m. Settlement area is on the hill and Atatürk Dam Lake coast. Çataltepe east of the village, west Sarısu village, north Arlı and Zeytin villages, on the south west Beşaltı hamlet is located in the south Büyükbey village. Settlement area is between 38.170 East longitude and 37.450 North latitudes. Dot village LC project area is 1605.84 hectares. There are 225 landholding and 143 blocks in the LC project area. There are 352 cadastral parcels and 688 numbers of shares in the LC project area. Preference of 3 different blocks is made for each share.

C. Data Tables and Constraints

Two data has been prepared for block reallocation. The first data include areas of cadastral parcels, the first degree fields of cadastral parcels prepared according to the index map and farmer preferences. According to the data; there are 225 landholdings, 352 cadastral parcels and 688 numbers of shares in the LC project area. Total of the first degree areas in cadastral parcels is 9,528,608.84 m² in the LC project area.

The second data include block areas and the first degree block fields. According to the data; there are 143 blocks in the LC project area. Total of the first degree areas of blocks is
9,528,608.84 m² in the LC project area. Cadastral parcels and block plan of DOT village are displayed in Fig. 2 and Fig 3 respectively.

The constraints of block reallocation process are in the following:
1- The first degree areas of the parcels.
2- Three preferences for parcel shares of landholdings.
3- Fixed installations.
4- Defendant parcels and grasslands located in multiple blocks.

D. Artificial Bee Colony Algorithm

Artificial Bee Colony algorithm was firstly proposed as an optimization algorithm by Karaboga in 2005 [18,21]. Karaboga artificially simulated the intelligent behaviours of bees in a real bee colony to solve multidimensional optimization problems. There are three groups of bees which are employed, onlookers and scouts bees in the artificial bee colony model. Initially, colony is divided two parts. The first part of the colony includes the employed bees and second part consist the onlookers. In the artificial bee colony the numbers of food sources are equal to the number of employed bees in the artificial colony. The employed bee becomes the scout after the related food source is exhausted by the bees. The pseudo-code of ABC algorithm is given in the following Fig. 2 [18,21].

- INITIALIZE.
- REPEAT.
  (Step-1)Place the employed bees on the food sources in the memory;
  (Step-2)Place the onlooker bees on the food sources in the memory;
  (Step-3)Send the scouts to the search area for discovering new food sources.
- UNTIL (requirements are met).

Fig. 2 The main steps of ABC algorithm.

E. Application of Algorithm

Our model includes three external functions. These three functions generate population according to the constraints expressed in section 2.C (function 1), calculate the fitness of population (function 2) and select best population (function 3) respectively. A population in our model includes 100 rows (ensembles) and columns as the number of landholder. Each column stores block numbers in which one landholder area is located. Each landholder areas are randomly distributed to the blocks except fixed installations in each ensemble. Our model proposes to select the best ensemble in the population.

In the algorithm process, we set the initial values such that colony size (number of employed bees + number of onlooker bees) was 100; maximum cycle number in order to terminate the algorithm was 2000; number of parameters of the objective function was 225; control parameter in order to abandon the food source was 100 and number of the runs was three.

Generating of population worked as an external function in the model. This function was designed such as; areas of landholders having installations were fixed to their blocks for each ensemble in the population because the fixed installations found in the block areas couldn’t be changed. So this situation was a limitation in the block reallocation process. Areas of landholders having no fixed installations were reallocated to remaining blocks in the model. Areas of landholders having no fixed installations were fixed to first preferences and second preferences in the first and second ensembles of populations respectively. Third ensembles of population were generated such as; areas of landholders having second preferences but third preferences and having three preferences were jointly fixed to their preferred blocks in third ensembles. The rest of the ensembles of the population were composed such that the blocks were
randomly reallocated for landholders regardless of their preferences.

Fitness function worked as an external function in our model too. When one ensemble in the population was tested with the fitness function in our model, we calculated the settled areas and assessed the remaining areas information in m2 for each block. And, we calculated settlements status to the first, second and third preferences for each landholder. Lastly, arithmetic means of these outputs assessed the fitness status for each ensembles of population.

III. RESULTS AND DISCUSSION

In this study, we proposed to prepare the data tables of a land found in DOT village, Adıyaman Turkey. Moreover, a model was secondly developed to apply automatic block reallocation in the land consolidation project. This model aimed to use ABC algorithm. When we determined to use ABC for block reallocation in land consolidation projects, the previous studies in literature were examined and this algorithm was observed to be more feasible than the other optimization algorithms. As a result of the study, we developed the pseudo codes of the model and the flow chart of the algorithm applying automatic block reallocation process. The flow chart (in Fig. 4) and the general pseudo code of the study are given in the following;

Step 1. Set the initial values (Colony Size, Max Cycles, Run Time, Number of Parameters of objective function)
Step 2. Load data belonging to the all areas and blocks
Step 3. Set the global minimum (The amount of empty area in blocks must be min).
Step 4. If runtime number is achieved, finish the loop else go to next step.
Step 5. Generate the initial colony
Step 6. Divide the colony in two parts for employed and onlookers bees phases.
Step 7. Calculate the fitness of the employed colony
Step 8. If max cycle is achieved, finish the loop else go to next step.
Step 9. Change the individuals among ensembles as much as employed population size and derive the new population.
Step 10. Calculate the fitness of the new generated employed colony.
Step 11. Greedy selection between the old and new employed colony.
Step 12. Normalize the preferred colony.
Step 13. If the population size of onlookers is achieved finish this loop else go to next step.
Step 14. Change the individuals among ensembles as much as onlookers’ population size and derive the new population.
Step 15. Calculate the fitness of the new generated onlookers’ population.
Step 16. Greedy selection between the old and new onlookers population
Step 17. Go to step 13.

Step 19. Control the amount of food source in a limit rate.
(Scout phase)
Step 20. Go to step 8.

![Flow chart of the proposed algorithm](image)

IV. CONCLUSIONS

In this study, required model to apply the land reallocation using artificial bee colony algorithm in the land consolidation projects were designed. In this design, the first three steps before stage of writing codes with artificial bee colony algorithm for land reallocation were completed. Namely, data tables were prepared for a project land and reallocation conditions, constraints were identified for an example landholding and pseudo code and flow chart of block reallocation algorithm were prepared. In the future study, the codes of the block reallocation algorithm will be written according to developed these three steps.

Abstract—A variety of methods are used in order to classify cancer gene expression profiles based on microarray data. Especially, statistical methods such as Support Vector Machines (SVM), Decision Trees (DT) and Bayes are widely preferred to classify on microarray cancer data. However, the statistical methods can often be inadequate to solve problems which are based on particularly large-scale data such as microarray data. Therefore, artificial intelligence-based methods have been used to classify on microarray data lately. We are interested in classifying microarray cancer gene expression by using both artificial intelligence based methods and statistical methods. In this study, Multi-Layer Perceptron (MLP), Radial basis Function Network (RBFNetwork) and Ant Colony Optimization Algorithm (ACO) have been used including statistical methods. The performances of these classification methods have been tested with validation methods such as v-fold cross validation. To reduce dimension of DNA microarray gene expression has been used Correlation-based Feature Selection (CFS) technique. According to the results obtained from experimental study, artificial intelligence-based classification methods exhibit better results than the statistical methods.

Keywords—DNA microarray, classification, v-fold cross validation, feature selection, gene expression data

I. INTRODUCTION

Gene expression analysis of thousands of genes can be performed with a technique called microchip thanks to innovations in technology and research [1]. DNA microarray is high intensity gene array and it makes possible to examine thousands of gene expression profile [2]. Microarray technology provides abundance of knowledge on expression levels of thousands genes that has been used for diagnostic and prognostic purposes for various types of diseases. Microarray technology is an invention that allows for detection of too many genes. This technique is also used in many fields including medicine primarily [3]. The activity of genes in patient and healthy cells that get same tissues can compare through DNA microarray technology. This technique can help find genes associated with disease. For example, it can be used to identify a gene associated with a disease thanks to compare gene expression level of healthy and diseased cells [3]. The interest in working with the rapid advancement of DNA microarray technology is increasing day by day. These studies, is a comprehensive technology used in molecular biology and medicine. DNA microarray data analysis plays an important role the identification of genes associated with diseases such as cancer. It can be calculated in high probability that any individual is ill or healthy by identifying disease-related genes. Therefore, high performance classification methods are very important for microarray data.

Statistical methods such as Support Vector Machines, Decision Trees and Bayesian Network are the most frequently used methods in microarray classification. However, these methods can often be inadequate to solve problems which are based on especially large-scale data. Therefore, it is important to develop methods that can be effective to solve such problems.

In the last few decades, artificial Intelligence techniques are methods which are commonly used and preferred to solve difficult problems. That’s why, we are interested in classifying central nervous system microarray cancer gene expression by using artificial intelligence based classification methods including statistical methods in this study.

In the experimental analysis, the results of classification obtained by artificial intelligence methods are compared with the results of classification obtained by statistical methods. The rest of this paper is organized as follow: We describe the relevant methods in our comparison study part in Section 2. In Section 3, we introduced our experimental dataset called central nervous system cancer microarray gene expression dataset. We report the results of our experiments which are followed by statistical analysis and discussions in Section 4. Finally, we conclude the paper with an outlook to our future work about the control parameter optimization of classification algorithms.

II. METHODS

A classification function consists of two parts. First part is about selecting important features by using “feature selection” methods. Second part is about classifying data thanks to
classification methods. System component used in this study are described below.

A. Feature Selection

The number of features is usually very high in gene expression dataset. Therefore we need to reduce dimension on dataset to make better classification. Feature selection is very important process to make classification with high accuracy on microarray cancer datasets. We examined various feature selection methods and preferred Correlation based Feature Selection (CFS) because it made a successful choice among all features.

1) Correlation based Feature Selection (CFS): CFS is a simple filter algorithm that ranks feature subsets and discovers the merit of feature or subset of features according to a correlation based function. According to this approach, subsets which has the best attributes consist of attributes which have a high correlation with the corresponding class label and have low correlation with each other. The rest of features should be ignored. CFS feature subset evaluation function is shown as follows:

\[ G_S = \frac{k \overline{r}_{ci}}{\sqrt{k + k(k - 1) \overline{r}_{ii}}} \]  

(1)

where \( G_S \) is the heuristic merit of a feature subset \( S \) containing \( k \) features, \( \overline{r}_{ci} \) is the mean feature–class correlation, and \( \overline{r}_{ii} \), is the average feature-feature intercorrelation. This equation is, in fact, Pearson’s correlation, where all variables have been standardized [4].

B. Classification

1) Support Vector Machine (SVM): SVM is a statistical algorithm found by V. Vapnik [5] in the late 1960s. It is a method which is used particularly in classification microarray gene expression levels. SVM is a supervised classification algorithm based on statistical learning theory. SVM initially had designed for two-class classification of linear data and then was generalized to classify non-linear and multi-class data. The working principle of SVM is based on predicting the optimal decision function that can separate two classes from each other, in other words, the most appropriate way to define SVM is the hyper-plane, which can separate two classes each other [6]. An infinite number of non-optimal hyper-plane can be drawn to split the two sets from each other. However, SVM try to find optimal hyper-plane that provides the maximum margin to separate the two sets from each other. There are linear and nonlinear forms of classification based on kernel function. Radial basis kernel function is frequently used in classification applications. SVM is an important classification method because it is fast and especially perform good results on high dimensional attributes.

2) One Rule (OneR): One-R or “One Rule (a Rule)” is a simple algorithm proposed by Holt R.C [7]. This algorithm produces a rule in training data for each feature and then rule which has minimum error rate according to One-R is selected.

3) J48 Decision Tree: J48 is the Weka implementation of the C4.5 algorithm, based on the ID3 algorithm. The main idea of this method is to generate decision trees by using the information entropy. The method divides dataset by calculating the information gain of each attribute and attribute which provides the most benefit is used to make a decision [8].

4) Multi-Layer Perceptron (MLP): This model on which Rumelhart and his friends worked together is called error propagation model or the back-propagation model (backpropagation of the network) [9]. There are one or more hidden layer excluding an input and output layer in this model. Neurons in layers is associated with other layers. Information flow direction is forward and there is no feedback on the network in MLP. Therefore it is known as feed forward neural network. Data is not processed in neurons in the input layer. The number of neurons in this layer depends on the number of dimensions of the problem to be applied to the network. The number of hidden layer and neuron are randomly determined. The number of neurons in the output layer depends on the type of problem [10].

5) Radial basis Function Network (RBFNetwork): RBFNetwork was revealed in 1988 by inspiring the behavior of biological neurons [11]. Training of this model can be compared to curve fitting approach in multidimensional space [12]. It is used radial basis activation functions the transition from the input layer to the intermediate layer unlike other neural network structure in RBFNetwork and a non-linear clustering (cluster) analysis is performed. There are three layers called input, hidden and output on RBFNetwork like general ANN structure. The structure between the intermediate and output layer is also same in other types of Artificial Neural Networks, and training is performed among neurons which are intermediate and output layer.

6) Ant Colony Optimization Algorithm (ACO): ACO is a proposed algorithm inspired by the behavior of real ants in nature [13]. This algorithm was proposed by utilizing the ability to find the shortest path between nest and food source of the ants [14]. The use of this algorithm for solution of classification problems has been just used and Ant-Miner has been proposed by Parpinelli and his friends [15] to classify data recently. After that, Ant-Miner was developed by Liu and his friends [16] by the same logic, but different heuristic and pheromone update strategy. cAnt-Miner algorithm was also developed for data which has continuous values. High-level pseudocode of cAnt-Miner algorithm is shown Figure 1. We used cAnt-Miner algorithm because central nervous system microarray gene expression dataset we use in this study has continuous values.
Central Nervous System Cancer dataset, provided by Pomeroy [17], contains the expression levels of 7129 genes. Each sample was obtained from brain tissues and was analyzed using Affymetrix microarrays. This dataset contains two subtypes of cancer, namely classic medulloblastomas (CMD) and desmoplastic medulloblastomas (DMD). After data preprocessing, 857 genes remain. The source of the 857 gene expression measurements is publicly available at [18]. Central Nervous System Cancer dataset is available at Schliep lab bioinformatics Repository of Rutgers University contains 857 genes with one class attribute. The dataset includes numeric attributes. The class shows two subtypes of cancer named CMD and DMD. The dataset contains 34 samples belonging to two different target class. Table 1 shows the summary of the characteristics of the dataset.

IV. EXPERIMENTAL RESULTS AND DISCUSSIONS

In this study, we compared the efficiency of the classification methods including; SVM, OneR, J48 Decision Tree, MLP, RBFNetwork and cAnt-Miner methods for the prediction of cancer risks. We used improved and modified Weka [19] software for applying classification on dataset. The classification accuracy is used as the performance measures. We transformed data into the format arff for Weka. At first, feature selection method was used to find relevant features in the central nervous cancer dataset and then, classification algorithms were applied to the selected features to evaluate the algorithms. Thirty features (genes) were selected by the feature selection algorithm. To select an important subset of genes from thousands of genes is pretty arduous. That’s why, gene selection becomes the most needed requirement for a diagnostic classifying system. For this reason, many researchers have applied different techniques to select a small subset of informative genes that can classify different subgroups of cancers accurately. The same experiment was repeated for six classifiers. The classification methods called statistical and artificial intelligence-based were applied to the dataset by performing feature selection and we tested the accuracy of our classification methods with 10-fold cross validation. The results of classification methods have been shown Figure 2.

According to Figure 2, Multi-Layer Perceptron (MLP) has the best performance among classification methods which performed on central nervous system microarray gene expression dataset with 97.06%. RBFNetwork and cAnt-Miner have the best results respectively, with 94.12% and 92.50% after MLP. SVM and OneR have the worst performance, with 73.53% in the experimental study.

As it is shown in Figure 3, the average performance of artificial intelligence-based methods is better than the average performance of statistical methods. Approximately, the average performance of artificial intelligence-based methods is 22.09% more than the average performance of statistical methods. Artificial Intelligence-based classification methods performed very well on Central Nervous System microarray cancer with, 94.56%. However, the average of statistical methods is less
than the average of artificial intelligence-based methods, with 83.33%.

V. CONCLUSION AND FUTURE EXTENSIONS

In this paper, we have conducted a comparative study of the classification methods for microarray data analysis on publicly available dataset including microarray central nervous system cancer dataset. Firstly we applied Correlation-based Feature Selection (CFS) which is method of dimension reduction on microarray dataset and then we compared the performances of six classification methods, namely Support Vector Machine (SVM), OneR, J48 Decision Tree, Multi-Layer Perceptron (MLP), Radial Basis Function Network (RBFNetwork) and cAnt-Miner on central nervous system dataset by using control parameters most commonly used in the literature. In conclusion, the experimental results show that the artificial intelligence-based classification methods have higher accuracy than the statistical classification methods. In the future, we will study on control parameter optimization of classification methods and then we will compare results of classification methods with parameters most commonly used in the literature and with optimal control parameters.

Route Planning for Multiple Unmanned Aerial Vehicles (UAVs) with Parallel Genetic Algorithm on GPU Using CUDA

Murat Cakir*, Guray Yilmaz+

Turkish Air Force Academy
Istanbul, Turkey 34149
{*mcakir1, +gyilmaz}@hho.edu.tr

Abstract—Unmanned Aerial Vehicles (UAVs) are designed as alternative solutions to traditional aerial vehicles controlled by human on-board. Recent advances in robotic and communication technologies have enabled UAVs to become convenient platforms for various missions from aerial surveillance to combat operations. Today, most of the efforts on UAV technologies from scientific and industrial communities are focusing on autonomy to provide self-decision skills to UAVs particularly on their mobility. In order to execute a certain mission effectively in the shortest possible time, an optimal pre-defined route plan which regulate the mobility of UAVs is required. Moreover, for multi-UAV systems, which consist of more than one UAVs perform their tasks in collaboration, this pre-defined route plan should be updatable during the mission in order to make the system fault tolerant. Route planning for multi-UAV systems is NP-hard problem which is also known as multiple traveling salesman problem (mTSP). Given a set of waypoints, multi take-off points for all UAVs, and a cost metric, the objective of the problem is finding a set of routes for a given number of UAVs so as to minimize the total cost. It is obvious that increase in the number of waypoints or UAVs cause exponential increase in search space. In order to find a solution with good quality from this huge search space within a reasonable amount of time, evolutionary algorithms and parallel computing techniques can be used. In this study, it is aimed to find near-optimal route plans for multi-UAV systems. The objective function used in this study provides that all individual routes of UAVs to be close each other as possible. The algorithm is implemented on GPUs using NVIDIA’s parallel computing platform, Compute Unified Device Architecture (CUDA). The efficiency and the effectiveness of the proposed parallel GA approach are demonstrated through simulations under different scenarios.

Keywords—parallel genetic algorithm, CUDA, multi-UAV systems, multi-TSP.

I. INTRODUCTION

The aviation is a discipline that doesn’t accept risks. Lots of R&D (Research and Development) activities has been made to decrease the risk factor to the lowest level and eradicate the risk at the end. The top of this activities is unmanned aerial vehicles (UAV). Technological investments and autonomous systems demonstrate that conventional air platforms are going to replace with unmanned aerial vehicles. Thus, people leave the platform will form the core of these systems that control program and structure.

It is aimed to improve the abilities of autonomous movement by calculating the routes fastly and effectively that unmanned aerial vehicles follow in this study. According to Scholer [11], autonomy consists of six parts that are mission distribution, hazardous area detection, route planning, avoidance of collision, generation of trajectory and vehicle control. By increasing autonomy, the stress on the operator decreases and it provides an environment that can be used by lots of unmanned aerial vehicles. Therefore, while data obtained by using only one UAV takes a long period of time, using multiple UAVs simultaneously may provide time efficiency.

Using a big UAV at the duties is not economic. Besides, using the smaller UAVs together that is equipped with payload increases the success of the duties. The problem is that calculate the routes of lots of UAVs both accurately and fastly. This problem is in the NP-Hard category according to the target points that will be gone. In this structure that can be named as the traveling salesman problem, increasing the target points that form the field of problem means that increasing the calculating time exponentially that is required for route planning. So, genetic algorithm offers a good solution in an acceptable time as the other evolutionary solution methods.

The time that genetic algorithm requires to find the solution increases with increasing the number of target point. In this situation, the information of route that UAVs, which is controlled simultaneously, need must be calculated in a shorter time. To attain the requiring time we must ensure that the algorithm of finding route process in parallel. Briefly total process time can be shortened by calculating in parallel, using the parts of program that don’t effect each other in lots of operation simultaneously and gathering the results. On account of requiring equipment, using the GPU cores that works at low frequencies unlike the high frequency CPU cores and has lots of in its is eligible for parallel calculating.

In this study, taking advantage of the power of the NVIDIA’s CUDA architecture, it is aimed to adopt the genetic algorithm approach to solve route planning problem for multiple UAVs. By this way, it is intended to find near-optimal route plans for multi UAV systems. All UAVs are assumed to be resided at different locations. One of the goals in this study is making all individual routes of UAVs to be close as possible. For this reason, the objective function used
in this study preferred from a study conducted by Gomez et al. [12]. The proposed genetic approach for multi UAV systems is implemented using on GPUs using NVIDIA’s parallel computing platform, Compute Unified Device Architecture (CUDA). The efficiency and the effectiveness of the proposed parallel GA approach are demonstrated through simulations under different scenarios.

The rest of the study is arranged at this array: At the second part, the basic information is given about the multiple traveling salesman problem and genetic algorithm. The other part, the similar studies is expressed. At the fourth part, CUDA architecture is explained. At the fifth part, the designing system is explained. At the other part, test results and comparisons is expressed. Finally, a brief explanation is made about the result and next studies.

II. BasiCS

A. Multiple Traveling Salesman Problem (mTSP)

In this study, it is observed that m number of UAV control n number of target points and turn back to the initial point again. This problem is defined as a generalization of widely known travelling salesman problem which more than one salesman is allowed. It is called as multiple traveling salesman problem (mTSP). Given a set of points, m depots where m salesmen are located, and a cost metric, the objective of mTSP is to determine a route for each salesman such that the total tour cost is minimized and that each city is visited exactly once by only one salesman. In mTSP, all of the routes must start and end at the same depot and each city must be visited exactly once by only one salesman. Sorting targets in the best order is not enough to get the optimal solution. It is also imported that which point is assigned to a salesmen [1].

Kara and Bektas [7] have provided a number of variations on the mTSP by presenting a mathematical model. With this model, sub-tour creation is prevented by detecting neighbors counts to visit.

B. Genetic Algorithm

Genetic algorithm can be defined as similar to the evolution observed in nature. Because it provides an heuristic search method, it does not necessitate to search all solution space of the problem. The terms used in this algorithm are very similar to the ones in biology. Some of these terms are chromosome, generation, choosing parents, crossover, mutation, etc.

In GA, each candidate solution represents chromosomes. Each chromosome is organized as an array of genes. In addition, a number of chromosome forms a generation. In this regard, chromosomes in the generation are sorted in terms of their solution quality according to fitness function. Each generation forms a new generation using GA operators such as crossover and mutation. As a result of new generations, the population becomes more qualified having individuals with better fitness values.

Fundamental phases of GA is shown in Figure 1.

III. RELATED STUDIES

Dantzig and Ramser [4] have provided an algorithmic approach to Vehicle Routing Problem (VRP) which is represented as in mTSP model by considering transport costs of vehicles. The main objective here was the minimizing the total cost by using Vehicle Routing Problem (VRP). This study is considered as the first study of VRP which is still agreed to be used in today’s vehicle systems.

In a study conducted by Ercan and Gencer [5], route plans for UAVs have been accepted as VRP and their types have been inspected and classified according to the needs.

Sahingoz [10] have proposed a flyable route which fits to multiple UAV’s maneuver angle in his study. The route is calculated with the genetic algorithm and the solution is produced in a faster way. In order to make the route flyable, Bezier curves are used in his study.

In another route planning study, Karakaya [8], has provided multiple Traveling Salesmen Problem approach to detect minimum count of UAV to spy a single target and to obtain a near-optimal route. The Ant Colony Optimization (ACO) Algorithm is used in his work. With a single vehicle base, considering the range limitations and coordination’s of targets 20% saving is achieved in the number of used unmanned vehicle number.

Ergenze and Leblebicigolu [6] have studied on the most efficient way that unmanned vehicles can obtain information from the desired locations. It is aimed to solve Traveling Salesmen Problem by staying away from the restricted regions. Matlab’s genetic algorithm tools have been used for the calculation of the route.
Valero et al. [12] have made the route planning using genetic algorithm for robots which are planned for the service to the patients. The scenarios which have 2, 3, 4, and 5 robots have been tested for the problem areas which have 30, 40, and 50 targets.

Cekmez [3], [2] and the others revealed that the route planning of one UAVs can be calculated faster by operating ACO and genetic algorithm on GPUs in parallel.

IV. CUDA ARCHITECTURE

This section describes the CUDA architecture through the example of the GeForce GTX 480 GPU card, which is used in our experiments.

In terms of hardware, CUDA GPUs are regarded as two level shared-memory machines. Processors in a GTX 480 are grouped into streaming multiprocessors (SMs). Each SM consists of 32 processors. The GTX 480 has 15 SMs. Therefore, the GTX 480 is equipped with total of 480 processors. CUDA is highly multithreaded architecture that allows a maximum of 1536 concurrent threads per SM. Hence, the GTX 480 can run a maximum of 23040 threads concurrently. Processors in a SM can exchange data via fast shared memory. On the other hand, data exchange between SMs can be performed via VRAM. VRAM is also like main memory for processors. So, code and data in a CUDA program are basically stored in VRAM.

CUDA programming model is one of multi-threaded programming models. In the following, we describe an overview of CUDA programming model using Fig. 2.

In a CUDA program, threads form two hierarchy: a grid and thread blocks. A thread block is a set of threads. A thread block has dimensions 1, 2, or 3. A grid is a set of blocks with the same size and dimension. A grid has dimensions 1 or 2. Each thread executes the same code specified by the kernel function. A kernel function call generates threads as a grid with given dimension and size. The reason why threads form two hierarchy is as follows. Threads in a thread block can share data efficiently via shared memory. However, the maximum number of threads per block is limited to 1024. So, if more than 1024 threads are required, we have to partition threads into several thread blocks with the same size.

V. PARALLEL GENETIC ALGORITHM

A parallel genetic algorithm was designed for multiple UAV route planning in this paper. Each solution in the genetic algorithm is named as chromosome. A cluster formed by these chromosomes is named as a population. After crossover and mutation over the members, the population, which is formed randomly at the beginning, has become a more acceptable situation. We express every candidate solution with a chromosome in our algorithm. We evaluate the quality with a fitness function which we determined. Algorithm stages, parallel design, and performance comparison according to the results will be explained in detail at the next sections.

A. Codification of The Chromosome

To make the route solution of multiple UAVs, it is required that number of UAV and number of target must exist in the candidate solution (chromosome). Therefore, we can see that which UAV will follow which route. In our study on one chromosome, number of UAV is shown with the values between [0, m – 1] and number of target is shown with the values between [m, m + n – 1] [12]. Every chromosome must be started one value showing a UAV. Providing that the index repetition does not occur, the sequence that comes after index of UAVs shows the route that UAV follows.

For example, the sample chromosome structure provided below shows route plans for 3 UAVs for 12 targets:

\[ 2-5-7-8-11-0-4-6-10-3-9-1-12-14-13 \]

In the solution:

- UAV 0 : 4-6-10-3-9
- UAV 1 : 12-14-13
- UAV 2 : 5-7-8-11

route is followed.

B. Calculation of The Fitness Value of Chromosome

It is required that the total route distance has to be its minimum value at standard mTSP. However, in our case, it is different from the standard mTSP. For route planning problem for multiple UAVs, it is required that duty execution time must be its minimum level. So, we can reduce the duty time by shortening UAV’s routes that has the maximum route distance in the candidate solution.

We want to minimize the total route distance (1st term in Eq. 11) and maximum subtour distance (2nd term in Eq. 11) in our study. Besides we provide that the route distance of every UAV to be close to each other by trying to increase the maximum base tour distance (3rd term in Eq. 11) [12].

\[
Fitness(ind_i) = \sum_{i=0}^{m-1} +0.9*\max(R_i) - 0.9*\min(R_i) \quad (1)
\]
shows the number of UAV, $R_i$ shows the total route distance which is charged to the UAV in the function.

C. Establishment of The Initial Population

In this phase, the initial population members build up with the threads. Threads create the initial population according to the index number that they have enhanced randomness. Thereby, it is produced quickly from each other as different candidate solutions. In addition, the prospect of going local optimum which is one of the missing side of genetic algorithm is reduced.

D. Parallel Evolution Process

Our approach is different from the algorithm proposed by Gomez et al. [12] in that we adopt the GA to CUDA GPUs in order to take the advantage of massively parallel programming. With our parallel GA approach, we provide significant increases in computing performance owing to parallel compute mechanism of NVIDIA GPUs.

- Initial population is created by an approach is increased randomness using time more efficiently. Here, working in parallel random number seed produced by each thread, mix the points of the problem with the random numbers to produce population that contains many different chromosome.
- Our work have local optimization step. This is provided as an alternative way to avoid local optima.

Elitism which is part of this process, parent selection, crossover, mutation, and local optimization is performed simultaneously by each thread.

**Elitism:** It is intended to protect the elite individuals with the Elitism. An individual which has a suitable previously determined value, displaced to the next population. Each thread between the index number 0 and 31 will transfer individual concerned to the next generation.

**Parent selection:** Two members selected randomly in the population to form the remaining members of the population. Eligibility value is better kept as the first parents. Similarly, the second parent is selected too.

**Crossover:** Creating a new individual which has the characteristics of selected individuals. The individual is produced that the thread which select Parent will settle the represents index number. This study uses *one point crossover*.

**Mutation:** That is the stage where genetic algorithms gets his actual power and genetic diversity is maintained. Swap mutation technique is used here. Changes in chromosome mutates at a rate of ten in thousand within the algorithm may allow access to the global optimal.

**Local optimization:** It is used 2-opt local optimization to prevent produced individuals from unsuitable results. Thereby the algorithm has produced much better results.

Crossover and mutation can’t reach the best results every time. At the end of the iteration to reduce the possibility of convergence of poor results can be found in solutions called local optimization structure aimed at removing crosslinks. The 2-opt basically removes two edges from the tour, and reconnects the two new sub-tours created. 2-opt local optimization is used as shown in Figure-3 in this study.

Finally, population which passed this stage is ranked according to the fitness value of individuals. This processes continue until it reaches the criteria finalization specified maximum number of iterations which is 200.

VI. EXPERIMENTAL RESULTS

A. Performance Comparison Between GPU and CPU

GA is implemented both on CPU and GPU for performance comparisons. Table I shows some specifications of the hardwares. Sequential genetic algorithm and the introduced parallel genetic algorithm are run on this system. All GPU tests are executed with 5120 threads. CPU version tests are executed with 512 population size. Elitism size is set to 32 because of the number of the warp size. At the same time maximum 32 threads are processed at the GPU. The parameters of the genetic algorithm chosen in this study are as shown in Table II.

Multi-UAV system is considered as consisting 4 UAVs. Data sets with 52 and 100 and waypoints are used in the experiments. As it is presented in Fig.4 and Fig.5, GPU implementation provides better total travel cost values for the same number of iterations. It is therefore important to note that GPU implementation of genetic algorithm provides better solutions as compared to serial CPU implementation.

surveillance data. At this point, it is required to find near optimal individual routes for UAVs in the system. In order to compute these routes as soon as possible, proposed parallel genetic algorithm is implemented on CUDA GPUs. It is assumed that proposed algorithm is performed at ground station which have NVIDIA’s CUDA capable GPU cards. After the computation each route plans are send to respective UAVs.

In this simulation study, it is aimed to observe the effects of number of population used in the algorithm on average convergence time. It is important to note that number of population is equal to the number of threads used in the algorithm. The optimum number of threads can be found in this way.

The parameters used in this simulation study are presented in Table III above. This study is performed on TSPLIB [9] data sets whose details given in Table IV.

Fig. 4. Comparison of CPU and GPU performance for 52 waypoints using 4 UAVs.

Fig. 5. Comparison of CPU and GPU performance for 100 waypoints using 4 UAVs.

B. Effects of Number of Threads on Average Convergence Time

In this paper, it is consider that UAVs are planned to visit pre-defined geographical locations in order to obtain

Fig. 6 shows the results for NVIDIA’s GTX480 graphic card. As it is shown in the figure, average convergence time decreases up to a certain point. This is because hardware resources can be utilized up to a certain number of threads which is determined as 5120 threads. However, when the number of threads are kept to increase, average convergence time starts to increase due to the insufficient hardware
resources of graphic card. As it is presented in Section IV in detail, each CUDA capable graphic cards consist of a constant number of streaming multiprocessors (SMs). Also in each SM, there are a certain number of CUDA cores (streaming processors-SPs). Additionally, the number of resident warp executed by each SM simultaneously is also constant. Each warp has 32 threads for all CUDA architectures. Within this context, the maximum concurrent number of threads executed by SMs for CUDA capable GPUs can be calculated as: Max. Number of Threads = Total Number of SM x Resident Warp x 32 threads.

The number above is the maximum number of threads whose resources can be stored on-chip simultaneously. In CUDA architecture, the hardware switches between warps constantly to help hide the large latency of memory accesses. However, even each SM has a certain number of resident warp, it can only issue instructions from a small number of warps at each clock cycle. Therefore, as it is shown in Figure 6, in most cases, while it can be launched more threads concurrently on the GTX480 the optimal value of number of threads is lower.

This result shows that round-robin thread scheduling mechanism is used in CUDA architecture in order to meet the increasing number of threads. In this context, threads waiting in ready queue cause increased average convergence time. As a result, the lowest average convergence time obtained in this simulation study also shows that the optimum hardware utilization for the GTX480.

C. Effects of objective function on average flight cost

As it is presented in Section V, in order to obtain individual routes for each UAV as close as possible, a modified objective function is used in genetic algorithm. In this simulation study, the objective function, which is used for route cost calculation, is analyzed. By this way, the objective function do not consider traditional point to point Euclidian distance used in classical TSP problems. The parameters used in this simulation study are presented in Table V. The objective function used in this study adds additional cost value according to penalty factor chosen. Therefore, each individual routes for UAVs are made close each other in terms of total flight cost.

Figure 7 shows the result of effects of objective function on average total flight cost. The detailed results are shown at Table VI. NVIDIA’s GTX480 graphic card is used to observe the behaviour of objective function on kroA100 data set. As it can be understood from the figure, penalty factor is increased gradually from 0 to 0.9. Vertical axis shows the average flight routes for each UAVs. It is obvious that while average flight route cost tends to maintain its stability, the standart deviation of these average values tends to decrease. Standart deviation of these average values shows the quality of individual flight route similarities in terms of route cost. Low standart deviation indicates high similarty among individual flight routes in terms of route cost. This is because as the value of penalty factor is increased, additional cost applied to total cost is also increased. The acceptance probabilty of the flight route is decreased in this way due to the low solution quality. Consequently, choosing high penalty factor enables to obtain individual flight routes as close as possible.

VII. CONCLUSION

Today, most of the efforts on UAV technologies from scientific and industrial communities are focusing on autonomy to provide self-decision skills to UAVs particularly on their mobility. An optimal pre-defined route plan which regulate the mobility of UAVs is required in order to execute a certain mission effectively in the shortest possible time. Moreover, route planning for multi-UAV systems is NP-complete problem which is also known as multiple traveling salesman problem (mTSP). It is quite known that increase in the number of waypoints or UAVs cause the exponential increase in the search space. Evolutionary algorithms and

parallel computing techniques can be used in order to find a solution with good quality from this huge search space within a reasonable amount of time.

In this study, it is aimed to adopt parallel genetic algorithm on CUDA capable GPUs to compute flight routes for multi depot multi-UAV systems efficiently. The objective function used in this study has provided that all individual routes of UAVs to be close each other as possible. GPU performance of proposed genetic approach is compared with the CPU version. Simulation studies shows the efficiency of proposed parallel GA approach on CUDA platform under different scenarios. As a future work, it is planned to improve the performance of the parallel genetic algorithm by considering CUDA hardware performance issues. It is also intended to conduct simulation studies on large scale mTSP systems.

kalinli@erciyes.edu.tr

Abstract—In this study, the premise and consequent parameters of ANFIS are optimized using Genetic Algorithm (GA) based on a population algorithm. The proposed approach is applied to the nonlinear dynamic system identification problem. The simulation results of the method are compared with the Backpropagation (BP) algorithm and the results of other methods that are available in the literature. With this study it was observed that the optimisation of ANFIS parameters using GA is more successful than the other methods.

Keywords— neuro-fuzzy, ANFIS, genetic algorithm, system identification

I. INTRODUCTION

System identification is a model generating process that is developed to predict the behaviour of a system between its input and output signals. The approaches based on the fuzzy neural networks and artificial neural networks are among the methods that are used commonly for the dynamic systems identification. However, due to some of its superior features, studies towards using ANFIS for the purpose of dynamic system identification, have started to increase gradually in the recent years [1-5].

Training the ANFIS model is basically the determination process of the optimal values for the model’s premise and consequent parameters. Derivative-based algorithms are commonly used for training of ANFIS. But there is a problem of getting stuck in a local minimum in derivative-based algorithms. In this context, various methods have been proposed in recent years in order to train ANFIS parameters. Some of these methods are artificial intelligence optimization algorithms and heuristic algorithms such as Genetic algorithm, PSO and Differential Evolution Algorithm that are not derivative-based [6].

In this study, an approach is presented towards the training ANFIS by using GA based on a population algorithm. The performance of the presented approach is tested on non-linear system and the results are compared with different methods. In the following section, the basic structure of ANFIS is introduced, in the third section, information about genetic algorithm is given, in the fourth section, information about the presented approach is given and the obtained results are given in the section 5.

II. ADAPTIVE NEURO-FUZZY INFERENCE SYSTEM (ANFIS)

Adaptive Network-based Fuzzy Inference System (ANFIS) is a network model which Sugeno-type fuzzy system is combined with neural learning ability. The main aim of ANFIS is to optimize the parameters of the equivalent fuzzy logic system by using input-output data sets via a learning algorithm. Parameter optimization is carried out in such a way that the error value between the actual output and the target output to be minimum.

ANFIS contains two parameters as antecedent and consequent parameters. Those two parameter types connect the fuzzy rules to each other and training of the model is provided with the optimization of these parameters. ANFIS basically consists of five layers. A basic ANFIS structure consisting of two inputs and one output is given in Fig. 1.

Fig. 1 A basic structure of ANFIS [9]

A. Layer 1

This layer is named as the fuzzification layer. The signal that is obtained from each node is transferred to the other layer. In this layer, for the outputs of the cells, \( O_i \), Equation (1) and Equation (2) are given [10].

\[
O_i = \mu A_i(x) \quad i = 1,2 \\
O_i = \mu B_{i-2}(x) \quad i = 3,4
\]
In here, $A_i$ and $B_i$ are any membership functions belong to the inputs, $\mu_{A_i}$ and $\mu_{B_i}$ are membership degrees that are calculated for this function. For the bell-shaped membership function $\mu_{A_i}$ is calculated with the equation below.

$$\mu_{A_i} = e^{-\frac{(x-c_i)^2}{2\sigma_i^2}} \quad i = 1, 2 \quad (3)$$

In here, $\sigma_i$ and $c_i$ are sigma and central parameters of the membership function respectively.

**B. Layer 2**

This layer is named as the rule layer. Each rule’s firing strength is calculated with the membership degrees that are coming from the previous layer.

$$O_{3i} = w_i \cdot \mu_{A_i}(x) \cdot \mu_{B_i}(y) \quad i = 1, 2 \quad (4)$$

**C. Layer 3**

In this layer which is named as the normalisation layer, each rule’s normalised firing strength is calculated.

$$O_{si} = w_i = \frac{w_i}{w_1 + w_2} \quad i = 1, 2 \quad (5)$$

**D. Layer 4**

This layer is the defuzzification layer. Output value for each rule is calculated using the value of firing strength from previous layer.

$$O_{ai} = w_i \cdot f_i = w_i \cdot (p_i x + q_i y + r_i) \quad i = 1, 2 \quad (6)$$

**E. Layer 5**

This is the sum layer. ANFIS’s output is obtained by collecting the output values belong to the each rule that are obtained in defuzzification layer.

$$O_{si} = f = \sum w_i f_i = \frac{\sum w_i f_i}{\sum w_i} \quad i = 1, 2 \quad (7)$$

### III. GENETIC ALGORITHM

Genetic Algorithm (GA) which its fundamental principles are set forth by John Holland in 1970’s, is implemented with success on many problem types [11]. GA is a heuristic algorithm which is used for being able to find exact or approximate results in optimization or search problem. This algorithm is developed by being inspired from the techniques in the evolutionary biology such as inheritance, mutation, selection and crossover. GA can be implemented quite effortlessly even on the multidimensional problems with large-size search space and also with too many number of variables.

GA is a population based optimization algorithm. Equivalent of the candidate solutions that generate the population is chromosomes. Due to the various evolution processes, these chromosomes transform into the solution candidates that represent better results. This process is maintained until reaching an acceptable compliance value or until meeting the criteria such as pre-determined processing time or generation number. Basic steps of the Genetic Algorithm are given in Fig. 2.

1. Generate random population of $n$ chromosomes
2. Evaluate the fitness of each chromosome
3. Create a new population by repeating following steps until the new population is complete
   i. Select two parent chromosomes from a population according to their fitness
   ii. With a crossover probability cross over the parents to form new offspring
   iii. With a mutation probability mutate new offspring at each locus
   iv. Place new offspring in the new population
4. Use new generated population for a further run of the algorithm
5. If the end condition is satisfied, stop, and return the best solution in current population
6. Go to step 2

**IV. TRAINING ANFIS USING GA**

In this section, GA usage for updating ANFIS parameters is explained. ANFIS has two parameter types that have to be updated. These are premise parameters and consequent parameters. Premise parameters belong to the gauss membership function that is given as $\{a_i, c_i\}$ in Equation (3). The total number of the premise parameters is equal to the sum of the parameters in all membership functions. Consequent parameters are the ones that are used in defuzzification layer, shown in Equation (6) as $\{p_i, q_i, r_i\}$.

The method that is suggested in this study is applied to the dynamic system identification problem. For the error value between the output obtained from ANFIS and the output obtained from non-linear dynamic system to be minimum, ANFIS parameters are optimized with GA. Block diagram showing this structure is given in Fig. 3. RMSE error function which is obtained by using Equation (8), is used for determining the error value of the solution. $\bar{y}_i$ is used in Equation (8), is showing the output obtained by ANFIS at the time $i$ and $y_i$ is showing the actual output of the system. $N$ is showing the instance number used in the application.

$$RMSE = \sqrt{\frac{\sum_{i=1}^{N}(y_i - \bar{y}_i)^2}{N}} \quad (8)$$

The selection of the input array which will be used in training is important on the success of training. The elements of the input array are usually chosen from sinusoidal and random input values [13]. In the carried out simulation studies within this study, $u(k)$ input signal array which has proper distribution, randomly generated in the range of $[-2, 2]$ is used.
V. SIMULATION RESULTS

In this section, Applications have been performed by using non-linear dynamic system for the training ANFIS with GA. In order to measure the performance of the system 250 input and output data sets are generated. 200 of these data sets are used for training, the remaining 50 are used for the test.

For the dynamic system, that is going to be modelled, ANFIS structure that consists of 3 inputs and 1 output is created respectively. For each of the input of created ANFIS structure, gauss membership function with 2 parameters is used. Therefore there are 2^n rules in the used ANFIS model [14]. In this way, ANFIS structure consisting 12 premise parameters and 32 consequent parameters with 8 rules is used for the system.

In the study, many attempts have been made in order to decide upon the various parameter values that are required for GA. As a consequence of these attempts, population size is chosen as 200, crossover rate is chosen as 0.8 and mutation rate is chosen as 0.01.

Besides, the performance of the suggested approach is also compared with the results taken from the literature, which belong to the Elman feedback artificial neural network that is commonly used in the identification of the dynamic systems [15,16]. In the considered studies, Kalinli has suggested an approach based on training Elman network by using Tabu Search Algorithm (TS), SA algorithm and Parallel Tabu Search Algorithm (PTS) for the identification of dynamic systems and achieved more successful results than the traditional BP algorithm [15,16].

Sample non-linear system which is used for simulation belongs to a simple pendulum, swinging through small angle that is taken from [15] and defined with Equation (9). The system’s discrete time definition is as follows:

\[ y(k) = A_1 y(k-1) + A_2 y(k-2) + A_3 y^3(k-2) + B_1 u(k-2) \]  

where, \( A_1 = 1.040000, \) \( A_2 = -0.824000, \)  
\( A_3 = 0.130667, \) \( B_1 = -0.160000 \)

\textbf{RMSE} error values that are obtained following the simulation studies, and the error values belong to different methods and that are taken from the literature are given in Table 1. From the results that are given on Table 1, it is clearly seen that the performance of the approach suggested in this study has quite high success comparing to the other methods. Standard deviation for the training and testing processes of the error values that are obtained in 15 different attempts towards training ANFIS with genetic algorithm is found as 0.0032 and 0.0022 respectively. The low standard deviations show that \textit{RMSE} values are close to each other, so it means that the results are reliable. The system that belongs one of the attempts towards training ANFIS with GA and the answers of ANFIS model are given in Fig. 4.

VI. CONCLUSIONS

It has been seen that the best training and test error values obtained are found with the suggested method. Following the studies, finding the admissible \textit{RMSE} error value shows that the training of ANFIS using GA for identification of non-linear systems is quite effective. Besides, the results with the low deviation value has been obtained within the suggested method. Having low deviation value shows that \textit{RMSE} error values obtained from trainings started with different initial solutions are close to each other which means the results are reliable. Also, by reason of the fact that Genetic algorithm does not have restrictions as the derivative-based algorithms have and it is easily applicable on the problems, it is assessed that ANFIS model can be used on its applications for different problems.

Abstract—Fast moving electro-mechanical and wireless communication technologies have made it possible to design and implement multiple unmanned aerial vehicle (multi-UAV) systems which promise more efficient and reliable ways to perform application-specific missions through their simultaneous execution capability and fault tolerant potential. In a typical surveillance-based multi-UAV application, each individual UAV collects required data from its area of interest and transfer it to a ground station (GS) through a shared communication link. In some challenging cases, e.g. in a hostile environment such as battlefield communication, which is unable to establish and maintain a reliable end-to-end communication link between UAV and the GS, Delay Tolerant Network (DTN) paradigm which is based on store-carry-forward data delivery technique can be applied. However, in such system, link layer packet collisions may occur because it is quite possible that multiple UAVs may arrive at communication range of the GS at overlapping times and need to transfer their data simultaneously. This paper presents deadline-sensitive medium access control (DSMAC) protocol designed for DTN based multi-UAV systems. The DSMAC protocol provides a non-preemptive medium access scheme in a centralized manner to make the medium free of collisions. The main objective is to enable UAVs to transfer their large amount of surveillance data as fast as possible to the GS by taking deadline-constrained data delivery requirement into consideration. Our protocol differs significantly from commercially available technologies such as 802.11, 3G or LTE in that deadline meeting rate is the main performance metric in our case rather than providing general connectivity and fair medium sharing among large number of UAVs. Simulation studies are conducted by using NS-2. Results show that DSMAC protocol provides considerable performance improvements in terms of average waiting time and deadline meeting rate when compared to PCF (Point Coordination Function) mode of widely used IEEE 802.11 technology.

Keywords— medium access control, delay tolerant networks, multi-uav systems, deadline sensitive.

I. INTRODUCTION

Recent developments in micro electro-mechanical systems and wireless communication technologies have enabled the realization of unmanned aerial vehicle (UAV) systems. Single-UAV systems, which consist of only one large UAV with powerful hardware, have produced at relatively high costs and provided successful results in many application areas for about last twenty years. On the other hand, much smaller UAVs can be produced at lower costs with the downsizing trend experienced in embedded systems today. The decrease in the size of UAVs brings out strict limitations over maximum take-off load capacity so that application-specific payloads used in these small UAVs have more limited capabilities. For this reason, required efficiency for some UAV applications cannot be achieved by using a single small UAV. In this context, it is considered that a multi-UAV system, which is composed of multiple small UAVs, may offer more efficient solutions by performing jointly missions such as surveillance, reconnaissance, monitoring etc. Using multiple UAVs allows establishing a fault tolerant structure along with providing task completion in a shorter period of time owing to the advantage of its capability of simultaneous task execution in multiple locations. Also, potential coordination capability of multiple autonomous UAVs may provide to accomplish missions that no individual UAV can accomplish on its own. However, multi-UAV approach brings many distinctive challenging design problems.

Communication is one of the most important design problems for multi-UAV systems. The main objective for a multi-UAV application which performs a typical reconnaissance/surveillance mission is increasing success rate of the mission and providing time efficiency by distributing tasks on multiple UAVs. It is required for each individual UAVs in the system to collect application-specific data from its own area of interest and transfer it to a ground station (GS) as soon as possible for further data processing phases. In such applications, it is difficult to setup a reliable end-to-end communication link between UAVs and the GS in cases which locations to be visited for data collection remain out of the communication range provided by the GS or, in more general terms, which there are some challenging conditions in the communication environment such as battlefield communication, disaster rescue etc.

For multi-UAV applications performing tasks which require collecting data in a certain operation area and then deliver it to a GS, it is obvious that there is no need for immediate or real-time data transmission in cases which the application-specific data has a certain degree of delay
tolerance. Clearly, for such cases, it is required to collect delay tolerant data from the operation area, store it into the on-board memory of UAVs, and carry it until reaching required wireless communication range for reliable connection with the GS. In this context, it is considered that using Delay Tolerant Network (DTN) [1] model, which have been developed for similar needs, may provide considerable advantages for such multi-UAV applications. The DTN based data delivery technique considered in this study for multi-uav systems is first proposed by Spyropoulos et al. [2] and it is also known as Direct Delivery. Fig.1 below illustrates a multi-uav system which performs its operation within the context of this simple single-copy DTN delivery scheme. UAVs, as source nodes, carry their application-specific data until they reach the GS.

DTN paradigm has been developed for abnormal network conditions where a reliable communication and a complete end-to-end connectivity between the data source and destination may not exist. Different from traditional networking approach, DTNs are characterized by long latencies, unstable network topologies, and inconsistent connectivity. With these characteristics, DTNs find places in such applications that traditional networks cannot work effectively, for example, data communications in rural area where communication infrastructure cannot be deployed or costly [3], disaster rescue [4], military/battlefield communications [5], etc.

Most of the research efforts on DTN in the literature focus on data delivery/routing schemes for different network scenarios assuming that mobile communication devices are distributed sparsely and network traffic is low. However, link layer packet collision problem in DTN-based applications is not considered in these studies. Within this context, a study conducted by Jindal et al. [6] shows that the packet collision problem should not be overlooked especially for densely distributed communication devices are on subject. In another study, Liang et al. [7] has proposed a DTN-friendly MAC protocol (DFMAC) which is developed for radio resource allocation for a DTN/WLAN integrated networks. In order to address the problem of large delay variance in underwater acoustic channel, Zhang et al. [8] has proposed a cluster based delay tolerant MAC protocol (CBDTP) for underwater wireless sensor networks which is based on predicating a value for a sensor node if its data were not received at the sink node instead of having the sensor node retransmit its data. In another study, Zhong et al. [9] has proposed UMACAW as another delay tolerant MAC protocol which utilize the rest time of RTS/CTS/DATA/ACK exchange period by taking advantage of long propagation delay in underwater channels. However, none of these efforts made on MAC protocols intended for DTN paradigm in the literature take deadline-constrained data delivery requirement into consideration.

For DTN based multi-UAV applications considered in this study, the problem of link layer packet collisions may occur when multiple UAVs arrive at the GS at overlapping time periods and attempt to transfer their data simultaneously, as it is shown in Fig.1. In general, COTS technologies such as IEEE 802.11, 3G, and LTE are used to overcome link layer packet collision problem for such applications. However, the main objective of these technologies is providing medium sharing as fair as possible for large number of stations. Although multi-UAV applications perform their tasks by using DTN model, there may still be some deadline constraints for collected data within certain scenarios. Therefore, the most important need for multi-UAV systems which perform their tasks under such scenarios is providing medium access for UAVs by taking deadline constraints of their data into account and data transmission without any interruption in order to ensure UAVs to continue their tasks as soon as possible. To the best of our knowledge, medium access in DTN has not been studied from this perspective before and this is the first research effort focusing on deadline sensitivity of channel allocation for DTN based multi-uav systems.

To address these needs, in this paper, a MAC protocol for DTN based multi-UAV systems is proposed which eliminates the link layer packet collisions, ensures UAVs to return their operation area as soon as possible by providing data transmission without suspending it because of any other possible transfer requests, and uses deadline information of collected data as a priority measure for medium access. Because the main criteria for medium access is deadline for transmission of data to the GS, the proposed MAC protocol is named as “Deadline-sensitive Medium Access Control” (DSMAC). DSMAC protocol provides a centralized medium access model using two different communication channel. Tests for DSMAC protocol are conducted by using NS2. DSMAC’s superiority over PCF (Point Coordination Function) [10] mode of widely used IEEE 802.11 protocol are analyzed through performance metrics such as average waiting time and deadline meeting rate. Simulation results show that channel allocation scheduling mechanism and centralized MAC model provided by DSMAC protocol outperforms IEEE 802.11 PCF in terms of average waiting time and deadline meeting rate for aforementioned multi-UAV applications.

The remainder of the paper is organized as follows. The protocol design issues and its operation details are described in Section II. Medium access scheduling mechanism of
DSMAC is provided in Section III. Performance evaluation and simulation results are presented in Section III. Finally, the paper is concluded in Section IV.

II. DSMAC PROTOCOL

In the following sections, we first present an overview of proposed DSMAC protocol to discuss the main objectives and then we provide the design issues of DSMAC with its operation details.

A. Overview

For a DTN based multi-UAV system considered in this study which performs a surveillance-based mission, UAVs are required to collect application-specific data from their area of interests, store data in their own on-board memory, and then deliver them to the GS by moving to it until they arrive at required communication range for reliable wireless connection. Clearly, there is a need for a MAC protocol in order to regulate medium accesses of UAVs in such cases that multiple UAVs arrive at GS for data transmission at overlapping time periods and attempt to access the medium simultaneously.

One of the most important limitations for UAVs is endurance capability. In order to utilize limited flight duration of UAVs within the context of data transfer to the GS, it is quite important to consider this fact at MAC level operations. Besides that, certain applications may necessitate specific amount of delay tolerance for data delivery rather than completely disregarding it even they perform under DTN paradigm. For these reasons, to assure effective usage of limited flight duration and timely data delivering, deadline-constraint data transmission to the GS as fast as possible must be effectively handled by an efficient MAC protocol mechanism. To this end, the main objectives of DSMAC protocol we design for DTN based multi-UAV systems are:

- creating a centralized channel allocation mechanism in order to provide contention-free medium access for UAVs,
- using two different communication channels for data and control frames to utilize data channel effectively,
- making channel allocation scheduling non-preemptive to avoid suspending ongoing transmission,
- taking record deadlines into consideration for channel allocation to increase the deadline meeting rate as much as possible

B. Design

DSMAC protocol is designed to provide a centralized MAC scheme for DTN based multi-UAV systems. Accesses to the medium are controlled only by the GS. It performs its operations as a coordinator while UAVs in the system are its associated mobile nodes. None of the UAVs has a direct access permission to the medium. UAVs are allowed to transmit their data only when the GS sends a special frame to them, which is called START. Fig.2 below shows the START frame format. It is important to note that Frame Control field which has a number of sub-fields such as protocol version, frame type/subtype, retry flag, etc. is inherited from the 802.11 protocol specifications due to its ease of NS2 implementation.

As it is shown in Fig.3, UAVs arriving at the GS wait for the START frame to start transfer their data to the GS. The GS, as a coordinator, is responsible to decide which UAV is allowed to use the channel first. The details of this decision process is described in Section III. Because UAVs are not allowed to access the channel freely, an ongoing transmission is not interrupted by other UAVs. Clearly, there is no contention among UAVs to gain the access to the channel due to the centralized mechanism of DSMAC. To this end, additional frame exchanges between the communication nodes in order to avoid packet collisions such in CSMA/CA are not needed in DSMAC protocol.

In DSMAC protocol, it is assumed to be used two different transceiver in UAVs with two antennas and their associated communication circuitry. One of them performs on data channel while the other uses control channel. It is also assumed that possible interference between two transceivers are resolved using a kind of digital signal processing methods or physical precautions.

It is clear that the GS has to be informed by UAVs in some way to notify that they have records to be transferred to the GS. In this regard, we introduce a term meta-info, which is a brief information of records to be transferred to the GS. Since the DSMAC provides coordinator initiated data transmission, this information is used by the GS to schedule
the channel allocations properly and to send a START frame to a UAV. The control channel mentioned above is used by UAVs to send their meta-info to the GS when they arrive. Thus, UAVs are able to send their data transfer requests using control channel without violating the data channel. Because the size of meta-info is quite small and the essential need for control channel is to provide a reliable communication link between UAVs and the GS, it is considered as a contention-based channel which can be implemented by using one of the COTS technologies such as XBee 802.15.4 [11] or Wi-Fi [10] modules. Data channel, on the other hand, is the channel allocated by the GS to a UAV for reliable data transmission using ARQ. Contention-free medium access for data transfer is provided using the data channel. Thus, DATA-ACK exchanges start between the UAV#1 and the GS. After a short time, as this frame exchange continues between the UAV#1 and the GS, UAV#2 arrives at GS and sends its meta-info using control channel as it is shown as red frames in the figure. In this way, the meta-info transmission does not disturb the ongoing data transmission. In order to notify the GS for last DATA frame, UAV#1 set a flag into the Frame Control field of DATA frame which is shown in the figure as a red marker on the end of the last DATA frame sent by UAV#1. The GS notices that it can send START frame to allocate the data channel to the UAV#2. To assure its last ACK frame as a feedback is received by the UAV#1, it waits for a \( t_D \) period of time before sending a new START frame to the UAV#2. Although the details of channel allocation scheduling performed by the GS is provided in Section III, at this point, it is important to note that the GS does not stop the current data transmission even that UAV#2 has a record with higher priority than the UAV#1 has. This is because the GS schedules channel allocations based on non-preemptive Earliest Deadline First service discipline as described later.

\[
t_D = TX_{ACK} + DSSS_{MAX} + TX_{DATA} + DSSS_{MAX}
\]

The time period of \( t_D \) used in NS2 implementation of DSMAC is calculated as below. It is the sum of transmission time of ACK frame (\( TX_{ACK} \)), maximum propagation time for ACK, transmission time of DATA frame (\( TX_{DATA} \)), and maximum propagation time for DATA. Additionally, in order to provide reliable communication between UAVs and the GS, retransmission timers for DATA packets sent by UAVs and START packets sent by the GS are also implemented in a similar way in NS2.

III. CHANNEL ALLOCATION SCHEDULING

As described before, DSMAC protocol provides a centralized channel access scheme. Access to the medium is completely controlled by the GS so the possibility of contention for the medium is eliminated. UAVs arrived at the GS send their meta-info using control channel. The GS uses meta-info to create an access priority plan by considering delivery deadlines of records. An example meta-info sent by a UAV to the GS is presented in Table I below.

<table>
<thead>
<tr>
<th>UAV Id</th>
<th>Record Id</th>
<th>Deadline (sec)</th>

<td>3</td>
<td>830</td>
</tr>
</tbody>
</table>

Channel access function implemented in the GS uses a service discipline based on Earliest Deadline First (EDF) [12] scheduling algorithm which is generally used in real-time operating systems. The channel access function places transfer requests into a priority queue. Whenever a data transfer is completed, the queue is searched for the transfer request which has minimum delivery deadline value for the
next data transfer. Unlike EDF, scheduling algorithm used in DSMAC is non-preemptive. This means the GS does not suspend ongoing data transfer to start another one. Although a newly received meta-info has a record with higher priority, which means a closer deadline value, current data transfer is waited for to end. The reason that we are using such non-preemptive mechanism for channel access service is limited flight duration of UAVs. It is important to note that one of the major objectives of DSMAC is to allow UAVs to continue their operation as soon as possible in addition to satisfy deadline constraints of the records.

It is better to present a case study to gain more insight regarding different scheduling mechanisms. To this end, we provide a sample transfer requests made by three UAVs in Table II.

</tbody>
</table>

Based on the transfer requests provided in Table II, Gantt charts and results for some performance measures are provided in Fig.6 and Fig.7 according to round-robin and non-preemptive EDF scheduling algorithms corresponding to 802.11 PCF and DSMAC, respectively. Gantt charts show the order of data transfers for corresponding scheduling algorithms. Performance measures used in this case study can be defined as:

- The **Waiting Time** is an amount of time a data transfer is waiting in the ready queue or sum of time waiting in ready queue.
- The **Turnaround Time** is an amount of time to complete a data transfer (time from first placed in ready queue to transfer completion).
- The **Response Time** is an amount of time it takes from when a transfer request is placed in ready queue until the first response is produced (not completion of transfer).
- The **Deadline Meeting Rate (DMR)** is the rate of satisfied deadline constraints of records.

If round-robin scheduling is applied to sample transfer requests provided in Table II, as it is shown in Fig.6, transmission of records is performed in a fragmental manner with the 10 sec quantum value. Because round-robin scheduling is a preemptive approach, it gives relatively high average times compared to non-preemptive EDF (Fig.7). The reason that we prefer to use round-robin scheduling mechanism to compare it with the scheduling algorithm used in DSMAC (non-preemptive EDF) is because it is used in 802.11 PCF.
PCF which also provides a centralized and contention-free medium access as DSMAC we propose.

![Fig. 7. Results for non-preemptive EDF scheduling.](image)

As it can be seen from Fig.6 and Fig.7, non-preemptive EDF provides considerable performance improvement in terms of DMR. This is because it schedules data transfer requests by considering deadlines of records even it does not suspend ongoing transfer. The round-robin scheduling also satisfies a number of deadline constraints, but this is made unconsciously.

### IV. PERFORMANCE ANALYSIS

Studies on performance issues are conducted by using NS2. As another centralized medium access mechanism, 802.11 PCF, is used to compare it with proposed DSMAC protocol. DSMAC is implemented by making modifications on 802.11 PCF support patch [13] in NS2. Contention period of PCF is deactivated so only centralized contention-free medium access scheme is considered for comparison between PCF and DSMAC. PHY layer parameters are set based upon 802.11b standard. Deadline Meeting Rate (DMR) and Average Waiting Time (AWT) are considered as main performance measures that we employ to measure the performance of DSMAC protocol. All simulation results provided below are average results of 20 experiments. Table III shows general parameters used for wireless node configuration in simulation studies.

![Table III](image)

A. Effects of Average Inter-arrival Time

One of the main factors which effects DMR is inter-arrival times of UAVs to the GS. When real-world conditions are considered, arrivals of UAVs to the GS are completely random and independent from each other. However, when these random occurrences of arrivals are observed long enough, a certain occurrence rate can be obtained. For this reason, random UAV arrivals to the GS are considered as a Poisson process which is widely used random process to model random points in time. In this context, inter-arrival times between UAV arrivals to the GS are produced based on exponential distribution which arise naturally from the Poisson process.

![Table IV](image)

![Fig. 8. Change in DMR with respect to average inter-arrival times.](image)

Simulation result provided in Fig.8 shows how average inter-arrival times effect DMR both for DSMAC and PCF. In this simulation study, a multi-UAV system is considered to be formed by 4 UAVs. Number of records per UAVs are determined as a random integer between 1 and 5. Record sizes are randomly generated between 5 and 10 MB considering that UAVs collect data as 720p (1280x720) video with the length between 30 and 60 seconds. Deadlines for each records are also randomly generated between 1.5 and 5 times of delivery time estimation of corresponding record to the GS. All random generations are based on uniform distribution except random inter-arrival times which are generated based on exponential distribution. Parameters used in this simulation study is provided in Table IV.

![Graph](image)

As can be seen from the Fig.8, there are similar trends for DSMAC and PCF with respect to DMR. DSMAC outperforms PCF for all average inter-arrival times used in the simulation. When it is considered that a UAV in the...
system has 3 records and 7.5 MB each on average, average total transfer time of these records to the GS is calculated approximately as 77 seconds according to parameters used in the simulation. Performance gain obtained for average inter-arrival times which are close to this average value (50, 75, 100) is about 8% on average while more relaxed average inter-arrival times provide performance gain up to 15% as it is shown in Fig.8. For shorter average inter-arrival times, PCF, which do not take record deadlines into account, may complete most parts of the records which have longer deadline early in the process owing to its round-robin based medium access scheduling mechanism. On the other hand, even DSMAC considers record deadlines for medium accesses, it may suffer from convoy effect problem for shorter average inter-arrival times because of its non-preemptive scheduling scheme. For these reasons, the diversity on performance gain for different average inter-arrival times is observed in the simulation.

Another performance measure which is effected from inter-arrival times to the GS is AWT for records. Fig.9 above shows the change in AWT with respect to average inter-arrival times for the same parameter configuration described for the previous simulation. Both DSMAC and PCF have similar trends for AWT. AWT decreases as average inter-arrival time is increased. It is observed that DSMAC has lower values of AWT for all average inter-arrival times used in the simulation. For more frequent arrivals of UAVs, the difference between AWT values for DSMAC and PCF is much more as it can be seen from the Fig.9. This is because of that DSMAC provides non-preemptive medium accesses while PCF provides round-robin based scheduling. When average inter-arrival time is relaxed enough, both protocols converges to their worst-case AWT values and the AWT gain obtained after their convergence is up to 17 seconds approximately.

Parameters used for another simulation study which is conducted to observe how DMR is effected by different UAV arrival periods for multi-UAV systems consisting different number of UAVs are provided in Table V. An arrival period indicates a period of time which all UAVs of a multi-UAV system should arrive. In this context, a certain arrival period provides different average inter-arrival times for different multi-UAV systems. Table VI shows corresponding average inter-arrival times for three different multi-UAV systems used in this simulation.

</tbody>
</table>

In this simulation, three different multi-UAV systems which consist 4, 8, and 12 UAVs are considered to arrive at the GS in 5, 10, 15, and 20 minutes. Simulation result is presented in Fig.10. As it can be understood from the Table VI, for the same arrival period, inter-arrival times for different multi-UAV systems varies because of the number of UAVs they consist. For arrival period of 5 minutes, multi-UAV systems of 4, 8, and 12 UAVs have 100, 42, and 28 seconds average inter-arrival times respectively. Therefore, results obtained for DMR in 5 minutes of arrival period...
show that 4-UAV system has a DMR about 80% while 8-UAV and 12-UAV systems have about 20% and 10% DMR respectively for DSMAC protocol. Also, it is observed that DSMAC outperforms PCF with respect to DMR for all arrival periods used in the simulation. In addition, multi-UAV systems consisting much more UAVs reach their maximum DMR slowly while systems that contain fewer UAVs converges its maximum DMR more quickly because of varying corresponding average inter-arrival times.

B. Effects of Average Record Size on Average Waiting Time

Size of records UAVs have directly effects the AWT performance for both protocols due to its first-hand relation to the transmission time. This simulation study is conducted to show how AWT changes through the average size of records. Simulation configuration is provided in Table VI below.

<table>
<thead>
<tr>
<th>TABLE VII</th>
<th>SIMULATION PARAMETERS</th>
</tr>
</thead>
<tbody>
<tr>
<td>Parameter</td>
<td>Value(s)</td>
</tr>
<tr>
<td>Number of UAV</td>
<td>4</td>

</tr>
<tr>
<td>Deadline Range</td>
<td>[tTx x 1.5, tTx x 5] s</td>
</tr>
<tr>
<td>Average Inter-arrival Time</td>
<td>75 s</td>
</tr>
</tbody>
</table>

As shown in Fig.11, AWT is increased as the average record size is increased. DSMAC outperforms PCF for all average record sizes used in the simulation. This is because DSMAC do not interrupt an ongoing transmission in its operation while PCF performs a preemptive medium access scheme allowing all UAVs arrived at GS to access the medium for short periods by turns.

C. Effects of Delivery Deadline Range on Deadline Meeting Rate

Delivery deadlines for records is another consideration for DMR. The delivery deadline generation range that we use in simulation studies have a great impact on performance of meeting these delay bounds. In simulation studies, deadlines are generated within a certain range using random uniform distribution. Based on the fact that UAVs are assumed to be capable of making delivery time estimation for each record they have, deadlines for each records are randomly generated between 1.5 and \(i\) times of delivery time estimation of corresponding record. The value of \(i\) indicates the maximum boundary of the delivery deadline range. Fig.12 shows the change in DMR with respect to deadline generation range for DSMAC and PCF. Parameters used in this simulation is provided in Table VIII.

TABLE VIII

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Value(s)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number of UAV</td>
<td>4</td>
</tr>
<tr>
<td>Number of Record for each UAV</td>

<td>[tTx x 1.5, tTx x 3, 5, 7, 9] s</td>
</tr>
<tr>
<td>Average Inter-arrival Times</td>
<td>75 s</td>
</tr>
</tbody>
</table>

Here, our aim is to observe DMR performance of DSMAC and PCF by relaxing the deadline range gradually. As shown in Fig.12, both DSMAC and PCF have poor performance results for initial deadline range which is too strict to meet the deadline constraints of records in this simulation configuration. As this range is relaxed by increasing the maximum limit of the range, both protocols have started to produce better results in terms of DMR. This is because the value of average deadline is also increased when the range that we generate random deadlines is relaxed. It is also shown that DSMAC gives better DMR performance results than PCF for all ranges that we choose due to its deadline sensitivity. Although the performance difference between two protocols is much less for too strict deadline ranges, it grows as the range is started to be wider until reaching a certain point. If the maximum boundary of the range is increased too much, it is obvious that both protocols will be capable of meeting deadlines of all records naturally due to high average deadline range obtained in this case.

Fig. 11. Change in AWT with respect to average record size.

Fig. 12. Change in DMR with respect to delivery deadline generation range.
V. CONCLUSION

Research efforts on DTN in the literature mainly focus on data delivery/routing schemes. However, link layer packet collision problem should not be overlooked for DTN based applications, particularly, densely distributed nodes are on subject. Additionally, certain applications may necessitate specific amount of delay tolerance for data delivery rather than completely disregarding it even they perform under DTN model. Based on such DTN-based applications under multi-uav system scenario, Deadline Sensitive Medium Access Control (DSMAC) protocol is presented in this paper.

The DSMAC protocol is a novel medium access solution that seeks to achieve timely data transfer as possible with contention-free and centralized access mechanism. It enables UAVs in a DTN-based multi-UAV system to continue their operation as fast as possible with non-preemptive scheduling executed on channel access function in the GS. To the best of our knowledge, medium access in DTNs has not been studied from this perspective before and this is the first research effort focusing on deadline sensitivity of channel allocation for DTN based multi-uav systems.

To investigate the performance of DSMAC protocol, we have developed an evaluation environment by implementing it on NS2. In addition, DSMAC has been compared to PCF mode of widely used IEEE 802.11 protocol in terms of deadline meeting rate and average waiting time performance measures. Simulation results show that DSMAC protocol provides considerable performance improvements in terms of average waiting time and deadline meeting rate.

Abstract - Nowadays, many companies meet the needs of data from different data sources in different formats in order to line with changing business needs. Data is managed and stored in different parts of the system. Business intelligence is the most effective solution that allows to see big picture by integrating all of the distributed data within a storage. Business intelligence has emerged as a natural result of the previous system designed to support the decision-making process. Over time, visual deficiencies discovered in decision support systems, difficulties of usage and mismatch between applications, is one of the major factors in the rise of business intelligence technology. Such solutions are up to date and integrated view of business performance it offers the greatest benefits to decision makers.

By increasing centralization of data quality, control and scheduling capabilities have allowed us to take quick and right decisions in the evolving competitive environment. The concept of business intelligence is an important element of taking strategic decisions and implementation point in globalized world. This study has designed by Oracle business intelligence tool and results have been a key element of evaluation in decision making processes of the companies.

Keyword – Decision making, business intelligence, big data

I. Introduction

Rapid changes in the business life and complex situations that come along with these changes force businesses to make fast and accurate decisions. This journey started with the use of decision support systems which are being replaced by business intelligence technologies due to changing business needs.

Instead of depending on their personal predictions and intuition, decision makers must adopt approaches based on facts in order for companies to have competitive advantage. With the introduction of business intelligence tools, centralized data sources enhance data quality and control, as well as shortening decision-making and action-taking time by preventing decision makers from getting lost in different data sources. Centralized data sources may sometimes appear in the form of data warehouses and sometimes in the form of data marts containing department- or issue-specific solutions.

The number of studies in Turkey on business intelligence systems, which are recognized more and more by companies for their importance, is insufficient. The purpose of this study is to emphasize the effect of business intelligence solutions used in the finance sector, which has a direct relationship with money, on company strategies and explain their advantages for companies.

II. Strategic Decision-Making

Strategic decisions have long-term and profound impacts. Access to complete and accurate information in line with business needs on time has made decisions more structured. Data warehouses store the data constantly cleaned and updated with ETL (Extract-Transform-Load) processes, which are designed in a planned way, and fulfill the quality data element, which is one of the important factors in the decision-making process. Softwares that allows for the management of the business intelligence process contribute to the decision making process by bringing all the technical work to a level which the decision maker will understand using visual tools such as display panels, pivot tables or graphs.

Decision-making and action-taking occur after the intervention of many factors simultaneously. Considering today’s conditions, competition between companies seem to be getting fiercer with each passing day with emerging technology. To be able to survive in the dynamic business life is not possible with adopting emerging technologies to the company alone. The cornerstone of fast and effective decision-making is to provide analyses designed in accordance with today’s needs to competent decision makers who are able to accurately assess results of these analyses, which provides a considerable competitive advantage for companies.

It has been found in recent studies that most companies cannot use corporate data in decision-making processes efficiently. The amount of collected data increases exponentially with each passing day, which means that the competition between companies increases at the same pace. It is of great importance to have different and well-integrated information sources for an effective decision-making process. At this point, business intelligence is provision of a powerful,
low-cost, easy-to-use and sharable source, which can meet the needs.

The resulting heaps of information with changing technology were not useful to upper management. A need for management information systems allowing for the presentation of integrated and summary data emerged. Decision support systems were developed for this purpose. However, visual inadequacies, usage difficulties and integration problems between applications created the need for a new system to achieve this purpose and established a ground for the introduction of Business Intelligence Systems.

III. Business Intelligence

Business intelligence as a term was used for the first time in 1989 by Howard Dresner, who worked as an analyst and researcher at Gartner Group. Howard Dresner saw business intelligence as a decision support system based on facts and an umbrella covering all methods and ideas that enhance the ability of business-related decision-making.

Humanity’s endless search has been an important driving force in the advance of technology, as in many areas of life. Findings and results obtained from research have been the harbinger of new technologies of future. Business intelligence designs and softwares are a new technology developed in order to overcome deficiencies experienced by companies in relation to support the decision-making process and increase administrative decision-making efficiency, which has began to be used in practice.

Business intelligence application softwares are considered to be the latest point that decision support systems have reached. Therefore, they have a wider scope compared to decision support systems. They contain a higher level of analysis and more estimation algorithms. In addition, offering a powerful visual tool support is one of the important reasons why they are used widely today.

A well-designed technological infrastructure is not enough for a new solution to be adopted widely. To correctly describe and explain the philosophy behind the solution and its meaning is at least as important as the solution itself. Many definitions have been made for business intelligence to emphasize its contribution to the decision-making process and effectiveness of administrative decision-making ([1-6]).

Kraft Foods, which has its head office in Illinois, USA, employs about 125,000, has a annual revenue of USD 110 million with its more than 70 brand, has 40 brands in the market for more than 100 years and has an asset size of USD 49 billion and is the second biggest food company in the world, started to use SAP Business Objects BI 4.0 business intelligence application in 2012. The main purpose of the project was to make it possible to rapidly and effectively reach the rich data in the ERP system of the company through user-friendly interfaces. Mike Walsh, the Business Intelligence Director of Kraft Foods expressed his satisfaction with the installation and implementation by saying, ”These solutions have made everything we do easier”. In addition, improved query performance and more self-serve reporting across the company are other positive outcomes of the project.

Considering success stories with business intelligence softwares, the following are observed ([7.8]):

- It is possible to access the desired data at the desired place through visual graphics comfortably and understandably without needing IT specialists,
- It is possible to access appropriate data among million lines of data in a shorter time and ensure a faster decision-making process,
- The huge amount of time spent for data tabulation and evaluation can be channelized to customers and decision makers,
- A lower number of key performance indicators are used,
- A higher level of report optimization is achieved,
- The simplification of data is much more comfortable.

IV. Experiments

In terms of accounting and financial reporting, the information required by banks for analysis and interpretations such as the following is prepared in a standard way:

- Ensuring uniformity,
- Obtaining uniform balance sheets and income statements directly,
- Obtaining information required for auditing and supervision in a verifiable and auditorable manner,
- Reaching information required by authorities to monitor and direct the economy and other statistical data,
- Financial analysis,
- Risk analysis,
- Efficiency analysis.

Oracle Business Intelligence 11.1.1.7.140527 was used in the implementation of the study. Within the scope of our study, we held meetings with finance group employees in different periods in order to determine business needs both verbally and in written. As a result of these meetings, the study was shaped on a business model covering technical analysis documents and queries that end-users desire and may desire in future.

Database which was used

- Oracle Database 11g Enterprise Edition Release 11.2.0.4.0 - 64bit Production
- PL/SQL Release 11.2.0.4.0 - Production
- CORE 11.2.0.4.0 - Production
- TNS for Linux: Version 11.2.0.4.0 - Production
- NLSRTL Version 11.2.0.4.0 – Production

Business Intelligence Production

Oracle Business Intelligence web interface is a reporting tool that allows us to reach the data in the system in line with defined targets, perform analyses that make is possible to make healthy decisions and present these with visual richness. Once the Data Mart design, which is the first phase of the study, is completed, we can go on with the next phase, which is providing an Oracle web interface for end-users. This phase which emerges after needs analysis allows end-users to create reports using a drag and drop technology. The relevant screenshot is given in Fig.7.

![Figure 7. Displaying analysis results](image)

V. Conclusion

Reports obtained as a result of the solution designed within the scope of the study allows us to find customer details based on the ledger account number.

The solution, which began to be used by the finance group of the bank, allows us to find customer details based on the ledger account number and evaluate loans given or taken by the bank from a financial perspective. Requested data presents periodic profit and loss information to the bank. It also allows for a cross-check between bottom totals of accounts found on the basis of customer and voucher number and bank balance, which is used a checking tool in accounting. These checks lay the groundwork for preparation of steps that will allow for healthier banking operations by detecting vouchers prepared for the wrong account number. For example, it is possible to make improvements in the current banking software thanks to detection of continuous mistakes. Also, long-term and short-term loan information that banks are obliged to report to the tax office periodically, constitute a resource for decisions related to loans for the government.

Elevator System. A Case Study of Coloured Petri Nets

Eman Assiri², Mohammed Assiri¹, and Ryszard Janicki¹

¹Department of Computing and Software, McMaster University, Hamilton, Ontario, Canada L8S 4L8
²Mohawk College, Hamilton, Ontario, Canada L9N 1E9

Abstract—A fairly general model of the elevator system is presented. Coloured Petri Nets (CPN) and CPN tools are adopted as modeling tools. The model, which is independent of the number of floors and elevators, covers different stages of the elevator system in substantial detail. The model assists simulation-based analysis of different algorithms and rules which govern real elevator systems, including calculating serving time and waiting time. The results prove the compatibility and applicability of this model in various situations and demonstrate the expressive power and convenience of CPN.

I. INTRODUCTION

Coloured Petri Nets (CPN), first proposed in [7] and later substantially modified and enhanced in [8] and [9], are an extension of Petri Nets (c.f. [13]), and are often used to model behaviours of large variety of complex systems. Nevertheless, the question whether or not CPN are an effective technique for modeling real-world applications of interconnected communicating systems is still of interest for software developers and modelers. In this paper we discuss a CPN model of the elevator system. The elevator system is one of the software engineering benchmarks that are frequently used to test the expressive power, readability and convenience of various formal specification techniques [5].

This paper is an extension and refinement of the results presented in [1], however it can be read independently. The main difference is calculating service time and waiting time.

Various types of Petri nets have been used to model the elevator system before, a detailed list of references can be found in [1], here we mention only [4], [6], [10] and [11].

Nevertheless, all the previous models (except [1]) are either static, or the concept of colour as a data type was not fully utilized, or other formalisms as UML were substantially involved.

The model presented in this paper is independent on the number of floors and elevators, it covers in substantial detail different stages of the elevator system. We believe our model is flexible enough to be adapted to different algorithms and rules, and may eventually evolve in a ‘standard’ formal model of the elevator system.

II. THE ELEVATOR SYSTEM

Elevator systems are an integral aspect of most buildings. Transportation between floors, often with heavy goods, is in many cases almost impossible just by using stairs, especially for high-rise buildings. Quite often multiple elevators are required and such systems are usually very complex. Multiple elevators must be controlled by a centralized control mechanism. The complexity of these elevator systems arises from factors such as scheduling needs, resource allocation, and stochastic control, to name a few. Handling these jobs usually results in systems behaving as discrete event systems [12]. Moreover, the differences among the types of buildings and their traffic patterns also add to the complexity of the elevator systems. For example, elevator passengers in residential, institutional, or commercial buildings might face some mix of popular traffic patterns as: up-peak traffic (also called incoming traffic) where the traffic flows mostly from the first floor to other floors, down-peak traffic (also called outgoing traffic) where the traffic flows mostly to the first floor from other floors, and balanced traffic (also called random traffic) where none of the two previous patterns dominates [2], [14].

The elevator system is usually defined as follows [5]: An elevator system is to be installed in a building with m floors and n cars. The elevator and the control mechanisms are supplied by the manufacturer. The internal mechanism of an elevator system is assumed (given). The problem concerns the logistics of moving cars between floors according to the following constraints:

• Each elevator’s car has a set of buttons - one for each floor. These buttons illuminate when pressed and signal the elevator to move to the corresponding floor. The illumination is canceled when the corresponding floor is visited by the car.

• On the wall outside the elevator each floor has two buttons (with the exception of the ground and the top floors). One button is pressed to request an upward moving elevator and another button is pressed to request a downward moving elevator. If both buttons are pressed, then each direction is assigned to a different car. These buttons illuminate when pressed. The illumination is canceled when the assigned car visits the floor.

• When an elevator has not received any requests for service, it should be held at its parking floor with its doors closed until it receives further requests.
• All requests for elevators from floors (i.e. hall calls) must be serviced eventually. The applied algorithm controls the priority of floors. 
• All requests for floors within elevators (i.e. car calls) must be serviced eventually, with floors usually serviced sequentially in the direction of travel. 
• Each elevator’s car has an emergency button which when pressed causes a warning signal that is sent to the site manager. The car is then deemed “out of service”. Each car has a mechanism to cancel its “out of service” status. 

### III. COLOURED PETRI NETS

Coloured Petri Nets are a discrete-event modelling language combining the capabilities of Petri Nets with the capabilities of a high-level programming language. Petri Nets provide the foundation of the graphical notation and the basic primitives for modeling concurrency, communication, and synchronization. Coloured Petri Nets allow tokens to have a data value attached to them. This attached data value is called token colour. Coloured Petri Nets allow tokens to have a data value attached and to be used to model concurrency, communication, and synchronization.

A semi-formal definition can be given as follows: A Coloured Petri Net is a tuple:

\[ N = (P, T, A, \Sigma, C, N, E, G, I) \]

where:

- \( P \) is a set of places and \( T \) is a set of transitions.
- \( A \) is a set of arcs and \( P \cap T = P \cap A = T \cap A = \emptyset \).
- \( \Sigma \) is a set of colour sets defined within CPN model. This set contains all possible colour, operations, and functions used within CPN.
- \( C \) is a colour function which maps places in \( P \) into a colour in \( \Sigma \).
- \( N \) is a node function which maps \( A \) into \( (P \times T) \cup (T \times P) \).
- \( E \) is an arc expression function which maps each arc \( a \in A \) into the expression \( e \). The input and output types of arc expressions correspond to the type of nodes which the arc is connected to.
- \( G \) is a guard function which maps each transition \( t \in T \) into guard expression \( g \). The output of the guard expression should evaluate to Boolean value \textit{true} or \textit{false}.
- \( I \) is an initialization function which maps each place \( p \) into an initialization expression \( i \). The initialization expression must evaluate to a multiset of tokens with a colour corresponding to the colour of the place \( C(p) \).

CPN support hierarchical modeling and are equipped with a modeling language called CPN ML which is based on the standard functional programming language ML. There are a variety of tools that can be used. In this paper the tools from [3] have been used. For more details and theory of CPN, the reader is referred to [9].

Throughout this paper we will use \( \mathbb{R} \) (\( \mathbb{R}^+ \)) to denote \textit{Reals} (non-negative \textit{Reals}), \( \mathbb{Z} \) (\( \mathbb{Z}^+ \)) to denote \textit{Integers} (non-negative \textit{Integers}), \( [x_1, \ldots, x_n] \) to denote the list \( x_1, \ldots, x_n \), and \( \text{lists}(X) \) to denote finite lists built from the elements of \( X \).

### IV. CPN-BASED MODELLING OF ELEVATOR SYSTEM

Our model of the elevator system consists of four major interconnected but independent sub-models, namely: \textit{timing car-structure}, \textit{timing hall-call}, \textit{timing car-call}, and \textit{timing system-cycle}.

Their functions and interconnections are described as follows. The timing car-structure sub-model represents the elevator’s cars. It is at the centre of all other sub-models that concurrently control the elevator’s cars. Typically, an elevator car is requested by either a hall-call or a car-call. A hall-call is placed by pressing a button located in the hallway of a given floor while a car-call is placed by pressing a button inside the car of the elevator. When a hall-call is placed, the timing hall-call sub-model will assign the hall-call to the appropriate car of the timing car-structure sub-model (details depend on the algorithms that are used). Similarly, the timing car-call sub-model coordinates the placed car-calls with the cars of the timing car-structure sub-model. Finally, the timing system-cycle sub-model operates the cars of the timing car-structure sub-model to service the requested calls.

#### A. Timing Car-Structure

The timing car-structure sub-model (Figure 1) is composed of two places: Timing Cars and Timing Database, that also belong to other sub-models. The Timing Cars place is a Cartesian product defined in Table I. The Timing Database place, defined in Table II, is just a list of cars’ states data. Hence, both places are initialized dynamically by the functions \textit{initialize cars} and \textit{initialize database} respectively (see Figure 1).

![Fig. 1: The timing car-structure sub-model](image)
hall calls are used to transfer the tokens of assigned hall calls from the timing hall-call sub-model to the timing system-cycle sub-model. The other elements of the colour set Timing Cars are rather self-explanatory.

</tr>
</tbody>
</table>

**B. Timing Hall-call**

This sub-model executes an algorithm, giving by the user, that assigns a hall-call to the most appropriate car. It also can generate hall-calls from arbitrary floors, selected floors, or both.

Invoking hall calls, which involves button illuminations, starts from place Hall Buttons, which contains a single token from the colour set defined in Table III. In principle, it is a list of triples (IB, USB, UUB), where IB - illuminated buttons (IB), USB - unilluminated-specified buttons, and UUB - unilluminated-unspecified buttons, are also (internal) lists.

Invocation of a Hall Call requires the firing of transition Release Hall Call. This transition is enabled if and only if the following conditions are satisfied:

1) At least one of USB or UUB is not empty,
2) If the limit of producing calls is finite, then it has not been already reached,
3) The number of produced calls is less than the value of parameter pause number (see Table IV).

The condition (3) guarantees the balance between the producing process and the assignment process.

After firing the transition Release Hall Call, an appropriate tuple from either the USB list or the UUB list is removed and placed into both the IB list and place Requested Hall Call. The choice between the USB list and UUB list is based on the following rules:

1) When one list is empty, the other list is always selected.
2) The difference between both lengths of lists is less or equal to the value of parameter frequency of most requested floors.
3) The internal choice between tuples is sequential for USB list and arbitrary (non-deterministic) for UUB list.

The waiting time is calculated in three steps. First, when a hall call is released from place Hall Buttons and put in place Requested Hall Call, the current times of all cars become attached to this hall call (see Table V). Second, when the placed hall call is assigned to a car, it is removed from place Requested Hall Call and the lists: desired-floors and served-hall-calls (see Table I) are appropriately modified.

Third, when the assigned car arrives at the floor of the placed hall call, then the waiting time is calculated as the absolute value of the difference between the time of the car’s arrival and the registered time when the hall call was released. For more details and particular algorithms, the reader is referred to [1].

Fig. 2: The timing hall-call sub-model
The parameters of the timing hall-call sub-model

<tr>
<td>Production pause number</td>
<td>{ p</td>
</tr>
</tbody>
</table>

The transition Place Car Call is enabled if and only if the following conditions are satisfied:
1) At least one of the lists UUCB and USCB is not empty,
2) The selected car has not reached its maximum number of accepted calls,
3) If the limit of producing calls is finite, then it has not been reached yet.

A selected algorithm in Timing Hall-call sub-model may also affect car calls process. Firing the transition Place Car Call modifies two lists: most-desired floors (see Table VII) and illuminated car buttons (ICB), by placing appropriate floor number in both of them respectively.

</tr>
</tbody>
</table>

D. Timing System-cycle
The Timing System-cycle (Figure 4) models three stages: maintenance, arrival, and transition, of cars operations. In addition, it makes a simulation-based analysis possible.
At the arrival stage, when a car reached its desired destination, transition Arrival fires and the time of a delivered call is calculated and logged. If the delivered call was a hall call then the waiting time is the absolute value of the difference between the arrival time of the car and the registered time when the hall call was placed. The calculated result is stored in place Hall Call LOG (see Table VIII for an appropriate colour sets).

Similarly, the serving time of a delivered car call is the absolute value of the difference between the arrival time of the car and the registered time when the car call was placed (see the timing car-call sub-model). The result is stored in place Car Call LOG (c.f. Table VIII). The type of a delivered call (i.e. whether it is a hall call, a car call, or both) is determined by checking simultaneously the illuminated-car-buttons list of a place Car’s Buttons, the illuminated-buttons list of place Hall’s

![Fig. 3: The timing car-call sub-model](image-url)
Buttons, and the served-hall-calls of place Timing Cars. Moreover, each delivered hall call or car call is returned to its original list after it was removed from the illuminated-buttons list or illuminated-car-buttons list, respectively. The doors operations are represented by the colour set Doors (c.f. Table VIII).

![Diagram](image_url)

**Fig. 4:** The timing system-cycle sub-model

In the maintenance stage, when a car is suspended either by an emergency case (i.e. emergency button was pressed) or an operation failure case, the transition Maintain, which has the highest priority of firing upon enabling in the entire model, is fired. In such case the pending car’s token is transferred temporarily to place out of service, which is not accessible by any other sub-models, all assigned hall calls and car calls of the pending car are returned to places Hall’s Buttons and Car’s Buttons, respectively, and a warning message is sent to the site manager, which is denoted by place warning to manager. A suspended car may be restarted, either automatically or manually based on the value of parameter restart cars automatically that controls the enabling of transition Restart.

Cars movements between floors are modeled in the transition stage. Transitions Transfer and Maintain are mutually exclusive. Enabling and firing the transition Transfer requires that the car desired-floors list is not empty, and the car current floor matches no calls of the desired-floors list. After firing transition Transfer, the car token is updated in the following way. If the car desired-floor list has calls beyond the car current floor, it continues moving in the same direction. Otherwise its direction is reversed. In both cases, the token in place Database is updated accordingly.

Once a car reached its desired destination, it is in the arrival stage. At this stage, transition Arrive is enabled provided that transition Maintain is disabled and the car current floor matches a requested call from the desired-floors list. After firing transition Arrive, car’s token is updated by dropping the requested floor from the car desired-floor list. Additionally, the car state is set to one of three cases. If the car desired-floor list

<table>

</tr>
</tbody>
</table>
has more calls, then it continues serving the requested calls. Otherwise, the car is set to idle, if the car current floor agrees with its parking floor, or alternatively, the car is dispatched to its parking floor with an appropriate direction.

V. ANALYSIS

CPN models can be analyzed and evaluated by various techniques and tools [15]. In this paper, we used the simulation-based performance analysis using tools from [3], with various parameters including numbers of cars and floors, types of decision algorithms, specified floors, etc. The results of our simulation-based performance analysis has proved validity and applicability of our model in various situations.

Due to page limit, we mention only one case study: five cars serving a twenty-floor building. Among others, we obtained the following results.

1) Car calls were produced by timing car-call sub-model for each car to each floor. Additionally, the car-call buttons were illuminated when released and unilluminated when the cars visited the corresponding floors.

2) Hall calls were produced by timing hall-call sub-model from all floors to request cars. Additionally, the hall-call buttons were illuminated when released and unilluminated when the cars visited the floors of the requested hall calls.

3) All requested hall calls were eventually served for all algorithms used.

4) All requested car calls were served eventually and sequentially in the direction of car movements.

5) If no calls, all cars were held at their parking floors.

6) The maintenance stage worked as it supposed to.

The results of two particular experiments are presented in Figure 5.

VI. CONCLUSION

In this paper, a fairly general CPN-based model of the elevator system, one of specification benchmarks [5], is proposed. The model consists of four separated but interconnected parts and it emphasis the expressive power and convenience of Coloured Petri Nets. Our model is quite flexible and it allows using different algorithms and different rules at ease. Division into four sub-models allows easy tracking of errors and faults. A thorough simulation-based performance analysis by using the simulator provided in [3].

APPLICATION OF FUZZY LOGIC IN LAND CONSOLIDATION-CLASSIFICATION STUDIES

Ela Ertunç *, Tayfun Çay*

*Selcuk University, Geomatic Engineering
Konya, Turkey
elaertunc@selcuk.edu.tr
tcay@selcuk.edu.tr

Abstract—Land classification is one of the most important stages of consolidation projects. The success and timely completion of this project depends on that this classification is useful and fair and are accepted by landowners. Different methods have been developed for the classification. Effects on the success of the land consolidation of the results of these methods are being investigated.

In this study, fuzzy logic method has been used for land classification according to Law No. 5403. In Mamdani Type Fuzzy Logic, Values of soil index, productivity index and the location index, which are used to determine the value of the parcel index, have been defined as input, whereas the value of parcel index have been defined as the output. Inputs and outputs have been converted to the linguistic terms (such as very efficient, inefficient, somewhat efficient, remote, near) by creating membership functions. Rule base has been created for calculating of the parcel index. As a result of fuzzy inference and defuzzification process, the model formed by Mamdani Type Fuzzy Logic gives the value of parcel index. By giving random input values to test generated model, results has been compared with results obtained manually.

Keywords—fuzzy logic, land consolidation, land classification, fuzzy systems, soft computing

I. INTRODUCTION

Land consolidation studies have a set of technical services in order to increase productivity in agriculture regulating agricultural space along with a variety of infrastructure services (road-irrigation network, drainage, soil leveling, construction of village settlements etc.) [1].

To give lands equal to their previous lands to landowners after the consolidation process in land consolidation area, classification process based on specific criteria of their existing plots must be made [2].

Land classification according to Soil Conservation and Land Use Law (Law No. 5403) has been defined as values found based on soil and productivity etudes and been basis to the change of land with soil's natural and permanent features and the distance to settlement or business center of land. The aim of classification is obtained according to certain criteria of the previous value from land consolidation of lands belonging to businesses.

Land classification, which is the process to estimate the ability of the land yield, includes studies relied that the soil, topography and other features of the land are interpreted and carried out in order to make comparisons between certain forms of evaluation [2].

Land classification is one of the most important stages of consolidation projects. The success and timely completion of this project depends on that this classification is useful and fair and are accepted by landowners. In order to classify lands in many countries of the world, various methods have been developed and have been put into practice [2].

Values of soil index, productivity index and location index is determined when the classification maps for land consolidation are generated, 70% of the index obtained the results of the soil etudes (TE) is taken. By adding the index scores determined for productivity (VE) and location (KE) to this value, value of parcel index is determined. Obtained values of parcel index are evaluated in particular group ranges, and thus, map of classification is formed.

Classifications of parcels according to determined the parcel index are made according to Table 1.

Parcel index (PE) = TE*70% + V + k

Discovered fuzzy sets, logic and system concepts by Zadeh in 1965 have occured the result that much nonlinear equations are used, method is complicated and solution becomes difficult in order to working of this researcher for many years in the control area and obtaining the control he wants [3].
The concept of fuzzy logic generally tries to modelling the thinking style of people. It is communicable that turbidity signify the tentative information as a concept, in other words uncertainty. Fuzzy logic is defined as an artificial intelligence technique which run with uncertainties instead of certainties by using verbal variables. Typical value of the verbal variable is expressed with words, such as "hot" or "cold", also, these values are represented by membership functions of fuzzy sets.

The difference from standart mathematical methods of fuzzy logic is runnig with uncertainties instead of certainties and allowing the qualitative definition. That uncertainties are expressed mathematically is evaluated as the greatest convenience which is brought by fuzzy logic the modeling of complex systems [4].

In classical set theory, any object is a member of a cluster or not. This object only has the value of “0” or “1”. The medium of these values is not possible. In fuzzy logic unlike classical logic, members belong to partially the fuzzy cluster and is used in values between '0' and '1'. In the following Figure 1, the difference of binary (classical) logic and fuzzy logic is schematically shown. In Figure 1 it is shown that intermediate values do not exist in classical logic.

The processes of fuzzy logic consists of stages which the problem is analyzed and is defined, sets and logical relationships are formed, available information is converted into fuzzy sets and model is interpreted. By using a lot of prerequisites, it can be decided whether fuzzy logic solves the problem or not. Originally for the problem to be solved, it is decided whether fuzzy logic approach is the right choice or not. If the system's behavior to be applied can be expressed with rules or it requires a complex mathematical operation, fuzzy logic approach can be applied. Otherwise, The results obtained by the fuzzy logic will not give the desired values most likely [5].

Fig. 1 Representation of the difference between fuzzy logic (a) and classical logic (b)

![Fig. 2 Blurring defuzzification fuzzy system with unit](image)

Fig. 2 Blurring defuzzification fuzzy system with unit

1) **General Information Base Unit:** It contains the input variables which are affected of event which will be examined and all informations about these. The reason which it is called as the general data base is numerical and / or verbal of the informations here.

2) **Fuzzifier:** This is a processor that assigns to membership degrees in fuzzy sets that has been described as verbal to the digital input values.

3) **Fuzzy Rule Base Unit:** This includes all of rules that connect to output variables to inputs in the database and that can be written in logical IF – IF type. While these rules are written, all intermediate (fuzzy set) connections which may be only between input datas and outputs is considered. Thus, each rule logically connects to the output space to a part of the input space. All of this contexts creates a rule base.

4) **Fuzzy Inference Engine Unit:** This is a mechanism that contains processes community that provide that the system behaves with output by collecting together all of the piece relationship established between the input fuzzy sets and the output fuzzy sets. This engine benefits that How to give an output under inputs of whole system is determined by huddling together the implications of each rule.

5) **Defuzzifier:** This converts to sharp digital output values to results of fuzzy inference obtained result of fuzzy processes.

6) **Output Unit:** This unit specifies community of the output values obtained by the interaction by means of fuzzy inference engine of information and fuzzy rule bases [6].

In this study, fuzzy logic method has been used for land classification according to Law No. 5403. In Mamdani Type Fuzzy Logic, Values of soil index, productivity index and the location index, which are used to determine the value of the parcel index, have been defined as input, whereas the value of parcel index have been defined as the output. Inputs and outputs have been converted to the linguistic terms (such as very efficient, inefficient, somewhat efficient, remote, near) by creating membership functions. Rule base has been created for calculating of the parcel index. In order to benefit from fuzzy informations obtained, this informations have to be defuzzification. Centroid method has been used as defuzzification method. As a result of fuzzy inference and defuzzification process, the model formed by Mamdani Type Fuzzy Logic gives the value of parcel index. By giving random input values to test generated model, results has been compared with results obtained manually.

II. MATERIALS AND METHODS

While fuzzy system is established, the soil index (TE), the productivity index (VE) and the location index (KE) has been defined as the input values of system, whereas, parcel index (PE) has been defined as the output value of system. The general structure of the fuzzy model is shown in Figure 3.

Firstly, while fuzzy model is created, it must be determined that values of soil index, productivity index and location index will be divided how many sub-regions and that what kind of membership function (such as triangular, trapezoidal, Gaussian...).
curve etc.) will be used. In this study, the seven sub-regions for soil index, the five sub-regions for productivity index and the four sub-regions for location index have been determined and triangular membership function has been used.

![Fig. 3 The general structure of Fuzzy Logic Model](image)

**A. Membership Function**

While the fuzzy model is established, different membership functions have been formed for soil index (TE), productivity index (VE) and location index (KE). The membership functions for input and output variables are shown in Figure 4, 5, 6 and 7. Units of factors used are: TE (unit), VE (unit), KE (unit) and PE (unit). TE membership function is in the range of 0-100, VE membership function is in the range of 0-10, LI membership function is in the range of 0-20 and PE membership function is in the range of 0-100.

That the factors used are blurred are carried out with help of the following functions determined by benefiting from an expert's opinions and informations.

- **TE (A)** = \{a; 0<a<100\}
- **VE (B)** = \{b; 0<b<10\}
- **KE (C)** = \{c; 0<c<20\}
- **PE (D)** = \{d; 0<d<100\}

![Fig. 4 The membership function of soil index (TE)](image)

![Fig. 5 The membership function of productivity index (VE)](image)

![Fig. 6 The membership function of location index (KE)](image)

![Fig. 7 The membership function of parcel index (PE)](image)

Such as, The mathematical representation of each membership function of the location index (KE) is as follows:

\[
\mu_{far} (C) = \begin{cases} 
\frac{5-a}{5} & ; 0 < a < 5 \\
0 & ; \text{in different conditions}
\end{cases}
\]

\[
\mu_{near} (C) = \begin{cases} 
0 & ; a \leq 3.5 \\
\frac{1.5}{a-3.5} & ; 3.5 < a \leq 5 \\
\frac{4}{10-a} & ; 6 < a < 10 \\
0 & ; a > 10
\end{cases}
\]

\[
\mu_{the \ nearest} (C) = \begin{cases} 
0 & ; a \leq 10 \\
\frac{1.52}{10-a} & ; 10 < a \leq 12 \\
\frac{6}{12-a} & ; 12 < a < 18 \\
0 & ; a \geq 12
\end{cases}
\]

\[
\mu_{the \ nearest} (C) = \begin{cases} 
\frac{17-a}{3} & ; 17 < a < 20 \\
0 & ; \text{in different conditions}
\end{cases}
\]
B. Rule Base

An appropriate rule base is required for fuzzy logic system. The total of 140 rules have been written for fuzzy system in this study. The portion of them is seen in Table 2. The relationship with parcel index (PE) that is the output value of soil index (TE), location index (KE) and productivity index (VE) that are input values are shown in Figure 8, 9 and 10.

III. CONCLUSION

The method developed in this study has been applied the first time for the land classification, according to Land Law No. 5403. As shown in Table 3, the results of Fuzzy Logic Model are compared with results of traditional method. It is seen in Table 3 that both the results obtained from the fuzzy logic model and the results obtained from the traditional method are similar one another. The system is fast and is more accurate than traditional methods. This system also has a high reliability. Besides, accuracy of established fuzzy system has been shown on stabilizing right graph that its angle is 45 degrees (Figure 11).

Simulation and Analyses of Heterogeneous WSN Clustering Protocols

Korhan Cengiz
Department of Electrical-Electronics Engineering
Trakya University
Edirne, Turkey
korhancengiz@trakya.edu.tr

Abstract — Limited battery supply of a sensor node is one of the most important factors that limit the lifetime of the WSNs. As a consequence, prolonging the lifetime of WSNs through energy efficient mechanisms has become a challenging research area. Previous studies have shown that instead of implementing direct transmission or multi-hop routing, clustering is a kind of key technique used to reduce energy consumption. Clustering can increase the scalability, decrease the energy consumption and extend the lifetime of the network. Also, energy-efficient clustering protocols have been designed for the characteristic of heterogeneous wireless sensor networks to obtain additional energy savings. In heterogeneous wireless sensor networks, some of sensor nodes is equipped with additional energy resources. In this paper, comparison of stable election protocol (SEP), distributed energy-efficient clustering (DEEC) scheme with LEACH which has also advanced nodes is aimed. Same simulation parameters are used for comparison. The nodes in all heterogeneous algorithms are equipped with same total energy. The protocols are compared in terms of number of alive nodes, lifetime and energy-efficiency in MATLAB. The results of the simulations are discussed in details.

Keywords— Energy Efficient Routing, Clustering, Wireless Sensor Networks.

I. INTRODUCTION

A WSN is obviously formed by a collection of sensor nodes and corresponding protocols for routing messages in this network. A typical wireless sensor node consists of a sensory unit, a communication unit, a power unit and a processing unit. Sensory unit consists of a data acquisition component and ADC (converts the sensed real world data to the digital form). Communication unit has a radio transceiver and the power is backed by a battery source. The WSN node can be equipped with a limited power source (0.5 Ah, 1.2 V). The node remains active as long as the battery is alive and hence power saving is a crucial criterion in this domain of applications. Energy consumption happens in three domains: sensing, data processing and communications. The sensing, signal processing parts operate at low sequential and consume less than 1mW. This is over an order of extent less than the energy consumption of the communication part. Therefore we have to assign less communication/data exchange between sensor nodes.

The traditional infrastructure based protocols cannot be used for WSNs because of the limited storage and power of the sensor nodes. Because WSNs often use broadcast based radio communication.

Limited energy availability in sensor nodes makes network lifetime an important issue in WSN applications. To extend the network lifetime, energy efficient wireless sensor network protocols and algorithms have been devised in the literature. Node clustering, in-network data processing, data fusion and network coding are some of the measures taken to reduce the amount of data that is processed, sensed or transmitted. Minimization of energy spent in processing, sensing and transmission of data allows sensor nodes to save energy. Such energy savings help to extend the lifetime of WSN applications.

The main goal of cluster-based routing protocol is to efficiently maintain the energy consumption of sensor nodes by involving them in multi-hop communication within a cluster and by performing data aggregation and fusion in order to decrease the number of transmitted messages to the sink and transmission distance of sensor nodes.

There are two kinds of clustering schemes. The clustering algorithms applied in homogeneous networks are called homogeneous schemes, and the clustering algorithms applied in heterogeneous networks are referred to as heterogeneous clustering schemes. It is difficult to devise an energy-efficient heterogeneous clustering scheme due to the complicated energy configure and network operation. Thus most of the current clustering algorithms are homogeneous schemes, such as low energy adaptive clustering hierarchy (LEACH) [1] and their variants [2].

The most successful heterogeneous clustering protocols are stable election protocol (SEP) [3] and distributed energy-efficient clustering scheme (DEEC) [4].

LEACH is one of the most popular distributed cluster-based routing protocols in WSNs. LEACH randomly selects a few nodes as CHs which aggregate data arriving from nodes and forward the aggregated data to BS and rotates this role to balance the energy consumption of the sensor nodes in the network.

In LEACH protocol, the time is divided into parts called a round. Each round consists of two phases. The first phase is setup phase which is the phase of node formation. The second phase is related to the normal function of the network and is called the Steady-State phase. In the first phase, the CHs are elected based on a probability function. This election is as follows: each sensor node selects itself to be CH at any given time with a certain probability. Any node in the network
chooses a random number between 0 and 1. Then this number is compared with threshold limit, if the number is less than a threshold, the node becomes a CH for the current round. This probability function is designed in such a way that within a specific number of rounds each sensor becomes a CH only once and thus the energy consumption is distributed over the whole network. After the set up phase of the round, where the CHs are elected, each CH announces its election to other nodes and each node chooses a suitable (nearest) CH for itself; and then it announces this decision to the related CH and thus the clusters are formed and the network comes into the steady-state operation i.e data transmission. Then each CH creates a TDMA schedule in each cluster to organize the communication among cluster members. When the non CH nodes receive the TDMA scheme, nodes send their data to the CH once per frame during their allocated transmission TDMA slots. This allows the radio components of each non-cluster-head node to put the sleep mode at all times except during its transmit time, thus minimizing the energy dissipated in the individual sensors. After a certain amount of frames i.e. a TDMA round, the network re-elects CHs and re-form clusters. Then CH, after combining all the received data, will send the results to the BS. Besides, to prevent the interaction of the transmissions which occur in clusters at the same time, LEACH uses different CDMA codes. Existing CH chooses randomly a unique code from a list of spreading codes. The CH filters all received energy using this spreading code. Consequently, the radio signals of the neighbouring nodes are filtered out hence interference of the transmission of the nodes is minimized.

While many homogeneous LEACH variants have been developed as described above, there are also heterogeneous cluster based WSN routing protocols. SEP is a fundamental protocol for WSNs and contains advanced nodes which are fitted with extra energy resources. SEP uses a weighted election probability based approach to determine CHs according to the residual energy of each node. In SEP, \( m \) corresponds to fraction of the advanced nodes which are fitted with \( a \) times more energy than the normal nodes. As a consequence, the total initial energy of the WSN is increased by \( 1 + a.m \) times. The additional energy of the advanced nodes forces them to be elected as CHs. Each node is informed the total energy of the network in order to adjust its election probability to become a CH according to its residual energy. The remaining energy values of normal and advanced nodes are transmitted to the CHs while members send data. The remaining energy values of the nodes are delivered to the BS by using CHs. The results of the simulations of the SEP show that, SEP provides significant energy savings, lifetime gains and throughput improvement when compared with LEACH for both homogeneous and heterogeneous scenarios.

DEEC is another heterogeneous and distributed clustering protocol where the CHs are determined by a probability based on the ratio between residual energy of each node and the average energy of the network. The nodes which have high residual energy are more probable to become CHs. Adaptive approach of DEEC provides for controlling the energy consumption of the nodes to provide the energy-efficiency. In DEEC, there are advanced and normal nodes. \( m \) is the fraction of the advanced nodes and these nodes have \( a \) times more energy than the normal ones. Therefore, DEEC network has \( a.m \) times more energy and virtually am more nodes. The results of the simulations of DEEC protocol indicate that, DEEC prolongs the time of first node death when compared with LEACH variants and SEP in heterogeneous networks.

II. SIMULATION ENVIRONMENT AND PARAMETERS

The simulations are conducted in MATLAB. 100 sensor nodes are randomly deployed in a 100 m x 100 m field as shown in Fig. 1 and BS is placed outside of the sensor field which have coordinates of (150,50). Same simulation parameters of LEACH are used for all simulations in this paper. Each simulation is realized for 100 independent iterations to obtain more scalable results. Table I summarizes the simulation environment parameters used for simulations.

III. SIMULATION RESULTS

In this section, the performance comparisons of LEACH, SEP and DEEC protocols are made for residual energy, number of alive nodes and lifetime. To obtain more scalable results, 100
iterations are realized. For each iteration, the average values of the results are collected. In SEP and DEEC simulations, same parameters are used. The nodes in SEP and DEEC networks are equipped with 250 J total initial energy.

A. Residual Energy

Fig. 2 illustrates the total residual energy of the nodes in terms of rounds. With advanced, it can be observed that DEEC and SEP provide significant energy savings when compared to LEACH. After 2000 rounds, while LEACH holds 15% of its initial total energy, SEP and DEEC hold approximately 30% of their initial total energies. When the network lifetime ends under LEACH, SEP and DEEC still maintain approximately 10% of its initial total energy. For same simulation parameters, DEEC and SEP have approximately same performance.

B. Number of Alive Nodes

Fig. 3 shows the number of alive nodes thus the network lifetime for LEACH, SEP and DEEC. Under SEP and DEEC, the network lifetime increases from 3237 rounds to 5000 rounds, approximately 50% improvement compared to LEACH. Although, node deaths start earlier under DEEC, since the CHs are abused, the rate of the number of dead node increases is significantly less and this yields to a longer lifetime. One major difference between LEACH and DEEC can also be observed from this figure. Right after the first node death under LEACH, the remaining node deaths will follow quickly. But with DEEC, node deaths are distributed evenly for the network lifetime. SEP provides to delay first node failure in the network because it uses advanced nodes. It allows to select advanced nodes to become CHs more frequently thus it provides to delay the CHs in the network. SEP also utilises CH determination approach which provides to select CH nodes according to their residual energy.

For each algorithm, the simulations are repeated 100 times for different topologies and the maximum and average observed lifetimes are presented in Table II as well as the initial network energies. DEEC’s conservative energy consumption ratio increases the lifetime of a WSN significantly. DEEC outperforms LEACH and SEP.

</table>

IV. CONCLUSIONS

Nowadays, saving energy, extending lifetime and designing green networks [5, 6] for WSNs has become an essential research area. By placing or determining advanced nodes and providing more energy-efficient CH determination approaches, DEEC and SEP decrease the energy consumption of cluster formation. The results of the simulations demonstrate that, SEP and DEEC algorithms provide significant energy efficiency, lifetime gains when compared with LEACH. DEEC also delays the first node death and provides equal alive node distribution in the WSN.

Robots are located at every stage of our lives with developing technologies. Interest in the field of robotics is increasing every day. There isn’t a course on robotics in primary school curriculum in Turkey. Facilities of educational institutions is limited and primary school teachers is inadequate in robotic. Therefore, many educational institutions aren’t given to students in robotics education. Shown in programming courses in private schools, Lego Mindstorm robot module constitutes awareness in children from early ages. This study aims to increase the interest of children in Turkey to robotics. To improve the students’ creativity and motivation, a simple robot design supported with Augmented Reality education related notes have been prepared. A simple model for the implementation of robotics in primary education has been constituted.

Keywords— Robotic, Education, Augmented Reality, Primary School

I. INTRODUCTION

Today, in the face of rapidly evolving technology and increasing information needs to be trained individuals who can adapt to change. Knowledge of age together with our ability to quickly increase, based on the technology and the training of information technology, including new technologies, the question of how it illustrates the way in the field of educational technology [1].

A new term in the field of technology is Augmented Reality (AR) which is some- how can be considered as a different version of virtual reality. It allows users to get experience of using virtual objects in real world. So, Augmented Reality is rapidly growing and developing. This technology supplements the real world with composite 3D virtual objects that are integrated into the real world. This technology is very interesting and interactive and therefore there is a vast range of potential applications of Augmented Reality such as in the field of medicine, manufacturing, urban planning, architecture, archaeology, education and many more [2].

According to the research, it was determined that 4-5-6 graders have more creative and original ideas, according to the 7th and 8th grade students [3]. In elementary schools of Turkey, computers first come to mind when term of technology is said. However, we see that take out different terms the mention of technology in the World. Robotics comes at the beginning of these terms.

Robotics is an area that needs to be focused on in primary school age children. With applications of robot design, robot contests, robot projects, it is seen that children gain a lot of property, such as problem-solving, finding practical solutions to problems, learning by doing and experiencing and critical thinking [4].

This research aims to provide information on the use of robotics in the education of primary school age children, and to help planning applications about robotics in Turkey. It also aims to provide the students get closer with the robotic and technology. In this context, a document prepared that supported by augmented reality robot construction and programming for the 4th and 5th grade students who are studying in primary schools.

II. RELATED WORK

When the studies related to robotics in schools are analyzed, it is seen that students were affected in a positive way [5].

In the study of Vollstedt, Lego Robotics learning program has been performed on about 300 students in secondary schools [6]. As a result of the analysis made, it is seen that students' interest and knowledge of science, technology, engineering and mathematics has been increased with robotics [2]. Hacker has developed “Robolab” project for his work, and observed the effect of robotics on learning basic science and mathematics principles of 3-6 grade children. With the study, it is seen that the stu- dents were affected positively with learning by doing and living practices [7]. Teixeira uses robotics in secondary
education and suggests usage of robots as a pedagogical agent especially in project development [8].

Balaji et al. created a robotic education tool named “FASTBOT" to create an awareness before the students plan their career. This tool provides students to pro- gram, find solutions to the given tasks and apply their knowledge in addition to pro- gramming [9]. Wei et al. in their study, present a general technical creative design- teaching scheme that includes Augmented Reality. The result of study that Keller method is also used , show that the proposed teaching scheme significantly improves learning motivation, student creativity and teaching of creative design [10][11].

Augmented reality applications related to education seem to increase in the world and Turkey. Comparing with traditional classes, it is seen that augmented reality applications are increasing the students learning rate [12][13]. As a result of spreading usage of smart phones, the number of augmented reality applications and researches on mobile devices are increasing [14].

One of the augmented reality technologies thought that can be used in education is “Google Glass” technology created by Google. The study of Demirer and Erbaş, "Augmented Reality Applications in Educa- tion: Google Glass Case" can be shown as an example. In this study, the information about augmented reality and Google Glass technology is given, studies about the usage of this technology are reviewed and suggestions are made [15].

Küçük et al. developed an augmented reality application for learning English. In the application, the success, comportment and cognitive load levels of secondary school students in English learning were examined [16]. As a result of studies, it was determined that students are satisfied, their level of anxiety is low and they want to use the application in the future in their classes.

Çetinkaya and Akçay in their study "Augmented Reality Applications in Educa- tional Environments", say that augmented reality applications for different needs are started to be used widely in the world and foresee that FATIH project is an important opportunity to spread augmented reality in Turkey [17].

The use of augmented reality is increasing in daily life, too. Large companies are developing applications to their customers and users. The companies BMW, Marshall and Ikea develop some of these applications. The glasses designed by BMW for these of maintenance and repairing is shown in Figure 1 [18].

Marshall company has developed applications for wall color test in the house. Images of the application is shown in Figure 2 [19].

The images of the augmented reality application developed by Ikea to show table, armchair etc. home accessories in 3D is shown in Figure 3 [20].
III. METHOD

Turkey’s private schools use robotics kits, "PicoCricket" and "MINDSTORMS® LEGO® NXT" which has developed by MIT University and Lego Group, on their robotic courses. Students produce original designs by using robotic kits. They learn gears and simple machine mechanisms. They try the mechanisms they produced using sensors and motors. Robotic studies aims to gain skills that students use technology, design, science and mathematical operations about the subject.

Students think them- selves as a scientist, an engineer or a designer when they work on robotic studies. They begin to examine the problems in daily life in time. They feel more confidence about creating solutions to these problems [21].

There are a variety of applications that can run in mobile operating systems to develop Augmented Reality projects. Some of them are Alive, Augmented, Aurasma, Blippar, Junaio, Layar and Wikitude in applications. The features of these programs are presented in Table 1 [14].

Table 1. Augmented Reality Programs

Videos are added to document using Aurasma Studio which is one of the freeware augmented reality program. Aurasma Studio software is an easy to use application. Aurasma Studio, unlike the other applications, allows to create augmented reality projects with personal mobile devices.

Aurasma Studio application needs to be downloaded to smart phone via the web site of the application. In this application, any image prerecorded databases, whether in the form of a banner outside or a computer located image, it could be scanned to be transformed into an interactive view rather than an image.

As one of the application's functionality, while video viewing on tablet or phone device pointed on an image, if the device removed from image video stops and if the device replaced back on the image, video will continue where it left.

For example, on Figure 4, the application executed by a picture, an animation presented to the user's access. Simple images can be a gate to easily access different videos or animations [22].

![Fig. 4. Aurasma Samples](image1)

IV. RESULT AND DISCUSSIONS

When analyzed international studies on robotics, it is seen that robotics education is given importance. Recently in Turkey is given courses of robotics education. Augmented Reality applications will be more imported to improve robotic educations.

The importance of robotics education in primary schools is also emerging at this point. It is necessary to find different

Wavelet Based Medical Image Watermarking Scheme for Patient Information Authenticity

L Lukman ÇERKEZİ¹, Gökçen ÇETİNEL²

¹²Electrical and Electronics Engineering Dept., Sakarya University, Sakarya, Turkey
lukmancerkezi@gmail.com, gceтинel@sakarya.edu.tr

Abstract—Telemedicine is an important technique that permits transmission of medical and imaging data from one place to other, ensures the reliability of data and provides a convenient communications between patient and medical staff. In this study, Discrete Wavelet Transform (DWT) and Singular Value Decomposition (SVD) based medical image watermarking method that hides the patient information into medical image without affecting the image quality is proposed for the purpose of authentication. At the watermark (secret image containing patient information) embedding process, a chaotic map called as Arnold Cat Map (ACM) is applied to the watermark to improve the security of the method.

So that the aim of the proposed watermarking scheme is personal authentication by ensuring the perceptual invisibility, PSNR (Peak Signal-to-Noise Ratio) values are calculated during the simulations. According to the experimental results, we can say that the proposed method provides higher PSNR values than compared current methods. Furthermore, in simulations DWT and SVD based watermarking scheme is implemented as chaotic and non-chaotic watermarking scheme to investigate the effect of chaotic map on the performance of the proposed algorithm.

Keywords—Medical image watermarking, discrete wavelet transform, singular value decomposition, PSNR.

I. INTRODUCTION

Telemedicine is a technique which aims to provide clinical and health assistance to remote areas by utilizing telecommunication and information technologies. Through telemedicine, patients benefit from far away specialists for medical diagnosis without travelling. By telemedicine, it is possible to transmit medical and imaging data from one place to other and to communicate the patient with the medical staff. Transmitted medical images help physician to decide diagnostic procedures. Then, to evaluate the progress of treatment, telemedicine can be used again [1].

During the transmission, medical image may be destroyed by intruders or attacked by noise. We need to ensure reliable data transmission to not cause the wrong diagnosis. For this purpose, digital image watermarking is found to be an effective and promising mechanism by the researchers [8, 9].

Digital image watermarking is a technique of embedding a secret information (watermark) to a cover image. There are three common requirements for watermarking schemes: robustness, capacity and invisibility. However, there is a trade-off between these requirements. For example, a stronger watermark can be used to increase the robustness, but in this case watermark becomes noticeable. On the contrary, increasing the capacity decreases the robustness. Consequently, one must make a choice between these three requirements according to the application. For telemedicine technique, during the storing and transmission of medical images (i.e. Computed Tomography (CT), Magnetic Resonance Imaging (MRI) and X-ray imaging) the security of the digital data has a critical importance. Furthermore, we need to embed patient’s information to the medical image without causing any perceptual changes. So, the perceptual invisibility of the watermarking scheme must be very high to maintain the quality of original medical image [2, 3].

According to the embedding domain, watermarking techniques can be classified in to two groups as spatial domain watermarking techniques and frequency domain watermarking techniques. In spatial domain techniques, the secret data is directly inserted into the samples of the cover signal. In frequency domain techniques, embedding process is performed in the frequency domain by modifying the coefficients of the transformed image. The transformed image can be obtained by applying Discrete Cosine Transform (DCT), Discrete Fourier Transform (DFT), Discrete Wavelet Transform (DWT) or Redundant Discrete Wavelet Transform (RDWT) [4]. Although spatial domain techniques has low computational cost and are less complex, the transform domain techniques are most popular because of their significant advantages such as robustness and imperceptibility.

In this study, DWT and SVD based medical image watermarking scheme is proposed. In the proposed scheme, patient’s information is embedded to the medical image as a binary watermark. The aim of this study is to embed the patient’s information to the medical image without degrading the quality of medical image for personal authentication. At the watermark embedding stage, original cover (medical) image is decomposed by DWT into LL, LH, HL and HH sub-bands. Then SVD is applied to each sub-band. On the other side, ACM and SVD are performed for
the original watermark, respectively. Then, the singular values of the medical image is added to the singular values of chaotic watermark in all sub-bands. Finally, by using invers SVD and inverse DWT the watermarked image is obtained.

The paper is organized as follows. In section II, in order to better understand the proposed algorithm, DWT, SVD and ACM are discussed. Watermark embedding and extracting algorithms are explained step by step in section III. Section IV gives the experimental results and compares the proposed method with related studies. Finally, Section V concludes the paper.

II. APPLIED TECHNIQUES

In this section, the techniques used in the proposed method are explained briefly to better understand the watermark embedding and extraction steps.

A. Discrete Wavelet Transform (DWT)

DWT is a common tool used in watermarking schemes which transforms the image from spatial domain to frequency domain. It is shown in many papers that DWT is superior then other transform techniques in watermarking algorithms. By applying DWT, 1-D original signal is separated into the low-frequency and high frequency sub-bands. This process is called as decomposition and gives us DWT coefficients. The original signal can be reconstructed by using DFT coefficients. This reconstruction process is referred as inverse DWT (IDWT) [5].

By performing DWT on image (2-D signal) one time, the image is split into four sub-bands, LL₁, LH₁, HL₁, and HH₁.

LL₁ is the low frequency sub-band and it contains the maximum of energy while the other sub-bands are middle (LH₁, HL₁) and high (HH₁) frequency sub-bands. These middle and high frequency sub-bands represent the edges, outline, texture and other detail information of the original signal. If we want to perform again DWT to signal, we should apply the DWT to the LL₁ sub-band. This process can be repeated until we get the appropriate decomposition level for our application.

Watermark embedding process is done by changing the wavelet coefficients according to the embedding algorithm. The watermark can be embedded either in low- frequency sub-band or high- frequency sub-band with respect to the purpose of the application. Embedding watermark to the high- frequency sub-band provides high imperceptibility advantage but robustness and stability of the scheme will be decreased. Robustness can be improved by embedding watermark to the middle a frequency sub-band but this will cause decrement of imperceptibility.

B. Singular Value Decomposition (SVD)

In recent years, SVD has become an extremely valuable tool in signal processing area. Image compression, data hiding, noise reduction and image watermarking are just some applications of SVD [6].

Given the data matrix A of dimension N x N which has the independent column (i.e. rank (A) = N), there are two unitary matrices V and U such that

\[ A = USV^T \] (1)

Where S = diag(σ₁, σ₂, …, σₘ) is an diagonal matrix. Singular values are ordered as σ₁ ≥ σ₂ ≥ … ≥ σₘ > 0. The Equation (1) is mathematical the representation of SVD.

SVD is an optimal decomposition method that concentrates the maximum signal energy into as few coefficients as possible. From the image processing point of view SVD has three main advantages: i) it can applied to any dimension of image matrix, ii) after applying SVD to image the singular values S corresponds to the brightness of image while U and V denotes the geometric properties of the image, iii) the slight variations of singular values of an image may not affect the human visual perception. This stability property of SVD is the main reason why it is preferred for watermarking applications [7].

C. Arnold’s Cat Map (ACM)

Chaotic signals has very broad range of application in secure communications, signal processing and cryptography because of their inherent properties that can be taken into account such as high complexity. There are many chaotic maps in literature appropriate for image processing applications. ACM is one of the most famous chaotic map used for randomizing the pixel locations in the image matrix. This randomizing provides high security for the image watermarking schemes. ACM can be applied for only square matrix. For N x N square image matrix it can be expressed as

\[
\begin{bmatrix}
{x}_{n+1} \\
{y}_{n+1}
\end{bmatrix} = \begin{bmatrix}
\frac{1}{b} & a \\
1 & b + 1
\end{bmatrix} \begin{bmatrix}
{x}_n \\
{y}_n
\end{bmatrix} \text{mod } N = A \begin{bmatrix}
{x}_n \\
{y}_n
\end{bmatrix} \text{mod } N. \quad (2)
\]

where \((x_0, y_0)\) and \((x_{n+1}, y_{n+1})\) are the locations of pixels before and after iterations, respectively. In Equation (2) the coefficients \(a\) and \(b\) are selected such as \(\text{det}(A)=1\) [5].

After applying a few iterations into original image the locations of pixel will be scrambled but when the iterations are repeated enough we will attain the original image again. There is no any formula for exact number of iterations for given dimension of image, but for higher dimension we expect higher iterations. ACM transformation for different iterations is illustrated in Fig. 1. As a conclusion the number of iterations both in watermarking embedding and extracting must be selected carefully [10].
A. Watermark Embedding

In our algorithm, CT, MRI and X-ray images are used as a cover image. During the embedding algorithm, two, three and four level decomposition of DWT are performed to these images, respectively. The steps of the embedding algorithm are given below:

1. By performing the appropriate decomposition level to cover image, the image is divided into LL, LH, HL, and HH sub-bands.

2. SVD is applied to the each sub-band of the cover image as follows:
   \[ A^i = U^i S^i V^i T \]  (3)
   where \( A \) is the sub-band of cover image and \( i \) denotes the LL, LH, HL, and HH sub-bands, respectively.

3. We attain chaotic watermark \( W_{ACM} \) by performing 76 iterations ACM to the watermark image (W).

4. SVD is applied to chaotic watermark \( W_{ACM} \) as follows:
   \[ W_{ACM} = U_{ACM} S_{ACM} V_{ACM}^T \]  (4)

5. Singular values \( S^i \) of cover image are modified with singular values \( S_{ACM} \) of chaotic watermark image
   \[ S'^i = S^i + \alpha S_{ACM} \]  (5)
   where \( \alpha \) is fixed scaling factor for all sub-bands and \( i \) represents LL, LH, HL, and HH sub-bands.

6. Inverse SVD is performed by using modified singular values
   \[ A'^i = U^i S'^i V^i T \]  (6)
   where \( i \) represents LL, LH, HL and HH sub-bands, again.

7. Finally, we implement inverse DWT to get the watermarked image.

B. Watermark Extraction

The steps of the watermark extraction algorithm are given below:

1. We decide the most appropriate level of DWT and applied DWT to the watermarked medical images. By this way, we get LL', LH', HL' and HH' sub-bands.

2. SVD is applied to LL', LH', HL' and HH' sub-bands, as follows
   \[ A'^i = U^i S'^i V^i T \]  (7)
   where \( I \) denotes LL, LH, HL and HH sub-bands respectively.

3. Singular values of watermark image are computed as follows,
   \[ S^W = (S^W - S^i)/\alpha \]  (8)
   where \( \alpha \) is fixed scale factor for all sub-bands.

4. By applying inverse SVD, we obtain the chaotic watermark
   \[ W_{ACM} = U^i S^W V^i T \]  (9)

5. Finally, we perform 20 iterations ACM to \( W_{ACM} \) (for 128x128 image matrix 96-76=20), in order to get the original watermark image.

IV. EXPERIMENTAL RESULTS

The purpose of this section is to investigate the efficiency of the proposed medical image watermarking method by performing simulations. In order to expand the application areas of the proposed scheme the CT, MRI and X-ray medical images are utilized. MATLAB computer program is used during the simulations. The size of CT image is 1024x1024, MRI image 512x512 and X-ray image is 2048x2495. The watermark image of size 128x128, includes the patient’s information such as the name, surname, age and type of medical image. Since the medical images are used for diagnosis and treatment, the quality of medical image is crucial. So the imperceptibility of
watermark must be very high. In order to investigate the imperceptibility of the watermarking schemes, the peak signal-to-noise ratio (PSNR) criterion is commonly used in the literature. PSNR can be defined as the similarity between the original cover(medical) image and watermarked medical image and can be calculated as follows,

$$PSNR = 10 \log_{10} \left( \frac{\max(\{X(i,j)\}^2)}{MSE} \right)$$  \hspace{1cm} (10)

where the mean square error (MSE) is defined as:

$$MSE = \frac{1}{m \times n} \sum_{i=1}^{m} \sum_{j=1}^{n} [X(i,j) - Y(i,j)]^2$$ \hspace{1cm} (11)

In Eq. (11), size of the images are $m \times n$. The higher PSNR values means that the watermark is better hidden. The other criterion for evaluating the performance of algorithm is Normalized Correlation (NC) which measures the similarity between the original watermark and extracted watermark [2, 4]. It is computed from:

$$NC = \frac{\sum_{k=1}^{m} \sum_{j=1}^{n} W(k,j) W'(k,j)}{\sqrt{\sum_{k=1}^{m} \sum_{j=1}^{n} [W(k,j)]^2} \sqrt{\sum_{k=1}^{m} \sum_{j=1}^{n} [W'(k,j)]^2}}$$ \hspace{1cm} (12)

where $W$ and $W'$ represent the original and extracted watermarks, respectively. The correlation coefficient takes on values in the interval [-1, 1]. If it is near 0, the extracted watermark is completely uncorrelated with the original one. Generally, the NC is considered acceptable if it is 0.75 or above.

In Table 1, PSNR and NC values are given for CT, MR and X-ray image. The watermarking algorithm is performed with and without chaos. As can be seen from the table, for both cases the PSNR values are almost over 90 dB and NC values are over 0.98. According to these results it is clear that the imperceptibility of watermark in the proposed scheme ensures the desired demand. In the Table 2, the comparison between the proposed scheme and reference [2] is illustrated. Watermark is embedded in LL sub-band for comparison. The superiority of our method can be seen obviously. Furthermore, in Figure 2 each step of proposed watermarking scheme is shown with corresponding images. The other advantage of proposed scheme is that acquired imperceptibility values are independent from decomposition level of DWT.

V. CONCLUSION

In this study, DWT and SVD based medical image watermarking scheme is proposed. In the proposed scheme, patient’s information is embedded to the medical image as a binary watermark. CT, MR and X-Ray images are used as medical image in the simulations. At the watermark embedding process, a chaotic map called as ACM is applied to the medical image to improve the security of the method.

The aim of the study is to hide patient’s information to the medical image without degrading the quality of medical image for personal authentication. By calculating PSNR and NC values we prove that the proposed method ensures the desired property. Furthermore, we exhibit that the proposed method provides higher PSNR values than compared current methods. The proposed scheme can be applied independently of type and size of medical image.

Comparison of the effect of unsupervised and supervised discretization methods on classification process

Mehmet HACIBEYOĞLU*, Mohammed H. IBRAHIM*

Computer Engineering Department, Necmettin Erbakan University, Konya, Turkey

*hacibeyoglu@konya.edu.tr

*mibrahim@konya.edu.tr

Abstract— Most of the machine learning and data mining algorithms use discrete data for the classification process. But, most data in practice include continuous features. Therefore, a discretization pre-processing step is applied on these datasets before the classification. Discretization process converts continuous values to discrete values. In the literature, there are many methods used for discretization process. These methods are grouped as supervised and unsupervised methods according to whether a class information is used or not. In this paper, we used two unsupervised methods: Equal Width Interval (EWI), Equal Frequency (EF) and one supervised method: Entropy Based (EB) discretization. In the experiments, a well-known 10 dataset from UCI (Machine Learning Repository) is used in order to compare the effect of the discretization methods on the classification. The results show that, Naive Bayes (NB), C4.5 and ID3 classification algorithms obtain higher accuracy with EB discretization method.

Keywords— Discretization, Supervised and Unsupervised Discretization, Continuous Features, Discrete Feature, classification algorithms.

I. INTRODUCTION

Many Machine Learning and Data Mining classification algorithms have application possibility only to the discrete data. But, most data in practice have continuous feature. The datasets usually contains mixed forms of nominal, discrete, and continuous data. Discrete values have intervals between a continuous series of values. The number of continuous values for an attribute can be endless, but the number of discrete values may be few or have an end value [1]. An example to continuous features is blood sugar content. Whereas an example of discrete features is gender. Process of converting continuous values to discrete values is called discretization. Discretization is generally used to sort and reshape continuous variables of attributes into categorized features. However, there are endless possibilities of discretization methods depending on the intervals which exist within domain. The idea of discretization is to divide the range of a numeric or ordinal attribute into intervals through user given or computed cut points. [2] made a comparison between unsupervised discretization method (Equal width, Equal frequency) and supervised discretization method (Entropy-based, Purity-based) from classification accuracy point of view. They found that the classification accuracy of the classification algorithms (Naive-Bayes, C4.5) significantly improved when features of the datasets were discretise using an entropy-based discrete method. At [3], the results of comparison between using discrete method and continuous method for six datasets showing that the performance of the classification accuracy is improved, when the features of datasets discretise. Studies for Cluster Algorithm also can be used as discretise values. [4] proposed accounting the interdependencies among different attributes and discretise the data using minimum entropy with minimum description length as the stopping criteria, used K-mean clustering methods and shared nearest neighbour. While [5] used the K-means clustering algorithm for discretization.

In this study, we applied supervised EB and unsupervised EW and EF discretization methods on 10 UCI dataset with continuous values. These datasets are applied to classification algorithms that work on discrete features, and then the accuracy of classification methods are compared. At the next section, the discretization methods unsupervised EW & EF and supervised EB are explained. At section 3, the classification algorithms are given. The experimental results are shown at Section 4 and the paper is concluded at Section 5.

II. DISCRETIZATION AND CLASSIFICATION OF DISCRETIZATION METHODS

Data discretization process is a method aims to reduce the volume of distinct values of continuous variables through dividing its range into limited set of unrelated intervals and then relating these intervals by specific descriptive labels. Usually discretization steps are sorting continuous values, finding cut points and finally applying conversion process [1].

Discretization methods are categorized along different needs, discretization of continuous values to obtain higher accuracy rate on handling data with high cardinality. Main classification of discretization is as supervised and unsupervised. Generally the categorization of the supervised and unsupervised discretization techniques depends on class information, for example if the discretization process uses class information, then we say it is supervised discretization. Otherwise, it is called as unsupervised discretization [1], [2]–[3].

A. Unsupervised Discretization Methods

The simple discretization (equal-width and equal-frequency interval binning) is among the unsupervised discretization methods and binning does not use class information.
Continuous ranges are subdivided into smaller ranges through user specified width or frequency. Usually in the unsupervised discretization methods, the number of parts must be supplied by the user [1], [2]–[6].

1) Equal Width Interval Discretization: The simplest discretization method is equal-width interval discretization which divides the range of observed values for a feature into equal sized bins represented by $k$ that is a parameter supplied by the user [1]–[2]. The process involves finding the minimum and maximum observed values through sorting of a continuous feature, $A = \{a_0, a_1, a_2, \ldots, a_{n-1}, a_n\}$, $a_{\text{min}} = a_0$ and $a_{\text{max}} = a_n$. $A$ is a continuous value array. Computing the interval may be done by dividing the range of the observed values for the variable into equally sized bins using the following formula: [1], [2]–[5].

$$\text{Interval} = \frac{a_{\text{max}} - a_{\text{min}}}{k}$$

$$\text{Boundaries} = a_{\text{min}} + (i \times \text{interval})$$

The boundaries can be formed by $i = 1, \ldots, k-1$ using the above formula. Equal Width Interval discretization steps as shown in Fig. 1. And these steps are given as an example in Table I below. Where $I$ is the instance, $T$ is the temperature, $C$ is the classes value, $A$ is the sorted value of $T$ and $D$ is the discretised value of $T$.

**Input:** data is the array having continuous values of the attribute, $A = \{a_0, a_1, a_2, \ldots, a_{n-1}, a_n\}$ and $k$ is the number of parts, where $k > 0$;  
**Output:** data having discrete values.

Step 1: Sort the value $A$ in increasing order  
Step 2: Calculate the interval by equation 1
Step 3: Binning the data by boundaries formula and determine the split point for $A$
Step 4: The value of attribute in the array must be placed in the same boundaries

**Fig. 1 Equal Width Interval Discretization algorithms**

2) Equal Frequency Interval Discretization: In the equal-frequency discretization algorithm the minimum and maximum values are determined for discretized attribute, and then all values are sorted in ascending order, and sorted continuous values divided into $k$ intervals in a way that each interval contains approximately $n/k$ data instances with adjacent values, $A = \{a_0, a_1, a_2, \ldots, a_{n-1}, a_n\}$ where $n$ is a number of element in $A$.

And $A$ is set of data with array having continuous values [1], [2], [5]–[7]. In proportional $K$-interval discretization method, the data instances with identical value must be placed in the same interval, so it is not always possible to generate exactly $K$ equal frequency intervals [7]. Equal Frequency discretization steps as shown in the Fig. 2. And these steps are given as an example in Table II below. Where $I$ is the instance, $T$ is the temperature, $C$ is the classes value, $A$ sorted value of $T$ and $D$ is a discretised value of $T$.

**Input:** data is an array having continuous values, $A = \{a_0, a_1, a_2, \ldots, a_{n-1}, a_n\}$ and $k$ is the number of parts. Where $k > 0$;  
**Output:** data having discrete values.

Step 1: Sort the value $A$ in increasing order  
Step 2: Determine the split point for $A$ and calculate the data instances in each interval by dividing the number of elements in the array by number of parts.
Step 3: The value of an attribute in the array must be placed in the same boundaries

**Fig. 2 Equal Frequency Discretization algorithms**

**B. Supervised Discretization Methods**

This discretization method converts numerical data to their categorical counterparts and use class information while choosing discretization nodes. Entropy based discretization is an example of this method [1], [2]–[5].

1) Entropy Based Discretization: This method uses division approach. Entropy (or information content) is calculated based on class labels. Intuitively works towards purifying each data group by finding the best cut points, so each data in the pure groups will have the same class label as much as possible. It is characterized by finding intervals that gives the maximum information gained [1]–[8]. The formula to calculate Entropy is as follows;

$$E(S, A) = - \sum_{i=1}^{n} P_i \log_2(P_i)$$

$$P_i = \frac{v_i}{v}$$

Entropy means “impurity”. But the impurity here means: diversity, having too much data with different specifications in one group. When calculating entropy, we will first calculate
entropy for estimated class value \(E(S)\). Then we will calculate entropy for specified cut points \(E(S, A)\). Finally, the best cut point by calculating information gained by the following equation is determined [1–8].

Information Gain = \(E(S) – E(S, A)\)

Entropy based discretization pseudo code is shown in Fig. 3 below. All these steps are given as an example in Table 3 below.

Input: Data is an array having continuous values, \(A = \{a_{0}, a_{1}, a_{2}, \ldots, a_{n}, a_{n+1}\}\)

Output: Data has discrete values.

Step 1: sort the value \(A\) in increasing order

Step 2: calculate entropy for class data

Step 3: determine the best split point for \(A\) by

- Calculate Entropy for each split point
- Calculate information gain for each split point

Step 4: select the split point with highest information gain

Step 5: recursively the partition on each split point when terminate once information gain falls below a certain threshold or once you reach a specified number of bins.

A. Decision Tree Algorithm

Decision trees are frequently used data mining approaches for classification and estimation. Despite the fact that other methods such as ANN can be used for classification, decision trees provide advantage of easy interpretation and comprehensibility to the decision makers [3]. Classification of the data using decision tree technique is a two step process comprising learning and classification. A previously known education data is analyzed by the classification algorithm in order to constitute a model during the learning phase. The constituted model is shown as classification rules or a decision tree. During the classification phase, on the other hand, test data is utilized in order to determine the accuracy of the classification rules or a decision tree. If the accuracy is in an acceptable range then the rules are used for classification of new data. It should be determined that which domains will be used in what type of order to constitute the tree. Entropy metric is the most widely used measurement for this purpose. The results obtained using the domain are uncertain and instable proportionally to the entropy measurement in that domain. Thus the minimum entropy or maximum information gain measurement of the domains are used in the roots of the decision tree. Entropy can be mathematically defined as; if \((p_1, p_2, \ldots, p_n) = \sum_{i=1}^{n} p_i \log_2 p_i\) then the sum of all these probabilities should be exactly 1. Finally the information gain is calculated for each \(p\) via the following equation [9–10].

\[ \inf \text{gain}(D, S) = H(D) – \sum_{i=1}^{n} P(D_i)H(D_i) \]

In a decision tree, all paths from the root node to the leaf node proceed by way of AND [11]. There are multiple modules of the decision tree algorithms [10], ID3 and C4.5 modules are used in this paper.

B. Naïve Bayes Algorithm

Naïve Bayes Classifier is an approach of probability, which can be used with a proposition that first seems to be very limiting in classification problems [10]. This proposition is the necessity of independency of each defining quality or parameter to be used in pattern identification in respect of statistics. No matter how this proposition is limiting the application field of Naïve Bayes Classifier, this approach yields results comparable to more complex methods such as ANN by stretching statistical independency condition.

Naïve Bayes Classifier is the simplified state of Bayes theorem by means of the independency proposition. Bayes theorem is expressed with the following equation:

\[ P(A|B) = \frac{P(B|A)P(A)}{P(B)} \]

\( P(A|B)\): The probability of incident A when incident B is realized

\( P(B|A)\): The probability of incident B when incident A is realized

\( P(A)\) and \( P(B)\): Prior probabilities of incidents A and B.

<table>
<thead>
<tr>
<th>TABLE III</th>
<th>EXAMPLE FOR ENTROPY-BASED DISCRETIZATION</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 2 3 4 5 6 7 8 9 10</td>
<td></td>
</tr>
<tr>
<td>T 85 90 86 96 80 70 65 95 75 91</td>
<td></td>
</tr>
<tr>
<td>C no no yes yes no no yes yes yes</td>
<td></td>
</tr>
<tr>
<td>A 65 70 75 80 85 86 90 91 95 96</td>
<td></td>
</tr>
</tbody>
</table>

\( \text{No} = 4, \text{Yes} = 6 \text{ probability } \text{No } P_{\text{No}} = 4/10 = 0.4 \text{ probability Yes, } P_{\text{Yes}} = 6/10 = 0.6 \)

Entropy (Play) = \(E(4,6) = E(0.4, 0.6) = -0.4 * \log_2(0.4) – 0.6 * \log_2(0.6) = 0.970\).

Let \( k = 2 \) (80 and 86) then.

For 1. Split \(<80 = \{65, 70, 75, 80\}\) and \(>80 = \{85, 86, 90, 91, 95, 96\}\)

For 2. Split \(<86 = \{65, 70, 75, 80, 85, 86\}\) and \(>86 = \{90, 91, 95, 96\}\)

Calculate entropy and information gain for each split then chose the split with the highest information gain.

Entropy \(E = \Sigma p_i \log_2 (pi)\)

Entropy for split 1 = 0.954 and Entropy for split 2 = 0.888.

Information Gain = \(E(S) – E(S, A)\)

Info for split 1 = 0.970 - 0.954 = 0.016 and

Info for split 2 = 0.970 - 0.888 = 0.082 then

\( D = \{0, 1\} \)

III. CLASSIFICATION ALGORITHMS

Classification concept is basically the distribution of the data among predefined various classes on a dataset [1]. Classification algorithms learn this distribution type from the given education cluster and they try to distribute data when unclassified test data are received. The values indicating these classes on the dataset are named as labels and they are used in order to denote the classes either for education and test. Some classification algorithms process according to categorical values (Decision Tree, Naïve Bayes) while others process with numerical values (ANN) [1].
Here, prior probabilities add subjectivity to the Bayes theorem. In other words, for instance, \( P(A) \) is the information that is obtained prior to any obtained data about incident \( A \). On the other hand \( P(B|A) \) is post probability because it gives information about the realization probability of incident \( B \) when incident \( A \) is realized after data collection \([1]–[10]\).

IV. THE EXPERIMENTAL RESULTS

In this study, using discretization methods of unsupervised (EW and EF) and supervised (EB) to convert an attribute’s continuous value of UCI dataset of Table IV into discrete values. Where \( NS \) is The Number of continuous Attributes, \( ND \) is The Number of discrete Attributes, \( NI \) is The Number of Instance and \( NC \) is The Number of Classes. Using Machine learning classification algorithms (NB, ID3, C4.5), we carried out the classification process on discrete datasets of converted values. Number of parts used in EW and EF discretization methods are \((k = 3 \text{ To } 22; k=2)\), the means \((3, 5, 7, ..., 21)\) are used, and at each \( k \) value classification performance is calculated, as a result, we have taken the average of overall part numbers according to the high performance value of each classification algorithm, in this case \( k = 9 \), in Table V and VI we have given classification accuracy according to the value of \( k \). In EB discretization method, as we mentioned above, the number of parts is calculated according to the data information gain, each attribute of data set is divided into different number of parts. In Table V, VI and VII classification results are given according to discretization methods used.

<td>75.13</td>
</tr>
</tbody>
</table>

The analysis of the results given in Tables V, VI and VII, from 8 datasets show that in EW method provides high classification accuracy for only Breast Cancer Wisconsin and Iris datasets and in EF method provides high classification accuracy Glass Identification and German Credit datasets while in EB method provides high classification accuracy for the remaining four datasets. In general supervised EB provides better accuracy then unsupervised EW and EF.

V. CONCLUSIONS

Discretization algorithms are known to have advantages and disadvantages relative to one another. Several new methods have been developed keeping these advantages and disadvantages in mind. As it is mentioned before; such as, in equal width discretization method, even if this bare discretization method is attractive among the others, there are reported opinions about major loss of data after discretization process, because of determining the gap width is not done correctly during the division into equal intervals. Other methods, such as the EW and EF require the user to enter the parameters while EB method determines the parameters itself. It is possible to say that, in this case, if user entered values are wrong parameters it could pose a problem in terms of results obtained. Data discretization process plays an important role in the data classification process, since it is the process of entropy based discretization data depends on the class of data in discretization data the discretization is relatively true, and it increases Probability of data classification is relatively. As a result of this study in categorization algorithms (NB, ID3, J4.5) which discretization method gives better performance than the others.

Abstract— Multivariate mapping is the visual exploration of multiple attributes using a map or data reduction technique. The simultaneous display of sometimes multiple features and their respective multivariate attributes allows for estimation of the degree or spatial pattern of cross-correlation between attributes. Multivariate mapping integrates computational, visual, and cartographic methods to develop a visual approach for exploring and understanding spatiotemporal and multivariate patterns. More than one attribute can be visually explored and symbolized using numerous statistical classification systems or data reduction techniques. In this sense, clustering analysis methods can be used for multivariate mapping. k-means and k-medoids methods which are non-hierarchical clustering analysis methods were analyzed in this study. The aim of this study is to determine the success of the spatial analysis of the multivariate maps produced by these methods. For this aim, classes and multivariate maps created with these methods from traffic accident data of two different years in Turkey were presented. In addition usability of such maps in risk management and planning was discussed.

Keywords— multivariate mapping; data mining; cluster analysis; visualization; cartography

I. INTRODUCTION

Multivariate mapping is the graphic display of more than one variable or attribute of geographic phenomena. The simultaneous display of sometimes multiple features and their respective multivariate attributes allows for estimation of the degree or spatial pattern of cross-correlation between attributes. Multivariate mapping integrates computational, visual, and cartographic methods to develop a visual approach for exploring and understanding spatiotemporal and multivariate patterns [1].

A fundamental issue in multivariate mapping is whether individual maps should be shown for each attribute or whether all attributes should be displayed on the same map ([2], p.327). Producing separate maps for each attribute would make it difficult to compare two objects which have various attributes. Therefore methods in which various attributes are shown in the same map are preferred more. In this sense, Trivariate Choropleth Map which is created by overlapping of two colored choropleth map [3]-[6], Multivariate Dot Maps method in which specific color or symbol is used for each attribute in the map [7], Multivariate Point Symbol methods which are used when multivariate data can be shown with point symbols [8]-[15], method in which combining different type of symbols is used for representing multivariate data [16] and method of separating different attributes from integral symbols [17] can be listed.

Different from the methods above, in order to represent many attributes in the same map, classification method based on clustering methods in data mining can be used as well. With the use of clustering methods, similar aspects of different spatial objects can be revealed by considering more than one attribute [18]-[19]. In this sense, spatial analyses that would make important contributions for risk analysis, planning etc. can be done.

It is quite important to make use of more than one attributes of current spatial event and determine similarity of spatial events in order to detect future events. For this aim, different spatial and non-spatial analysis methods are used for determining common properties of the spatial events. In this context, [20], [21], [22] and [23] used different clustering methods for determining common properties of different spatial events. Mapping of spatial events according with common properties is also significant for estimating types and effects of future events. Multivariate maps of occurred spatial events are more effective on determining common properties of spatial events and planning investments according to these properties. The aim of this study is to determine the success of the spatial analysis of the multivariate maps produced by k-means and k-medoids clustering analysis methods. For this aim, k-means and k-medoids methods are used for designing multivariate mapping of traffic accidents in Turkey with data of two different years, and result maps are compared. Success of these methods is determined with comparison of maps designed in different years according to two different methods.

In this study, Cluster Analysis and k-means and k-medoids methods in the second section, application in the third section will be explained in details, results and suggestions will be shared in last section.

II. CLUSTER ANALYSIS

Cluster analysis is the process of grouping information in a data set according to specific proximity criteria. Similarity of element in the same cluster should be high, similarity between clusters should be low [24]. In the process of classification, classes are determined before. In clustering method, classes
are not determined before. Data are separated different classes according to the similarity of data obtained.

Cluster methods are classified in different ways in various resources. In general sense, cluster methods can be classified as hierarchical and non-hierarchical methods [2].

- Non-hierarchical Methods: In non-hierarchical methods, n objects are divided into k clusters according k number (k<n) given before. This method divides data in a way that there will be at least one object in each cluster and each object will be included at least in one cluster [25].
- Hierarchical Methods: Hierarchical clustering methods group data objects in tree structure. Hierarchical clustering methods are classified as agglomerative or divisive according to hierarchical division being bottom-up or top-down [26].

In this study, k-means and k-medoids methods from non-hierarchical methods will be analyzed.

A. K-Means Method

This algorithm which was introduced by Mac Queen for the first time in 1967 is a cyclical algorithm in which clusters are continuously renewed until the most suitable solution is attained. General logic of k-means algorithm is to divide a data set composed of n data object to k clusters determined depending on preliminary information and experience of researcher. The aim is to provide the intracluster similarity is high, but the intercluster similarity is low. Similarity of clusters is calculated with the mean value of objects.

The k-means procedure is summarized as below [25]:

Input:
- k: the number of clusters,
- D: a data set containing n objects.

Output: A set of k clusters.

Method:
1. (1) arbitrarily choose k objects from D as the initial cluster centers;
2. (2) reassign each object to the cluster to which the object is the most similar, based on the distance between the object and the cluster mean;
3. (3) update the cluster means, i.e., calculate the mean value of the objects for each cluster;
4. (4) repeat until no change; (Fig.1)

Fig. 1 Clustering with k-mean Algorithm [26]

B. K-Medoids Method

In this algorithm which was developed by Kauffman and Rousseeuw in 1990, instead of mean value of each cluster, an object in each cluster is taken as representative. This representative object, called a medoid, is meant to be the most centrally located object within the cluster [25]. After k medoids chosen for k-clusters are determined, each remaining object is clustered with the representative object to which it is the most similar [27].

Steps of k-medoids algorithm are summarized as below [28]:
1. (1) Determination of k-cluster number.
2. (2) Choose of k objects as initial medoids
3. (3) Assign the remaining objects to cluster which has the most similar x medoid.
4. (4) Calculate aim function (sum of distances of all objects to the closest medoid)
5. (5) Arbitrarily choose of y point which is not medoid.
6. (6) If change of x and y would minimize aim function, change the place of these two points (x and y)
7. (7) The process is repeated between 3rd and 6th step until there is no change.

III. APPLICATION

Casualties, injuries and financial damages as a result of traffic accidents are among the most important problems of Turkey. When data of the last 5 years are analyzed, it is seen that there have been more than 1,000,000 traffic accidents, 145,000 of them ended up with death and injury, and nearly 1,060,000 of them results with financial damage. 4000 people lose their life on average in these accidents and nearly 250,000 people are injured. It is quite important to make use of more than one current traffic accidents attributes and determine similarity of traffic data on city basis in order to detect measures to be taken for traffic security in Turkey and future investments to be done. For this aim, in this study, clustering analysis will be made in 3 different methods by using number of motor land vehicles based on city, number of traffic accidents resulting in death and injury, number of casualties and injuries (4 different values) for the years 2011 and 2012 prepared by Turkish Statistical Institute (TÜİK) and multivariate maps will be produced according to analysis results. Maps designed for both years with 3 different methods were compared, it will be evaluated which method is suitable for the success of multivariate mapping and clustering.

In the application of clustering analysis methods, RapidMiner software developed in Dortmund Technology University Artificial Mind Unit by Ralf Klinkenberg, Ingo Mierswa and Simon Fischer was used. Multivariate maps were designed by ArcGIS software developed by ESRI group.

A. Multivariate Map Design with k-means Method

RapidMiner software was used in application of k-means method. As a result of test made in this sense, k cluster number is 5, number of highest iteration that would be made during operation of algorithm for once is 100, and maximum cycle of algorithm is 35. The method was applied separately for 2011 and 2012 data. Centroid Tables of clusters generated as a result of clustering processes are given in Table 1 and Table 2.
With the help of classes obtained by using 4 different values (number of motor land vehicle, number of traffic accidents resulting in death and injury, number of casualties and injuries) in clustering processes, multivariate maps showing similarity of traffic accidents on city basis for Turkey were designed (Fig. 2).

B. Multivariate Map Design with K-medoids Method

RapidMiner software was also used in application of k-medoids method. Different from k-means algorithm, k-medoids process operator was used instead of k-means operator. In this scope, k cluster number was again taken as 5, and maximum cycle of algorithm was taken as 35. Centroid Tables of clusters generated as a result of clustering processes are given in Table 3 and Table 3.

Again with the help of classes obtained by using 4 different values in clustering processes with k-medoids method, multivariate maps were designed for the years 2011 and 2012 (Fig. 3).

**FIG. 3** Multivariate maps designed with K-medoids for the years 2011 (above) and 2012 (below)

### IV. CONCLUSIONS

In the scope of multivariate mapping, more than one attribute can be displayed in separate maps or in the same map. Designing separate maps for each attribute would make it difficult to compare two objects which have various attributes. Therefore methods in which various attributes are shown in the same map are preferred more. One of the methods in which various attributes are displayed in the same map is to generate thematic map classes by determining the effect of different attributes with clustering analysis. In this sense, in this study, considering traffic accidents in 2011 and 2012 in Turkey, number of vehicles in traffic in these years, number of traffic accidents resulting in death and injuries, number of casualties and injuries parameters, multivariate maps were designed with 2 different cluster analysis method.

K-means and k-medoids non-hierarchical clustering algorithms divide n objects into k clusters according to k input parameter. They form the same cluster if objects resemble each other but not with the objects in other clusters. The greatest problem in applying these algorithms is determination of k cluster number. This can be determined with some of the practices experiences. When k=5 cluster number is given for data sets used in the study, it is observed that better clustering
results were obtained. Although clustering success of both algorithms are similar, when centroid tables of clusters formed with both methods (Table 1-4) are observed, it was detected that clusters are separated better in k-medoids algorithm. Since the aim is to provide high intracluster similarity and low similarity between different clusters, it can be said that k-medoids method gives better results for these data. When the maps designed using k-medoids method are examined, it is observed that 61 of 81 cities are located in the same cluster for two years. On the other hand, using k-means method 58 of 81 cities are in the same cluster. These results exhibit that foresights using these methods with 2011 data are highly consistent with 2012 data.

With this study it was shown that by using clustering methods, similar aspects of different spatial objects can be presented by considering more than one attributes. It is thought that by using multivariate maps designed with clustering methods, spatial analyses which have important contributions for practices such as risk management, planning etc. can be made.

Automatic Voice and Speech Recognition System for the German Language with Deep Learning Methods

Cigdem Bakır*

*Yildiz Technical University
Computer Engineering Department
İstanbul, Turkey
cigdem@ce.yildiz.edu.tr

Abstract—In our age, technological developments are accompanied by certain problems associated with them. Security takes the first place amongst such kind of problems. In particular, such biometric systems as authentication constitute the significant fraction of the security matters. This is because sound recordings having connection with the various crimes are required to be analyzed for forensic purposes. Authentication systems necessitate transmission, design and classification of biometric data in a secure manner. In this study, analysis of German language employed in the economy, industry and trade in a wide spread manner, has been performed. In the same vein, the aim was to actualize automatic voice and speech recognition system using Mel Frequency Cepstral Coefficients (MFCC), MelFrequency Discrete Wavelet Coefficients (MFDWC) and Linear. Prediction Cepstral Coefficient (LPCC) taking German sound forms and properties into consideration. Approximately 2658 German voice samples of words and clauses with differing lengths have been collected from 50 males and 50 females. Features of these voice samples have been obtained using wavelet transform. Feature vectors of the voice samples obtained have been trained with such methods as Boltzmann Machines and Deep Belief Networks. In the test phase, owner of a given voice sample has been identified taking the trained voice samples into consideration. Results and performances of the algorithms employed in the study for classification have been also demonstrated in a comparative manner.

Keywords—Boltzmann Machines, Deep Belief Networks.

I. INTRODUCTION

In our day, security problems have been unearthed along with the developments in the technology. Certain studies have been accomplished especially in order to prevent information belonging to some people from being transferred to other people in commercial transactions. Some of such studies are hand script recognition, signature recognition, face recognition, iris recognition and voice recognition [9].

German language belongs to the Germanic branch of Indo-European language family. Approximately 120 million people are speaking German language in the world. In addition, Germany has an important standing in respect of economy, trade, industry and many other fields in the international sense.

For this reason German language is used in a quite widespread manner. However, common usage of this language to such an extent, brings security problems for biometric data in this field. Accordingly this calls for the requirement of a secure, fast automatic voice and speaker recognition.

German language comprises of roots (words) and suffixes & prefixes and included in the inflected languages if we consider properties of the German language. German is written using the Latin alphabet and there are 29 letters in its alphabet. An article appears before each noun in German. Words are pronounced as they are written. In addition, it is distinguished from other languages with various developed sound shifts and intonation.

Various studies have been carried out in order for voice and speaker recognition. Jie-Fu et al. have collected voice samples in Chinese from 7 males and 5 females whose ages were ranging between 25 and 45 [8]. Attempts have been made to identify the owner of the voice by trying to analyze these voice samples by means of their tones, vowels, consonants and syllables. Voice samples have been separated into four frequency groups, and each frequency band has been analyzed. However, this study has not been tested for very big data. In addition, intended success was not exactly achieved since it was performed taking its similarities with the English language into consideration.

Tokuda et al. have developed English speech synthesis system using Hidden Markov Model [4]. This system has been developed for speaker recognition and specifies the structure by changing the voice feature. However characteristic feature of the synthesized voice in the study, is pretty low.

Reynolds et al. have implemented SuperSID project in order to enhance performance of speaker recognition systems [1]. Purpose of this project is to develop speaker recognition systems and employ the most suitable features in order to increase its accuracy. However this study failed to completely achieve the acoustic characteristics of the voice and removal of the noise.

Reynolds et al. have attempted to substantiate speaker identification and verification using Gaussian Mixture Model
Mel shows the frequency of voice tone. Mel smoothen the transition of speech samples between the frames. Hamming window has been used in this signal is divided into frames after the pre-processing step. MFDWC feature extraction method. Speech processing. It is used to extract significant information and features by dividing the sound data to its subsets. Feature extraction ste from men and women. These voice samples were used to create a unique database comprising German voice samples collected from men and women. These sound samples are trained by getting dispersed to various feature vectors with MFDWC, MFCC and LPCC. In the second stage, the feature vectors of the recorded sound signals are trained with classification algorithms, such as Boltzmann Machines and Deep Belief Networks. The gender of the speaker is decided by looking at sound signals at the test data and training data after the system is trained. Furthermore, the classification success in recognizing the gender of speaker has been calculated separately for 1, 3 and 5 and 9 feature vectors and the success of the methods have been presented comparatively by training the feature vectors, obtained from speaking signals with Boltzmann Machines and Deep Belief Networks.

II. FEATURE EXTRACTION METHODS

German language is widely used in economy, industry and trade. Therefore, examinations have been made on German language in this study. The study has been realized on a unique data base, which have been formed from the German sound samples, taken from men and women. These sound samples are trained by getting dispersed to various feature vectors with MFDWC, MFCC and LPCC. In the second stage, the feature vectors of the recorded sound signals are trained with classification algorithms, such as Boltzmann Machines and Deep Belief Networks. The gender of the speaker is decided by looking at sound signals at the test data and training data after the system is trained. Furthermore, the classification success in recognizing the gender of speaker has been calculated separately for 1, 3 and 5 and 9 feature vectors and the success of the methods have been presented comparatively by training the feature vectors, obtained from speaking signals with Boltzmann Machines and Deep Belief Networks.

A. Mel-frequency Discrete Wavelet Coefficients (MFDWC)

The study in question has been performed, based on a unique database comprising German voice samples collected from men and women. These voice samples were separated into various feature vectors with MFDWC, and trained. MFDWC is a feature extraction method employed in the speech processing. It is used to extract significant information and features by dividing the sound data into subsets. Feature extraction steps of MFDWC technique is shown in the Figure 1 [7].

Sample speech signal is shown between the 40-40000 Hz range in the MFDWC feature extraction method. Speech signal is divided into frames after the pre-processing step. Hamming window has been used in this study in order to smoothen the transition of speech samples between the frames. One Mel shows the frequency of voice tone. Mel-scale is scaled between actual frequency of voice signal and estimated voice frequency. For this reason total energy of every frame is calculated. Classification success in speaker identification has been calculated on an individual basis for MFDWC-3, MFDWC-5 and MFDWC-9 vectors by training the feature vectors obtained from voice signals by means of Boltzmann Machines and Deep Belief Networks.

B. Mel Frequency Cepstral Coefficients (MFCC)

MFCC is a feature extraction method, that is used in sound processing. It is used to extract important information and features by dividing the sound data to its subsets. The steps of feature extraction technique of MFCC is indicated in Figure 2 [11].

![Feature extraction steps of MFDWC](image1)

![Feature extraction steps of MFCC](image2)
Two filters are used in MFCC feature extraction method. The first filter has a linear distribution of frequency values under 1000 Hz and the other has a logarithmic distribution of frequency over 1000 Hz. Pre-emphasis stage is the first stage in obtaining MFFC feature vector.

The sound signals, which have high frequency, are passed through a filter at this stage. This way, the energy of the sound is increased at high frequency. The sound signals are analog. The sound signals are converted from analog to digital by getting divided into small frames between 20 and 40 ms during the framing stage and it is divided into N frames. The sound signal is moved by sliding the sound signal at the windowing stage. This way, the closest frequency lines and the frame, which will come by windowing, that is used are combined. The window type, width and sliding amount are determined at this stage. Each of N frames is transmitted from the time space to the frequency space with Fast Fourier Transform (FFT). The spectral features of sound signals are shown in frequency space. MEL spectrum is obtained by calculating the total weight of these spectral features. This MEL spectrum is formed from triangle waves and are formed by getting passed through a series of filters. The logarithm of signal is taken at the stage of MEL spectrum and the signal is transmitted back again from frequency space to the time space. MEL frequency cepstrum factors are obtained by using DCT (Discrete Cosine Transform) in time space.

C. Linear Prediction Cepstral Coefficient (LPCC)

LPCC is a well known and commonly used technique to obtain the characteristic features from sound signals. In this technique, each sample of sound signal is based on the conversion of linear prediction coefficients obtained as a linear weighted total of previous sound signals into cepstral coefficients. This is not a method preferred for sound signals exposed to various environmental effects or noise. LPCC utilizes functions that model the sound path.

LPCC method is obtained by converting LPC coefficients into cepstral coefficients through Fourier conversion. Preliminary process is completed by transmitting speech signal through high filter. Auto correlation characterizes the signal by determining the similarity of each sound signal with itself. This step is materialized in frame of each signal. Signal is analyzed by converting the auto correlation values into LPC parameters by using Levinson-Durbin recursion. In final phase, LPCC parameters are obtained with cepstral analysis [12]. Steps of LPCC feature extraction are provided in Figure 3.

\[
s(n) = \sum_{n=1}^{p} a_i s(n - i)
\]

Fig. 3 Feature extraction steps of LPCC

III. CLASSIFICATION METHODS

Depth learning algorithms are used in certain fields primarily in sound processing in recent years. In particular, depth learning algorithms are developed for the solution of complicated problems. They are comprised of multi layers. Therefore, they may contain numerous hidden information. In this study, two depth learning algorithms are used as Boltzmann machines and Depth belief Networks. Steps of the study are presented in Figure 4.

Receiving of sound records

Extraction of sound features with MFDWC, MFCC and LPCC

Modelling the system by training with depth learning algorithms

Comparison of test sample given with the sound samples in the models

Automatically determining the speaker according to model created

Fig. 4 Study Steps
A. Boltzmann Machines

Boltzmann Machines (BM) are used in the modelling of units between entry layers and hidden layers. Therefore, parameters learnt in hidden layer are the entry parameters for next BM. So, BM is very significant for deep neural networks.

Boltzmann machines are a stochastic process comprised of recursive artificial neural network. It has multilayer structure. It is used frequently for the solution of searching and learning problems. All artificial neural networks are not linked with each other.

Restricted Boltzmann Machines (RBM) are the structures limiting the connections to be formed on the layers between units within the entry layer and the units within the hidden layer. All artificial neural networks are not linked with each other. Sample of RBM neural networks are indicated in Figure 5.

\[
p(l = k|h; \theta) = \frac{\exp(\sum_{i=1}^{n} \lambda_{ik} + a_k)}{Z(h)}
\]  

(2)

Entry signal in Equality 2 is processed through all layers and converted into output multiple distribution. Entry signal is divided into \( k \) and \( e \) in final layer weights between \( k \) class and hidden units are indicated.

It is recommended to materialize the learning of DBM network in two phases. In preliminary training phase as first stage, weight parameters modelling the entry data are learnt. Second phase is referred as finetuning and aims for the learning of network parameters classifying the training set [15].

![Fig. 5 Boltzmann Machines](image)

RBM is a directional graphical model comprising the hidden and visible units on a layer. All hidden units are indicated as dual graph since they are linked with visible units. Creation of RBM model is indicated in Equality 2 [16].

\[
p(v, h, \theta) = \frac{\exp(-E(v, h; \theta))}{Z}
\]

(2)

In this equality, \( v \) indicate the visible unit, \( h \) hidden units, \( \Theta \) model parameters and E function of model comprised of \( (v, h; \theta) Z = \sum_v \sum_h \exp(-E(v, h; \theta)) \) normalization factor.

B. Deep Belief Networks

Depth Belief Networks (DBM) are the architectures providing modelling of data within hierarchical structure. DBM comprised of subsequent connection of multiple RBM materializes the learning process by subsequently training the RBMs creating its structure. Structure of DBM is indicated in the Figure 6. It is formed of numerous hidden layers. Next possibility of each hidden layer for the data of which entry data is given. Weight of subsequent RBMs are found from hidden activities [14]. This possibility distribution is calculated as in Equality 2 [16].

![Fig. 6 Deep Belief Networks Structure](image)

IV. EXPERIMENTAL STUDY AND RESULTS

In this study, an authentic and unique German database has been used. The names, surnames, ages, sexes and speeches of persons have been added into this data base. The different number of feature vectors of sound components have been extracted with MFDWC, MFCC and LPCC feature extraction method. In the next stages, the sound samples have been trained by using methods Boltzmann Machines and Deep Belief Networks. The features of the recorded sound samples have been indicated in Table 1.
Feature vectors of voice components with different quantities; have been extracted by means of MFDWC, MFCC and LPCC feature extraction method. Voice samples have been tested by training them, using available feature vectors by means of Boltzmann Machines and Deep Belief Networks methods.

Success rates of speech samples obtained utilizing MFDWC different feature vectors are given for Boltzmann Machines and Deep Belief Networks in the Table 2. Success in the speaker identification increases as the number of words used increases in all techniques employed. Deep Belief Network gave more successful results when compared to Boltzmann Machines.

V. CONCLUSION

Voice recognition plays an important role in our day due to security and many other reasons. Person and speaker identification systems have been developed, being based on an unique database obtained by utilizing German language in this study. Classification success of the methods employed in the study have been calculated separately for men and women, and results are demonstrated in a comparative manner. Deep Belief Networks provided more successful results compared to the Boltzmann Machines when the results are taken into consideration. Speaker recognition system is more successful for men compared to the women. 9 feature extraction is more successful compared to the results obtained utilizing for all other feature extraction techniques.

Abstract—There are many microcontroller training kits available on the market. Most of them are equipped with DIP-switched circuit boards that are configured mostly by students during the experiments. Intensive use of DIP-switch sockets, cables, and materials on the experimental kits leads to circuit breaks and faulty connections easily. Therefore, many institutions face undesired hurdles in maintenance and repairing procedures even though they have skilled technicians or instructors.

In this paper, we have designed and implemented a software-configured microcontroller training set to overcome adverse conditions originated by conventional microcontroller kits such as time-consuming maintenance procedures and circuit faults caused by improper configurations. In doing so, an analog switch matrix board has been designed to perform connections between the microcontroller port pins and external peripherals. The system eliminates the possibility of the user errors or electrical faults caused by improper wiring along with mechanical damages caused by forceful interventions. Hence, the students can concentrate on the technical aspects of the experiment rather than mechanical inconveniences.

The software designed, which manages an analog matrix switch board, has many scenarios and configuration files for each experiment. The students decide the type of the experiment and he/she configures both the microcontroller and the CPLD using software interfaces provided. The CPLD configuration file is fixed for each scenario but the microcontroller hex file must be developed by the students. The CPLD and the 8051 development board are connected to the computer via a USB 2.0 port.

Keywords—Microcontroller, Training Set, Experiments, CPLD, Matrix Switches

I. INTRODUCTION

Since the time microprocessors and microcontrollers courses first appeared at the universities and colleges, there has been always a strong demand for experimental sets to comprehend the backgrounds of the subject. Emerging technologies like flash programming, high-level language compilers, and simulation tools increase the number of candidates who are willing to develop embedded systems. At the same time, many companies promote their chips and education or training kits to draw the attention of the engineers from the world. Initially, the price of the kits was too high for educational institutions. So, many local companies were emerged to market the educational kits for institutions that have short budgets. Since then, several types of experimental kits have been marketed by different producers with diverse elements and components.

Almost all experimental kits have sockets and cable pairs for the connection of the desired experiment. Since each experiment has different connection setup, the users must configure both the cables and sockets on the board before the test run. This procedure should be done with great care and in a proper manner. Despite diligent operations, the user can harm the sockets and cables during the insertion or remove procedures because of the mechanical forces. In addition, the user can connect the ports in the wrong way inadvertently. The potential problems mentioned can increase the time and maintenance cost dramatically along with reduced level of availability of the kits.

In the literature, there are many approaches to ease the laboratory burdens. For example, an educational kit has been designed to configure the program of the microcontroller and port connections in a straightforward fashion. The educational kit also incorporates a software interface to ease the procedure of the experiments [1].

Another paper presents a microcontroller training set which is also supported by training sets and video courses along with a virtual laboratory [2].

In a master thesis, which is the origin of this study, an 8051 based microcontroller training kit and its peripheral modules are connected each other with a matrix switch configured by a CPLD. In that study, there is no software interface used to configure both CPLD and microcontroller devices respectively. However, the user must configure both the microcontroller and CPLD boards manually using software tools provided by manufacturers [3].

An 8-bit Motorola 68HC11 microcontroller training kit employed with RS-232 serial communication has been designed. The connections for each experiment are performed by on-board DIP-switches and the hex code files are downloaded into the chip through RS-232 protocol [4].

Virtual platforms used in embedded systems training are examined and it is claimed that students prefer virtual environments rather than hardware based platforms since they are considered more efficient compared to conventional approaches [5].
An MC68C11/12 based experiment kit has been designed for engineering laboratories. The system includes only hardware based components and modules [6].

An MC68000 microprocessor based standalone educational board has been designed. The board incorporates keypad, LEDs, LCD, DIP switches, 7-segment display, DC motor and a couple of I/O peripherals. All hardware connections are implemented by DIP-switches and cables [7].

A microcontroller (ATmega128) processor based educational kit, which is targeted for bachelor engineering students, has been examined. Again, entire hardware connections are implemented by DIP-switches and cables [8].

In another study, a PIC 16F84 based training program and an accompanying experimental set have been designed. Programme includes some experiments related to basic operations for target microcontroller [9].

In this paper, we propose a new design and test environment used in microcontroller training to eliminate the drawbacks originated from conventional microcontroller experimental kits. The method includes a matrix switch circuit and a user interface to configure the experimental kit within a couple of seconds without mechanical or physical interventions.

II. SYSTEM ARCHITECTURE

The system architecture is consist of 4 main modules as seen in Fig.1:

- The PC and accompanying software
- An 8051-based microcontroller kit
- A Matrix switchboard
- Various experimental modules

![Fig. 1 General system block diagram](image)

Low impedance analog switches, which are types of SP3T (Single pole, three throw-TSSA3359), connect 8-bit microcontroller ports to various peripheral experimental modules such as display modules, keypads and etc. We have used 32 (4x8) analog switches in the whole system. The switches have 1x3 multiplexer behaviour. Thus, any port of the target microcontroller can be redistributed to one of three testing ports. In order to redistribute each bit of the port of the microcontroller, 8 analog switches are required and they are controlled by 2-bit selection signals (IN1, IN2) provided by CPLD outputs as shown in Fig. 2. In fact, the microcontroller has four port sockets deployed with 10-pin IDC headers, however, in each port header two extra pins are used for power pins i.e. GND and VDD. So, there is no need to redistribute those power pins and they are shared with all ports by default.

The software interface developed incorporates following features:

- All configuration procedures have visual icons
- Experiment selection by the user
- HEX file selection and experiment setup facilities
- The circuit schematic of the experiment is loaded on the screen when an experiment is selected.
- ‘Status’ pane shows the procedures step by step to inform the user
- ‘Experiment summary’ pane informs the user on the details of the experiment such as port routing schemes and the materials used

![Fig. 2 Analog matrix switch block diagram](image)

The user can either select regular experiments or user-defined experiments by clicking tabbed windows on demand as
demonstrated in Fig. 3. In the user-defined mode, many types of peripherals such as LCDs, LEDs, and Dip-switches can be selected and all wiring procedures are done by the user directives.

![Image of User Interface](image_url)

Fig. 3. The User Interface

III. HEX FILE AND CONFIGURATION FILE SELECTION

If the user selects a user defined experiment, the hex code of the experiment and C or assembly source code of the experiment must be provided by the user. Having compiled and produced the hex code by any development tool, the ‘open’ button must be clicked to select intended hex file. After hex file selection, “Prepare Experiment” button is clicked and this step causes two consecutive procedures performed: the background worker programs namely Flip.exe and impact.exe are executed respectively. While Flip.exe configures the target microcontroller using the hex file provided, impact.exe configures the CPLD using a jeld file generated for the intended experiment architecture.

When a regular experiment is intended, any desired experiment listed in the pane is selected by clicking the corresponding radio button. The rest of the configuration procedures are performed automatically without the intervention of the user.

IV. CONCLUSIONS

In this paper, we have designed and implemented a user-friendly, low cost and low maintainability laboratory kit used in embedded systems classes. The system includes hardware and software modules and enables students to focus on programming of the embedded system and its modules other than the hardware connection burdens. Since there is no student intervention on the experiment kits, the risk of the mechanical failures or breaks. The system also provides time advantages, thereby promising more experimental opportunities for the students. The system has been tested with a limited number of modules and it would be better if the number of modules is increased.

Abstract— In this study, research was carried out in order to compare the effects of basic imaging applications such as image rotation and image filtering on a noisy image and determine whether image rotating application can be used instead of image filtering application. In the study, it was aimed to compare bilinear, bicubic and nearest methods, among commonly used interpolation methods of image rotating, with average, wiener and median filters, which are the linear filters among image filtering methods, in terms of image quality factors. PSNR (Peak to Signal Noise Ratio), MSE (Mean Square Error), SSIM (Structural Similarity Index) were determined as quality factors to be used in the study, and the processed image was a baboon image, an 8-bit gray-scale image of 512*512 dimension that is the most common image used in image processing.

Keywords— Image rotating, Image filtering, PSNR, MSE, SSIM

I. INTRODUCTION

The noise which is one of the most common encountered problems in image processing operations consists of noises such as photon shot noise, dark current noise, read noise, quantization noise [1]. These noises can occur within the digital systems due to the reasons such as data transmission and data storage. The random noises such as Gaussian Noise and Salt&Paper Noise which are the most commonly used images to model these noises and create algorithms based on this can be created in software environment [1].

The filtering technique which is one of the most frequently used methods to eliminate noises on the image is divided into two: linear, non-linear and spatial-frequency domain filters [2,3]. Linear filters are generally defined as low-pass filters, create blurring on the image and smooth the image while nonlinear filters make the noise filtering process by preserving the edge information defined as a high frequency [3]. Average filter and wiener filter from linear filters and median filter from non-linear filters were used in this study [4, 5, 6]. Image rotating operation is one of the most frequently used applications in program-based and real-time processing in image processing applications [7].

Calculating a new pixel value of each pixel which is known as interpolation during image rotating application is an important operation. For this application, bilinear, bicubic, nearest interpolation methods were developed in the Matlab environment and put into practice [8].

The comparison of image rotating operation and the mentioned interpolation methods noise elimination based on image rotating process idea and implementation with the mentioned filtering methods was a fundamental aim of this study [8].

The measurability and comparability of an application performed are important in terms of science. Therefore, image quality factors are important in image processing applications in order to obtain the measurements of the original image and the image obtained after the performed operation [9].

II. METHOD

A. Image And Noise Filtering

The basic logic of the median filter algorithm that is one of the filters used in this study is realized by a mask and making ascending and descending order of the pixel values within the neighborhood of this mask and appointing the mean value to the center pixel value of the mask determined [4].

The second filter used in this study is called average filter and is one of the most basic linear and spatial filters. The average filter is found by taking the arithmetic average of the sum of pixel values in the whole neighborhood of a mask with certain neighborhood [5].

Another filter used in this study was determined as the wiener filter, and the use of the mentioned filter structure was realized in the Matlab environment and is currently used in academic studies [6].

B. Image Rotating

The methods used in image rotating operation were realized by using the available Matlab functions. The relevant methods are bilinear, bicubic, nearest interpolation methods. The comparison of image rotating operation with image filtering
operation through interpolation methods was studied in the literature, and various image rotating algorithms were observed to have given good results [10,8].

C. Image Quality Factors

Image quality factors are calculated with the relational mathematical functions of the operations performed on images by taking the original image as reference[9]. These were determined as PSNR (Peak to Signal Noise Ratio), MSE (Mean Square Error) and SSIM (Structural Similarity Index). The mathematical expressions of PSNR, MSE, and SSIM, among the relevant quality factors, are as follows [9].

Taking $M \times N$ as the image, 8-bit-gray-scale can be calculated in the $f$ reference image with the same values and in the $g$ test-processed image[9] as follows:

$$
PSNR(f, g) = 10 \log_{10} \left( \frac{255^2}{MSE(f, g)} \right)
$$

$$
MSE(f, g) = \frac{1}{MN} \sum_{i=1}^{M} \sum_{j=1}^{N} (f_{ij} - g_{ij})^2
$$

Similarly, mathematical expressions related to SSIM are as follows:

$$
SSIM(f, g) = l(f, g) c(f, g) s(f, g)
$$

"l" represents lighting, "c" represents contrast, and "s" represents correlation. The SSIM factor represents a value within the range of $(0 \rightarrow 1)$. The closer the image value is to the reference image, the closer SSIM value is to 1 [9]. Again, the higher PSNR value is, the closer image to the reference image is obtained, and it takes values between $(0 \rightarrow 99)$ [9].

The farther the MSE quality factor is to the reference image, the higher value MSE takes [9].

The values in this study and their results are shown in the figures and charts in the following section.

III. EXPERIMENT AND RESULTS

The results obtained in this study were obtained as follows in the form of charts and graphs.

Fig.1 512*512 Gray-scale 8-bit baboon image.

Baboon image which is frequently used in image processing studies is shown in Fig.1. Again, zero-padding processing was performed for image rotating operation performed by acquiring new dimensions on the same image, and a sample image rotating of 20 degrees is shown in Fig.2 and Fig.3.

Fig.2 The baboon image to which zero-padding processing was applied

Fig.3 The baboon image to which zero-padding and Salt&Pepper noise adding processing were applied and which was rotated with 20-degree angle of rotation

The PSNR, MSE, SSIM values of the angular changes on the image to which no noise was added in this study are shown in Figure-4, 5 and 6.

Fig.4 Unnoised Baboon Image and 45 degree rotation with PSNR
Again, the change in the noise density which was added to the image in this study and the PSNR values of the relevant image following the application of the median filter were obtained. The results are shown in Fig. 7.

However, the PSNR, MSE, SSIM values in the image to which noise was added and which was rotated at the angles determined in the image and the comparison of the PSNR, MSE, SSIM values in the image of the same picture after filtering through the Average-Wiener filter are shown in Figure-8, 9, 10, 11,12,13.
In this study, as a result of the comparison made between the interpolation methods realized in the image rotating operation during obtaining the values shown in Figure 8-13 and the characteristics of the mentioned filters, it was observed that the characteristics of the filters did not give the expected good results in terms of image quality factors. However, while the conclusion that increasing the values determined as spatial filter masks gave similar results to image rotating operation or it could be used instead of image rotating was valid for the average filter, it was observed to have given an exactly opposite characteristic for the wiener filter. Furthermore, it was observed in the study that the bilinear method which is one of the interpolation methods gave better results that the other methods.

Abstract— Edge detection has important applications area in image processing field. Today, it is a fact that the image processing used in many fields. Therefore, the applicability of edge detection process in the field is also has great importance. In this study, mainly used edge detection algorithms in the literature; i.e., Sobel, Prewitt and Canny algorithms is provided using the verification and inspection on FPGA (Field Programmable Gate Arrays). Program files required for FPGA is prepared by Xilinx System Generator DSP blocks, which can work integrated with Matlab/Simulink. For this study; gray format images, which is stored on the computer has been sent to FPGA with USB configuration port interface on FPGA. Edge detection process is realized by moving subject images from the computer with the same connection to FPGA and then, Sobel, Prewitt and Canny algorithms are applied to the images on FPGA respectively. Edge detection process for the same images are performed by Simulink and FPGA board at the same time and then, edge detected images obtained from these two environment are compared and also it has been observed on the FPGA resource usage.

Keywords— FPGA (Field Programmable Gate Arrays), Sobel, Prewitt, Canny, Matlab/Simulink and Xilinx System Generator, DSP (Digital Signal Processing)

I. INTRODUCTION

Today, with the development of image processing technology it is also used quite a lot. Most of our lives intertwined with a technological structure is wrapped in an image processing device is configured on. The algorithms used in this field of technology with the speed proportional manner are developing very rapidly. Work is done in many areas, i.e.; Security systems, traffic warning systems, microscopy and medical imaging systems, making use of image processing techniques such as remote sensing systems.

One of the most important areas in the image processing is an edge detection process. Edge detection is one of the most important task of finding the image. Edges is the most important information in the image. Human visual system is based on the direct detection of edges [1]. To distinguish objects in the images, the display of details which can not be noticed with the naked eye, in situations such as edge detection algorithms to compare the two different patterns are used quite extensively. Haralick, found that the gradient value using the derivative value interpolation equation is found through applied on pixels in the direction of the gradient on the second derivative method caller has provided a transition to zero [2]. Canny, the implementation of the operator derived from the Gaussian mask derivative based proposed a method [3]. Roberts is the first method used in image processing, Prewitt and Sobel operators are an example to the most appropriate operators [4]. Because image processing and edge detection processing speed for applications that require processing typically computer-based applications, DSP-based methods and FPGA's are used.

We can sort out some work done using image processing FPGA said. Chris and his friends for the detection of tumors in the brain images taken by MRI device, brands have benefited from Xilinx FPGA development board. Implemented on FPGA determined the tumor site with different filters. Create a system in which they work in a way that is integrated with Matlab, compared to other systems available in the literature, 50% less use of resources has been realized [5]. Rodriguez and colleagues while running real-time median filter design on FPGA, have created a system that enables visual identification of errors in production centers [6]. Nelson, a team using different FPGA hardware produced by the master's thesis on Xilinx Spartan-3 FPGA's need to work * .bit extension file has been created with the Xilinx System Generator. Chris and his friends while improving the resolution of an image taken using DSP with FPGA hardware have gained a clearer picture. In this process; They used the Xilinx Spartan-3 FPGA hardware configuration of the image and they have developed the resolution with DSP [8].

This article made a thorough research on the FPGA programmable logic devices and technologies and the basic operators used in edge detection Sobel, Prewitt and Canny operator of the implementation on FPGA and is provided to be examined. In this study, Matlab / Simulink and Xilinx System Generator can run Xilinx integrated DSP blocks in Simulink and Simulink blocks with the tool is used. Due to prepared system 256*256 gray formatted images on computer sent to Simulink and FPGA at the same time and Sobel, Prewitt and Canny operators were applied to the images. In prepared system, data transmission between computer and FPGA is provided with USB configuration port. FPGA's need to work * .bit extension program file has been created with the Xilinx System Generator. In practice, Spartan3E XC3S1600 belonging to the company Xilinx FPGA device is used.
The following sections of this article consists of more than four sections. Scope of issues examined in this section are as follows: Section 2 in this article; edge detection, edge detection methods and general information about the basic edge detection operators are given. At Section 3; information about Xilinx System Generator, which used for programming of FPGA board and Simulink DSP blocks are given. Section 4 in this article; implementation of Sobel, Prewitt and Canny edge detection operator on FPGA and Simulink side is explained in detail. Results and conclusion parts are shown in sections 5 and 6 respectively.

II. EDGE DETECTION AND OPERATORS

Visual system in humans is first trend detection edges in the image of the object located on any image. This is because the stationary location typically does not contain information. In an image, the image improvement is of great importance how important is the determination of the edges. Generally such high levels of image processing in the edge detection operators are implemented as a precursor [9]. Different features depending on optical and shape of an image leads to the formation of the edges. Shape-based features in the appearance of the edges; changes in the direction of surface texture or color, object, borders, colors observed two objects sourced from the top are differences in the appearance and texture [10]. Edges which some of their optical properties are; the direct reflection light, shadows caused from a part of the same object or other objects, reflections arising from the intermediate part of the same object or other objects, texture or color variation [11].

One of the most efficient methods to detect edges in the image that exists is to identify instant gray value changes on the image. One of the main approaches used by many edge detection method which involves calculating the derivative locally. In the first derivative of the edges of the image locally reached the highest value, while the second derivative image in the edge of regional zero. 1st and 2nd derivatives are calculated for the image as a result of this, a local maximum and edges with the zero crossing points for the examination of the image is determined. Fig. 1 shows derivative values of image function at edge points.

![Image](image_url)

Fig. 1 Derivative of edge transition of edge points

A. The First Derivative(Gradient) Based Methods

Gradient based single variable is expressed as the first derivative of a function. This operation is a function which depends on two variables calculated by applying the process according to the 1st derivative of each variable. As an image is expressed as a function of two changes, the necessary information about the direction of the gradient edge angle as can be seen by looking at the size gradient to be applied to the edges in an image display function will give us. \( f(x,y) \) as an equation for an image display function, gradient magnitude and gradient angle is calculated by equations below.

\[
G[f(x, y)] = \begin{bmatrix} G_x \\ G_y \end{bmatrix} = \begin{bmatrix} \frac{\partial f}{\partial x} \\ \frac{\partial f}{\partial y} \end{bmatrix} = \lim_{\Delta x \to 0} \frac{f(x+\Delta x,y)-f(x,y)}{\Delta x} \quad \lim_{\Delta y \to 0} \frac{f(x,y+\Delta y)-f(x,y)}{\Delta y}
\]

(1)

\[
G = \sqrt{\left(G_x^2 + G_y^2\right)} \quad \theta = \tan^{-1} \frac{G_y}{G_x}
\]

(2)

Roberts, Sobel, Prewitt and Canny 1st derivative (gradient) based methods are the most well-known among operators.

1) Roberts Operator: Roberts’s operator on the image of a mask with a drizzle of 2x2 at every point allows for the calculation of the approximate gradient vector. The magnitude of the gradient vectors is calculated, it is placed on the edges of a pixel matrix of image size designated image can be obtained.

Gradient operation on the image convolution operation result is calculated using two different masks image horizontally and vertically. The result of using the first derivative of the convolution equation gives two masks, which is given below.

\[
G_x = \begin{bmatrix} 1 \\ 0 \\ -1 \end{bmatrix}, \quad G_y = \begin{bmatrix} 0 & 1 \\ -1 & 0 \end{bmatrix}
\]

(3)

2) Sobel Operator: Another fundamental edge detection operator is Sobel. This provides operators with the direction to make an efficient assessment as more independent gradient calculation based on more extensive use operators like Robert [12]. The basic idea underlying the creation of Sobel operator edge can be explained as follows. The total value of the gradient of a digital image to 3x3 neighbourhood center and 4 formed in the direction vector is based on a function that is considered. Sobel horizontal and vertical masks are given below.

\[
G_x = \begin{bmatrix} 1 & 2 & 1 \\ 2 & 4 & 2 \\ 1 & 2 & 1 \end{bmatrix}, \quad G_y = \begin{bmatrix} 1 \\ 2 \\ 1 \\ 0 \\ 0 \\ 0 \\ -1 \\ -2 \\ -1 \end{bmatrix}
\]

(4)

3) Prewitt Operator: Prewitt edge operator is an operator that calculates the gradient vector at each point on the image pixels. Found the gradient vector magnitude edge image that made improvements, while the direction of the gradient vector gives the edge direction [13]. Prewitt edge gradient values using the two different masks in horizontal and vertical pixel on the image is calculated by convolution operation. The masks are used during this process include using difference equations.
of the first derivative. Prewitt horizontal and vertical masks are given below.

\[ G_x = \begin{bmatrix} -1 & 0 & 1 \\ -1 & 0 & 1 \\ -1 & 0 & 1 \end{bmatrix}, \quad G_y = \begin{bmatrix} -1 & -1 & -1 \\ 0 & 0 & 0 \\ 1 & 1 & 1 \end{bmatrix} \] (5)

4) Canny Algorithm: Canny has been working for optimum edge detection algorithm [3]. Determining this algorithm has been designed to provide the following features:

- Developing a great possibility that when determining the value of the algorithm places where the edges, the edges are not able to determine locations with a small probability value.
- To be defined edges should be on the edge to be the closest to real edge.
- Real edge should be detected only once.

Canny edge detection algorithm work consists of five steps. These steps are as follows, respectively:

- Smoothing
- Gradient Calculation
- Non-maximum Suppression
- Double Thresholding
- Edge Tracking with Hysteresis

All of the amount of noise present in the images obtained by the camera is inevitable. During the edge detection process on the noise image to image will cause errors need to be cleaned out. In order to cleaning Gaussian filter is applied to the image. This process is for smoothing and equations given below is for Gaussian filter.

\[ G_x = \frac{1}{2\pi\sigma^2} \exp \left( -\frac{x^2+y^2}{2\sigma^2} \right) \] (6)

\[ G = \frac{1}{15} \begin{bmatrix} 2 & 4 & 5 & 4 & 2 \\ 4 & 9 & 12 & 9 & 4 \\ 5 & 12 & 15 & 12 & 5 \\ 4 & 9 & 12 & 9 & 4 \\ 2 & 4 & 5 & 4 & 2 \end{bmatrix} \] (7)

For calculation of gradient magnitude and gradient angle Sobel filter are applied to the images and equation (2) is used.

The main objective of making the process non-maximum suppression is sharpen the edge of the image with a blurred gradient magnitude. This process is mainly performed by making all pixel values of the non-local maximum points in the gradient image to zero.

After non-maximum suppression process some of pixel values is not real edge pixels due to noise and color variation. The aim of double thresholding is elimination of these pixels. Canny edge detection algorithm uses two threshold, including high and low thresholds. Edge pixel density greater than high threshold pixels that "strong" as classifying edge pixels which are printed below the lower threshold pixel density. Edge pixel value between the low and high threshold in case the edges of the pixels are "weak" as classified.

After double thresholding process the pixels, which are classified “strong” as determined edge pixels precisely. If the pixels, which outside of that and classified “weak” is neighbourhood of “strong” pixels remain otherwise value of them became zero.

B. The Second Derivative(Laplacian) Based Methods

In this method when we take the first derivative of image function, at the edge points value of derivative become maximum and minimum. After this we take second derivative and it will give us edge pixels at zero values of image function. Noise sensitivity of this method is higher than the first derivative method. Marr-Hildreth(LoG) operator is well known operator for the second derivative based methods [1].

1) Marr-Hildreth(LoG) Operator: Marr and Hildreth applying Laplace filter to image the function passed through the filter Gaussian filters were developed in 1980, allows the presence of edges on the image. High frequency noise on the image cleaning with a Gaussian filter operation, and applying Laplace filter by taken second derivative of image function gives edge detection of image. Equations given below is about Laplacian and Gaussian of image function respectively.

\[ h(x, y) = \nabla^2[g(x, y) * f(x, y)] = [\nabla^2 g(x, y)] * f(x, y) \] (8)

\[ \nabla^2 g(x, y) = \left( \frac{x^2+y^2-2\sigma^2}{\sigma^4} \right) e^{-\frac{(x^2+y^2)}{2\sigma^2}} \] (9)

III. PROGRAMMING FPGA WITH XSG

Xilinx System Generator (XSG) is produced by the Xilinx DSP design tool. This software tool MATLAB model-based design environment that enables the use of Simulink for FPGA. System Generator using the design is carried out using hosts Xilinx special design blocks in DSP functions in Simulink. FPGA program file that is necessary for creating synthesis and placement/ routing steps are automatically executed in this environment.

System Generator is working according to the Simulink model-based design methods. Usually, executable functions are created using standard Simulink blocks. This feature of System Generator is designed using floating point number system without function hardware details. System Generator uses the Xilinx DSP blocks in Simulink and automatically run to perform the core functions of a high degree of conformity of the connection required for the DSP blocks.

The Xilinx DSP block are accessed through the library operated with Matlab Simulink tool. Blocks can be made easily for the search process is divided into sub-categories. "Index" is keeping all blocks and sub-categories shortcuts to frequently used blocks, offers ease of use possibilities. DSP building blocks over 90 in the System Generator to design a DSP system is located. System Generator DSP blocks are located in Matlab/Simulink and its image windows is given in Fig. 2.
System Generator works with standard Simulink models. “Gateway In” and “Gateway Out” is defined as two blocks in Simulink simulation model and they define the input and output of the FPGA device is used. "Gateway In" block, converting floating point to fixed-point number type. "Gateway Out" is transforming the FPGA block out the double-precision number type. After FPGAs limits determined by the gateway blocks, DSP designs using the Xilinx DSP block can be realized. Standard Simulink blocks is not used between the “Gateway In” and “Gateway Out” blocks.

IV. PROPOSED DESIGN AND IMPLEMENTATION

The implementation of edge detection algorithms on FPGA realized in three steps, which are image pre-processing, image post-processing and edge detection with XSG. Addition to this, hardware implementation is realized by using XSG for preparation of programming file (*.bit) for FPGA. Fig. 3 shows system diagram for implementation of edge detection algorithms on FPGA.

A. Image Pre-Processing

During this process the data entry format of the “Gateway In” the blog entry block for FPGA card in gray format image on a computer and converted into serial digital data format. Simulink blocks used in image pre-processing steps are given in Fig. 4.

D. Edge Detection with XSG

In order to implementation of edge detection on FPGA, XSG DSP blocks on Simulink is used. For implementation of Sobel operator, gradient calculation and thresholding operation is done XSG DSP blocks, which is shown in Fig. 7 and Fig. 8 respectively. Gradient calculation blocks give the convolution of Sobel mask coefficient with original image pixels and thresholding blocks give the binary edge detected image with respect to a threshold value.
Implementation of Prewitt operator is done same as Sobel operator. Because only the convolution coefficient of Prewitt mask is different from Sobel operator.

Finally, double thresholding is applied to image pixels and binary edge detected image is obtained. Double thresholding XSG blocks are shown in Fig. 11.

For implementation of Canny algorithm; first of all, Gauss filter is used to remove noise from original image. Fig. 9 shows Gauss filter blocks for XSG.

After that, Sobel operator is applied to image pixels for gradient magnitude and gradient angle calculation. And then, NMS (non-maximum suppression) is applied to image pixels, which is shown in Fig. 10.

V. RESULTS

The proposed work is implemented by using Matlab and XSG (Xilinx System Generator) simulink blocksets. This method has been tested on some standard test image like 'Cameraman'. Fig. 12 shows edge detected images, which are detected by Matlab/Simulink and FPGA board for Sobel, Prewitt and Canny algorithms.
FPGA resource usage of Sobel-Prewitt and Canny algorithms on Spartan3E XC3S1600E is given in Table I and Table II respectively. Sobel and Prewitt resource usage is given in one table, because they use the same resource usage on FPGA.

The proposed designs use low resources on FPGA. Sobel and Prewitt resource usage is same value, because only their convolution mask coefficient is different from each other. Resource usage of Canny algorithm is greater than Sobel or Prewitt, because Canny algorithm includes more processing steps from Sobel or Prewitt.

The performance of edge detected image is analysed by using Mean Squared Error (MSE) and Peak Signal to Noise Ratio (PSNR). Equation (10) and (11) show calculation of MSE and PSNR respectively.

\[
    MSE = \frac{\sum_{m \in M, n \in N} (I_1(m,n) - I_2(m,n))^2}{MN}
\]

\[
    PSNR = 10 \log_{10} \left( \frac{R^2}{MSE} \right)
\]

For MSE value; \(I_1\) is pixel value of original image, \(I_2\) is pixel value of edge detected image, \(M\) and \(N\) is horizontal and vertical pixel size of original image. \(R\) is taken 255 in this work, because original image data format is 8-bit unsigned integer. Table III shows quantitative results of MSE and PSNR values for proposed works.

MSE gives mean square difference between original image pixel and edge detected image pixel. If this difference is high, this means that similarity between images is low [14]. For edge detection process, high MSE means that edge detection performance is better. Therefore low PSNR value gives better edge detection performance [15].

### VI. CONCLUSION

In this proposed work, edge detection algorithms used in literature is introduced. Implementation of Sobel, Prewitt and Canny edge detection algorithms are done in Matlab/Simulink and FPGA board at the same time. When we look at the resource usage on FPGA board, proposed designs used small part of FPGA resources. If we analysis edge detection performance due to Matlab/Simulink and FPGA platform, we can see that MSE values of edge detected images from FPGA is greater than Simulink and therefore PSNR values of edge detected images from FPGA is less than Simulink platform. Because of this, results have shown edge detection performance of FPGA is better than Matlab/Simulink. Another performance investigation is that algorithms, which used for edge detection. That is Prewitt operator gives better results than Sobel operator due to edge detection performance because of its MSE and PSNR values. Canny algorithm has the best edge detection performance than Sobel and Prewitt operators. Because, it has highest MSE and lowest PSNR values comparing with them. As a result, more complex system can be implemented on FPGA, and advantages of edge detection implemented on
FPGA is that; it is field programmable and economic for
design, it has flexible structure and parallel processing
capability.

Investigating the Effects of Facial Regions to Age Estimation

Asuman Günay*, Vasif V. Nabiyev*

*Department of Computer Technologies, Trabzon Vocational School, Karadeniz Technical University, Trabzon, Turkey

Abstract— Aging process causes evident alterations on human facial appearance. Real world age progression on human face is personalized and related with many factors such as, genetics, living style, eating habits, facial expressions, climate etc. The wide degree of variations on facial appearance of different individuals affects the age estimation performance. In accordance with these facts discovering the aging information contained in facial regions is an important issue in automatic age estimation. Thus the facial regions emphasizing the aging information can be used for more accurate age estimation. In this context, age estimation performances of facial regions (eye, nose, mouth and chin, cheeks and sides of mouth) are investigated in this paper. For this purpose, an age estimation method is designed to produce an estimate of the age of a subject by using the texture features extracted from facial regions. In this method the facial images are warped into the mean shape thus variations of head pose and scale are eliminated and the texture information of facial images are aligned. Then the holistic and spatial texture features are extracted from facial regions using Local Phase Quantization (LPQ) texture descriptor, robust to blur, illumination and expression variations. After the low dimensional representation of these features, a linear aging function is learned using multiple linear regression. In the experiments FGNET and PAL databases are used to evaluate the age estimation accuracies of facial regions i.e. eye, nose, mouth and chin, cheek and sides of mouth, separately. The results have shown that the eye region carries the most significant information for age estimation. Also the mouth and chin, cheek regions are effective in the prediction of age. The results also have shown that, using the spatial texture features enhances the discriminative power of the texture descriptor and thus increases the estimation accuracy.

Keywords— Age estimation, Local Phase Quantization, Facial Regions, Regression

I. INTRODUCTION

Age estimation is the process of estimating the age or age group of an individual according to his/her facial information. During the aging process, evident alterations occur on human facial appearance. These variations are personalized and affected by factors such as race, genetics, living conditions, eating habits, the frequency of facial expressions, etc. This makes the age estimation problem much harder than other facial image processing problems. Therefore the accuracy of the age estimation systems is insufficient, even the human skills about age estimation are limited. In this context, discovering the amount of aging information contained in facial regions and thus improving the accuracy of age estimation systems by using the facial regions emphasizing the aging information is an important issue in this field.

In this paper we investigate the age estimation performances of facial regions: eye, nose, mouth and chin, cheek, sides of mouth. For this purpose we designed an age estimation system using the texture features of these facial regions to produce an estimate of the age of a subject. The block diagram of the system is shown in Fig.1. In our method the input images are normalized so that the shape variations such as scale, head pose are eliminated and the facial texture is aligned. Then Local Phase Quantization (LPQ) is used to extract holistic and spatial texture features from facial regions. After feature extraction, dimensionality reduction is performed with Principal Component Analysis (PCA). Finally an aging function is learned using Multiple Linear Regression (MLR) for age estimation. The feature extraction, dimensionality reduction and aging function learning steps are performed separately for each of the facial regions to discover the amount of aging information contained in that region.

Fig. 1. System overview

The rest of the paper is organized as follows. A survey on the age estimation methods are given in Section 2. The proposed age estimation approach is explained in Section 3. In Section 4 the experimental results on various databases are reported and analyzed. Finally, the conclusions are outlined in Section 5.

II. RELATED WORK

Age estimation systems generally consist of age image representation and age estimation modules. The aim of age image representation module is to extract the shape or texture based features from facial images. Then classification techniques are used to classify the facial images into multiple
age groups or regression techniques are applied to estimate the age of the subjects.

The age image representation techniques can be grouped under five topics. The anthropometric models relays on the facial geometry. In these models the distances and the ratios of these distances are calculated using the fiducial points on the facial images. As these geometrical features can only deal with young ages, wrinkle features are used with geometric features to strengthen the classification performance for older ages [1-3]. Active Appearance Model (AAM) based age estimation methods incorporate shape and appearance information together. For this reason AAM’s are frequently used in age estimation methods [4-6]. In some studies AAM features are extracted as global facial features and fused with local facial features for efficient age estimation [7]. In Aging Pattern Subspace method, the sequence of an individual’s aging face images are used to model the aging process [8]. But age manifold methods uses the images of different individuals at different ages to learn the common aging pattern. They utilize manifold embedding techniques to discover the aging trend in a low dimensional space [9, 10]. Appearance models are mainly focused on aging-related facial feature extraction using various texture descriptors such as local binary patterns, Gabor filters, histograms of gradients etc. [7, 11-13].

All the studies mentioned above generally uses the whole face in feature extraction phases. Unfortunately the number of works examining the age estimation performances of facial regions/parts is insufficient in the literature. Lanitis [14] investigated the significance of facial parts in age estimation. In the experiments, the age estimation performances of whole face (including the hairline), internal face, upper part of the face and lower part of the face are calculated. AAMs are used to represent the shape and appearance of facial parts with model parameters. The results showed that the upper part of the face gives the minimum age estimation error than other parts. El-Dib and Onsi [15] used bio-inspired features to analyze the different facial parts: eye wrinkles (covering the eyes and the area under the eyes), internal face and whole face. They built six support vector regression and one support vector machine model to estimate the age of a subject. Their results showed that the eye region covering the eyes and the area under the eyes contains the most important aging features when compared with others.

III. PROPOSED METHOD

A. Image Normalization

In order to eliminate the shape variations such as head pose, scale, size, etc. and to align the texture information, image normalization is applied on facial images. Image normalization is performed by warping the facial images into the mean shape obtained from training set. The facial images in the training set are labelled with 68 landmark points as shown in Fig.2-a. Mean shape is obtained by taking the mean of all coordinates of these points. Then all the images are warped into the mean shape using Delaunay triangulation as shown in Fig. 2-b and affine transformation, so the landmark points of all images are matched with the mean shape and also the texture information is aligned. The result of warping process is given in Fig. 2-c. As the head poses of facial images varies, the warped images can be inclined, therefore rotation is the last step in image normalization as shown in Fig.2-d.

Fig. 2. Image normalization a) Facial image labeled with 68 landmark points b) Delaunay triangulation c) The image after warping into the mean shape d) Rotated image

B. Facial Regions

Investigating the aging information contained in facial regions is important for age estimation system’s design. In this way, the accuracies of age estimation systems can be improved by using the facial regions emphasizing the aging information. For this purpose the facial images are divided into regions and the age estimation algorithm is applied to these regions separately. In the study the age estimation performances of eye (190×55), nose (55×70), mouth and chin (85×70), cheek (65×60) and side of mouth (40×45) regions are determined. The facial regions used in the experiments are shown in Fig. 3.

Fig. 3. Facial regions a) eye b) cheeks (left and right) c) nose d) side of mouth (left and right) e) mouth

C. Feature Extraction with LPQ

LPQ is a blur insensitive texture descriptor based on the blur invariance property of the Fourier phase spectrum [16]. In this method LPQ codes are computed in local image windows using discrete Fourier transform (DFT) and the results are presented as a histogram.

The spatially invariant blurring of an image can be expressed by a convolution between the image and the point spread function (PSF). In the frequency domain this is equal to \( G(u) = F(u) . H(u) \), where \( G(u) \), \( F(u) \) and \( H(u) \) are the DFTs of the blurred image, the original image and the PSF, respectively. Considering the phase of the spectrum we have \( \angle G(u) = \angle F(u) + \angle H(u) \). If we assume that the blur PSF \( h(x) \) is centrally symmetric, \( h(x) = h(-x) \), its Fourier transform is always real valued, 0 for \( \angle H(u) \geq 0 \) and \( \pi \) for \( \angle H(u) < 0 \). This means that \( \angle G(u) = \angle F(u) \) for all \( H(u) \geq 0 \) and \( \pi \) for \( H(u) < 0 \).
0. In other words the phase of the observed image $\angle G(u)$ is invariant to centrally symmetric blur, at the frequencies where $H(u)$ is positive.

If the $N \times N$ neighborhood around a pixel $x$ is denoted as $N_x$, the two dimensional (2-D) DFT of $N_x$ is defined by,

$$ F(u, x) = \sum_{y \in N_x} f(x-y) e^{-2\pi i u y} = w_{f}^T f_x $$

where $w_{f}$ is the basis vector of the 2-D DFT at frequency $u$, and $f_x$ is the vector containing all $N^2$ pixels in $N_x$. Only the complex coefficients of $u_x = [a, 0]^T$, $u_y = [0, a]^T$, $u_z = [a, a]^T$, $u_w = [a, -a]^T$ are considered in LPQ. $a$ is a scalar frequency below the first zero crossing of $H(u)$ that satisfies $H(u) \geq 0$. For each pixel position this results in a vector given by

$$ F'_x = [F(u_1,x), F(u_2,x), F(u_3,x), F(u_4,x)] $$

$$ F_x = [\text{Re}(F'_x), \text{Im}(F'_x)]^T,$$

where $\text{Re}()$ and $\text{Im}()$ return real and imaginary parts of a complex number, respectively. Then $G_x$ is computed for all image positions, i.e., $x \in \{x_1, x_2, \ldots, x_n\}$, and the resulting vectors are quantized using a simple scalar quantizer,

$$ q_j = \begin{cases} 1, & \text{if } g_j \geq 0 \\ 0, & \text{otherwise} \end{cases} $$

where $g_j$ is the $j^{th}$ component of $G_x$. The quantized coefficients are represented as integer values between 0-255 using binary coding using (5), and the histogram of these integer values is used as a feature vector.

$$ b = \sum_{j=1}^{b} q_j 2^{j-1} $$

The LPQ texture descriptor represents the input image as a histogram of 256 bins. In this holistic representation, the histogram is produced without taking into account the spatial information of the pixels. The discriminative power of the texture descriptor can be enhanced by using the spatial histograms. The spatial histograms are produced by concatenating the local histograms extracted from small image blocks.

**D. Dimensionality Reduction**

In order to find a lower dimensional subspace of the extracted features and to obtain the significant features for age estimation, dimensionality reduction is performed using PCA. PCA method finds the embedding that maximizes the projected variance given by $W_{opt} = \arg \max_{W} \|W^T S W\|$ where $S = \sum_{i=1}^{n}(x_i - \bar{x})(x_i - \bar{x})^T$ is the scatter matrix, $x_i$ is $i^{th}$ feature vector with $x_i \in R^D$ and $\bar{x}$ is the mean of the feature vectors. By solving this problem, a set of $d \leq D$ eigenvectors associated to the $D$ largest eigenvalues of $S$ is obtained. Then dimensionality reduction is performed by projecting all samples on the projection subspace using $y_i = W^T x_i$ with $y_i \in R^d$.

**E. Age Estimation**

After finding the low dimensional representation of features, the age estimation problem is recast as a multiple linear regression as $L = YB + e$ where $Y$ is the data matrix, $B$ is the unknown parameter vector, $L$ is the age label vector and $e$ is the error vector. In the learning phase the unknown parameters are estimated by means of least squares, or robust regression. The regression function used in this study is a linear function given by $\hat{l} = \beta_0 + \beta_1^T y$ where $\hat{l}$ is the estimate of age, $\beta_0$ is the offset, $\beta_1$ is the weight vector containing the coefficients for each value in the feature vector and $y$ is the low dimensional representation of the extracted feature vector.

**IV. EXPERIMENTS AND RESULTS**

In this paper the FGNET and PAL databases are used to evaluate the age estimation performances of facial regions. FG-NET database [17] is composed of 1,002 images that were retrieved from real-life albums of 82 subjects, thus includes variations of head pose, occlusion, illumination, facial expressions, etc. The age range in this database is 0-69 years, but the images are not uniformly distributed according to the ages. This can be a disadvantage for the estimation accuracy.

The PAL aging database [18] contains 580 images of different persons taken under natural lighting conditions using a digital camera. The images include various expressions such as neutral faces, anger, sadness or smiling. The age distribution of the images in this database is between 18 and 93 years old and also not uniform.

The age estimation performance of the system is evaluated using $n$-fold cross validation method. In this method all the samples are randomly partitioned into $n$ equal sized subsamples. Then one subsample is used as test set and $n-1$ subsamples are used as training set. This procedure is repeated $n$ times until each of the subsamples are used once as a test set. Then the average of all $n$ estimations is considered as the system performance. In our experiments we set $n=3$.

The performance is measured using the Mean Absolute Error (MAE) metric given as,

$$ \text{MAE} = \frac{1}{N_t} \sum_{i=1}^{N_t} |\hat{l}_i - l_i| $$

where $\hat{l}_i$ is the estimated age value of $i^{th}$ test sample, $l_i$ is the real age value of $i^{th}$ test sample, and $N_t$ is the total number of test samples.

In the experiments the age estimation performances of facial regions are calculated using the features extracted with LPQ texture descriptor and regression. LPQ is performed on $5 \times 5$ local image windows. The LPQ histograms are first extracted from the whole facial region resulting the holistic description of that region. Then the region is divided into $n \times n$ blocks, LPQ histograms are extracted from each block and concatenated to obtain the spatial description of the region. The spatial features are used to enhance the discriminative power of the texture descriptor. The spatial LPQ histograms are extracted for $n=2, 3, 4, 5, 6$ and age estimation is performed using these features. The effect of using the spatial texture features of facial regions for age estimation on FGNET and PAL databases are given in Fig. 4. We can see from the figure that the holistic feature representation is not
encouraging and increasing the number of blocks in spatial feature representation generally increases the estimation accuracy of the facial regions.

![Graph](image)

The age estimation accuracies of the whole face and facial regions are tabulated in Table 1. We can see from the results that the age estimation accuracy of the whole face and the eye region are close to each other. These results indicate that the eye region carries the most significant information for age estimation. Also the mouth and chin, cheek regions are more effective than other regions in the prediction of age.

V. CONCLUSION

In this paper the age estimation performances of the facial regions are investigated. For this purpose the facial image is divided into five regions: eye, nose, mouth and chin, cheek, side of mouth. Then LPQ is used to extract features from these regions. In the feature extraction phase holistic representation of the region is obtained by applying the texture descriptor on the whole region. Also the spatial representation is obtained by dividing the region into number of blocks, extracting features from these blocks and concatenating them. The age estimation accuracies of the facial regions are evaluated separately and the experiments on FGNET and PAL databases have shown that the most of the aging information is contained in the eye region. Moreover the age estimation accuracy of the eye region is close to the whole face. As the estimation of the whole face is better than the regions alone, determining the weights of these regions in age estimation and thus achieving better estimation accuracy is our future work.

Detection of Rail Switch Passages Through Image Processing on Railway Line and Use of Condition-Monitoring Approach

Mehmet Karakose *, Orhan Yaman*, Erhan Akin*

Firat University Elazig, Turkey
{mkarakose, orhanyaman, eakin}@firat.edu.tr

Abstract— Today, railway transportation is one of the transport modes commonly used. Compared to other transport modes, railway traffic is highly critical. Multiple railway vehicles run constantly on one or two lines. Rail switch passages are used to prevent locomotives from colliding with one another and avoid traffic disruptions. Through switch passages, locomotives pass from one line to another. Friction between rail and wheels on switch passages is considerably high. This friction leads to failures on switch passages. Unless these failures are diagnosed early and remedied, significant accidents emerge.

In this study, a new approach based on image processing has been presented for detection of rail switch passages on railway lines. A test vehicle has been created in order to test the proposed approach and apply it on a real-time system. Railway line is monitored by digital cameras fixed on this test vehicle. Image-processing approach is developed on the real-time images captured from the railway line and the switch passages on the line are detected. The image-processing approach consists of three main parts including pre-processing, feature extraction and processing of the features obtained. At the pre-processing stage, the basic image processing methods are used. At the feature extraction stage, Canny edge extraction algorithm is used and hence the edges in the image are detected. Hough transform method is used at the stage of processing of the extracted features. Following Hough transform stage, straight lines and angles of these lines are obtained on the image. Taking into account the angle of each straight line, the junction points of the lines are calculated. Thus, rail switch passage and switch types are detected. The proposed image-processing approach is highly fast and real time-based. Compared to the existing studies in the literature, it is seen that the proposed method gives fast and successful results. This study intends to diagnose the failures on switch passages early and prevent potential accidents.

Keywords— Railway, Condition Monitoring, Fault Detection, Image Processing, Railroad Switches.

I. INTRODUCTION

Railway transportation is commonly used in the freight and passenger transport. Railway vehicles provide transportation using a particular rail line [1,2]. These vehicles are preferred by people because they can carry quite heavy loads and large number of passengers. It is very important for rails to be robust because railway vehicles provide transportation on the rails [3]. The railway lines are the most critical components for this transportation. The switch has been developed for more than one train can use the same railway line. Trains can change their direction, give way to another train or proceed to the standby points at the station due to the switch system. The development of the switch system has made the railway line quite utilizable. Therefore, the switch system has a great importance for the railway transportation. Excessive friction and wear occur during switching [4]. Such undesirable situations lead to major wear on the rail in time. Major accidents may occur in the event of failure in the early diagnosis of these wears. The accidents that may occur can cause loss of life and injury for passengers. However, the railway line hinders the traffic for a while during the accident, and major financial losses are formed. Today, the railway line is inspected at regular intervals, and the faults which may arise are diagnosed early. There are many literature studies related to switch system. Johansson et al. [5] conducted a study for the detection of the corrosion faults caused by friction and wear during switching. In the study, Switches & Crossings components are monitored. They modeled the contact of the wheel with the rail by simulation during switching. As a result of modeling, observation was made according to the loads that may occur on the rails. Boccialone et al.[6] proposed a signal processing-based method for the detection of the faults that occur on the rail surface. In the proposed method, the vibration signals made by the train while going on the railway line were used. Fault detection is performed by improving the signal processing methods through vibration signals. Palsson [7] completed a thesis study on optimization in the Switches and Crossing sections on the railways. In this thesis study, Switches and Crossing components were monitored and the faults that occurred in these components were examined. The changes in the Switches and Crossing areas were observed during switch transitions. The load distribution from one rail to another rail was examined. In addition to these studies, many studies have been conducted for the detection of the faults occurring on the rail surface and in its components. Quingyong et al. [8] an image processing based contactless method is proposed and detected faults on rails in real-time. Rail surface is extracted by using railway images. Surface faults are determined by contrast stretching of the obtained surface. This method, is used only railway surface to detect faults. Limin et al. [9]
proposed a method that detects faults on the surface by using machine vision techniques. The roughness and cracks are determined with image processing algorithms. Edge detection and feature extraction methods are used.

Ying et al. [10] proposed an automatic monitoring approach to detect and evaluate the railway components. The proposed method is working on a train with 16km/h speed. Ray component detection is carried out by applying Sobel edge detection and Hough transform methods. Status and positions of the components are observed and analysis of them is carried out. The general architecture of the proposed railway inspection system is presented in Figure 1.

Fig. 1 General architecture of the railway inspection system proposed in the literature [10]

In this study, an image processing-based method was proposed for the detection of the crossing points on the railways. Images were taken for different types of switches using a camera fixed on the train. The switch crossings were determined using image processing algorithms on the images taken.

II. TYPES OF RAILWAY SWITCHES

The apparatus for changing the way that allow railway vehicles moving on the rail to pass from one rail to another rail are called "switch". In switch systems, the change of way of railway vehicles is carried out by ensuring the movement of the Switch part of the junctions with human or electric power [11]. Each switch has a right track and a diverted track. The sleepers of the switches on conventional lines are wooden. The radius of the curve located on the diverted track that provides transition to secondary roads is R=300 m, the maximum length standard of single turnout is 34.20 m. The sleepers of the switches on high-speed trains are concrete, the radius of the curve located on the diverted track that provides transition to secondary roads is R=1500 m, the maximum length standard of single turnout is 72 m.

Railways have switch crossings for the control of the traffic and a line to be used by more than one trains. A train moving on a line can easily switch to the other line due to switch crossings [12]. An example of a switch crossing system and components is given in Figure 2.

As it is seen in Figure 2, the switch crossing system has many components. The components of Switch Blades, Toe, Stretcher and Heel serve as a switching. The components of Crossing, Check Rails and Wing Rails allow train to switch to another rail in a secure way. The components of Check Rails and Wing Rails are the most important components that prevent the derailment of the train. The switch crossings are very important on the railway line. Major faults may occur as a result of the failures of the components on the switch crossings. Therefore, the railway line especially the switch crossings should consistently be inspected. It is required to make the necessary maintenance even considering the small faults. On switch crossings, to which direction the train will go is determined using the components of Switch Blades, Toe, Stretcher and Heel. The changes that occur on the switch crossings when a train goes straight or to the right direction on an example railway line are seen in Figure 3.

In the sample images given in Figure 3, a train coming from X direction in Figure 3.a goes straight ahead, namely to the Y direction. In Figure 3.b, a train coming from X direction turns right, namely to the Z direction. There are many types of switch crossings which are commonly used on the railways. These types of switches vary depending on the number and position of the railway line. The types of switch crossings and their sample images are given in Figure 4.

The sample images of the switch crossing types given in Figure 4 are presented in Figure 5.
III. THE METHOD PROPOSED FOR SWITCH DETECTION

In this study, an image processing-based method was developed for detecting the switch crossings on the railway line. In the proposed method, feature extraction was performed by performing pre-processing on the image. The lines on the image are obtained as a result of feature extraction. The intersection points are calculated by considering the start and end positions and slopes of the lines obtained. The calculated intersection points are called switch crossing zone. The flow chart showing the main stages of the proposed method is presented in Figure 6.

In the proposed method, images are taken from a camera placed on the locomotive. The colorful images taken from the camera are primarily converted into gray format.

Canny edge extraction is performed using the gray image obtained. The edges on an image are defined as the sudden change of the pixel values on the edge zones. The edge extraction methods are very important for feature extraction in image processing applications [16,17]. Canny edge extraction algorithm is an edge extraction algorithm which is realized as multi-staged. The general steps of Canny edge extraction algorithm are as follows:

- Performing smoothing by applying Gauss filter to the image
- Performing edge extraction in the X and Y directions
- Calculation of gradient magnitude and angle
- Elimination of undesirable details and obtaining image

In Equation 1, \( f(i, j) \) represents the gray level image matrix, \( R(i, j) \) represents the red image matrix, \( G(i, j) \) represents the green image matrix and \( B(i, j) \) represents the blue image matrix. The image smoothing process is performed by applying gauss filter to the image in gray format obtained. A gauss mask in 5x5 size is used in the Gauss filter.
After the gauss masking process, edge extraction is performed by using the canny masking matrix of the image from X and Y direction. The image is formed according to certain angle limits by calculating the gradient magnitude on the image matrices obtained.

The edge extraction process is achieved more successfully because Canny edge extraction algorithm uses the Gauss filter before performing edge extraction on the image. Canny edge extraction algorithm gives better results compared to other edge extraction algorithms.

Hough transform is used to obtain the lines on the image after the edge extraction process [18]. Hough transform is generally used in detecting geometric models on the image in combination with the edge extraction methods. Hough transform is applied onto the images, the edge information of which are obtained. The method transforms the problem of finding a shape into a problem of finding a density by transferring the information in the image space to the parameter space [19-21]. Hough transform does not require that the points on the image are side-by-side or connected to detect an image. The pseudo code of Hough transform used in the proposed method is given in Figure 7.

A binary-based image obtained as a result of edge extraction is primarily used in the pseudo code of Hough transform given in Figure 7. The straight lines are expressed as in equation 1.

\[ y = mx + n \]  (1)

This equation has two parameters to specify any straight right. These parameters are slope \((m)\) and junction point \((n)\). A point in the straight lines parameter space is shown as \((m,n)\). The straight lines are transformed into coordinate system and shown in equation 2.

\[ r = x\cos(\theta) + y\sin(\theta) \]  (2)

In this equation, the nearest vector from the origin is represented by a pair of \((r,\theta)\). All lines with angles ranging between 60 and 150 on the detected lines are taken into account. The junction points of the lines are calculated using the angle values of the lines obtained and the start and end points of the line. The method of the slope of a line two points of which are known was used in obtaining these lines. The lines representing the rails are detected by considering the slope ranges of the lines on the railway image. The slope of a line two points of which are known is given in equation 3.

\[ m = \frac{B_y - A_y}{B_x - A_x} \]  (3)

In equation 3, \(m\) represents the slope, \((A_x, A_y)\) represents the location information of the A point and \((B_x, B_y)\) represents the location information of the B point. The switch crossings on the railway line are detected according to the slope value obtained by applying this equation on the gray image. Two points of each line are known. These two lines intersect and give the switch crossing zone. For the calculation of the crossing point, the required calculations were made for the junction point of the line two points of which are known. First of all, the points of the line taken from the normal image are A, B, C, and D. The junction point of these two lines is E. The junction point of two lines two points of which are given is shown in the analytical plane as in Figure 8.

In order to calculate the values of the E point given in Figure 8, another line passing from E, F, and G point is drawn. The equation of the line the slope of which is \(m_i\) is given in equation 4.

\[ m_i = \frac{G_y - F_y}{G_x - F_x} \]  (4)

By calculating the location information of F and G given in equation 4, the final state of the equation 4 is given in equation 5.
m_i = ((D_i - C_i) \times (C_i - A_i)) - ((C_i - A_i) \times (D_i - C_i))

(5)

By using \( m_i \) value given in equation 5, \( E_x \) and \( E_y \) values are calculated in equation 6.

\[
\begin{align*}
E_x &= A_x + (B_x - A_x) \times m_i \\
E_y &= A_y + (B_y - A_y) \times m_i 
\end{align*}
\]

(6)

The switch crossing zone is detected on the image using \( E_x \) and \( E_y \) values obtained in equation 6.

IV. EXPERIMENTAL RESULTS

In this study, an image taking environment was created to take sample images on the railway line. The images of the railway are taken by the camera installed on the train as in Figure 9.

Fig. 9 The test vehicle used to take image

In the proposed method, the switch crossings were detected by taking images in different situations on the railway line. The dimensions of the images taken are 640 x 480 pixels. The color image was firstly transformed into gray image, and then edge extraction was performed. The lines are obtained by Hough transform on the image obtained. The images used during realization of the proposed method are given in Figure 10. The results were obtained by performing edge extraction on the image given in Figure 10. These results are presented in Figure 11.

Fig. 10 The images belonging to different types of switch crossings taken from the railway

![Fig. 10](image10.jpg)

a) b) c) d) e) f)

Fig. 11 Performing feature extraction by applying edge extraction on the image
The edge extraction results of different images are presented in Figure 11. After the edge extraction process, Hough transform was used in order to detect the lines on the image. The lines were detected by taking into account the angle value and the positions of the line during Hough transform. The switch crossings were detected by improving a method on the lines detected. The result of detecting the switch crossings on the sample images is presented in Figure 12.

![Detection of the switch crossings on the railway line by Hough transform](image)

As it is seen in Table 1, the proposed method is highly successful in the images belonging to the types of single left and right switch. The success ratios of other types of switch are not very good because they are a little more complicated and due to the clarity of the image.

### V. Conclusions

An image processing based method for the detection of railway switch crossings was proposed in this study. In the proposed method, the switch crossings were detected by image processing methods using railway images. Canny edge extraction and Hough transform were used as the image processing methods. When the studies in the literature are analyzed, it is seen that there is not a study on the detection of switch crossings and condition monitoring by using image processing based methods. It is seen that the proposed method is successful when its results are taken into account. However, different methods will be used in future studies to make study more qualified and successful. In addition, the detection of the faults occurring in the components on the switch crossings and the detection of the rail surfaces on the switch crossings are aimed in future studies.

Trust in Wireless Sensor Networks

Gulustan Dogan*, Koksal Avincan*
*Yildiz Technical University
Istanbul, Turkey
{gulustan, kavincan}@yildiz.edu.tr

Abstract—Wireless sensor networks are used widely in daily life. With that increase the problems faced in WSN usage have become more interesting for the research community. The problems that outstand the most are related to the trust and energy issues. As wireless sensor networks have limited energy and computing power, cryptographic algorithms are not suitable for these type of networks. Along with that line, in this work we explore trust models developed for wireless sensor networks.

Keywords: Wireless Sensor Networks, Trust, Trust Models

I. INTRODUCTION

Trust is quite important for self-configurable and autonomous systems such as WSNs [15]. WSNs are very vulnerable environments due to computational limitations, energy constraints and network attacks. In addition, WSNs are very open to physical world effects such as a person walking on a field can step on a sensor and make it dysfunctional. A trust management scheme can make a WSN tolerant to node failures and misbehavior by assisting decision making process. For example, a node can decide to cooperate with a node or not based on the feedback it will receive from the trust model. Trust research on WSN is very new, few systems have considered it [17], [45]. More research has been done on Trust in Ad-hoc and P2P networks. Although these network types have many similarities to WSN, still a separate trust management system has to be developed for WSN because of their specific characteristics such as energy and communication constraints.

Data collection is very important in the process of designing a trust management system. The system should be history aware, past behaviors should be taken into consideration [15]. WSNs should be history aware as the trust calculation is considering past behaviors. Moreover, every node keeps their past behavior statistics regarding the data they produce such as average error of the created data in the past time intervals. One of the biggest constraints is the overhead that can be caused by the trust model. Trust model should be as lightweight as possible [15].

There are many different data that can be used as input of the trust model. For example, a node that is not alive for a long time or a node that appears or disappears randomly may not be trusted. On the communication layer, a node which is misreporting will not be trusted. For instance, a node which is giving a fire alarm when conditions are calm should be given a low trust value [15].

II. DEFINITIONS: TRUST, TRUSTWORTHINESS, RISK, REPUTATION

Josang et al. [20] define trust and trustworthiness based on the definitions of Gambetta [16]. Solhaug et al. [39] define trustworthiness as objective probability that the trustee performs a particular action on which interests of the trustor depend. Trust is a subjective probability varying from 1 (complete trust) to 0 (complete distrust) [20].

As trust is the believed probability and trustworthiness is the actual probability, there can be a difference between them. This difference introduces the risk factor [12]. Risk increases if the trust is misplaced.

Reputation is also a concept that is very related to trust. Sometimes reputation and trust is used in the same context however they have different meanings. Reputation is the opinion of an entity about the other entity. However trust is derivation of reputation of an entity.

A. Information Trust

There are different types of trust such as social trust, cognitive trust, and communication trust. In this work, we are assessing the information trust of data items and sensor nodes.

Information trust or data trust refers to the trust placed on data produced by objects or processes. Information trust in a network is important because it can prevent erroneous data to accumulate in the network. In a network, a node can (i) create data (ii) process the data such as fusion (iii) pass the data along. The trust of data depends on the trust of the node that creates the data and the trust of the nodes the data has visited. Information trust in a network can be categorized into three: (i) creator node’s subjective view of the trust (ii) objective trust assessment of the data by the neighboring nodes (iii) changes in information trust as the data travels along the network.

B. Properties of Trust

Cho et al. [12] list characteristics of trust as follows in their survey paper.

- dynamicity : Due to node failures and mobility, sensor network is highly dynamic hence trust should be dynamic too.
- subjectivity : Nodes might decide to put different levels of trust on same nodes due to dynamicity of the network [1].
• transitivity: Trust is not necessarily transitive. For transitivity, we need two types of trust, trust in a trustee and trust in recommendations of the trustee.
• asymmetry: Trust is not necessarily transitive. A node may trust a node however the trustee node may not trust the trustee.
• context-dependency: Trust is context-dependent [7]. For instance, a node may trust the image data coming from a node but may not trust the audio data coming from the same node.

III. TRUST AND REPUTATION IN DIFFERENT DOMAINS

Below we give information about trust literature in social science, e-commerce, distributed systems and ad-hoc networks based on the survey of Momani and Challa [27].

A. Trust in Social Science and E-Commerce

Trust is very related to social sciences because it is a part of human life [38]. It has a very big impact on human relationships such as making friends, sharing secrets, selling/buying things, working together. It eases the everyday life by helping in the decision making process, delegation, certification, resource access [36].

One of the motivating domains for trust research is e-commerce. In internet, buyers and sellers have a trust relationship. Buyers will buy from sellers that they trust. The trust will be formed based on the reputation of the seller. Seller gains a reputation based on past behavior. E-commerce systems such as eBay [35], Yahoo [35], Keynote [8], [9] keep a centralized trust authority to maintain the reputation and trust values.

Abdul-Rahman and Hailes designed a trust model based on sociological characteristics of trust [3]. In their model, entities are given trust based on their reputation (indirect) and their direct experiences. They also consider the word-of-mouth mechanism. Agents put different importance (weights) to opinions of different agents.

Josang and Ismail developed a reputation system for electronic markets [21]. Most reputation systems are intuitive and ad-hoc however they have built their reputation systems on beta probability density function in statistics. The beta distribution is mapped to an opinion, which is a belief about the truth of statements.

B. Trust in Distributed and Peer-to-Peer Systems

In distributed systems, there is no central authority for assessing the trust of entities. Hence entities form their own opinions of trust by exchanging information with their peers. Generally methods from game theory [44], bayesian networks [43] are used for trust calculation distributedly. Aberer and Despotovis were one of the first researchers to propose a reputation management system for P2P systems [4]. They employ algorithms and data structures that require no knowledge from a central authority. The trust model is based on the past interactions between the nodes. One drawback of their method is that only the negative feedbacks are considered and the system is sensitive to misbehavior of peers. The resurrecting duckling model in [40] and its descendants [6] use out-of-band channels to authenticate key exchange. The established trust between the nodes is binary, either secure or not secure.

There are other trust models for peer-to-peer systems which we do not want to go into details of as we are interested in trust models for sensor networks. Other trust mechanisms surveyed by Momani and Challa [27] are SECURE[11], Distributed Trust Model[2], Bayesian Network Model [43], UniTec[22], BambooTrust[23], B-trust model[34].

C. Trust in Ad-hoc Networks

In ad-hoc networks, nodes join to networks or move networks very often. There are no trusted nodes to support the network functionality. Trust relationship between the nodes is also dynamic as the network is constantly changing [46]. A majority of the trust mechanisms in ad-hoc networks use game theory and bayesian network approaches. Two examples of these systems are CONFIDANT [10] and CORE [26].

IV. TRUST IN WSN

There are some surveys done on trust in WSNs [5], [15]. WSNs face different kinds of attacks such as eavesdropping, fabrication, injection, modification of packets, node capturing and many others [27]. These attacks raise issues such as privacy, accountability, data integrity, data authentication and data freshness. Some research has been done on security of WSN as surveyed by Momani and Challa [42], [30], [46], [41], [28], [48], [31], [40], [47], [33]. Cryptographic mechanisms do not completely solve the problems. System faults, erroneous data, bad routing by malicious nodes can cause network breakdowns. Cryptography is not sufficient to solve the security problems, cryptographic approaches should be integrated with tools from domains such as statistics, e-commerce, social sciences. Some nodes can behave maliciously or selfishlessly. Trust architectures have to discover and isolate these nodes. There are different approaches followed by researchers [46].

- Maintain a trust and reputation table for all nodes in a sub-network
- Use a watchdog mechanism to monitor the behavior of the nodes
- Discover faulty nodes and exclude them from the network
- Reward nodes so that they comply with protocol rules
- Use of low-cost cryptography to protect the integrity of the data

Trust has been researched for a long time [25]. It has been studied by many disciplines such as social sciences [37], economy [13]. Yet we cannot say that there is a formal definition of trust. Trust establishment between the nodes is a security approach that is very effective in WSNs. As nodes work cooperatively, trust relationship between them improve the security of WSN.

Security and trust are very related concepts and sometimes they are used interchangeably [32]. However security is
different than trust. It is broader than trust and overhead is higher in security.

Trust is used in restructuring WSNs such as omitting nodes, adding nodes, merging clusters. Trust establishment is a must because WSN depends on cooperative and trusting nature of its nodes. However due to limited resources in WSN, it is not possible to use the traditional cryptographic approaches [14]. Different trust mechanisms are needed for wireless sensor networks. Trust in WSNs is still an open and challenging field.

A. Best Practices of Trust in WSNs

Lopez et al. describe the best practices of trust management in WSNs in their survey [24] based on the other surveys [15], [19], [18].

B. Trust and Reputation

Reputation and trust should be maintained separately in a WSN. Reputation builds in time. To make an accurate decision, trust should be calculated based on reputation. Without reputation trust will have a value based on the instant behavior. For instance, a node that has behaved maliciously in the previous 10 time intervals can behave good, however the network will not be deceived by the last action as the reputation will reflect the bad behavior history.

C. First-Hand Information Gathering

There are many events in a sensor network that can be used as a base for trust computing such as hardware errors, energy issues, node relocations, sensor reading deviations. These are considered first-hand information and they should be taken into consideration. A trust management system that considers multiple sources of information will be more robust.

D. Second-Hand Information Gathering

As sensor networks consist of nodes that are working collaboratively, second hand information should be considered for trust management. A node can have local intelligence. To some extent it can detect abnormal activities of itself and can report this to its neighbour nodes. It can also report a bad behavior of its neighbor to another neighbor. However when considering second hand information, we should be careful about bad mouthing attack. Bad mouthing attack happens in WSNs when a node gives bad reports about a good node and good reports about a bad node misleading the trust calculation.

E. Initial Values

The nodes in the network should be given initial trust values at the deployment time. As we assume that a network administrator has configured them and tested them, they should all be equally trusted. However the system should be suspicious about the nodes added to the network after the deployment, as they can be part of a white-washer attack, where a node throws away its bad reputation by creating a new identity.

F. Granularity

Nodes in a wireless sensor network might have different actions such as sensing, routing. Different trust values should be assigned to different actions of a sensor node.

G. Updating and Aging

Trust should build overtime. When trust of a node is updated, the past trust values should not be overwritten. The previous trust state of the network should be remembered. If bad behaviors are not remembered, the network will be vulnerable to on-off attacks [29].

ACKNOWLEDGMENT

This research was sponsored by the Technological Research Council of Turkey and was accomplished under Project Number TUBITAK 2232 114C143. The views and conclusions contained in this document are those of the authors and should not be interpreted as representing the official polices, either expressed or implied, of the Technological Research Council of Turkey or the Turkish Government.

A Review of Automatic Text Summarization

Erkan BAYDAR*, Rıdvan SARAÇOĞLU
Electrical and Electronics Engineering Department, Yüzüncü Yıl University, Van, Turkey
ercanbaydar@gmail.com
ridvansaracoglu@yyu.edu.tr

Abstract — Giant information is available on the digital environments. Due to it has hard to get the information what you want to achieve it, fast and most efficiently. For example, if a researcher has a summary of the literature about a topic, this will be much shorter than the duration of the research. From this perspective, automatically occurring the summary of any text, it is very important for those who want to be informed. Text summarization is the compression of large document. This paper presents a review of automatic text summarizations’ approaches, studies, software, algorithms, and methods which is written by English, Turkish and some other languages in the last decades. Automatic text summarization is generally divided into two systems. There are extraction based summarizations and abstraction based summarizations. Firstly, extractions summarization approach involves selecting sentences of high score from the document based on word and sentence features. In short, finding the most important sentences from text is performed. Secondly, it is examined the semantic relationships between words and sentences in abstraction approaches. The most important difference from the first approach, made semantic analysis of words and sentences afterward new words are obtained. Mostly, optimization algorithms, genetic algorithms, fuzzy logic systems, machine learning, graph trees, statistics and probability techniques are used in automatic text summarization systems.

Keywords—Semantic analysis, text Summarization, natural language processing

I. INTRODUCTION

The development of technology with increasing speed has brought about textual data in digital cases. Under these circumstances attaining the desired information in textual data has become in terms of time. The desired textual data will be regarded as successful in terms of time expense if it includes fewer sentences alongside with useful information. This subject is crucial as for the usage of effective time consuming, has led to studies about the solution of the problem.

The fact that a sentence has been cleared of unnecessary words and sentences can be possible by means of a successful summary of that text. The aim of this review is to provide information about strategies developed and studies conducted for successful summarization. What I paid importance to while informing has been putting more emphasis on the studies carried on after 2000s. While technology and communication tools are improving rapidly, researches have come to the point of communicating more easily has been the reason for this. And at the end of this some standards about summarising studies are being developed. They have employed success measurement softwares and summary of data sets so that they can be of help in evaluation and increase of success. Another aim is the awareness of scientists who are to study on this subject.

This review consists of 3 parts. The definition of summarization and what kinds of strategies have been used will be explained in the first part. Information will be provided about summarising strategies in the second part. Some strategies will be provided about how summarising affects the evaluation of success in third part.

II. SUMMARIZATION AND APPLICATIONS HELPFUL TO SUMMARISING

A. Summarization

Text summarization can be defined as a process, which takes a text as input, includes the most important context and replaces the original and is shorter [1]. One or more textual equipment which are desired to be summarised as an input for system are provided and in the end a comparatively shorter text is provided as the summary. With this transaction a text is given to the computer programme and a summarily text which belongs to the input and includes its most important content as the output.

The emphasis of only the crucial content of a text to be summarised is called summarization process. What should be paid attention here is to determine what the content is. The content which is relevant to the topic is regarded important.

Majority of the researchers dealing with text summarization have focused on summarising the texts in English language. Therefore these studies which have been done according to grammatical structures of English language cannot be directly applied to Turkish summarization methods due to the latter’s grammatical and structural differences from of the former. For instance some structural methods where there are strong meanings of the text are free from language. Semantic analyse methods in which methods such as parsing and natural language operation are employed however cannot be used in Turkish text summarization.

A number of distinctions have been done in literature for text summarization. For example, choosing the important sentences and translating them without making any difference and evaluating this under another title is called summarising based on extractive. Another one is to comment the content from a text and rewrite it in shorter and new sentences and this method is called summarising based on abstractive. Summarising studies based on abstractive require the employment of natural language operations and detailed examination of the equipments. In abstractive based methods various parsing algorithms are used. In Turkish the by adding derivational affix to a word a parsing word is formed and by
eliminating the inflection from a word and thus finding the main word is called stemming [2]. In order to help the methods used in summarization there are a great number of other applications. Some of these are dividing a full sentence into its components, analysis and morphologic analysis (finding the stem of word, suffixes or prefixes) [3]. For instance words can be eliminated to their stems and therefore now words can be formed.

Researchers have developed softwares so as to determine the adaptive relations between words and division of words. In this part brief information about some these softwares will be provided.

B. Species of Summarization

Contrary to the abstractive based summarization, extractive based summarizations are handier and more common. Summarising without being bound to any particular word and just using some key words is called general summarization system. Summarizations limited to questioning the content is called inquiry based summary system. There are classifications based on the number of the sources of the text. In this case summarization is divided into two groups as either one document source or multiple documents. Single document based summarization, is the one whose input is a single textual data, whereas the multiple documents based summarization is the one which gets multiple documents as input, evaluates them, deals with the important parts and brings together the similar information in them and eventually summarises them on a single document. Alongside with all these groupings the document to be translated might be written in one or more different languages. Some of these approaches, represent documents to be translated with both semantic features and some structural features which enable sentences to be stated through sentence scores functions belonging sentences’ importance level.

1) Zemberek: Zemberek is open coded NLP (natural language processing) libraries which can basic NLP such as decoding, spell checking, back formation written for Turkish and other Turkish based languages. Due to its being open-coded and unignorable feat it possesses an important position among the natural language transactions. Many researches have employed Zemberek while studying Turkish summarization methods [4]. Researches have quite often used Zemberek in their studies on decoding which reveal the parsing and stem of words. In terms of structure Zemberek, consists of two parts as detailed language transactions and language structure information. The library mainly includes the softwares necessary for detailed language transactions as well as structures including stem and additions. It also contains XML libraries, which have extra information about other Turkish based languages for extra information. The additional function specially in accordance with algorithms those are sensitive for special cases. There is also a unit which controls voice cases such as sound falls, softening and assimilation. To enable these graphs tree algorithms are used. Zemberek has the ability of processing 12000 words simultaneously [4]. Zemberek, used as a tool in Turkish summarization studies is of rather high importance as an assistant. Researches use Porter Stemmer algorithms [5] to decode words in English texts.

2) Wordnet: For those researches who want to use the semantic relation between words, Wordnet [6] synonym dictionary, which define the correlation between words is a significant tool. Wordnet came about in 80s, was developed to 3.0 in 2006 and includes 155,287 words in English. For the researches working on summarization subject of Wordnet, it is of great importance that it includes a word group consisting of synonyms. The synonyms are correlated in the dictionary. Birant, in his study [7], has developed software which does summarization on its own for Turkish language as well as a dictionary of the semantic relation which he employed in his study and he has also argued that he has improved some natural language transaction tools. The two dictionaries; synonym and close-meaning dictionary and opposite meaning dictionary that he has provided in his study, have been approved by Turkish language constitution. The text summarization system based on rules which he has developed has given out results similar to those of others. In another study [8] in which sentence purification for Turkish text summarization techniques were used, methods of finding the stem of word were used as well. In this rule-based study in which syntax features are used rather than structural features, omitting letters from the end of words technique has been successfully used. In the same study the success of techniques which shorten sentences and divide sentences into shorter and multi-meaning sentences.

III. STUDIES ON SUMMARIZATION

The majority of studies on summarization are in English language. The first studies regarding textual summarization was around 50 years ago and for English texts. Although numerous newer techniques for various problems have been developed, still the traditional techniques are employed in the present and most of the problems. The reasons for them to be used are their being simple, successful, efficient and low cost. The methods requiring abstractive and natural language processing, cannot enable the methods developed for English being employed for Turkish too due to Turkish language’s suffixes structure. We can list the studies done on summarization under two general headings [9].

Extractive summarization (summarization with sentence selection) approaches are to select sentences from a text according to various techniques and combining them into a meaningful text so as to get the summarization. These methods are also called extractive methods. Another approach is abstractive summarization. In which parsing, natural language transaction techniques are used and analysing words in details, brand new words are emerged contrary to sentence selection method. For example instead of this sentence “Selim checked the menu, asked for his meal and ate” the following sentence can be used as ”Selim enjoyed his meal”. A rich symbolic list of words is necessary for this method to be used [10].
A. Extractive summarization Studies

The main focus of sentence selection technique summarization is the presence of the sentence which is regarded of vital importance. How will be the decision of whether a sentence is important? The answer to this question is significant in determining the success rate of the sentence selection summarization technique. In studies prior to 2000s, it has been decided that some sentences were far more important than others and thus be secluded from others according to a grading key. In these techniques simple but effective deductions are present. The thing that is desired to be emphasised is used more often. For example if the innovations in the field of technology are mentioned, the word technology will be used more often and the sentences in which it is present need to be present in summarization. Here, the point which should be kept in mind is that the conjunctions such as and- or – but - which are used in daily life conversations, don't in fact represent a content. This method called word frequency was used by Luhn in his study [11].

The name of this method is frequency of the word. Luhn used this method in his study. In addition that, Edmundson claimed in his study [12] that a summary must contain sentences which included some words such as "as a result", "in summary" etc. Edmundson gives more points sentences like these. This method is known as clue words phrases. His other idea is that give more point sentences that contains introduction and conclusion paragraphs. This method is called as sentences location. Also, sentences that contain the words in a title and subtitle are important according of Edmundson’s thought. The name of this method is title method.

Knowledge of date, history, arithmetic, numeric character, location, titles words, positive and negative words phrase are show importance of a sentences. Yeh et al. [13], Hernandez and Ledeneva [14] and Quyang et al. [15] have used this feature in their studies.

Study of Altan [16] is the first study on Turkish texts. He has used for data sets which written 50 document in financial issues. Firstly, he has separated heading and paragraphs using by HTML tags. Then, he examined word frequency, sentences location, words in a title, positive and negative words phrase techniques in his study.

Kılcı et al. [17] have examined date words, key words phrases, punctuation marks and proper nouns as addition to working Altan. Weighting of the sentence has already been entered in their study.

Pembe [18] has carried out query based summarization system for using web search. Then, she has given score to sentence and chapter.

Distinguishes the work of alien Çığır et al. [19], scoring was normalized. The position in the sentence of the text has been examined in this study. It was also examined according to central position of sentence.120 document is used as text data set.

We have explained structural feature of language up to now. We have seen methods of finding some most important sentences in a text. Then found sentences are rated. There are techniques combined these methods in the literature.

Suanmali et al. [20], Babar and Patil [21], Kyoomarsi et al. [22], Binwahlan et al. [23] used fuzzy logic technique for combine these methods. Silla et al. [24], Witte et al.[25], Berker and Gündör [26], Filatova et al. [27] and Mcdonald [28] have rated the important sentences with heuristic, genetic and Swarm-based optimization algorithms in their studies.

Alguilev et al. [29] have tried to solve summarize problem with nonlinear programming method. Svore et al. [30], Wong et al. [31] have used to learning machine, Bayesian classifier, support vector machines, artificial neural networks techniques. Agrawal and Gupta [32] have used the similarity of sentences to each other. For this, the K-means method is used. In the work of Seimberger et al. [33] and Orasan [34], utilizing the semantic relationships between words cohesion-based techniques are used. They have benefited from the Wordnet. D'avanzo [35] has carried out a study that knows the name of the entity and finds multiple words and based on supervised learning in his study.

We have also seen event-based methods in summarization studies. Liu et al. [36], Filotova et al.[37] examine the events in the text with the help of causality techniques. An event-term graph is obtained. The same event terms are grouped.

Uzundere et al. [38] have examined 13 different features in their study. According to this;

- Head: The words are listed in the titles and subtitles. Sentences are checked whether they have these words.
- High Frequency: Holding the number of repetition of all words in the text is created. List is sorted in descending direction. Would not include frequently used words in everyday like "and", "but", "or" etc. in this list. Words are included in summary according to determined by a percentage. Percentage is determined by the genetic algorithm or heuristic methods.
- Location: Paragraphs of sentences is determined like which sentence in the introductory paragraph or conclusion paragraph.
- Key Words: Important words for the user entered previously. Sentences that contain these words are important. For example, rebound is important word about a sport text.
- Uppercase: Special names are pure information. It should be included in the summary.
- Positive Words: More points are given to sentence which contains some word phrase like "as a result", "at last" etc. in the text.
- Negative Words: Sentences containing details are given less points.
- Collocation: Words that reinforce the meaning is considered important.
- Numbers: The score of sentences containing the numerical is high.
- Quotation Mark: Sentences including quote is important.
- Ending Mark: Punctuation mark at the end indicates the importance of a sentence.
- Average Length: The mean number of words in the text is calculated. Nearest to average sentences is considered important.
• Day-Month: Sentences including knowledge of day and month are important.

In this study firstly text is divided into sentences and paragraphs. Zemberek is used in the separation process. Then allocated structures examined designated by 13 features. Heuristic method has been used for scoring. Weighting of sentences are shown in Table I.

For example, a sentence has two key words and three numerical characters in text. Total score of the sentence is $2(2*8) + 3(3*3) = 25$. Each sentence score is calculated. A rate is asked by users. This is called summarization percentage rate. Sentences are select according to this rate. For example, if summarization rate select 35 percent, 35 percent of the sentences of highest scores would select. Then, have been tried at different rate. They have taken an average and measured to success 55 percent in their study.

In another study [39], summary of Turkish web pages has been being studied. Sentence selection is determined by 12 different features. Heuristic method has been used for weighting. Success rate was measured as 59% in this web-based study.

In a study [40] that used a combination of text and sentence clustering techniques, similar words and documents are clustered. The highest frequency sentences have been selected in this cluster.

Pointed out that in another study [41], the information in the text is obtained in two stages. In the first stage, tagged sentences are separated according to certain rules. Word phrases, word frequency, and location methods were used with modal verbs in the second stage. This study was carried out for English texts. It has benefited from the tense of the sentence to filter the information.

Extractions summarization approach was used in a study carried out in 2014. Güran at al.[42] have argued that adding a new criteria for Extractions summarization system. Name entity recognition method was used for the first time.

In a thesis published in 2014, Attokurov [43] has claimed that the main purpose of text summarization systems is to prevent the repetition of information. Optimal Tree Pruning algorithm and HAC (Hierarchical Agglomerative Clustering) algorithm are used together to prevent the repeat of information. HAC was used for extraction to repetition. Optimal tree pruning algorithm has also been used to reduce repetition.

To solve the problem of summarization have also been used optimization algorithms. In a study [44], ant colony optimization algorithms, particle Swarm optimization, artificial bee colony algorithms and genetic algorithms are used to extract more effective summary.

B. Abstractive Summarization Studies

To good determine the relationship of word-event and grouping of terms in the event tag is very important to emergence of the meaning in a text. Based on this idea, success of summarization was attempted to increase with linear algebra methods. This method is briefly performed in the following:

Primarily text is divided into words and sentences. Then a matrix of term-sentence is obtained. Matrix is factorized. After that words and phrases are converted into linearly independent vectors. Words and phrases are grouped as semantic by these vectors. Important words and phrases are selected grouped with semantic matrix factorization. After this process, semantic analysis of texts is performed by methods of Latent semantic analysis or probabilistic semantic analysis.

Murray et al. [45], Steinberger et al. [46], Yeh et al. [13] have used latent semantic analysis in their studies. Lee et al. [47], Mashechkin et al. [48] and Güran et al. [49] have also used non-negative matrix factorization (NMF) algorithms.

Güran, in her study [50] has determined sequential words with the help of Turkish Wikipedia links. In Güran's study [50], structural and semantic features are used together.

A hybrid system that combines structural and semantic feature has been proposed in order to determine important sentences. The results of hybrid systems have been more successful than each individual system. The new techniques used in stage of creating term-sentences matrix have been explained. These techniques are based on location the words and importance of words in sentences to which they belong. Study has also produced to use two new data sets for next studies on Turkish language. The first one is 130 news document, second corpora is 20 shorter text news.

Bhandari et al. [51] Chris, H. and Ding, Q. [52] have used probabilistic latent semantic analysis in these studies.

In another study [53], Non-negative Matrix Factorization methods were used to determine the relationship between sentences. Clustering and clustering methods were used in text pre-processing. The study has also been highlighted to increase quality of summarization of clustering methods.

We continue to examine studies that using method of semantic analysis. Gong and Lui [54] have divided text to topic and they have chosen sentences from each topic. In contrast, Murray et al. [45] has chosen multiple sentences...
from each topic. Özsoy et al. [55], have proposed to eliminate the noise. They have also chosen all topics in text.

Özsoy et al. [55] have proposed two new methods in studies of semantic analysis named as Cross and topics. Topics method was used to separate main subjects from sub-subjects and make sentence selections from main subjects. Cross method was also used for observe whether sentences are important. Cross-method has produced more successful results.

There is a method that shows the interconnectedness of words named as word chains method in the literature. Berker [56] has benefited relationship between words in her study. Word chains were formed in this study. Then this deep knowledge was combined with a higher level analysis. Finally, this information at different levels is combined with the help of genetic algorithms.

In a study conducted in 2010 [57], a software has been developed named as FRESA (Framework for Evaluating Summaries Automatically). This software is content-based and it make summary assessment. A system which generic single-document summarization in French and Spanish and focus-based multi-document summarization in English was introduced in study. System performance is measured by assessment package ROUGE. ROUGE Package will be discussed later.

In another study called ARTEX (Another TEXt summarizer) [58], document vectors and lexical vector are kept. In order to rank sentences, a simple inner product is calculated between each sentence, a document vector (text topic) and a lexical vector. Highest ranked were combined. No ruled-based linguistic post-processing and based in sentences extraction on Vector Space Model (VSM) techniques have used. Ranking were normalized. Each sentence is calculated in the feature matrix format. The most important aspect of this study is not requires linguistic knowledge or resources. Study is tested on French and Spanish document and it has produced successful results.

In another project [59] that using latent semantic analysis techniques have presented it presented to comparison of different vector space model. Success was measured by Ngram assessment methods. Study has proved binary models more successful than complex term frequency models.

Looking at statistical distribution of words as semantically, language processing problems can be solution. In a study [60] carried out in this thought, firstly meaning the relationship between words was measured. Meaning of integrity and key phrase extraction using lexical chains has been used. This method requires more prior knowledge. In study, has been investigated the effect of the use of lexical cohesion features in key phrase extraction, with a supervised machine learning algorithm. Studies have shown that lexical cohesion based features improve key phrase extraction. Achieved good results, compared to some other lexical cohesion based algorithms.

M. Cakir and E. Çelebi have presented a method that includes all languages to summarize their works [61]. C3M (Cover Coefficient-Based Clustering Methodology) algorithms were used. Sentences are determined with the help of similarities between sentences. Success was measured by Rouge assessment package. Successful results were obtained. Dependency grammars has been used some problems that finding similarities between sentences. The usage of dependency grammars to compute sentence similarity has been proposed in a study [62]. This study have been achieved that dependency grammar representations of sentences find out to better results in finding the similarities between sentences. Details can be reached on [62].

Most studies in the literature have been made for summarization of English language. Studies for other languages are less. Therefore, minority of studies for written on Arabic language have been emphasized in a study [63]. It has also talked about the lack of Arabic language summarization standards. It has been mentioned that Arabic was included in TAC 2011 MultiLing Pilot and ACL 2013 MultiLing Workshop. Other methods of extraction summarization studied on Arabic in the literature has been presented and grouped on a table.

IV. MEASURING SUCCESS

In order to test the success must be we should have ideally summary. In study by Rath et al. [64], people have been requested to select sentences which could be important according to them from different at different times. Güran [50] has asked to select important sentences from some people. Thus Ideal summary was obtained. In another study [65] Morris, Kasper and Adams have suggested a method named as GMAT (Graduate Management Admission Test). A technique of answering questions which exercise of reading comprehension is recommended.

Success is evaluated by various methods. To compare Ideal summary with the summary created by the system is the most known method. In order to measure success such as information retrieval, text categorization and question answering are used. The most common methods in the literature are precision/recall/F-score, value of relative benefit, cosine similarity and ROUGE.

A. Value of Precision-Recall-F-Score (PRF)

The purpose of this method is to find the number of common sentences between ideal summary and measured summary. The number of common sentences is divided to number of measured sentences. This is called precision (P). Recall value (R) is found by dividing number of common sentences to number of measured sentences. The harmonic mean of P and R is F-score (F). Formulas are shown below.

\[
P = \frac{|S \cap T|}{|S|} \quad R = \frac{|S \cap T|}{|T|} \quad F = \frac{2PA}{P + A}
\]

B. Value of Relative Benefit

This method has been proposed to correct deficiencies in PRF method. In Dragomir's study [66], sentences are rated heuristically. This is called utility score. Each sentence is rated. People are rated the sentences. "N" is number of people
and \( n \) is number of sentences in the following formula. \( Xi \) is shown \( i\)-th assessor and \( j \) is shown number of sentences. \( U \) is shown score of utility. Can be accessed for details of study here [66].

\[
Utility = \frac{\sum_{i=1}^{n} \delta_i \sum_{j=1}^{N} u_{ij}}{2 \sum_{i=1}^{n} \delta_i \sum_{j=1}^{N} u_{ij}}
\]

C. Cosine Similarity

Formula of another measurement method is given below. \( x_i \) is word frequency value at ideal summary. \( y_j \) is also word frequency value at measured summary. Can be accessed for details of study here [67].

\[
\cos(X,Y) = \frac{\sum_{i} x_i y_j}{\sqrt{\sum_{i}(x_i)^2} \sqrt{\sum_{j}(y_j)^2}}
\]

D. Ngram Statistics

Rouge (Recall-Oriented Understudy for Gisting Evaluation) software which a Ngram based technique was proposed in 2004 by Chin-Yew Lin [68]. It is produced by the Perl programming language and was used in DUC [69] (Document Understanding Conference) firstly. It is a method that based on comparison of the number of common words. There are five different measurement methods. There are ROUGE-N, ROUGE-L, ROUGE-S, ROUGE-W, ROUGE-SU and ROUGE-N. Ngram is number of 5-length sequential word group. ROUGE-N is number of common Ngrams between ideal summary and measured summary. It is calculated by the following formula. Can be accessed for details here [68].

\[
\frac{\sum_{\text{sentence groups}} \sum_{\text{gram sizes}} \text{calculate}(\text{gram sizes})}{\sum_{\text{sentence groups}} \sum_{\text{gram sizes}} \text{calculate}(\text{gram sizes})}
\]

IV. CONCLUSIONS

In this review, we have presented definitions, methods, approaches and studies about of Automatic Text Summarization. We have detected that studies was focused on English language. We have seen the success of Turkish studies around 50%. We have concluded that combination of techniques have been more successful.

Abstract— Merging systems, enhancing inter-disciplinary relations and increasing needs require multi objectives rather than a single objective in the optimization problems nowadays. However, the objectives are frequently conflicting. When an objective is improved, the other objective(s) may deteriorate. In the multi-objective optimization problems (MOOPs), the aim is to come up with the best solutions that can be an alternative for each other in terms of objective function values under the constraints caused by various reasons. During the last two decades, MOOPs and solution methods have been studied with great interest. It is possible to come across a MOOP in almost every discipline in the literature. MOOPs have been modelled and solved not only in the fields with more applications such as production, management, business administration, marketing, transportation and finance but also in the basic sciences such as chemistry, maths and statistics. Solution of MOOPs requires the simultaneous optimization of conflicting multi objectives. In MOOPs, an optimal solution set on which a compromise is reached among the conflicting objectives is obtained. In this study, the articles on multi-objective optimization written in 2015 and later are analysed and 61 articles are chosen among them. Classical and heuristic methods implemented for the solution of MOOPs presented in these articles are mentioned. The articles are classified according to their subject areas. The methodology used in each article is identified. According to their implementation areas, the multi-objective optimization methods and the areas they are implemented the most are discussed. The areas to be focused on in the future studies to obtain more robust results in the optimization are identified.

Keywords— multi-objective optimization, Pareto optimal set, genetic algorithm methods, particle swarm optimization

In this study, articles included in the literature in the last 15 years and referred more than other articles written in the same year are analysed in terms of subjects, methodologies and results for Multi-objective optimization. These concepts in the literature are handled under separate headings. Multi-objective optimization methods can be divided into two groups as classical and heuristic methods. In this study, we explain the methods mostly used or referred in the articles. Each article is analysed in terms of its methodology under the relevant heading. Other unexplained methods and new approaches related to multi-objective optimization are analysed under the same heading. Methods chosen in the articles are analysed along with the reasons in the conclusion part. Success criteria of the studies conducted in special areas are mentioned. Subjects are suggested for future studies to obtain more solid results from multi-objective optimization.

II. MULTI-OBJECTIVE OPTIMIZATION

The main difference between single objective problems and multi-objective problems is that; there is a single optimal solution or alternative optimal solutions in single objective problems while there is not any solution simultaneously delivering the best value for each objective in multi-objective problems. Since all objectives are important in these problems, looking for a solution only for one objective is wrong. Improvements in an objective cause deterioration in at least one of the other objectives due to conflicting objectives. Trade-off amounts are obtained among identified solutions depending on their function values because of conflicting objectives. Acceptable trade-off amounts depend on decision makers. In this case, there is generally not a certain optimal solution in multi-objective problems. Some of the solutions obtained and traded-off are presented to the decision maker as the best solutions.

A general multi-objective optimization problem includes n parameters (decision variable), k objective functions and a group of m constraints. Objective functions and constraints are written as the function of decision variables. Optimization process can be formulated as

\[
\min \ y = f(x) = (f_1(x), f_2(x), ..., f_k(x)) \\
e(x) = (e_1(x), e_2(x), ..., e_m(x)) \leq 0
\]
\[ x = (x_1, x_2, ..., x_n) \in X \]  
\[ y = (y_1, y_2, ..., y_k) \in Y \]

Here it is appropriate to describe \( y \) as the decision vector, \( y \) as the objective vector, \( X \) as the decision space and \( Y \) as the objective space. Constraints \( c(x) \leq 0 \) show accessible solution set for the described problem. [1].

### A. Concept of Domination

Let a, b \( \in \) X be two separate solution vectors of a multi-objective optimization. In a problem with maximization type objective functions, solution a dominates solution b if \( f_j(a) > f_j(b) \) \( j \in (1, 2, ... n) \) is the case for each \( i f_i(a) \geq f_i(b) \) \( i \in (1, 2, ... n) \) and at least one \( j \). In the cases without dominance, a and b solutions cannot dominate each other for at least one \( i f_i(a) < f_i(b) \) and at least one \( j f_j(a) > f_j(b) \).[2]

### B. Pareto Optimality

A solution can be the best, the worst or equal to other solutions depending on its objective values. The best solution means a solution which is not the worst solution in any objective and is better than the other solutions in at least one objective. Pareto-Optimal solution is the solution not dominated by another solution in the search space [2].

Considering all objective functions, the set of all dominant solutions is called Pareto Front. The real aim of multi-objective optimization is to find or approximate to the Pareto front and enable a fair distribution over this front.

### III. CLASSICAL METHODS FOR MULTI-OBJECTIVE PROBLEMS

These methods are effective if the structure of multi-objective decision making problem aimed to be solved is appropriate and finding the best solution is possible if available. Regarding the studies using classical optimization techniques in general, Diakaki et al [38] evaluated the success of classical optimization methods in energy efficiency of buildings. They analysed the suitability of multi-objective optimization techniques in the solution of problems related to energy efficiency of buildings. They observed in the practices of a simple example. Ren et al [48] designed a modelling for the distributed energy resource (DER) using multi-objective linear programming (MOLP). This modelling was implemented within the scope of a case study in a eco-campus in Japan. Giarola et al [53] realized bio-refineries spatial design with Mixed Integer Linear Programming framework. In this way, they succeeded in simultaneously optimizing economic and environmental performances. Asadi et al [56] presented a multi-objective optimization model with Thebycheff formulation in order to reduce energy cost of buildings. They applied the model on a house by conducting required renovations and showed the feasibility of these approaches. Karande and Chakraborty [60] introduced a new approach for material selection problems in product designs. They developed a multi-objective optimization on the basis of ratio analysis (MOORA) independent from weights of selection criteria and normalization procedures of decision matrices. Najafi et al [63] suggested a source optimization model using classical optimization methods in order to provide the best immediate aid possible in post-earthquake response. Ehrgot et al [79] presented Minmax Robustness approach to obtain more robust results in classical optimization methods. They tried their approach on many linear and quadratic programming. Nariman-Zadeh et al [45] suggested a new multi-objective uniform-diversity genetic algorithm (MUGA) procedure based on developed \( \epsilon \)-elimination for vehicle vibration systems.

### A. Weighted-Sum

In this method, objectives are given weights, these weights are added together and a single weighted objective function is obtained. Weights are determined according to the importance attached to the objective by the decision maker. Optimal result can be obtained using the function composed of weighted objectives. Determining the weights can be difficult due to the lack of information on the problem during implementation of the method. If the problem is convex and the weights are positive, Pareto optimal solution is obtained [4]. In the other cases, in other words; if the problem is concave and the weights are not positive, it is wrong to look for a solution using this method.

Considering the studies using weight-sum; Altiparmak et al [29] developed the weight-sum approach in the design of supply chains network and a procedure finding Pareto optimal solutions. An experimental study using actual data from a company, which is a producer of plastic products in Turkey, was carried out. Xiang et al [44] came up with the multi-objective optimization (MOO) formulation for human lifting simulation with weighted-sum approach. They observed that the results are more sensitive compared to single objective optimization. Marler and Arora [46] investigated the impacts of weight selection in the solution stages of weighted-sum method and tried to solve the problem without knowing the weights in advance. Devarajan et al [61] presented an optimization modelling using weighted-sum in order to reduce the cost of wireless communication. They observed the results of the approach on simulation. Gjorgiev and Cepin [62] suggested an optimization approach using weighted-sum method for the combined economic-environmental power dispatch problem. They tried the algorithm in different power systems and they compared the results with multi-objective differential evolution (MODE) and NSGA-II. Sun et al [83] presented optimization modellings for patient and resource allocation among hospitals during a pandemic influenza outbreak. Weighted-sum was used in mathematical modellings.

### IV. MULTI-OBJECTIVE DECISION MAKING PROBLEMS BEYOND CLASSICAL METHODS AND GENETIC ALGORITHM

For the majority of multi-objective decision-making problems, it is almost impossible to obtain Pareto optimal solution set with classical methods. The reason is that most of the multi-objective problems are NP-hard [6].

Problems with integers are generally quite complicated and have a concave search space and it its hard to find the best solution set. Convergence to Pareto optimal solutions is quite
slow in classical methods. Searching for the optimal solutions for these is only possible with heuristic methods [7].

Genetic algorithm (GA) is the application of genetic related mechanisms in optimization problems as an algorithm. Reproduction in genetic generally occurs through mutation and crossover. These are GA operators. The obtained individual (solution) should have a good fitness value to maintain its participation. In this way, strong individuals succeed in survival and can transfer their genes to the next generations. Therefore, better solutions can be achieved by transferring the information on the solutions with good results to the next solutions [8].

To be able to use GA in a computer, the most compatible coding method for the problems should be used. The mostly used methods are binary coding, permutation coding and real number coding.

Selection of the solutions to be used in the next generation is one of the important steps in GA operation. Various selection methods were suggested as a result of research studies. Selection methods commonly used in practice include roulette wheel [9], selection sort [10] and tournament selection [11]. The common feature of these methods is that solutions obtained are probabilistically selected according to their compatibility value. Probability of the solutions with good compatibility value to be included in the next generation is always high.

Crossover and mutation are used to obtain new solutions using the selected solutions. Crossover is more commonly used compared to mutation operator. There are one-point, two-point and multi-point crossover techniques. It is observed that one-point and two-point crossover techniques are used the most. Mutation is an operator applied on solutions obtained after crossover operation. It is applied on the solutions with a small mutation probability identified beforehand and various solutions are obtained in this operation. Mutation operator provides diversity in the formation of next generations. It is possible to obtain bad results as well as good ones with crossover and mutation; however, these solutions are eliminated during selection. In GA, population extent should also be determined in addition to crossover and mutation control parameters. Most of the problems are quite sensitive to these three sensitive and the best solution is obtained only with the right selection of parameters [6].

Considering the studies using GA, Rao and Patel [66] presented a new approach for heat exchangers optimization using modified teaching-learning-based optimization algorithm. They compared the results obtained with GA results. Omkar et al [50] compared the results of the system designed for Vector Evaluated Artificial Bee Colony (VEABC) and its multi-objective optimization with PSO, Artificial Immune System (AIS) and GA.

V. MULTI-OBJECTIVE GENETIC ALGORITHMS

There may not be a single best solution for all objectives in multi-objective cases. In this case, the decision maker is asked to select a solution from a compromised finite set. Appropriate solution should perform at an acceptable level for all objectives. It is know that using genetic and evolutionary algorithms for the solution of multi-objective optimization problems is advantageous.

A. Multi-Objective Genetic Algorithm

Multi-objective Genetic Algorithm (MOGA) was developed by Fonseca and Fleming [13]. Groups are formed starting with the non-dominated solutions in the first group and solutions dominated for once in the second group. In each group, only the proximity of solutions to each other in the same group is calculated. Following the calculation of proximities, fitness parameter \( \sigma_{share} \) which should be a small number depending on the problem is identified. It is easy to calculate fitness values of the solutions in MOGA method. Furthermore, MOGA can be applied in various optimization problems with fitness parameter \( \sigma_{share} \). However, in this technique, giving the same fitness value to different solutions on the same front may cause the algorithm to look for the solutions on the wrong front. In practice, it has been proved that MOGA is quite sensitive to the type of concerned solution area. Besides, the algorithm does not guarantee that a solution has always a better fitness value than a worse solution [14].

Considering the studies using MOGA, Wang et al [25] optimized the conflicting economic and environmental objectives in environment friendly building designs with MOGA. They presented a case study and demonstrated the effectiveness of their approach for identifying a number of Pareto optimal solutions for green building design. Tahara et al [30] optimized various objective values in ship design with Sequential quadratic programming (SQP) and MOGA. They formulated a multi–objective optimization problem where ship propulsion and maneuverability performances are considered. Pierobon et al [72] realized Rankine cycles optimization for waste heat recovery using MOGA. They observed in the results that they could prevent heat loss.

B. Non-dominated Sorting Genetic Algorithm

Non-dominated Sorting Genetic Algorithm (NSGA) was developed by Srisvas and Deb [15]. The method starts with sorting the solutions obtained randomly according to their dominance. As in MOGA method, proximity among the solutions in each sub-population is calculated. Solutions are selected with roulette wheel method. In this method, the chance of the solutions in the non-dominated 1st sub-population \( P_i \) to be selected is higher. New solutions are obtained by applying crossover and mutation on the selected solutions and the algorithm keeps looking for solutions until stopping criterion is formed. NSGA method classifies solutions according to their dominance and assigns fitness values. Various practices have shown that the algorithm is especially \( \sigma_{share} \) sensitive to its parameter [15].

Considering the studies using NSGA, Ahmadi et al [70] aimed to obtain maximized power, thermal efficiency and minimized pressure loss using NSGA in Stirling heat engine design. They observed the results using experimental data.
C. Elitist Non-dominated Sorting Genetic Algorithm

Elitist Non-dominated Sorting Genetic Algorithm (NSGA II) was developed by Deb and Goel [18],[19]. This algorithm is similar to NSGA method; however, parameters used in NSGA are not used in NSGA II. NSGA II $\delta_{share}$ does not need the fitness parameter. The algorithm gives more chance to the prominent results and it is almost impossible to lose these solutions. Therefore, the algorithm never loses the Pareto optimal solution found until the current step. Solution selection mechanism is used to limit the population size; however, in this case, the algorithm may lose its feature of proximity to the optimal solution. Since the number of solutions in the sub-set $P_1$ where first non-dominated solutions exist is not higher than the number of main population, all solutions in this set are selected. Therefore, diversity among the selected solutions is not ensured.

In the studies using NSGA-II, Sarkar and Modak [23] developed a solution method for fed-batch bioreactors with NSGA-II. They applied this method on two problems included in the literature and solved with many methods previously. Atashkari et al [26] found out Pareto fronts of conflicting objective functions in the thermodynamic cycle of turbojet engines using $\epsilon$-elimination and NSGA II. Further, they observed some interesting and important relationships among optimal objective functions and decision variables involved in the thermodynamic cycle of turbojet engines. Deb et al [31] developed a new robustness procedure in order to obtain more realistic results instead of a general pareto front. They used NSGA II to compare global and robust pareto fronts. They managed many limited and unlimited test problems to show the obtained results through simulation. Goel et al [32] realized approximations on the Pareto Front obtained with NSGA II. They showed that the approximated Pareto optimal front (POF) can help visualize balances and quantify values among objectives to select compromise designs. Mandal et al [34] obtained Pareto set by modelling electrical discharge machining (EDM) with NSGA II. They carried out experiments over a wide range of machining conditions for training and verification of the model. Testing results demonstrated that the model is suitable for predicting the response parameters. Jia et al [40] worked on the optimization of energy, cost and scope parameters in the use of wireless network with NSGA II. Numerical and simulation results validate that the procedure to find the optimal balance point among the maximum coverage rate, the least energy consumption, as well as the minimum number of active nodes is fast and effective. Shokri et al [67] suggested a new method by combining NSGA-II and artificial neural networks (ANN) in order to reduce time spent for the solution of multi-objective optimization problems with evolutionary algorithms (EAs). The suggested method was applied on three standard problems and one real-life problem. They were able to considerably reduce the time required to find Pareto optimal front compared to NSGA-II solutions used without ANN. Campomanes-Alvarez et al [74] realized surface simplification optimization for a 3D open model mesh simplification problem. They compared the results obtained from NSGA-II and MOEA/D with the results obtained from two classical methods. Ahmad et al [78] presented a new approach by using NSGA-II in order to optimize each stage of biomass energy. They showed the Pareto front and observed the results with statistical analyses. Song et al [80] suggested a semi-active battery/supercapacitor (SC) hybrid energy storage system (HESS) for electric vehicles. They realized parameter optimization using NSGA-II in their studies.

D. Strength Pareto Evolutionary Algorithm

Strength Pareto Evolutionary Algorithm (SPEA) was developed by Zitzler and Thiele [20]. In this algorithm, diversity in the selection of Pareto optimal solutions is ensured with clustering analysis. Calculation of proximities is easy and additional parameters are not required. In the algorithm, parameter $N_L$, which is the size of populations where prominent solutions will be tracked, should be identified. Furthermore, balance between the main population size $N_{main}$ and $N_L$ should be ensured in order to obtain good results from the algorithm. $N_L$ should be neither too big nor too small. If it is too big, the algorithm loses much time with prominent solutions and may not generate other solutions and converge to optimal solutions. If it is too small, solutions in the prominent set are not used enough and it may cause the algorithm to excessively look for the solutions outside the area where optimal solutions exist. A criticised feature of the algorithm is that it gives a fitness value for dominance criterion to the solutions in the main population during the formation of populations. Furthermore, the power values obtained sometimes cannot keep the non-dominated solutions of the same importance at the same value [2].

Considering the studies using SPEA, Farmani et al [24] focused on certain objectives such as capital, operation, life cycle, maintenance costs, system reliability and water quality which should be simultaneously optimized in the design of water systems. Two examples related to design of water systems were applied on each of MOGA, NSGA and SPEA algorithms and their Pareto fronts were compared. Ali et al [57] amended Differential Evolution (DE) algorithm and transformed it into Multi-Objective Differential Evolution Algorithm (MODEA). They introduced new approaches to mutation and selection mechanisms in the meanwhile. The new approach obtained was applied on different multi-objective problems and the results were compared with algorithms NSGA-II, SPEA and Pareto Archived Evolutionary Strategy (PAES) developed by Knowles and Corne [21].

E. Strength Pareto Evolutionary Algorithm 2

Strength Pareto Evolutionary Algorithm 2 (SPEA2) was developed by Zitzler et al. [22]. It is the developed version of SPEA method. SPEA2 introduces a better scoring mechanism, an intensity estimation technique and a developed archive (secondary community) management compared to SPEA method. SPEA2 uses fine-grained fitness assignment strategy using intensity information. Furthermore, size of the archive externally storing the non-dominated individuals is stable. If
the number of non-dominated individuals is lower than the previously identified archive size, the archive is filled with non-dominated individuals. Additionally, the clustering technique used when non-dominated surface is over the archive size was replaced with an alternative downsizing method that has similar features but does not lose front points. Finally, another difference from SPEA is that only the archive members are used in selection process.

Considering the studies using PSO; Wang and Singh [35] designed a developed optimization practice with NSGA-II and SPEA2. In this way, they realized meta-heuristic and experimental practices in the solution of multi-objective optimization applications. Xue et al [75] realized a feature selection optimization using PSO with the aim of reducing surplus and unnecessary features in the data sets and obtain more accurate results in a shorter time in classification. They compared the results obtained with NSGA-II, SPEA-II and PAES.

VI. PARTICLE SWARM OPTIMIZATION

Particle Swarm Optimization is a swarm-based algorithm developed by Kennedy and Eberhart in 1995 with the inspiration from fish schools and bird flocks in the nature [12]. The algorithm was built on the behaviours of flock animals practices in order to meet essential needs. Particle concept used in PSO algorithm represents each individual in the swarm. Each individual in the swarm has position information indicating the position of the individual in d-size solution space and speed information indicating its movement in d-size solution space. PSO is a repetitive algorithm. Therefore, speed and position information of the particle is updated during each repetition. While speed information of the particle is updated, not only the heuristic speed information from the previous step but also cognitive and social experiences are used. For the updated position information of the particle, position information and updated speed information of the particle from the previous step are used. [12, 16].

Considering the studies using PSO; Wang and Singh [35] suggested fuzzified multi-objective particle swarm optimization (FMOPSO) for the compromising economic and environmental objectives in electricity transmission. The performance of the suggested approach was compared with Weighted Clustering (WA) and evolutionary multi-objective optimization algorithms. Tripathi et al [36] developed Time Variant Multi-Objective Particle Swarm Optimization (TV-MOPSO) procedure based on PSO multi objective optimization approaches and measured the performance by comparing with algorithms such as NSGA II and PESA II. Zhang and Liu [39] presented a new formulation with fuzzy adaptive PSO (FAPSO) for multi-objective reactive power and voltage control. The proposed approach has been examined and tested with promising numerical results of the IEEE 30-bus and IEEE 118-bus power systems. Zhang and Xing [47] developed a construction method with PSO for the time–cost–quality trade-off problem. They applied the suggested method with computerized analyses and verified. Moslehi and Mahnam [49] presented a new approach for flexible job-shop scheduling problem using particle swarm optimization and local search. They compared the efficiency of the approach presented with other algorithms in the literature. Qasem and Shamsuddin [51] applied TV-MOPSO on radial basis function (RBF) used in the diagnosis of medical disorders. They compared the results with MOPSO and NSGA II. Yildiz and Solanki [59] presented a new method for the multi-objective optimization of crashworthiness of vehicles. The PSO-based method was applied on two optimization problems in the literature. Khalili-Damghani et al [64] suggested dynamic self-adaptive multi-objective particles warm optimization (DSAMOPSO) for the solution of multi-objective reliability redundancy allocation problems (MORAPs). They compared the results obtained from test problems with TV-MOPSO and NSGA-II results. Garg and Sharma [65] reformulated multi-objective reliability-redundancy allocation problem with fuzzy multi-objective optimization problem (FMOOP). They solved the fuzzy MOOP obtained using PSO. The approach has been demonstrated through the case study of a pharmaceutical plant situated in the northern part of India. Zhang et al [68] realized an uncertain orbit optimization using risk and orbit distance parameters in the problems related to orbit planning for robots. In their studies, they used PSO and observed the results from simulation. Taormina and Chau [82] created a multi-objective problem using cross-validation for PSO-trained neural network river forecasting (NNRF). They solved this problem with multi objective fully informed particle swarm (MOFIPS) approach using actual data.

VII. OTHER METHODS AND NEW APPROACHES

New approaches presented for the solution of MOOPs and methods developed for special systems are handled. Mahapatra and Roy [27] developed a new fuzzy multi-objective optimization method in order to increase system reliability. The main aim was to increase reliability while reducing the cost. Huang et al [28] developed a special interactive fuzzy multi-objective optimization model for engineering designs. In this model, balance matrix was used and weight coefficients of objective functions were identified depending on preference. Igel et al [33] transformed covariance matrix adaptation evolution strategy (CMA-ES) delivering quite good results in single-objective optimization for multi-objective (MO-CMA-ES) and elitists problems. Obtained results were compared with NSGA II. Jaeggi et al [37] adapted Tabu Search algorithm for the solution of MOOPs. All results were compared with MOTS (Multi-Objective Tabu Search), PRMOTS (Path Relinking Multi-Objective Tabu Search) and NSGA II. Thiele et al [41] elaborated the obtained pareto optimal set with the instantaneous preferences of the user in each repetition using multi-objective evolutionary algorithm (MOEA). In this way, they managed to include ignored but essential solutions in the pareto optimal set. Kim et al [42] designed multi-objective population-based incremental learning (MOPBL) for the fuzzy path planning of robots. Simulation and experiment results show the effectiveness of the proposed MOPBL from
the viewpoint of the proximity to the Pareto-optimal set, size of the dominated space, coverage of two sets and diversity metric. Chaudhuri and Deb [43] developed a procedure to assist users to select a specific solution on the obtained pareto optimal set with multi-objective evolutionary optimization (EMO). Huang et al [52] developed a new online multi-objective optimization algorithm for membrane computing. They prevented the formation of undesired and wrong solutions with online controls in this dynamic algorithm. Yang [55] developed the multi-objective bat algorithm (MOBA). He applied the algorithm on the problems related to welded beam design and observed its success in the results of simulation. Fesanghary et al [58] presented a model based on harmony search algorithm (HS) in order to minimize life cycle cost (LCC) and carbon dioxide equivalent (CO2-eq) and maximize energy efficiency of the buildings. To measure the efficiency of the proposed approach, they tested the performance of the model on a typical single-family house. Jiménez et al [69] conducted an optimization study on production planning using fuzzy multi-objective evolutionary algorithm. They compared the results with NSGA II. Sindhya et al [71] attempted to eliminate the problems arising in optimization process with multi-objective evolutionary algorithms (MOEA) using new hybrid systems. NSGA-II and MOEA types were transformed into hybrid systems and the results were compared. Niu et al [73] developed a new multi-objective Bacterial Foraging Optimization (MBFO) algorithm and compared the obtained results with NSGA-II and MOPSO. Wang et al [76] presented an approach for cost-energy optimization in the coal-fired thermal power plants. In their approach, they used multi-objective differential evolution (MODE) and showed the results with simulation. Huang [77] developed a design optimization for design exploration of three-dimensional transverse jet in a supersonic crossflow and observed the results with simulation. Wang et al [81] presented a multi-objective optimization for combined cooling, heating and power system (CCHP). In the experiments conducted, it was found out that a more comprehensive solution set is required to obtain more successful results from optimization.

VIII. CONCLUSIONS

In this study, 61 articles published in the last 15 years are selected and analysed. Each article is handled under separate headings in terms of their subjects, methodology and results. As a result of the analysis, it is observed that operations using multi-objective optimization techniques are quite successful in the solution of comprehensive problems which is a huge challenge for operators in the special areas. The method used in the solution of MOOPs should be chosen considering the objectives and constraints peculiar to each area. Because classical and heuristic methods do not deliver the same results in the same operation. While determining the classical and heuristic methods to be used in article analyses, the extent of information available on the handled problem is quite effective. If the importance of each objective and constraint is known in numbers for the problem aimed to be solved, mostly classical methods are preferred. To be more precise, the more the problem is complicated and unknown, the more the probability of selecting heuristic methods increases. Classical methods are chosen when complete and certain results are desired to be obtained. In the operations where solution performance is low due to the complexity of the problem, pareto optimal set which can satisfy the operator and show the approximate results is obtained. In the articles, finding the algorithms that can present the pareto optimal set most accurately and in the shortest notice becomes prominent as the main aim.

Another outstanding subject in the articles is NSGA-II which is one of the multi-objective genetic algorithm types among heuristic methods. It was observed this algorithm delivers the most diversity in the solution of problems. This algorithm either serves as the main method of many operations or the developers use a variant of this algorithm. The abundance of NSGA-II use in the measurement of special algorithms developed is outstanding. In the studies using PSO, the most remarkable feature of PSO is its easy practice in most of the systems. Developers have experimented many variants of PSO on the same problem and compared the results.

Considering the studies in the special areas, it is observed that multi-objective optimization methods in the literature are either used in the same way or their variants are applied. The success of algorithms developed in the studies are measured with the comparison of results from many methods applied on the same problem.

One of the biggest problems arisen during the studies is the ignorance of essential solutions for users while finding the pareto optimal front. All these observations bring this question to the mind: Is it possible to develop a multi-objective optimization method that can be applied on optimization problems in each area and provide the maximum performance in the solution? For the answer of this question, it is observed that studies on the performance of multi-objective optimization among the articles are quite important. The outstanding point in these studies is the interaction between application and user. If the future studies focus on increasing the performance and robustness of multi-objective optimization, methods delivering results where most approximate values to the solution are found in the shortest notice and essential solutions for the operators are not ignored can be developed.

Abstract— 802.11 Wi-Fi technology is commonly used for creating wireless access networks with a maximum range of one hundred meters. With careful planning and proper antennas, this same technology can also be used to make point to point links up to several kilometres. Since, it is not always feasible and wise to run cables over long distances to connect different networks, therefore, wireless links may turn out to be cost effective alternative to their counterpart wired links while creating long distance networks and providing network scalability. Wi-Fi-based point to point links can therefore be used to connect two local area network (LAN) segments, which besides being cost-effective, provides network scalability and other advantages such as high speed, centralized and easier management and high throughput for line of sight (LOS) applications. A Wi-Fi-based point to point link can extend the range of wireless LAN by a few hundred feet to few miles which can further be increased by using highly directional antennas for point to point links, while serving as a backup network in different organizations. So, we have designed a soft private branch exchange (PBX) system for a university campus or organization, facilitating voice over internet protocol (VoIP) calls and instant messaging, employing the idea of Wi-Fi based point to point links. Moreover, we have also analysed the quality of service (QoS) of the given setup in terms of data rate and connectivity using bandwidth test and ping test respectively, for both transmission control protocol (TCP) and user datagram protocol (UDP) scenarios.

Keywords— Wireless Point to Point Bridge Link, LAN segments, Soft PBX, VoIP, Instant Messaging, QoS.

1. INTRODUCTION

Many rural regions in developing and developed countries with low user densities do not have good connectivity solutions with a low budget. In low density environments, people are usually clustered around small localities, with large distances among these clusters. The example of such environments is a large enterprise situated in premises, with different departments or buildings at a distance or possibly villages or sub-urban areas. In such cases, traditional options to provide connectivity are not economically viable [1].

Fibre optics can be a very good choice for long distance backbone networks. It provides good reliability but it is not suitable for network scalability. Besides its installation and maintenance costs are quite high. So in case of low density environments and intranet connectivity, they turn out to be expensive and resources are wasted as well. Satellites technologies are very efficient for broadcast traffic, but when it comes to bidirectional internet and intranet access and interactive communications, they tend to be severely limited in throughput and costly. Traditional microwave links can scale in throughput but generally require licensing and hence are expensive to be utilized. Networks with base station model such as Worldwide Interoperability for Microwave Access (WiMAX) and cellular networks like General Packet Radio Service (GPRS) and Code Division Multiple Access (CDMA) consist of expensive base stations, which do not cover enough users in low-density regions and hence lead to the waste of resources [2].

Wireless mesh networks are generally established using the 802.11 Wi-Fi technology and serve to provide internet access in high user density environments. These wireless mesh networks provide full coverage of the region using Omni-directional Access Points (APs) over a range of about one hundred meters. But mesh networks suffer from two major short comings when scaled to larger areas. First, an increase in number of APs in the growing network with Omni-directional antennas leads to increased interference in over-lapping cells. Second, the use of low gain Omni-directional antennas increases the hop length, resulting in a decrease in throughput [2]. Thus, it can be implied that for low density of users, traditional approaches that provide full coverage or require wiring of sites are not feasible. The alternative is to cover only those few places where connectivity is required, by employing long distance wireless point to point links. Such links can be employed using Wi-Fi for low cost and ease of configurability. Hence, the best solution for internet access and intranet communications in low density environments and some organizations is using Wi-Fi in bridge mode providing point to point and point to multipoint links [1].

Wi-Fi-based point to point links have proved to be the cost effective alternative to their counterpart wired networks to provide communication over long distances, especially in rural areas and within an enterprise or premises. Wi-Fi-based point to point links are relatively cheap and provide a number of advantages such as network scalability, high speed, centralized and easier management and high throughput for Line of sight (LOS) applications. Wi-Fi-based point to point links can extend the range of wireless local area network
(WLAN) by a few hundred feet to a few miles, by segmenting it, using highly directional antenna and adequate planning for these point to point links. They can also serve as a backup network in different organizations.

Therefore, in this paper, we propose the idea of Wi-Fi-based point to point links for any type of low density environment with voice over internet protocol (VoIP) and instant messaging services in a soft private branch exchange (PBX) system. We setup a server to enable these applications at one end of the soft PBX system and configure the APs to enable Wi-Fi-based point to point links for providing services at the other end of the soft PBX system. Furthermore, we also analyse the quality of service (QOS) of the given setup in terms of data rate and connectivity using bandwidth test and ping test respectively, for both transmission control protocol (TCP) and user datagram protocol (UDP) scenarios.

The rest of the paper is organized as follows. In Section II, related terminology used in this paper is discussed and Section III puts light on the system model. Section IV explains the soft PBX system and Section V presents observations. Section VI finally concludes the paper.

II. RELATED TERMINOLOGY

A. Wireless Bridges

We use wireless bridges in our system to connect network segments using point to point links. LAN would be flooded with unnecessary traffic if the messages are broadcasted to every destination in that network thus bridges are usually used for the segmentation of LAN and interconnection of LAN segments. A bridge network solution does not necessitate difficult configurations, like IP routing. The bridge network manages LAN segments and creates a single subnet for the entire network. Bridges work at the data link layer of the Open System Interconnection (OSI) model. Bridges learn which addresses are on which network segment and develop a forwarding table so that subsequent messages can be forwarded to the right network segment. Bridges examine the incoming packets and look up the forwarding table for their destination media access control (MAC) address. If the destination MAC address is found in the forwarding table, the packet is forwarded to the corresponding port and if the destination MAC address is not found in the same segment, the bridge restricts the transmission [3].

Wireless bridges are same in functionality and used to connect two LAN segments via a wireless interface such as a radio link, to facilitate connectivity and data transfer between them. Wireless bridges are commonly used to interconnect wired network segments such as an Ethernet network via wireless link. In simple terms a wireless bridge is a device that allows two network segments of users to transparently communicate to one another over long distances without wires. They can be used to connect areas that are geographically apart like a remote building to the main building up to 30 miles, using proper antennas and LOS. Connecting two locations wirelessly through a wireless bridge is much more cost effective than the installation and maintenance of a wired network whether it is fiber optics or copper, for the same purpose. Wireless bridges provide connectivity when it is difficult to wire the sites. Moreover, with wireless bridges, network scalability can be performed very easily by just providing another AP working in the bridge mode at the place of interest [4].

B. Wireless APs

Wireless access points (APs or WAPs) are specially configured nodes on WLANs. These are the network devices used to connect multiple wireless devices to wired LAN, for accessing internet. APs act as a central transmitter and receiver of WLAN radio signals. APs used in home or small business networks are generally small, dedicated hardware devices featuring a built-in network adapter, antenna, and radio transmitter. APs support 802.11 wireless communication standards. Usually, WAPs operate in "root mode", a point to multipoint configuration in which the AP relays frames between many 802.11 stations and an adjacent Ethernet LAN. However, WAPs also have bridging mode that can be configured for connecting LAN segments in point to point link configuration. Wireless bridges relay frames between LAN segments using the same 802.11 wireless communication standards [4].

C. 2.1 FCC Rules for 802.11 Standards

Since, Wi-Fi 802.11 standard operates in an unlicensed Industrial scientific and medical (ISM) band therefore, the signals operating over that band can interfere with each other. So, there are some rules defined by FCC to cope up with it that put some limitations on the power or Effective Isotropic Radiated Power (EIRP) of the signals radiated on this band. These rules are different for 2.4 GHz and 5 GHz operating frequencies of ISM bands as well as for point to point and point to multipoint topologies. In this project, a point to point link is established between LAN segments operating on the 5 GHz band within the limitations defined by FCC, which state that, "For maximum transmitted power of 30dBm, a directional antenna gain of 23dBi can be used with no reduction of transmitter power output in point to point links. However, if directional antenna gain increases greater than 23dBi, a 1dB reduction in peak transmitter power is required for each 1dB increase in antenna gain greater than 23dBi" [5].

D. Fresnel Zone Clearance in Point to Point Links

We use 5 GHz ISM band to establish point to point link in our system that falls in the microwave region of electromagnetic spectrum. Microwave links are generally used for LOS communications as microwaves are highly directional and travel in straight lines. But the energy of microwaves is not pencil thin. They spread out the farther they get from the antenna. The area that the signal spreads out is called Fresnel Zone. If there is an obstacle in the Fresnel zone, part of the radio signal will bent away from
the straight line path which will result in the reduction of the amount of radio frequency (RF) energy reaching the receiving antenna. Fresnel zones can also be viewed as the concentric ellipsoids surrounding the transmitter, receiver and the LOS between them. The first Fresnel zone is the region where the microwave transmission energy is the most intense and it is the closest to the direct line between transmitter and receiver, as shown in Fig. 1.

![Fig. 1 Fresnel Zones](image)

The obstruction in the first Fresnel zone can even lead to link failures. Therefore, the Fresnel zone clearance is the most crucial phenomenon while designing the microwave point to point link. In order to provide a lossless communication via point to point microwave link, the radius of the first Fresnel zone should be 60 per cent clear of any obstruction. This Fresnel zone clearance can be achieved by adjusting the antenna heights at both the transmission and reception ends [6].

E. Devices for Point to Point Link

We use MikroTik SXT 5HnD devices to connect LAN segments with a point to point bridge link. These are low cost, versatile and high speed devices, operating at 5 GHz frequency of ISM band. The devices include many important features such as support for 802.11a/n wireless standard, transmitter power of 26dBm, built-in 16dBi dual chain antenna, 10/100 Ethernet port and others. These devices have their own proprietary wireless protocol, named as Nv2 for use with 802.11 wireless chips. Nv2 protocol is specifically based on Time Division Multiple Access (TDMA) technology for long range point to point links instead of Carrier Sense Multiple Access (CSMA) technology for 802.11 devices. Nv2 protocol in AP enables to control media access by dividing time in fixed size slots. These slots are dynamically allocated in downlink (data sent from AP to clients) and uplink (data sent from clients to AP) portions, based on queue state on AP and clients. Nv2 is different from 802.11 as the media access is scheduled by AP. AP controls that how much time is used by every client and time is assigned to clients according to some policy not according to contention based methods like in 802.11 standards. Also propagation delay is reduced in Nv2 as there are no per frame acknowledgements. Nv2 implements frame aggregation and fragmentation to maximize the assigned media usage and reduce per frame overhead. The devices also include high throughput (HT) to enable the use of MIMO feature of 802.11n standard used in the device. With HT chains 0 and 1 enabled at the transmitter and receiver sides, 2 by 2 antenna diversity and spatial multiplexing can be achieved which significantly increases the throughput of the device. With “HT guard interval” option, the length of guard interval can be adjusted to minimize the inter symbol interference while maintaining the desired throughput [9].

III. SYSTEM MODEL

The point to point microwave bridge link is established to connect the LAN segments in the two buildings that are 1km apart in the campus. For proper transmissions the two antennas should be properly aligned and should have a clear LOS with 60 percent of the Fresnel zone unobstructed. From the site survey, it was observed that there are obstructions between the two departments so the antennas are needed to be mounted at a considerable height to get an unhindered path. The system model in Fig. 2 shows how different devices are connected to establish the point to point link between LAN segments and provide intranet connectivity as well as internet access. The AP at one side of the link is configured as the bridge or AP while on the other side, it acts as the client. The client is connected to a switch/router to which wired device (such as PCs) as well as wireless devices (like laptops, phones) can connect and use the wireless link. The AP at the other end is also connected to a switch/router to which the IP PBX server is attached for VoIP communication and instant messaging. Other wired or wireless devices can also connect to it for intranet communication. The switches/routers transfer the VoIP calls/instant messages within a LAN segment and the APs (configured in AP or bridge mode) transfer the VoIP calls/instant messages to the other LAN segment. Ethernet cables and Power over Ethernet (POE) adapter are used for interface and power.

![Fig. 2 System Model for Wireless Point to Point Bridge link](image)

A. Configuration of Devices

We use two RouterBoard SXT G-5HnD access points to establish the link. One of them is configured as a bridge (AP) and other as a station bridge (client). The devices are graphically configured using Winbox software/ application. After logging into the devices at both AP/client end, both MAC and IP addresses are configured first and then their identities are defined as AP or client.
Wireless point to point link is created at both AP and client by defining different interfaces with address resolution protocol (ARP) enabled. The wireless characteristics of the point to point link such as band, channel width, frequency and wireless protocol are set to be 5 GHz, 20 MHz, 5180 MHz and Nv2 respectively at both AP and client end of the LAN segment. The manual transmit power is set to 30dBm as per FCC rules requirement at the client end. All HT chains are enabled at both AP and client ends to provide MIMO feature and the guard interval is kept 800ns to avoid inter symbol interference and get a more stable link. After setting the wireless point to point link, it is necessary to make bridge configurations at both ends of the LAN segment. At both AP and client side, rapid spanning tree protocol (RSTP) is used to prevent bridging loops and two interfaces are defined, one for the point to point bridge link and the other for connecting to the particular LAN segment. We use Dynamic host configuration protocol (DHCP) to provide automatic IP address to the devices, connected to each LAN segment for soft PBX calls and instant messaging. The configuration is made on AP device that is connected to the soft PBX server. A static IP is defined for the gateway DHCP and the rest of the IP addresses are allocated dynamically from the DHCP pool for a maximum lease time of 3 days.

IV. SOFT PBX

PBX is a telephone switching system owned by a company that manages incoming and outgoing calls for the company’s internal users. Companies lease only one line and have many people using it, with each one having a phone at the desk with different number, called extension. PBX automatically sends incoming calls to the required extensions. A PBX hence can switch calls within the organization and can also connect to the Public switched Telephone Network (PSTN) for calling outside the organization. A conventional PBX can be costly as it requires copper wires and other hardware equipment. Soft PBX (also called IP or virtual PBX) is a telephone system used for the sending voice over the internet protocol (IP) network and is same in application as the conventional PBX but functions differently. It is based on a computer PBX software and voice over internet protocol (VoIP) instead of relying on the traditional telephone hardware and copper circuits. A soft PBX system uses a single network for data traffic and voice calls, both encapsulated in IP packets and then transferred over the network, unlike conventional PBX. The major part of the soft PBX is handled by the software so they are relatively inexpensive. A soft PBX system consists of three components; phones, soft PBX server and an optional VoIP gateway. Phones should capable of supporting VoIP. Soft PBX software installed in PC can serve the purpose of a soft PBX server. VoIP gateways are optional and are used to connect to the external land line PSTN. The users in soft PBX register their session initiation protocol (SIP) address, very much like extensions in conventional PBX, with the soft PBX server, which maintains a database of all its users and their corresponding SIP addresses. The VoIP telephone calls are established modified and terminated using the IP telephony protocol SIP. To make a call, the server is requested to establish a connection. When the called party’s number is dialed, the IP address of the phone is mapped to the corresponding SIP address and then it is sent to the destination. The calls to and from PSTN are routed via VoIP gateway. If the call is to be made outside the soft PBX network, the server directs it to the gateways from where it is sent towards the PSTN. Similarly the calls from PSTN are directed to the server via the gateway and the server then sends them to the appropriate destination [8].

A. For VoIP calls

For VoIP calls, we use Asterisk which is open source soft PBX software that can use both traditional Time Division multiplexing (TDM) technology and packet voice protocols (VoIP and Voice over Frame relay). Asterisk acts as a full featured PBX, supporting virtually all conventional call features on SIP phones like Caller ID, Call waiting, Call forward/busy, Call forward/no answer, Voice mail, Least cost routing, Call conferencing and many more. Asterisk supports three VoIP protocols, two industry standards and one specifically for Asterisk. Inter-Asterisk exchange (IAX) is the de-facto standard for Asterisk networking. The other protocol used by Asterisk is Session initiation Protocol (SIP) which is an Internet Engineering Task Force (IETF) standard for VoIP. The last one is H.323 which is an International Telecommunication Unit (ITU) standard for VoIP. Asterisk provides seamless and transparent translation among so many codecs and file formats such as A-law, u-law, GSM 6.10, MP3, PCM, VOX and LPC-10 [9]. In order to configure soft PBX, we download and install Asterisk10 along with its packages on Ubuntu Linux operating system. SIP file is edited to define SIP clients, codecs used, mailbox addresses and other options. We set different extensions for each SIP client or user under the context of phones and a shared password is used to authenticate each phone. The user reachability checks are performed every 60seconds. Out of all codes available, we use only u-law, A-law and GSM codes in our soft PBX system. Mailbox is used for the voice mail messages such that the voice mails for the user having extension 101 will be saved at 101@default. Dial plan file is created to handle incoming and outgoing calls such that the commands are executed in the following order: when there is a call for some extension, direct the call to that extension. After 20s the called party is asked to leave their message which will be saved at extension@phones. The server is then directed to play an audio file and then hang-up the call. A separate file for voicemail is made with a separate extension such that the called party is directed to the main voice mail system to check the voice mails if there are any.
All files are reloaded after their configuration.

B. For Instant Messaging

Open fire version 3.8.0 server is used in the project to facilitate instant messaging which uses the only widely adopted open protocol for instant messaging; that is Extensible Messaging and Presence Protocol (XMPP) (also called Jabber). Jabber is an open, Extensible Mark-up Language (XML)-based protocol for instant messaging written in Java. Open fire can support Instant Messaging Transports that provides connectivity to external Instant Messaging services such as Yahoo Instant Messaging, Microsoft Network (MSN)/Windows Live Messaging and Google talk Messaging. The server is also compatible with the Asterisk 10 server used for VoIP calls in the system. Concisely, open fire is a freeware open source server that provides instant messaging, broadcast messaging, offline messaging and group chat. Open fire also provides a higher degree of security to the end user as the clients are connected to the server using the Secured Sockets Layer (SSL) secured connection so; the traffic streams in both directions are encrypted. The server also provides a way of authentication to its clients for improved security using a different user ID and password for each client. Whenever a client is registered to the server, the user ID and password for that instant messaging service are stored in encrypted form on the server and are used for client authentication. Open fire is based on the protocol that runs on Java so open fire requires Java Run time Environment (JRE) and Java development Kit (JDK) to operate. Open fire also requires MySQL server to make its user accounts database [10]. Therefore, first the latest versions of Oracle JRE/JDK are installed on the Linux server and then MySQL database server and client packages are installed. When the MySQL server and client packages are installed, the database or user accounts are ready to be set. MySQL has its own user accounts which are not related to the user accounts on the Linux machine for VoIP calls. By default, the root account of MySQL server is empty so, root accounts along with the passwords are defined. A new MySQL database is created for Open fire with a new username and password. After that, Open fire 3.8.0 is downloaded, installed and configured. For the configuration of Open fire, first administrator account is setup with email and password and then the administrator account is used to create users/clients with their corresponding usernames, email addresses and passwords.

V. OBSERVATIONS

Once the point to point bridge link is established and it is working properly, it becomes important to analyze the QOS provided by the link for the VoIP calls and instant messaging services. The key parameters to estimate the QOS of any network are its delay, bandwidth or data rate and packet loss. These parameters are tested one by one over the link to observe the QOS by the link for each service.

A. Bandwidth Test

Bandwidth test is done to get the bandwidth and data rate of the link in both directions that is transmit and receive, at both AP and the client. Bandwidth test also gives the packet loss at an instant when some particular number of packets is sent. Bandwidth test is done in two different scenarios of TCP and UDP as they provide different results in terms of data rate and packet loss. Bandwidth test performed at the AP device gives the results shown in Fig. 3. Results are taken for UDP as well as TCP in both directions when the transmitted and received packet sizes are 1500 bits. The QOS analysis for UDP shows that the data rate at the transmission is 45 Mbps and at the reception is 54.5 Mbps giving the total data rate of about 99.5 Mbps in both directions that can adequately make several voice calls and data transmissions simultaneously. For a packet size of 1500 bits per packet, almost 66,333 packets are transmitted per second in both directions at a bidirectional data rate of 99.5 Mbps, out of which 554 packets are lost at an instant. Therefore, the packet loss is never exceeding 1 percent which is optimum for voice calls and data transmission. For TCP, it can be clearly seen that the packet loss is 0 since TCP is a connection oriented reliable protocol in which each transmitted packet is acknowledged and none of the packet is lost. However, due to multiple acknowledgements, the data rate is significantly reduced to 9.1 Mbps at the transmission side, 24.3 Mbps at the reception side and a total data rate of 39.4 Mbps in both directions. But the data rate is still enough to send multiple voice calls and data files simultaneously. Bandwidth test performed at the client device gives the results presented in Fig. 4. The results for UDP show that the data rate at the transmission side is 61.5 Mbps and at the reception is 32 Mbps, giving a total data rate of 93.5 Mbps in both directions that is optimum for making several voice calls at the same time and the packet loss is seen to be zero even for UDP protocol. The results for TCP protocol at the client side show that the effective data rate is reduced to 25.8 Mbps at the transmission side and 11.3 Mbps at the reception side summing up to a total data rate of 37.1 Mbps in both directions. The packet loss is zero for the same reason of reliability.

B. Ping Test

Ping is an acronym for the word “Packet internet gofer”. Ping works over Internet Control Message (ICMP) protocol that checks for the relative connectivity in the network. So, ping test is performed to check the connectivity of the link and an average delay that it takes for a packet to be sent to a destination and receive a packet in response from the destination. Ping test is performed at both the AP and client devices to check connectivity and delay at both ends. Ping test is performed at AP to check its connectivity with the client. Ping test performed at the AP device gives the results, as depicted in Fig. 5. As seen from the ping statistics of the packets sent and ping replies, it is clear that
the average delay is not exceeding above 7ms that is quite appropriate for making several voice calls and data transmissions simultaneously. The continuity in ping replies also assures the reliability of the link for making voice calls. Ping test at the client is performed to check its connectivity with the AP client and delay in packet transmission and reception. Ping test made at the client device gives the results, as shown in the Fig. 6. The results show that the minimum delay of the link for transmission and reception of packets is 3ms and average delay is 18ms. This delay is a little greater than the delay observed in the ping test performed at the AP device but still satisfies the QOS requirements for voice calls and instant messaging.

![Fig. 3. Bandwidth Test at AP for UDP and TCP](image3)

![Fig. 4. Bandwidth Test at client for UDP and TCP](image4)

VI. CONCLUSION

In this work, we have used wireless point to point bridge link to connect LAN segments located separated 1km apart and provide VoIP and instant messaging service using soft PBX in both LAN segments. Although wireless bridge link operating in an unlicensed band and can suffer from interference and lack of reliability, but these shortcomings can be adjusted with proper planning of the link. Wireless bridge link can offer outstanding advantages such as cost effectiveness, suitable data rate, easier installation, easier trouble shooting and scalability for low density environments.

REFERENCES

Abstract — Detecting the rail surface faults is one of the most important components of railway inspection process which should be performed periodically. Today, the railway inspection process is commonly performed using computer vision. Performing railway inspection based on image processing can lead to false-positive results. The fact that the oil and dust residues occurring on railway surfaces can be detected as an error by the image processing software can lead to loss of time and additional costs in the railway maintenance process.

In this study, a hardware and software architecture are presented to perform railway surface inspection using three-dimensional laser cameras. In addition two-dimensional data that Ccd/cmos cameras have on the x-y plane, laser cameras have three-dimensional input data as they include precise distance information on the z plane. Generally, three-dimensional data acquiring processing is very commonly used in machine vision applications such as mobile robots, image enhancement, medical and fault diagnosis. The use of three-dimensional laser cameras in railway inspection process provides high accuracy rates. The reading rate of laser cameras to read 10,000-30,000 profiles per second is another important advantage provided in real time railway inspection.

Consequently, a computer vision-based approach in which three-dimensional laser cameras that could allow for contactless and fast detection of the railway surface defects such as fracture, scouring and wear with high accuracy are used in the railway inspection process was proposed in the study.

I. INTRODUCTION

In industrial applications, it is necessary to conduct activities such as maintenance, condition monitoring and fault detection as well as production and R & D activities. In recent years, these operations are commonly conducted using computer vision [1]. Computer vision ensures that these operations are conducted fast with high accuracy and without human dependence. Due to all these advantages offered by it, the maintenance, monitoring and fault detection conducted using computer vision are also commonly used in railway rail inspection as in other fields of the industry [2].

Rail transportation systems are widely used all around the world. The anomalies that could occur or are present on railway can lead to both troubles and financial losses and accidents in the transportation system. Therefore, the rail line should be checked periodically [3].

Today, the rail inspection operation is basically divided into two groups as contact and contactless methods. The simplest method of inspecting is that an expert visually inspects the rail line with mechanical measuring instruments. This method is limited by very slow, low accuracy specialized knowledge inspecting the rail line [4]. Another one of the contact methods is performing the rail inspection with ultrasonic devices. Fault detection is conducted by analyzing the data and graphics obtained by the friction of the mechanical device which is moved along the rail line to the railway rail line [4]. The inspection process is slow in this method shown in Fig. 1. Its most important disadvantage is that the mechanical device can increase the existing fault on the rail line or new faults may occur because of the device's necessity of friction to the rail line during inspection.

Although contact methods are low-cost, they have significant disadvantages because they do not have high accuracy ratios and the inspection process is long. Today, rail inspection operation can be performed rapidly as contactless and with high accuracy using computer vision. The general components of a computer vision-based rail inspection operation are seen in Fig. 2 [6].
The long rail inspections can be inspected real-timely in the contactless rail inspection operation that uses the computer vision. The inspection operation consists of the steps of determining the components of the rail line and the deficiency (such as missing traverse and bolt) or anomaly conditions in these components [7-13].

The rail inspection applications in which light source and high resolution cameras are used may lead to the generation of false positive results by detecting the stains formed by oil and dust particles on the rail line as anomaly in addition to high accuracy ratios and real-time operating speeds [8].

When three-dimensional laser cameras are compared with normal cameras, they involve both rgb data and precise distance information on the two-dimensional plane. Because of these features, they are widely used with the aim of finding faults in industrial products including rail inspection [9-12]. Although the cost ratio inspection with 3-d cameras is higher, it is the most advantageous method in terms of accuracy rate and operating speed. The rail inspection methods are comparatively presented with their specific advantages and disadvantages in Table I [4].

A typical rail inspection application running based on computer vision includes the following steps respectively [7].

**Preprocessing:** It includes the steps of preprocessing the camera data that constitute the input of the system for noise removal and similar purposes.

**Feature Extraction:** It includes the processes of obtaining eigenvalue from large-scale camera data by feature extraction methods to operate real-timely.

**Learning:** It includes the step of training the data obtained in the previous step by machine learning algorithms.

**Test:** It includes the step of classifying the new data according to values learned by the system during training and generating diagnostic results during test or real-time inspection.

**Other:** It includes the operations such as the evaluation of other sensor data such as accelerometer, gyroscope and encoder to be used in the system, and recording all data for system confusion matrix extraction.

A study that includes the steps of calibrating the cameras, extracting three-dimensional rail profiles by taking data from cameras, obtaining eigenvalue on these profiles by feature extraction methods, and training and testing of the system by machine learning for a rail inspection application in which 2 three-dimensional laser cameras are used for the left and right surfaces of the rail line is presented in this paper.

II. 3D LASER CAMERAS AND GETTING 3D DATA

The standard cameras operating with sensors such as Ccd and Cmos give two-dimensional image on x-y plane. This image is called as three-dimensional if it includes the depth information on the z plane. The methods of *stereovision, time of flight* and *laser triangulation* are used in obtaining three-dimensional image [14].

Stereo vision technique is the same as the principle of human vision. It is based on the principle of finding the pixel distance by measuring the projections of each pixel on two separate cameras by geometric methods because the distance and angle between cameras are known in imaging which is performed using two separate calibrated cameras. Although it is low cost, the accuracy performances depend on calibration and the sensitivity of camera parameters [15].

Time of flight cameras containing both rgb camera and an infrared sensor get depth information as well as rgb information by measuring the flight time of the infrared waves. They are particularly used in applications such as game consoles, virtual reality and three-dimensional modeling. They have cost effective and low accuracy solutions [14, 15].

Another method used in obtaining three-dimensional image is the use of laser cameras. Laser cameras consist of a calibrated camera, laser line source, light source and encoder as shown in Fig. 3. These components are usually integrated products. The system builds up the three-dimensional profile of the object by benefiting from the profile change in the laser line via constantly taking pictures. The object needs to move in a controlled manner while performing the profiling process in moving objects with laser cameras. How much the object has moved is determined by means of an encoder.
The simple mathematical provision of the process of obtaining three-dimensional profile matrix by reading the rail profile can be given as in (1). “x_{cam}, y_{cam}” gives the coordinate information of the laser camera in the matrix, “x_i, y_i” gives the real coordinate information of the scanned rail surface “p,i” gives the information of the total number of profiles to be read and the sequence information coming from the encoder, respectively. The typical features of 3d-laser cameras by taking the sick presented in the study as a reference are presented in Table II [16].

\[
\sum_{i=1}^{P} p_i = \sum_{i=1}^{P} \sqrt{(x_{cam} - x_i)^2 + (y_{cam} - y_i)^2}
\]

### III. PROPOSED METHOD

The test device and the block diagram of the proposed method conducted for the system are given in Fig. 4.

The proposed system works in four steps. In the first step, a test device that could carry the laser camera and the computer and move on the railway was developed. In the second step, a software providing the calibration of the camera and laser line source constituting the laser camera system was used with the purpose of obtaining three-dimensional profile. In the third step, pre-processing was performed on three-dimensional images obtained from the railway track; and three-dimensional railway profiles were obtained in the fourth step. The obtained three-dimensional railway profiles will constitute the input data of fault diagnosis algorithm.

### IV. EXPERIMENTAL RESULTS

In rail inspection operations conducted using three-dimensional laser cameras, the experimental results include the steps of calibrating the laser cameras and obtaining rail profiles by preprocessing the three-dimensional data obtained from the calibrated cameras. The obtained three-dimensional rail profiles will constitute the input data of the machine learning-based fault diagnosis algorithm.

In the next step, the eigenvalue was obtained on the rail profiles by feature extraction methods, and it was labeled as faulty and healthy to be used in training algorithm. The system was trained by using Random Forest (RF) which is a classification method using multiple decision trees [17].

It is one of the most suitable classification algorithms to be used in fault diagnosis since it functions rapidly even in large data sets, provides good results on lost data and generates high accuracy results.
The trained system was tested by measuring the operating speed and accuracy performance on a rail line for a short time in the test phase. A total of 400 rail profiles were collected on a 1 km-long rail line by the proposed system, and these profiles were trained by labeling as healthy and faulty. 75% of the dataset was used in training. The remaining 25% was used for testing purposes. 98% accuracy rate was achieved in the test phase. The receiver operating characteristic (ROC) analysis was used to obtain the accuracy performance values shown in detecting the "faulty" frames containing system anomalies and the "healthy" frames having no anomalies [18]. The roc curve obtained by the proposed method is given in Fig. 6.

V. CONCLUSIONS

Rail transportation systems are widely used around the world. The rail lines should be inspected periodically and their maintenance should also be performed to ensure the railway transportation safety. Today, this inspection process is commonly carried out using CVS. In this study, the software architecture is presented for a rail inspection conducted using 3-D laser cameras.

In general, there are three criteria expected from a rail inspection application. These are the high accuracy results, high operating speed and the cost of the system. 3-d laser cameras allow for obtaining higher accuracy rate in rail inspection because they include both RGB data and precise distance information that two-dimensional cameras have. When they are compared with normal cameras, their another advantage is that they are more susceptible to false positive result situations in oil and dust stains caused by image processing algorithms because they use distance information.

The second criterion expected in rail inspection applications is the high operating speed. Today, laser cameras are suitable for real-time operation on a real transportation device by their profile generation speed of 10,000-35,000 per second. The third success criterion expected in rail inspection applications is the cost of the system. High speed and accuracy rates can be obtained in applications using 3-d laser cameras, but their costs are higher. It is thought that this disadvantage is eliminated by their other advantages.

Abstract—In this study, three different apple varieties grown in Karaman province are classified using kNN and MLP algorithms. 90 apples in total, 30 Golden Delicious, 30 Granny Smith and 30 Starking Delicious have been used in the study. DFK 23U445 USB 3.0 (with Fujinon C Mount Lens) industrial camera has been used to capture apple images. 4 size properties (diameter, area, perimeter and fullness) and 3 color properties (red, green, blue) have been decided using image processing techniques through analysing each apple image. A data set which contains 7 physical features for each apple has been obtained. Classification success rates and error rates have been decided changing the neuron numbers in the hidden layers in the classification made using MLP model and in different neighbour values in the classification made using kNN algorithm. It is seen that the classification using MLP model is much higher. While the success rate of classification made according to apple type is 98.8889%.

Keywords—Image processing, Apple classification, kNN, MLP

I. INTRODUCTION

Apple production is an important economic activity in Karaman. The dominant apple varieties produced in Karaman, are Golden Delicious, Granny Smith and Starking Delicious. During marketing these apples, the product is wanted to be consisted of just one species of apples. The mixture rate of other apple varieties in the product is wanted to be at minimum level. For this purpose many selection system have been proposed in the literature.

He Yong et al. (2007) have evaluated the potential of visible/near-infrared (Vis/NIR) spectroscopy for its ability to non-destructively differentiate apple varieties. The chemo metrics procedures applied to the Vis/NIR data were principal component analysis (PCA), wavelet transform (WT), and artificial neural network (ANN). The highest level of correct classification (100%) of the apple varieties have been achieved with WT-ANN model [1].

Ronald et al. (2016) have proposed to investigate the applicability and performance of Naive Bayes algorithm in the classification of apple fruit varieties. Apple classification system prototype was built using MATLAB R2015a development platform environment. The results showed that the averaged values of the estimated accuracy, sensitivity, precision and specificity were 91%, 77%, 100% and 80% respectively [2].

Wu et al. (2016) proposed a novel fuzzy clustering model, called fuzzy discriminant c-means (FDCM) clustering, to classify apple varieties couple with near infrared spectroscopy. The 200 apple samples of four apple varieties were made experiments to collect the near infrared reflectance (NIR) spectra. The clustering accuracy of FDCM achieved 97% which was higher than FCM, possibilistic c-means and Gustafson–Kessel (GK) clustering [3].

Shahin et al. (2013) have proposed to detect bruises in apples by using line-scan x-ray imaging method. Spatial and transform features were evaluated for their discriminating contributions to fruit classification based on bruise defects. Red delicious (RD) and golden delicious (GD) apples have been used in this study. Separate artificial neural network (ANN) classifiers were developed for old (one month) and new (24 hour) bruises. When an ANN classifier was used to sort apples based on old bruises, it achieved an accuracy of 90% for RD apples and 83% (93% after threshold adjustment) for GD apples. For new bruises, the accuracy was approximately 60% for both RD and GD apples. New bruises were not adequately separated using this methodology [4].

In this study, 90 apples grown in Karaman have been used. 7 morphological attributes have been obtained from their images by using image processing techniques. The apples have been classified into 3 group (Golden Delicious, Granny Smith and Starking Delicious) with kNN and MLP algorithms by using the obtained attributes.

II. MATERIALS AND METHODS

An interface presented in Figure 1, have been designed by using GUIDE (Graphical User Interface Design) in MATLAB. The image of the apple under the camera is taken when the Take Button pressed on the GUI.

The mean of R (red), G (green) and B (blue) pixel values of the area where the apple is in the image have been calculated. These values have been used for classification of the apples for their colors. Then the colored images have been converted to grey level image by using image processing techniques. Morphological operations have been applied onto bitwise images. The image processing steps have been presented in Figure 2.

Figure 2.
Fig. 1 Graphical user interface designed in MATLAB GUIDE.

Fig. 2 The image processing steps

The physical properties of the apple like radius, perimeter, area, volume, mass and eccentricity have been extracted. So that creates 7 attributes by gathering 4 morphologic and 3 colour.

A. Software-WEKA

Developed by Waikato University in New Zealand, WEKA is an open-source data mining software with a functional graphical interface which incorporates machine learning algorithms [5]. WEKA includes various data pre-processing, classification, regression, clustering, association rules, and visualization tools. The algorithms can be applied on the data cluster either directly or by calling via Java code [6,7]. They are also suitable for developing new machine learning algorithms.

1) Multilayer Perceptron: It is a feed forward type artificial neural network model which maps input sets onto appropriate output sets. A multilayer perceptron (MLP) is composed of multiple layers of nodes where each layer is connected to the next. Each node is a processing element or a neuron that has a nonlinear activation function except the input nodes. It uses a supervised learning technique named back propagation and it is used for training the network. The alteration of the standard linear perceptron, MLP is capable of distinguishing data which are not linearly separable [7].

2) K-Nearest Neighbour Algorithm: The k-NN is a supervised learning algorithm that solves classification problems. Classification is the examination of the attributes of an image and the designation of this image to a predefined class. The important point is the determination of the features of each category in advance [8]. According to the kNN algorithm used in the classification, based on the attributes drawn from the classification stage, the distance of the new individual that is wanted to be classified to all previous individuals is considered and the nearest k class is used. As a result of this process, test data belongs to the k-nearest neighbour category that has more members in a certain class. The most important optimization problems in the kNN method are the identification of the number of neighbours and the method of distance calculation algorithm. In the study, the identification of the optimum k number is performed with experiments, and the Euclidean Distance Calculations method is used as a distance calculation method. Euclidean calculation method [9]:

International Conference on Advanced Technology & Sciences (ICAT’16) September 01-03, 2016 Konya-Turkey
xi and xj are two different points, and we need distance calculation process in between.

In classification procedure, inputs are diameter, perimeter, area, fullness, mean red, mean green and mean blue values. The outputs are Golden Delicious, Granny Smith and Starking Delicious. The whole classification system have been presented in Figure 3.

![Block Diagram of Classification Process](image)

**Fig. 3 The block diagram of the classification process**

### III. RESULTS AND DISCUSSION

In the study, WEKA software was used in order to classify apples by species (Golden Delicious, Granny Smith and Starking Delicious). Using the kNN algorithm, the classification success rates, mean absolute error (MAE) and root mean square error (RMSE) were obtained for various k-neighbour values. The classification success rates obtained with kNN algorithm, and MAE and RMSE values can be seen in Table 1. The success rate change versus number of neighbours for kNN method is presented in Figure 4.

The diagram demonstrating the changes in classification success rate based on the number of neuron in the hidden layer is demonstrated in Figure 5.

The model of MLP whose hidden layer consists of 5 neurons which creates the highest classification success rate is shown in Figure 6.

IV. CONCLUSIONS

In this study, classification of apples as Golden Delicious, Granny Smith and Starking Delicious have been proposed by using machine learning algorithms. The classification success rates and error values of data mining algorithms were calculated for kNN and MLP. It was observed that the success rate was higher for the classifications performed using the MLP algorithm. The highest classification success rate was achieved when the number of neighborhood was 3 and the success rate was 97.7778 %. The MAE and RMSE error value were 0.0364 and 0.1283 respectively. For the classification success rates obtained using MLP algorithm, the highest classification success rate and minimum MAE error value was achieved for 5 neurons in the hidden layer and it was 98.8889%. For this MLP structure, the MAE and RMSE error values were 0.1698 and 0.2225 respectively.

Role of Ethics in Information Security

Tuğç Aşuroğlu, Cemal Gemci
Computer Engineering Department, Başkent University
Ankara, Turkey
{tuncasuroglu, cgemci}@baskent.edu.tr

Abstract—Information is power. Nowadays, main concern of cyber community is to protect this valuable asset. Technical and technological security measures are sometimes insufficient to protect an information system. Because there is a human factor in information system. Ethics are set of moral rules that guide people. With the help of ethics a better and robust security can be achieved. In this paper role of ethics in information security is discussed. First of all law, ethics and information security concepts are briefly introduced. Later, some ethical concerns and perspectives in information security are given. To emphasize role of ethics in information security, several studies are reviewed. Finally, mechanisms to make ethical rules effective in an organization/community are discussed with several case studies.

Keywords— Ethics, Ethical Issues, Information Security, Cyber Security, Information Systems.

I. INTRODUCTION

With the advance of Information Technology, new threats and unauthorized actions arise each day. To be able to protect information assets against these threats and actions is one of the most important issues nowadays. But sometimes technical and technological measures are not enough to protect an information system. One of these parameters is people. These people can be system administrators, security professionals, employees and users. These are the people that interact with information system. In order to secure people parameter in an information system, a measure that employs moral judgment must be introduced. Computer and information ethics are studied by many researchers, scholars and practitioners [1]. To include ethical layer to information security is very important because it can fill the gap that people create.

In this paper role of ethics in information security is discussed. First of all law, ethics and information security concepts are briefly introduced. Some ethical concerns and perspectives of several researchers in information security are given. To emphasize role of ethics in information security, several studies are reviewed. Mechanisms to make ethical rules effective in an organization/community are discussed. Finally, paper finishes with conclusions and references.

II. LAW & ETHICS

Laws are a form rules that prevent certain behavior and actions happen. They are created from ethical structures. The major difference between law and ethics is: law needs an authority to process and ethics don’t [2]. Ethical behavior comes from individual’s conscience. Ethics are defined in the light of a group’s cultural customs. But as in laws it’s different, many laws are universal across the world.

Laws are the rules that all of the people must oblige to follow. If they don’t follow, they will be punished. That’s not the case in ethics; in ethics all people have their own will. They can choose to follow or not follow code of ethics. In ethics, it depends on a moral decision, many people agree upon ethical behaviors but some people can disagree on these.

Ethics can be seen from different approaches. These approaches are consequentialism and deontological [3]. Consequentialism claims that if actions have bad consequences they are bad after all. Deontological approaches don’t think like that. They assume that actions of people have neither good nor bad consequences they have only moral duties independent of their actions.

There exists a blurrieness of ethics in individual’s mind but with the help of the laws and regulations security and safety can be achieved. In a cyber world, law and ethics work together to form a security layer. Ethics can fill the void where laws cannot be applied.

III. INFORMATION SECURITY

Rapid growing of information technology enables many organizations, government and civilians exchange important information every day. So security issues arise when sharing information [4]. Nowadays relationship of organizations depends on computer and information systems, many organizations are concerned about information security because they use technologies like e-commerce, mobile and virtual private networks. With the increase of involvement of these technologies, number of threats to organization’s valuable assets also increases [4]. Information security protects confidentiality, integrity, and availability of information assets against various threats. Technical protection measures are not enough to provide information security. There must be other measures. To develop a robust and good information security; in addition to technical measures; operational, ethical, sociological and legal measures must be considered [5].

Organizations depend on processes, technology and people. Even if we have top of the line information systems and security, there are people operating these information systems [4]. They control daily activities and thus the entire information system. They need to have moral and ethical conducts, if they don’t have these conducts they will make information system vulnerable to threats. There is no efficient technical protection of information security because people are involved [4]. People are critical on ensuring a robust
There are different ethical views in information security. Researchers proposed several models to achieve better information security.

Hartmann [8] stated that security levels couldn’t consist of only a technical layer. It consists of technical, technological, organizational, legal, social and ecological levels. In addition to these levels Hartmann suggests ethical scope must be included in information security. The researcher also suggests that ethics is a so large question that developers, users and system admins cannot answer separately. Entire community should answer this question by discussing together. So Hartmann suggests that ethics should span an entire community and ethical rules should be prepared with a mixture of individuals from different areas.

Another ethical view in information security is proposed by Kowalski [9]. Kowalski stated several ethical problems and also stated that information security is threatened if these problems occur in information technology systems. These problems are as follows:

- There is a control gap in information systems and it is getting wider with every new technology. This control gap can cause problems in retaining security in information systems.
- Ethics must be a common language among individuals from different expertise. Ethics should also understandable by individuals from other communities besides computer society.
- Nowadays information systems are getting so large that it is getting harder to manage with only technological control mechanisms. So control mechanisms should be built on individuals control mechanism that can be achieved by ethical frameworks.

If these problems don’t answered right there can be an opening that leads to information security issues.

As seen from given perspectives complete security of information can only be achieved by the help of ethics and ethical frameworks.

VI. FRAMEWORKS FOR ESTABLISHING AN ETHICAL BASELINE IN DIFFERENT ENVIRONMENTS

Many researchers stated that information security is lacking without an ethical concept. So in order to establish a better security, they proposed frameworks that include ethical principles. These frameworks exist in many information environments like biomedical, e-banking and health and etc. Example frameworks will be discussed in this chapter to emphasize the importance of ethical principles in information security.

France [10] discussed ethical violations in biomedical area that leads to violation of patient privacy and medical records. He also stated some ethical codes and suggestions to overcome this security issue. These ethical codes include doctor and hospital staff jurisdictions, patient record storage, etc.

Abreu and co-workers [11] discusses fraud (phishing) in e-banking services. They point out several threats, vulnerabilities, incidents and impact of threats on e-banking services. Researchers suggested ethical rules and trainings on clients and bank personnel to overcome frauds in e-banking services. They also stated that Public discussion on incidents will develop awareness and creates a security behavior among e-banking service users.

Kluge [12] developed a code of ethics for health information professionals. He discussed several problems in health informatics domain and proposed code of ethics for several information security problems. He suggested that in addition to technical security layer in a health information system there must be an ethical layer that protects privacy of patients. He created this ethical layer on health information professionals.

VII. MAKING ETHICAL RULES EFFECTIVE IN COMMUNITY

Making ethical rules effective in a community plays an important role in security of information. Being able to give
individuals a set of ethical rules to follow and provide an awareness of ethics will surely establish a better security layer in organizations. To provide a better and robust security of information, there are two ways: Developing a code of conduct/ethics and provide trainings to individuals so they can gain awareness in security and ethics.

A. Code of Conduct

Nowadays many organizations and communities develop code of conduct for its members to follow [13], [14]. Without the development of these codes information security will have gaps because of laws couldn’t fill some gaps and ethics can. For example; in order to fill these gaps, computer ethics institute developed Ten Commandments of Computer Ethics [15]:

1. Thou Shalt Not Use A Computer To Harm Other People.
2. Thou Shalt Not Interfere With Other People’s Computer Work.
3. Thou Shalt Not Snoop Around In Other People’s Computer Files.
5. Thou Shalt Not Use A Computer To Bear False Witness.
6. Thou Shalt Not Copy or Use Proprietary Software for Which You have Not Paid.
7. Thou Shalt Not Use Other People’s Computer Resources without Authorization or Proper Compensation.
8. Thou Shalt Not Appropriate Other People’s Intellectual Output.
9. Thou Shalt Think About The Social Consequences Of The Program You Are Writing Or The System You Are Designing.
10. Thou Shalt Always Use A Computer In Ways That Insure Consideration And Respect For Your Fellow Humans.

This code of ethics guides individuals when interacting with an information system. Code of ethics is applied to all of the members in an information system including system administrators, developers, users and security professionals. Instead of applying general code of ethics, organizations can develop their own code of conduct. In our opinion this can be prove to be most effective because to target and fill specific gaps in information security, specific ethical codes must be defined. But in order to make users abide code of ethics and to a standard there is a need for collaborative effort [16]. Awareness training helps to establish this collaborative effort.

B. Awareness Training

Awareness training and security training takes a major part in establishing security. In order to provide security there must be awareness among individuals. This awareness spans to a large definition including; ethics, threats and how to deal with them, security incidents and so on.

Awareness training must provide an appropriate security and ethics behavior to all individual in an organization in order to full commitment to security policies [17]. There are some research that focuses on awareness training and how it is effective in providing security. Stephanou and Dadaga [17] have asked the question “to what extent does information security awareness training influence information security behavior?” and they discuss existing awareness training research and proposed a model to examine the impact of training on security behavior among individuals.

Aliyu and co-workers [18] conducted a study that inspects security and ethics behavior among students. They conducted several experiments among students to find out that is awareness actually affects security. The experiments showed that the awareness training created a conscience of security among students. Because of security awareness trainings and ethics courses students are more aware of security concerns and ethics than the students who receive no training.

So according to these studies that we mentioned above, we can say that awareness training actually can affect the security behavior of individuals. Also they are crucial in making ethical rules effective in community. Because this training also gives a conscience of ethics to individuals and in our opinion is crucial to establish information security.

VIII. CONCLUSIONS

Ethics play an important role in our lives and also in cyber technology domain. Ethics fill gaps in an information system that laws can’t be able to fill. In this paper the importance of ethical principles in information security has discussed. Different ethical perspectives in literature are inspected to show how ethical layer can be built on security layer. Also in this paper, to provide a solid proof that ethics complete information security, several ethical frameworks are inspected. Finally, methods to make ethical rules effective in a community are given. Several examined studies showed that awareness training and code of conducts are effective in this manner.

Abstract— The process for obtaining information that will create value on a large-scale data stack is called data mining by its general name. Data mining is commonly used in sales and marketing departments, in determining strategies and making critical decisions for the future in many sectors. Similarly, data mining is used in the determination of health policies, more effective implementation of health services and in the management of resources and institutions in the health sector.

In this study, it was aimed to create a software architecture of data mining that will help the personal monitoring of the pregnancy process in a more effective way in the health sector. Many different types of data such as age, gender, location, education, physical characteristics, lifestyle habits and medical history of the people that could be used for this purpose are stored online by health institutions. The machine learning algorithms have been created to determine classification, clustering and association rule on these data.

Keywords— Data Mining, Knowledge Mining, Health Monitoring, Classification, Clustering, Machine Learning, Association Rule

I. INTRODUCTION

The data generated by the computer systems do not make a sense by themselves, and their conventional analysis by human intervention is also impossible. Today, the diversity of data generated in fields such as stock market, trade, education, communication and e-commerce in addition to the fact that these data are large by volume and continue to increase are the main reasons of this.

In today's world, obtaining valuable information by interpreting these data by means of intelligent algorithms is called data mining. In other words, data mining is the discovery and interpretation of the significant relationships through computer programs that could be effective in providing future predictions from among large data stacks [1, 2].

Data mining has a great importance in many aspects from sales strategy of businesses to determination of Research and Development activities.

The analysis and interpretation of large-scale data and uncovering the relationships between data are difficult and long processes by human labour and talent. Today, performing knowledge retrieval using data mining is commonly used in many fields such as marketing, banking, stock market, communication systems, education, health and engineering.

In the marketing field, an attempt to bring out user patterns using data mining was made by Ünal et al. in order to determine the customer portfolio and to describe the user's shopping behaviors by using data of an internet retailer [3].

In the banking field, Tosun et al. tried to determine the customer losses and the reasons of the losses by constructing the profile of the 30,000 customers of Yapı Kredi Bank [4].

Between the years 2007-2013, Ocal et al. used data mining to make a qualitative classification according to the financial success or failure of the companies and the capacity situations of the companies by using the data of Borsa İstanbul [5].

A large telecommunication company's customers who showed a tendency to leave were determined by Gürsoy in 2010, and new campaigns for these customers and marketing strategies for the customer profile were developed by classification method [6].

In the research carried out by Gülen at al. on gifted children aged 7 years and older in Ankara science and art center, the education for the children's individual needs was differentiated through educational data mining and the course schedules were organized according to children's field of interest [7].

In the engineering field, Kaya et al. compared the open source data mining softwares Keel, Knime, Orange, R, RapidMiner (Yale) and Weka. In the study, which data mining method and which software would be more effective on which data set was investigated [8].

Tantuğ et al. examined the techniques used in data mining and especially investigated the clustering techniques. An efficient software architecture to reduce memory complexity was designed in the study. An efficient system with a lower complexity capable of clustering on large-scale data was developed by the software architecture designed [9].
The healthcare field is among the extensive areas of usage of data mining. Ertuğrul et al. constructed the patient profiles by processing and using the data in the patient information management system of Pamukkale University Hospital. Based on the patient profile information, healthcare professionals established a decision support system to provide taking most objective and effective decisions about the patient by reaching up-to-date information about the patient [10].

İrmak et al. processed the patients' information in the database of a hospital continuing to provide services via data mining techniques and developed an application for estimating the patient density of the hospital in the future [11].

By descending to particulars, in the applications in the field of health, Yıldız et al. developed an application that classifies the breast cancer types by using gene algorithm and data mining about breast cancer [12].

In this study, it was aimed to build software architecture of data mining for the effective personal follow-up of women during their pregnancy period.

Many different types of data such as the age, gender, location, education, physical characteristics, lifestyle habits and medical history of the pregnant could be collected and processed with data mining techniques.

Thus, the control frequency could be determined according to the personalized care, nutrition content, situations that require education and risk status during pregnancy by the expectant mothers' data interpreted. Consequently, an approach that uses data mining in following the pregnancy process was proposed in the study.

II. DATA MINING

As a general definition, data mining is the process of mining information by reaching the information from among large-scale data. With another definition, it is to search for the connections that could allow us to make predictions for the future from among the large-scale data stacks using computer programs [13].

In almost every stages of our life, electronic recording systems such as mobile phones, sensors and computers provide convenience for recording and storing information and reaching them where necessary along with the technological developments. To be able to make sense out of these data which are rapidly increasing by volume, to establish relationships by them and to finalize data by a decision or conclusion have led researchers to carry out much more investigations in the field of data mining.

Several processes and some techniques are used while performing data mining studies independently of the problem [13, 14]. These processes involve the use of data cleaning, data integration, data reduction, data conversion and data mining algorithms and ultimately the interpretation of the obtained results and the steps of verifying these results, respectively [15].

In general, the steps of retrieving significant knowledge on a purpose-specific data set are presented in Fig. 1. Data mining processes consisting of six steps are presented in Table I.

![Fig. 1 Data mining process](image)

<table>
<thead>

<tr>
<td>Application of Data Mining Algorithms</td>
<td>It includes the processes of applying machine learning algorithms on data which were made ready through the above processes for classification, clustering or determining the association rule.</td>
</tr>
<tr>
<td>Interpretation and Verification</td>
<td>The data on which algorithm was applied are verified by bringing out certain significance relationships.</td>
</tr>
</tbody>
</table>

There are three main methods of data mining to make interpretation and verification [15, 16]. These methods are called as classification, clustering and determining the association rule,

1) Classification: It is one of the fields where data mining is commonly used. People often adopt this method because they always classify, categorize or grade the data. Rules are determined by keeping some of the data found in the database separate for education, and how to decide when a new situation arises is determined by this rule.

2) Clustering: It is the process of grouping data by taking into account the similarities between them. By this method,
clusters and sub-clusters are generated based on the similarities and differences between variabilities.

3) Determining the Association Rule: It is a data mining method which is applied on the possibility of which situations can occur simultaneously by identifying the relationships of the data included in the database with each other.

III. PROPOSED METHOD

In this study, expectant mothers’ information shown in Fig. 2 were used and the process of knowledge retrieval was performed using data mining on these data.

The software architecture of the proposed method, the block diagram of which is given in Fig. 2, works in four stages. In the first step, a no-sql based database was created for storing data. In the second step, preprocessing was performed to extract information on data set. In the third step, classification, clustering and association rule were identified by running three separate data extraction algorithms. In the fourth and final step, estimation on new data, identifying the cluster to which it belongs and the process of finding the other data to which it is related were performed.

In the study, expectant mothers’ information shown in Fig. 2 were used and the process of knowledge retrieval was performed using data mining on these data. The sample training set, main data types and the normalization of the data type into a certain range if necessary are given in Table II.

All values shown in Table II were converted to integer numbers by normalization, if needed, depending on the primary data types. The values of the sets obtained after normalization constituted the input data of the training algorithm. According to what some values are normalized is explained as follows.

- Body mass index: It is a value calculated based on height and weight, and it is divided into 3 groups in practice [17].
- Age: It is normalized to 3 different groups by considering the fertility criteria [17].
- Disease: Whether the person has a disease is discussed as a Boolean value.
- Pregnancy History: It includes the statistics of the person’s pregnancy history, if available. They are numerical data such as the number of children if she had a baby, whether the previous pregnancies were concluded with healthy results, cesarean and the number of normal delivery.

Matlab and python (scikit library) are mostly used for data mining studies in computer environment. In addition to these, there are also various tools which are free and open source and also include sample data-sets [8, 19]. However, a data-set was generated in a synthetic dataset matlab environment in accordance with Table II because there was not any dataset specific to this study, and it was saved in json format as no-sql based.

In the sample application scenario, random forest for classification and k-means for clustering were used [18]. The target class labels chosen for classification in the training algorithm were identified as “healthy pregnancy” and “risky pregnancy”. In the test phase, the results were analyzed by achieving classification accuracy according to “1” based on the confusion matrix given in Table III.
Accuray = \frac{TP + TN}{N} \quad (1)

IV. EXPERIMENTAL RESULTS

In the study, classification was performed on the synthetic dataset generated in a Matlab environment by random forest method. 75% of the dataset was used in training. The remaining 25% was used for testing purposes, and the results were compared on confusion matrix by comparing with actual values. The classification accuracy performance was above 80% in the scenario chosen for the sample classification application.

V. CONCLUSIONS AND FUTURE WORK

Today, data mining is commonly used with the purpose of obtaining valuable information in fields such as banking, education, sales, stock market and health. The information obtained as a result of data mining are effective in making strategic decisions.

In this study, it was aimed to perform pregnancy follow-up process using data mining in the follow-up process of pregnancy and retrieve information related to this process. Thanks to the proposed method, it was aimed to use these information in the pregnancy periods of new expectant mothers. The classification application was performed by creating a sample scenario for the study.

In addition to the study, it is aimed to create other similar scenarios in the future and make comparison with other open source tools used for performing data mining.

Abstract — Nowadays, extending the lifetime of WSNs through energy efficient mechanisms has become a challenging research area. Previous studies have shown that instead of implementing direct transmission or multi-hop routing, clustering is a kind of fundamental technique used to decrease energy consumption. Clustering can increase the scalability, decrease the energy consumption and prolong the lifetime of the network. In literature, LEACH and its variants aim to use clustering mechanisms to provide energy-efficiency. However, most of the LEACH variants aim to form clusters in each round by changing CHs randomly. These formations cause to consume large amount of energy and bring additional network costs. Also, in some rounds of LEACH variants none cluster formations may occur because of the probabilistic CH selection process of these protocols. In this paper, an energy-efficient random selected constant clustering approach is proposed to solve the problems of LEACH based protocols. The proposed approach uses constant clusters which are formed only once at the beginning of the algorithm. The formed clusters remain fixed until all nodes are dead in the network. Proposed approach aims to select CHs in each cluster randomly without changing the cluster formations. It aims to reduce cluster formation packet overhead in the network. In addition, proposed approach aims to provide energy-efficiency by using fixed clustering. The results of the simulations show that, constant clustering approach saves extra energy and prolongs lifetime of the WSN when compared to LEACH and ModLEACH.

Keywords— Energy Efficient Routing, Fixed Clustering, Wireless Sensor Networks.

I. INTRODUCTION

A WSN contains sensor nodes and corresponding protocols for routing messages in this network. A typical wireless sensor node includes a sensory unit, a communication unit, a power unit and a processing unit. Sensory unit consists of a data acquisition component and ADC (converts the sensed real world data to the digital form). Communication unit has a radio transceiver and the power is backed by a battery source. The WSN node can be equipped with a limited power source (0.5 Ah, 1.2 V). The node remains active as long as the battery is alive and hence power saving is a crucial criterion in this domain of applications. Energy consumption happens in three domains: sensing, data processing and communications. The sensing, signal processing parts operate at low sequential and consume less than 1mW. This is over an order of extent less than the energy consumption of the communication part.

The traditional infrastructure based protocols cannot be used for WSNs because of the limited storage and power of the sensor nodes. Because WSNs often use broadcast based radio communication.

Limited energy availability in sensor nodes makes network lifetime an important issue in WSN applications. To extend the network lifetime, energy efficient wireless sensor network protocols and algorithms have been devised in the literature. Node clustering, in-network data processing, data fusion and network coding are some of the measures taken to reduce the amount of data that is processed, sensed or transmitted. Minimization of energy spent in processing, sensing and transmission of data allows sensor nodes to save energy. Such energy savings help to extend the lifetime of WSN applications.

The main goal of cluster-based routing protocol is to efficiently maintain the energy consumption of sensor nodes by involving them in multi-hop communication within a cluster and by performing data fusion in order to decrease the number of transmitted packets to the base station (BS) and transmission distance of sensor nodes.

Low energy adaptive clustering hierarchy (LEACH) [1-2] is one of the most popular distributed cluster-based routing protocols in WSNs. LEACH randomly selects a few nodes as CHs which aggregate data arriving from nodes and forward the aggregated data to BS and rotates this role to balance the energy consumption of the sensor nodes in the network.

In LEACH protocol, the time is divided into parts called a round. Each round consists of two phases. The first phase is setup phase which is the phase of node formation. The second phase is related to the normal function of the network and is called the Steady-State phase. In the first phase, the CHs are elected based on a probability function. This election is as follows: each sensor node selects itself to be CH at any given time with a certain probability. Any node in the network chooses a random number between 0 and 1. Then this number is compared with threshold limit, if the number is less than a threshold, the node becomes a CH for the current round. This probability function is designed in such a way that within a specific number of rounds each sensor becomes a CH only once and thus the energy consumption is distributed over the whole network. After the set up phase of the round, where the CHs are elected, each CH announces its election to other nodes and each node chooses a suitable (nearest) CH for itself; and then it announces this decision to the related CH and thus the clusters are formed and the network comes into the steady-state
operation i.e data transmission. Then each CH creates a TDMA schedule in each cluster to organize the communication among cluster members. When the non CH nodes receive the TDMA scheme, nodes send their data to the CH once per frame during their allocated transmission TDMA slots. This allows the radio components of each non-cluster-head node to put the sleep mode at all times except during its transmit time, thus minimizing the energy dissipated in the individual sensors. After a certain amount of frames i.e. a TDMA round, the network re-elects CHs and re-form clusters. Then CH, after combining all the received data, will send the results to the BS. Besides, to prevent the interaction of the transmissions which occur in clusters at the same time, LEACH uses different CDMA codes. Existing CH chooses randomly a unique code from a list of spreading codes. The CH filters all received energy using this spreading code. Consequently, the radio signals of the neighbouring nodes are filtered out hence interference of the transmission of the nodes is minimized.

In some studies, authors have tried to improve the performance of LEACH. They have designed some protocols which made extensions to LEACH.

Modified LEACH (ModLEACH) [3] includes an efficient CH replacement scheme and dual transmitting power levels. The amplification energy is set to be the same for all kinds of transmissions in LEACH. But with ModLEACH, low energy level is used for intra cluster communications. Multi power levels are used to reduce the packet drop ratio, collisions and interference from other signals. When a node becomes a CH, the routing protocol in ModLEACH informs it to use high power amplification and when a node becomes a regular cluster member, the mode of that node becomes low level power amplification mode. Threshold based CH changing mechanism is used in ModLEACH to provide more efficient CH replacement. If the energy of the existing CH is higher than the threshold it continues to act as a CH if not a new CH for that cluster is elected and the cluster is formed again. Simulations of ModLEACH show that, ModLEACH outperforms LEACH in terms of throughput, network lifetime and CH formation.

In this paper, Energy Efficient Random Selected Constant Clustering Approach (EERCCA) is presented. It aims to use fixed clustering approach. It determines CHs randomly at the beginning of the algorithm. The formed clusters remain constant until the batteries of all sensor nodes are drained. In each round, the CHs are changed randomly but the clusters remain fixed. EERCCA aims to solve the network cost issues which occur in new cluster formations of LEACH based protocols. The performance of EERCCA algorithm is compared with LEACH and ModLEACH in terms of lifetime, residual energy and throughput.

II. EERCCA ALGORITHM

At the beginning of EERCCA algorithm, the sensor nodes are randomly deployed in a field as shown in Fig. 1. EERCCA algorithm starts with the CH selection process. The CHs are selected randomly at the beginning of the algorithm. The clusters are formed only once in the clustering phase. The fixed clustering approach of EERCCA provides to decrease the networking and set-up costs of LEACH based protocols. The nodes in the network are static, thus transmission of position information is realized only once.

When the CHs are selected, they broadcast CH notification messages to the WSN. Each cluster member joins nearest cluster. After this joining process, the clusters are formed. In each cluster, CH is responsible for receiving data from its members. When data collection is completed, each CH delivers collected data to the BS which is placed outside of the sensor field. In EERCCA, each CH node selects randomly new CH node from alive members in the cluster for every round. After this selection, new elected CH starts to collect data from cluster members. Then this new selected CH transmits the collected data to the BS.

III. SIMULATION ENVIRONMENT AND PARAMETERS

The simulations are conducted in MATLAB. 100 sensor nodes are randomly deployed in a 100 m x 100 m field as shown in Fig. 1 and BS is placed outside of the sensor field which have coordinates of (150,50). Same simulation parameters of LEACH are used for all simulations in this paper. Each simulation is realized for 100 independent iterations to obtain more scalable results. Table I summarizes the simulation environment parameters used for simulations.

TABLE I. SIMULATION ENVIRONMENT PARAMETERS
IV. SIMULATION RESULTS

In this section, the performance comparisons of LEACH, ModLEACH and EERCCA protocols are made for residual energy, number of alive nodes, lifetime and throughput. To obtain more scalable results, 100 iterations are realized. For each iteration, the average values of the results are collected.

A. Residual Energy

Fig. 2 illustrates the total residual energy of the nodes in terms of rounds. With fixed clustering, it can be observed that EERCCA provides significant energy savings when compared to LEACH and ModLEACH. After 2500 rounds, while LEACH holds 5% of its initial total energy, EERCCA holds approximately 20% of their initial total energy. When the network lifetime ends under LEACH, EERCCA still saves approximately 5% of its total initial energy. EERCCA also outperforms ModLEACH in terms of energy-efficiency.

Fig. 2. Comparison of Total Residual Energy

B. Number of Alive Nodes

Fig. 3 shows the number of alive nodes for LEACH, ModLEACH and EERCCA. In EERCCA network, the network lifetime increases from 3000 rounds to 4500 rounds, approximately 50% improvement compared to LEACH. EERCCA algorithm provides longer lifetime when compared to LEACH and ModLEACH because it does not change cluster formations for every round. It gets rid of transmitting of cluster formation messages in the network. It does not consume energy for broadcasting cluster joining messages in the network.

Fig. 3. Round Number vs Alive Nodes

C. Network Lifetime

For each algorithm, the simulations are repeated 100 times for different topologies and the maximum and average observed lifetimes are presented in Table II as well as the initial network energies. DEEC’s conservative energy consumption ratio increases the lifetime of a WSN significantly. DEEC outperforms LEACH and SEP.

<table>

<td>200 J</td>
</tr>
<tr>
<td>LEACH</td>
<td>3478</td>
<td>4216</td>
<td>200 J</td>
</tr>
</tbody>
</table>

D. Throughput

The cumulative number of packets transmitted to the BS per round is plotted in Fig. 4. With fixed clustering, EERCCA can continuously collect data for every round to send to the BS. On the other hand, due to the probabilistic CH selection mechanism, LEACH based algorithms cannot form clusters for some rounds. As a result, the throughput of EERCCA is significantly better than the compared protocols. This exact cluster formation structure of EERCCA provides to collect information from any part of the network at any time.
V. CONCLUSIONS

Nowadays, providing energy-efficiency, prolonging battery life span of the sensor nodes and designing green network components [4, 5] for WSNs has become a promising research area. By using constant cluster formations, EERCCA minimizes the cluster formation overhead. When compared with LEACH and other protocols significant improvements are achieved in terms of energy usage, network lifetime and throughput. EERCCA prolongs the lifetime of the WSN, while reducing the energy usage. Also, the throughput performance of EERCCA makes it more possible candidate to be used in critical applications such as fire rescue, earthquake measurements and disaster relief.

Abstract— The classification of data on the internet in order to make internet use more efficient has an important place especially for network administrators managing corporate networks. Studies for the classification of internet traffic have increased recently. By these studies, it is aimed to increase the quality of service on the network, use the network efficiently, create the service packages and offer them to the users. The first classification method used for the classification of the internet traffic was the classification for the use of port numbers. This classification method has already lost its validity although it was an effective and quick method of classification for the first usage times of the internet. Another classification method used for the classification of network traffic is called as load-based classification or deep packet analysis. This approach is based on the principle of classification by identifying signatures on packets flowing on the network. Another method of classification of the internet traffic which is commonly used in our day and has been also selected for this study is the kernel based on extreme learning machine based approaches. In this study, over 95% was achieved accuracies using different activation functions.

Keywords— machine learning, classification, extreme learning machine, network classification, kernel activation function

I. INTRODUCTION

Traffic classification methods are used to provide the efficient realization of the data traffic on network resources, to do user analysis by using network data, to manage and plan network resources, to detect the attacks and the abnormalities on the network [1, 2]. Recently, the network traffic classification has been frequently used in order to improve service quality in big networks [3, 4], use the network effectively, develop new service packets and perform internet traffic analysis [5]. Internet traffic analysis can be done both on-line and offline. In the on-line traffic analysis, each data packet on the network are captured and analysed [6, 7]. In the offline traffic analysis, network traffic flow is firstly captured and stored; then the stored flow is analysed and classified [8]. In this paper, offline traffic analysis was performed. In the literature, three kind of classification technique, including port, payload and machine learning based, have been used.

Port based classification is performed by comparing the port information retrieved from flow data with the port numbers of protocols determined by Internet Assigned Numbers Authority (IANA) [9]. For instance; port 80 is used for http, and port 23 for telnet traffic. Especially with the widespread use of point to point (P2P) applications, this method has started to lose his functionality as some applications use non-standard port numbers to escape from firewall and network security tools and some use port hiding and dynamic port methods [10-13]. Payload based classification is based on the principle of Internet traffic classification by analysing TCP/UDP packet loads. The analysis of loads is performed by determining whether the known applications contain characteristic signatures [10, 14].

When the packets are not encrypted, it works quite successfully. However, because of the following reasons, this classification technique is not much preferred today:

- It causes privacy and security concerns,
- Some applications communicate by using encrypted packets,
- It can only make assessment based on the signatures which are experienced by the previous classification methods,
- As it requires high processing and storage capacity, it is not suitable for real-time classification [11-13].

The network classification method via machine learning algorithms is the most popular traffic classification method at the present time. In the studies, the classification is usually performed using supervised and unsupervised learning algorithms. Supervised learning algorithms perform classification by using the classification analysis methods in data mining; and unsupervised learning algorithms perform classification by using the clustering analysis methods. Machine learning algorithms perform the process of network traffic classification in two steps. In the first step, it forms a classification model; and in the second step, it performs the classification. Statistical methods and calculations are usually utilized when performing the classification process.

Machine learning based classification method uses the following TCP and UDP statistical attributes of the flow during the flow-based classification:

- Total size statistics,
- Total number of forward and backward packets,
- Total amount of forward and backward byte,
- The transit time between packets,
- And flow time.

There are many studies on the field of Internet traffic classification by using machine learning. In their study, L.
Yingqiu et al. tried to classify network traffic on the original and log-transformed data set by using K-means algorithm [13]. In J. Erman’s study, clustering algorithms of AutoClass, K-means and DBSCAN, were used [15]. S. Zander performed network classifications by applying Exception Maximization (EM) algorithm and method of attribute selection on WAND Research Group’s open data sets and different data sets [16]. S. Zander et al. and S. Agrawal et al. made comprehensive comparisons about classification algorithms by using algorithms and attribute selection methods like C4.5, Bayes Net, Naïve Bayes [16-20]. Apart from port, payload, and machine learning based classifications in the literature, T. Karagiannis et al. developed an important classification method by using host service providers instead of TCP and UDP protocols [21]. L. Bernaille et al.’s classification technique which was performed by using unsupervised learning method and checking only the first few TCP packets is among the important studies in the literature [22]. Recently, ELM pattern recognition, which was suggested by Huang et al., has aroused great interest in the fields of machine learning and data mining; and a lot of applications have been performed regarding the issue [23-25,35]. ELM was suggested as a newly learning algorithm for Single-hidden Layer Feedforward Neural Networks (SLFNs) [23, 27]. During the learning process, SLFNs refreshes network loads based on the gradient. However, in ELM, input sizes and biases are random selected, and output sizes are calculated with an analytical method contrary to SLFNs. In this case, ELM gains the advantages of a fast learning process, a good generalization performance and a low computational load [27-29]. A higher accuracy percentage was obtained with Tangent sigmoid and triangular basis among activation functions which were used for the classic ELM algorithms in this paper. With kernel based extreme learning machine algorithm, which used Radial basis and polynomial activation functions rather than classic ELM, the accuracy percentage was observed to be even higher. In this paper, Internet traffic classification process has been shown using KELM faster and high accuracy.

In the second part of this paper, working principles of ELM algorithms were mentioned. The third part of the paper mentioned how the data was obtained and which data were used for the classification in experimental studies. In addition, different classification algorithms were compared.

II. EXTREME LEARNING MACHINE

Extreme Learning Machine was recommended in G.B.Huang et al. [28-31]. ELM used from 2004 onwards for training the Single-hidden Layer Feedforward Neural Networks (SLFNs) [23, 24]. Dissimilar from the extensive understanding of training SLFNs, ELM employs randomize computational nodes in the hidden layer and computes its output weights analytically by solving a general linear system equation. Later, ELM theory was extended to the “generalized” SLFNs, where the hidden nodes need not be neuron alike. Fig.1 shows the generic architecture SLFNs.

Given $N$ arbitrary training examples $\{(x_j,t_j)\}_{j=1}^N \subset \mathbb{R}^d \times \mathbb{R}^m$, the output of the generalized SLFNs with $L$ hidden nodes can be obtained as:

$$f(x_j) = \sum_{i=1}^{L} \beta_i g_i(x_j)$$  \hspace{1cm} (1)

$$f(x_j) = \sum_{i=1}^{L} \beta_i G(a_i,b_i,x_j) = o_j, j = 1,\ldots,N$$  \hspace{1cm} (2)

If the SLFNs can approximate all the $N$ samples without error, that is

$$\sum_{j=1}^{L} \|o_j - t_j\| = 0$$  \hspace{1cm} (3)

There exist pairs of $(a_i,b_i)$ and $\beta_i$ such that:

$$\sum_{i=1}^{L} \beta_i G(a_i, b_i, x_j) = t_j, j = 1,\ldots,N$$  \hspace{1cm} (4)

The above $N$ equations can also be equivalently expressed in the compact matrix form

$$H\beta = T$$  \hspace{1cm} (5)

Where

$$H = \begin{bmatrix} G(a_1, b_1, x_1) & \cdots & G(a_L, b_L, x_1) \\ \vdots & \ddots & \vdots \\ G(a_1, b_1, x_N) & \cdots & G(a_L, b_L, x_N) \end{bmatrix}_{N \times L}$$  \hspace{1cm} (6)
of ELM based on Mercer's conditions can be defined as follows

\[
\beta = \begin{bmatrix} \hat{\beta}_1^T \\
\vdots \\
\hat{\beta}_L^T \end{bmatrix}, \quad T = \begin{bmatrix} t_1^T \\
\vdots \\
 t_N^T \end{bmatrix}_{N 	imes m}
\]  

(7)

\[H\] is called the hidden-layer output matrix of the SLFN. \(\beta\) is represents the output weight matrix, \(T\) is the matrix that consists of output labels for the \(N\) data samples.

To train a SLFNs as mentioned in (2), it is equivalent to finding the least-square solution \(\hat{\beta}\) of linear system (5), that is:

\[\|H\hat{\beta} - T\| = \min \beta \|H\beta - T\| \tag{8}\]

In the case that the number of hidden nodes \(L\) is coequal to the number of different training samples \(N\), it is possible to find a \(\hat{\beta}\) such that the training error reaches zero. The hidden layer output \(H\) is an invertible square matrix. Hence the solution of the linear system can be given as:

\[\hat{\beta} = H^{-1}T \tag{9}\]

In the case that the number of hidden nodes \(L\) is less than the number of distinct training samples \(N\), to achieve the smallest training error \(\|H\beta - T\|\), the solution of the linear system (5) can be obtained as:

\[\hat{\beta} = H^{\dagger}T \tag{10}\]

Where \(H^{\dagger}\) is called the Moore-Penrose universalized inverse [32].

The least squares solution of (8) based on Karush-Kuhn-Tucker (KKT) conditions can be written as

\[\hat{\beta} = H^{\dagger}\left(\frac{1}{C} + HH^T\right)^{-1}T \tag{11}\]

where \(H\) is the hidden layer output matrix, \(C\) is the regulation coefficient, and \(T\) is the expected output matrix of samples. Then, the output function of the ELM learning algorithm is

\[f(x) = h(x)H^{\dagger}\left(\frac{1}{C} + HH^T\right)^{-1}T \tag{12}\]

If the feature mapping \(h(x)\) is unknown and the kernel matrix of ELM based on Mercer’s conditions can be defined as follows [33]:

\[M = HH^T : m_{ij} = h(x_i)h(x_j) = k(x_i, x_j), \tag{13}\]

Thus, the output function \(f(x)\) of the kernel based ELM can be written compactly as

\[f(x) = \left[k(x_i, x_1), \ldots, k(x_i, x_N)\right]\left(\frac{1}{C} + M\right)^{-1}T \tag{14}\]

Where \(M = HH^T\) and \(k(x, y)\) is the kernel function of hidden neurons of single hidden layer feed-forward neural networks. There are many kernel functions satisfying the Mercer’s condition available from the existing literature, such as linear kernel, polynomial kernel, Gaussian kernel, and exponential kernel. In this paper, we use Radial Basis (RBF) and Polynomial kernel function for performance analysis.

III. EXPERIMENTAL STUDIES

Moore et al [34] used the data received from the Cambridge University campus in this study. The most important factor in this selection is to enable to make comparison of studies previously carried out by using these data with the methods used in this study. One of the important factors is the use of data having flows belonging to different classes. In addition, the use of existing data that everyone can reach will provide a basis to get more reliable results.

12 features were chosen from output data. The chosen features and their explanations are illustrated in Table 1.

IV. CONCLUSIONS

The classification of data on the internet in order to make internet use more efficient has an important place especially for network administrators managing corporate networks. Studies for the classification of internet traffic have increased recently. Machine learning methods of classification of the internet traffic which is commonly used in our day and has been also selected for this study is the kernel based on extreme learning machine based approaches. In this study, over 95% was achieved accuracies using different activation functions. In this study, the kernel based ELM function; Radial Basis and Polynomial functions are used. Functions classification performance by changing the parameters used were observed. RBF is used for the first parameter value. Polynomial function for changing the classification is made and 2 parameter values. With a decrease of the parameter value used for RBF was found that the accuracy increases. This parameter value is 0.01 and reached a value of 95.10% accuracy. With 0.001 of these parameters have reached a value of 96.27% accuracy. But the increase has been observed that a lot of work time. 2 parameter value for Polynomial function is used. The value of 1 and 10 Accuracy rate of 93.07% was observed with the election.

Hybrid Biometric System Using Iris and Speaker Recognition

Gökçen ÇETİNEL, LLukman ÇERKEZİ, Doğukan Uzuner, Barış Yazar

Abstract—In this study, a hybrid security system is proposed. The proposed system is composed of two subsystems namely iris recognition system (IRS) and speaker recognition system (SRS). Pre-processing, feature extraction and feature matching are the main steps of these systems.

In IRS subsystem, Gaussian filter, Canny edge detector, Hough transform, and histogram equalization is performed for pre-processing, respectively. After that, by applying 4-level Discrete Wavelet Transform (DWT) to pure iris image, the iris image is decomposed into four sub-bands (LL4, LH4, HL4 and HH4). In order to extract the feature vector from iris pattern, the LH4, HL4 and HH4 sub-bands (matrices) are merged into one matrix. Finally the matrix is transformed in vector to obtain the feature vector of iris image. For SRS subsystem, the pre-processing step includes spectral arrangement, silence part removing and band limitation operations. After pre-processing, frame blocking and windowing are applied to the long-term speech samples and then Fast Fourier Transform (FFT) is performed for the each short-term speech segments (frames). Finally, the Mel Frequency Cepstral Coefficients (MFCC) technique is performed in order to obtain feature vector of the speech.

The feature matching step of both IRS and SRS is implemented with Dynamic Time Warping (DTW) which is an efficient algorithm to measure the distance between two vectors. According to the DTW results, the false acceptance rate (FAR) is zero and false rejecting rate (FRR) is about 4% for the proposed hybrid system.

Keywords—Biometric systems, iris recognition, speaker recognition, DTW, security.

I. INTRODUCTION

Nowadays, with the emerging of information technology the security of digital data has gained a great importance. One way to protect the digital data from unauthorized persons is to use identification and access control mechanisms. In order to provide these mechanisms one emerging technology that becomes more widespread is biometrics.

Biometric systems are designed based on people’s physiological or behavioural characteristics. These systems can be defined as a pattern-recognition system which tries to recognize a person based on feature vector derived from her/his specific physiological or behavioural characteristics.

The physiological characteristics include fingerprint, face, iris, DNA, hand geometry whether the behavioural characteristics include gait, voice. Depending on application, a biometric system can operate for two main purposes: verification and identification. Verification refers the case where the user desires to be recognized by using an identity such as personal identification number (PIN), login name, smart card; and the system makes one-to-one comparison to determine whether this claim is true or not. The main goal is to prevent multiple people using the same identity. Identification refers the case where the system makes one-to-many comparison of user to determine who is exactly the user. The main goal is to prevent a single person from using multiple identities. One of the key advantages of biometrics over the traditional methods such as knowledge based systems is that biometrics cannot be lost or forgotten; they are difficult for attackers to forge and for user to repudiate [6].

Among biometric systems, iris recognition system is very popular due to significant reasons such as, uniqueness, non-invasiveness and high stability. Iris is part of human eye which lies between pupil and sclera. Iris cannot be copied so iris recognition system is the most reliable system in comparison with other biometric systems [2].

In recent years, speaker recognition also gained increased significance. Searching or controlling based on speaker identity is a growing interest in today’s technologies. Speaker recognition is commonly used in the applications of personal authentication, national security and general forensics. In this study, speech analysis and decision process is performed by computer analysis automatically. The main goal of the proposed speaker recognition system is to increase the security of entire hybrid system [5].

Speaker recognition consists of two main tasks: identification and verification. In speaker identification we intend to identify a speaker from a closed or open set of speakers. For speaker verification, the objective is to verify the claim of an unknown speaker is true or not. This verification is performed by comparing the speech samples of claimer and other speaker’s speech samples available in database. The characteristic of each speaker voice is typical and secret in her/his voice box. So, speaker recognition systems are the reliable biometric systems, too.

In this study, by connecting iris and speaker recognition systems in sequence, a hybrid high security biometric system is obtained. Both IRS and SRS are designed by applying pre-processing, feature extracting and feature matching (decision) steps. Used techniques in order to achieve these steps are explained in the corresponding sections. By performing computer simulations, it is shown that the proposed hybrid
biometric system (HBS) is more robust against to the intruders than separate biometric system. To evaluate the performance of the system FAR and FRR values are also calculated in the simulations. According to the results, we can say that the proposed systems ensure security requirements.

The paper is organized as follows. In Section II, IRS and SRS are explained with all steps, respectively. A brief information about used techniques in these steps are also given in Section II. HBS which consist of IRS and SRS is introduced in Section III. To evaluate the performance of the system, simulation results are given in Section IV. Finally, discussion and conclusion part is stated in Section V.

II. SUBSYSTEMS

In this section, two subsystems of the HBS are explained in details. Pre-processing, feature extraction and feature matching are the main phases of both subsystems.

A. Iris Recognition System (IRS)

Pre-processing: In pre-processing, eye image is transformed into an appropriate model to extract the distinctive features for recognition. Iris localization and normalization are two basic processes in pre-processing. In our study, before localization and normalization 2-D Gaussian filter is applied for noise reduction. Then, the edges are detected with Canny edge detector.

Iris localization is crucial for iris recognition systems. As we see, there are two contours in an eye. The first one is inner contour separating the iris and pupil; second one is the outer contour separating the iris and sclera. By using Circular Hough Transform (CHT), we obtain the inner and outer boundaries of iris. In other words, we estimate the centre and radius of contours.

Iris normalization is an operation converting iris region from Cartesian coordinates to polar coordinates. Thus, circular image turns into a rectangular form and now is suitable for feature extraction. As a last step, histogram equalization is used for enhancing the contrast of iris pattern. In Figure 1, pre-processing is illustrated.

Feature Extraction: In order to use iris signature for recognition systems, the representing of iris in an appropriate way is very important. To extract the specific features from iris, Discrete Wavelet Transform (DWT) is used. DWT is an efficient tool, which transforms the signal from time domain into frequency domain without losing time information.

In general, by performing DWT to 1-D signal, the original signal is divided in low and high frequency parts. This process is called as decomposition and it is provided through special analysis filters. The outputs of filter are referred as DWT coefficients and the original signal can be reconstructed from these coefficients by using appropriate synthesis filters (inverse DWT, IDWT). For 2-D signal case, after performing DWT, image will be divided into four sub-bands corresponding to low frequency (LL1), middle-frequency (LH1, HL1) and high frequency (HH1) components, respectively. DWT can be applied to the LL1 sub-band which concentrates the maximum energy of the signal, one more times until we get the desired level of decomposition. The middle and high frequency (LH1, HL1, and HH1) sub-bands represent the details of image such as edges, outline and texture.

In our study, we used 4-level DWT in order to extract the correct features from iris texture. By performing 4-level DWT we get LL4, LH4, HL4 and HH4 sub-bands. Since the distinctive features of iris are hidden in the high-frequency components, we constitute the feature matrix by merging LH4, HL4, and HH4 sub-bands in one matrix. Finally the matrix is transformed into a vector to obtain the feature vector of iris image.

B. Speaker Recognition System (SRS)

In SRS, at the beginning we record the speech of the users under same conditions. Since the SRS is text dependent recognition system, the users say the same words for database. The block diagram of the proposed SRS system is given in Figure 2. The steps of SRS can be explained as follows.

Pre-processing: In order to process a digital signal, first we must sample the analog signal by Nyquist frequency rate. Then, pre-processing step including spectral arrangement, silence part removing and band limitation operations is applied to the digitized signal.

For spectral arrangement, to enhance the high-frequency energy of the signal, we use a high-pass finite impulse response pre-emphasize filter. The transfer function of this filter is given as follows,

\[ H(z) = 1 - \mu z^{-1}, \quad 0.95 \leq \mu \leq 0.97 \]  

In silence part removing differentiation operation is performed on speech samples from left-to-right and right-to-
left to eliminate the non-variant (silence) parts. Then, in accordance with the human audio system, frequency components outside of 1KHz-5KHz band is stopped. This can be referred as band limitation.

**Feature extraction:** In general speaker recognition system, the critical step is feature extraction step. To achieve high recognition performance, it is known that the features should be extracted form short-time (20-25ms) speech segments. One of the most commonly used short-time features are Mel Frequency Cepstral Coefficients (MFCC). To calculate MFCC values, speech signals are divided into short overlapping frames. Then each frame is multiplied by a window function. In our study, we use Hamming window given as,

\[ w(n) = 0.56 - 0.46 \cos \left( \frac{2\pi n}{N-1} \right) \]  \hspace{1cm} (2)

where N is the length of the window. Then with Fast Fourier Transform (FFT), Fourier power spectrum is obtained. In the next step, the logarithm of the spectrum is calculated a Nonlinearly spaced triangular band

Frequency Cepstral Coefficients (MFCC). To calculate MFCC

we attain to MFCC.

The HBS is designed by connecting IRS and SRS subsystems as demonstrated in Figure 4. The HBS works as follows: at first the user tries to pass through IRS. If IRS denies his/her access, the system will automatically reject this attempt. On the other hand, if the user passes through IRS successfully, SRS is put into use. With the acceptance of SRS, the user will be able to enter.

**B. Feature Matching**

In this study, we use Dynamic Time Warping (DTW) technique to implement feature matching process. DTW is applied to feature vector which is constituted by combining iris image feature vector and MFCC. This technique is very efficient to find optimal distance between two vectors that may differ both in phase and length. The first step in algorithm is to determine local cost measure \( c(x, y) \) between each element of the X and Y vectors by calculating Manhattan distance. If \( c(x, y) \) is small, the similarity between X and Y is high and vice versa. In the second step, the cost matrix is obtained by evaluating the local cost for each pair of elements in X and Y feature vectors.

Algorithm tries to find a warping path \( p= (p_1, ..., p_u) \) which satisfies the following three conditions:

i) Boundary condition: \( p_1 = (1,1) \) and \( p_u = (N,M) \),

ii) Monotonicity condition: \( n_1 < n_2 < ... < n_u \) and \( m_1 < m_2 < ... < m_u \),

iii) Step size condition: \( p_{u+1} - p_u \in \{(1,0),(0,1),(1,1)\} \) for \( u \in [1:L-1] \)

The total cost \( c_p(X,Y) \) of a warping path between X and Y with respect to the local measure c is defined by

\[ c_p(X,Y) := \sum_{u=1}^{U} c(x_{n_u}, y_{m_u}) \]  \hspace{1cm} (3)

An optimal warping path between X and Y is a warping path \( p^* \) having minimal total cost among all possible warping paths. The DTW distance DTW(X,Y) between X and Y is then defined as total cost \( p^* \):

\[ \text{DTW}(X, Y) := c_{p^*}(X, Y) = \min \{ c_p(X, Y) \mid p \text{ is an } (N,M)\text{-warping path} \} \]  \hspace{1cm} (4)

DTW algorithm is widely used in speech processing applications due to the nature of speech waves. As far as we know, DTW algorithm is not applied for iris recognition systems. In our study, we used DTW both IRS and SRS and we obtained very promising results.
IV. EXPERIMENTAL RESULTS

In this section, the simulation results are given for IRS, SRS and HBS systems respectively. Simulations are performed by using MATLAB computer program. The performance of system is evaluated by calculating two rates defined as follows:

i) False Acceptance Rate (FAR): the probability of identifying an intruder as an enrolled user,

ii) False Rejection Rate (FRR): the probability of rejecting an enrolled user as if he was an intruder

Since the aim of HBS system is to ensure high security especially in a house, the database of our system is modelled for 10 people. For each user, 10 images of right iris and 10 sample voices are recorded. Two iris images and two sample voices are used for training among them. The iris images are provided by Casia Iris V4-Interval-R database. The size of iris images is 280x320. After applying pre-processing and feature extraction processes to the iris images we get a feature vector of size 1x84 for each image.

As discussed before, since our SRS sub-system is text dependent, the sentence “open the door” in Turkish is used as a password. The recording time is two seconds and the sampling frequency is 16kHz. After pre-processing and feature extraction we obtain a feature vector of size 1x40. Finally, we form feature vector for whole system by combining the feature vectors of IRS and SRS subsystems. The resulting vector’s size is 1x40.

After applying DTW algorithm to obtained feature vector we calculate the FAR and FRR values. These values are given in Table 1 for two subsystems and hybrid system. As can be seen from Table 1, the FAR values for these systems are zero. On the other hand FRR values are different in each system. By connecting IRS and SRS sub-systems we increase the security with HBS. A user must pass through both sub-systems in order to enter so it is almost impossible to cheat the system.

The FRR value of HBS is evaluated by using total probability theorem as given in the following equation

\[ \text{FRR(HBS)} = \text{FRR(IRS)} + \text{FRR}^C(\text{IRS}) \times \text{FRR(SRS)} | \text{IRS accepted} = 0.0125 + 0.9875 \times 0.025 = 0.037 \]  (5)

where FRR is false rejecting rate for HBS and \( \text{FRR}^C(\text{IRS}) \) is the probability of true decision in IRS.

It can be seen from Equation (5) that the FRR (HBS) value is smaller than FRR(SRS) value. Thus, by using HBS we can provide small FRR value and increase the robustness of system against fake biometric attack

V. CONCLUSION

In this study a novel Hybrid Biometric System (HBS) is proposed. First, the Iris Recognition System (IRS) and Speaker Recognition System (SRS) are designed and tested separately. The performances of sub-systems are evaluated by calculating FAR and FRR rates. Then, we connected two sub-systems to obtain the HBS system. The purpose of proposed HBS is to ensure high reliability. By means of the proposed HBS, to cheat system by spoof attacks is almost impossible.

Abstract—The number of products that simplify people’s lives are increasing with the enormous development of the technology. Mobile devices have a great importance for the provision of communication which is one of the most significant need of human beings. Mobile devices have gone beyond to be used originally as a mobile phone purposes and they have begun to be used as smartphones by taking in charge of computers. They are not only used for communication but also they are used like camera, photo camera, notebook, television and reminder. Google’s Android platform is a widely anticipated open source operating system for mobile phones. Google’s Android Operating System (AOS) in mobile phones are still relatively new, however, AOS has been progressing quite rapidly. The increasing number of smartphone users has prepared the ground for the emergence of new ideas to make life easier. Recently, especially some applications in health sector reflect one of the most important samples for making life easier. Some of mobile applications in this field used by humans are about hearing test, vision test, diabetes, pregnancy, and doctor appointment. This paper focuses on following of drugs, taken by patients, through mobile phones. The application running on the AOS provides the use of drugs on time with the alarm system. In addition to this, the application gives information (time, dosage, name) about drugs by reading data matrix located on the medicine box. Thanks to visual and understandable interface and easy usage, many difficulties experienced in drug reception can be eliminated with this application. Finally, the percentage of reception of drugs on time can be increased in the future.

Keywords—Android, data matrix, web service, drug alarm, prospectus, smartphones, mobile programming.

I. INTRODUCTION

Providing access to health records with the communication networks and mobile devices from the desired location has been suggested as a growing business value in the health field[1]. The drug which is one of the most important thing in the field of health disorder is one of the most effective methods used for immunity. For this purpose, following of medicine becomes more difficult and it reveals a dangerous situation in terms of health for patients. All these problems have emerged the idea of mobile drug tracking application. The main purpose of drug tracking is to prevent disease by providing medicine taking in the right time.

Positive impacts of the market of mobile applications in the health sector are increasing day by day. Elderly population has led to increase the health expenditures in a remarkable way. Until 2030, health spending is expected to absorb %15 of the gross domestic product of developed countries. These countries such as Brazil, Russia, India and China anticipate that 175-200 billion dollars will be saved in the management of chronic diseases using mobile health applications actively. This means that the area of the mobile health will gain more importance in the future.

There are some systems for tracking up chronic illnesses developed by mobile operators such as “Türkcell Health Monitoring Service” and “Avea Patient Status Tracking System with Chronic illnesses” in Turkey.

In literature, there are numerous examples of mobile applications to make people’s life easier. Hacer and Kürşat[2] developed a web based mobile application of child tracking system. In their study, GPS (Global Positioning System) technology was used to provide location data. Another mobile application developed by Yuce et. al [3] focused on asthma, a chronic disease which can be control with patient-doctor cooperation involving frequent medical review and regular self-monitoring by basic indicators. In their study, they proposed to help patients keep their asthma under control and enable doctors reach patients. Finally, Kato and Tan[4] reviewed the six 2D barcodes and then use an extra metric - a first-read rate - to quantitatively verify our earlier results and better gauge reading reliability.

II. BARCODE AND DATA MATRIX TECHNOLOGIES AND STANDARDS

Barcode technology is one of the information coding standard. Barcodes are interface elements that provide access to encoded data via the optical reader. As seen Fig. 1, barcodes, consisting of vertical lines and spaces of different thicknesses, is a method used to transfer data automatically and error-free manner to another environment.

Fig. 1 Sample barcode labels
The use of barcode system has provided great advantages in daily life and business. This technology provides fast and accurate data reading. In addition to this, it provides time saving in the processes such as data update.

There are many types of barcode which have the serious areas and development process past to present. Generally, the basic characteristic that distinguish species from each other are the amount of information that the code can hold. Fig. 2 demonstrates the types of barcode used in literature.

In this paper, data matrix is preferred because of its use in the pharmaceutical industry. Some basic information about data matrix is given as follows:

**Fig. 2 Some barcode types[5]**

- **A. Data Matrix**

  Data matrix code is a two-dimensional matrix barcode consisting of black and white "cells" structured in either a square or rectangular pattern. Encoded information on the data matrix can be text or numeric. Data matrix which can save 3116 numerical or 2335 character can hold more data than one-dimensional barcode. On data matrix, while each black cell refers "1", each white cell refers "0" mathematically.

**III. SYSTEM ARCHITECTURE**

In this study; we proposed a system which consists of an application to be installed on the mobile device with Android operating system, a database where the drug information is stored, and a Windows Communication Foundation (WCF) service which provides the data exchange between them.

- **A. Database**

  SQL Server Express is a database system, developed and distributed by Microsoft, which can be used to provide a basis for the applications running on desktop and small servers. Microsoft's Azure cloud infrastructure and application platform, provide easy way of moving SQL Server databases to Azure. The database is designed to be moved to cloud in the future. SQL Server serves the majority of the database and management tasks. Because of such facilities SQL Server has been the preferred database server for our application.

- **B. WCF Service**

  The main objective of WCF is to enable the communication between applications on the network or internet. Representational State Transfer (REST) is an architecture to provide the data transfer between client and server via Hyper-Text Transfer Protocol (HTTP). Since REST services are Platform-independent, language-independent an easy to scale, REST architecture is preferred in our system. The return types of REST Services can be used as Extensible Mark-up Language (XML), JavaScript Object Notation (JSON), etc. based on the need. JSON is preferred in our application because it can transfer smaller pieces of information while transferring data in the application, and it is easier to use on the mobile platforms. As an example, the barcode number and drug information which is sent to the service is illustrated in Fig. 3 in JSON format. Likewise the database system, the service is also designed to be moved to the cloud.

**Fig. 3 JSON Format**

- **C. Mobil Application of System**

  For the mobile application, the open source operating system, Android, is used, and Android Studio is preferred as an editor. The purpose of this mobile application is to let the users doing medication tracking via Android mobile devices. One of the most important features of the application is to notify the user when it is medication time and to let the medication is taken on time. The medication alarm can be set manually as well as via...
the QR code on the drug. In addition to this, multiple alarms can be set.

The QR code on the drug was created to enable drug tracking. The QR code consists of the barcode number for the drug (GTIN: Global Trade Item Number) and a Serial Number (SN). By integrating the Batch Number (BN) and the Expiration Date (XD) to this unified record system, the obtained information is written on the drug.

In this mobile application, information about drugs can be gathered not only by their names but also by their barcode number. For this solution, application needs a barcode scanner. There is a library for barcode scanning on mobile devices called Zebra Crossing (ZXing). In order to read the QR code, ZXing library is used. ZXing is an open source, multi-format 1D/2D barcode image processing library implemented in Java. This library enables users to scan and read the QR code on the drug, utilizing the camera on the mobile devices.

On the opening screen of the mobile application, the list of tracked medications takes place, as shown in Fig. 4. To add a new record to this list, we open the record screen in Fig. 5, via the “Plus” button. In this screen, a drug reminder can be set through entering the activeness, title, hour, repeating days of the medication reminder, the ring tone, and whether the vibration is on or off, or by reading the QR code in Fig. 6, and clicking the “SAVE” icon. After this stage, the application is redirected to the screen in Fig. 4.

In case the of drug is wanted to be deleted or the drug information is wanted to be updated, the deletion or update can be accomplished by selecting the item from the list in the opening screen and using the screen in Fig. 5. In order to delete the record easily, the item is pressed and hold for a while in the opening screen.
Either by clicking the “DRUG” icon on the opening screen or through the QR code reading screen shown in Fig. 6, the information about the drug can be seen as demonstrated in Fig. 7.

![Drug Information Screen](image)

**Fig. 7 Drug Information Screen**

**IV. CONCLUSION**

With the increased use of mobile devices, mobile applications have made a quick entry into our lives in many areas such as education and health. Health applications attract the interest of both health workers and patients.

In this application that users can use on smart phones and tablet computers, follow the prescription section, taking drugs time and amount of dosage reminders for informative system. Application makes possible to add up to the required medication reminder record. The reminder of each drug is shown separately and when desired a reminder notification can be added for each drug. The most important benefit of this application is that nearly almost problems about drug intake (dosage, time interval …etc.) will disappear. As a result, receiving time of the overall drug percentage will be raised by this application.

Abstract— Nowadays, automatic systems become a crucial in many factories to achieve some tasks such as minimizing cost, maximizing efficiency, quality, and reliability. The planning is important for manufacturing systems to adopt changing conditions. Also, manufacturers want to obtain fast, reliable, qualified and economic products. Flexible Manufacturing Systems (FMSs) are used to meet this need. FMSs make production fast, qualified, reliable and economic by using computer-controlled structure that includes robots and transportation systems. Automated Guided Vehicles (AGVs) and FMS are thought to be integrated because FMS uses AGV as a part of transportation in the factory. AGVs are used to carry loads, in other words products, in production areas, warehouses, factories that use magnets, landmarks, laser sensors, lines to know where they are. AGV scheduling and routing is NP-hard and open-ended problems. In the literature, there are many algorithms and methods are proposed to solve these problems. In this study, we present a hybrid algorithm that is composed of simulated annealing (SA) and Dijkstra’s algorithm to solve the routing problem. The hybrid algorithm is compared with SA algorithm in terms of distance cost using benchmark problems in the literature.

I. INTRODUCTION

Nowadays, there are many factories that use automated systems to improve quality while minimizing cost to meet demands of customers in competitive market. There can be uncertainties and changes due to this competition. The result of these uncertainties and changes is decreasing performance and flexibility. Therefore, routing and scheduling is important to prevent such an undesired condition. Flexible Manufacturing Systems are used to meet this need. FMSs make production fast, reliable, qualified and economic by using computer-controlled structure that includes robots and transportation systems. Coordination in FMS is important for production and transportation because it is required to schedule limited resources in industry. If FMSs are well-planned, coming jobs are done on time. Therefore, production and transportation is carried out smoothly. AGVs are indispensable parts of FMSs. Here, AGVs are responsible for transportation in FMSs.

AGV control includes duty assignment, routing and scheduling [1]. AGV routing and scheduling can be done either online or offline. While offline planning requires prior knowledge related to tasks (it can be nodes, duties and so on), online planning enable to give new tasks [2].

Actually, AGV scheduling and routing problems are very complex in reality. However, this problem will be solved in this paper by simplifying and ignoring some conditions. Details related conditions, assumptions and constraints will be given in following parts.

The paper is organized as the follows. Related works in literature for AGV routing is given in section 2. Section 3 focuses on problem statement, in other words, assumptions, constraints and information about used algorithms. Test results for proposed algorithm are given in section 4. Finally, conclusion part summarizes all written things in the paper with short paragraph in section 5.

II. LITERATURE REVIEW

As mentioned before, scheduling and routing of AGVs is NP-hard problem. Therefore, there are so many researches and solutions in literature and also researchers have been still trying to deal with it. There are so many methods to solve AGV or vehicle routing problem such as simulated annealing algorithm, genetic algorithm, tabu search and so on. Also, some hybrid algorithms that are composed of two or more algorithms are available in the literature.

Liu and Fu [3] dynamically solve the vehicle routing, scheduling and planning problem by using A* algorithm, minimax criterion and some heuristic rules. They model the problem as optimal routing assignment of ‘p’ AGVs among ‘m’ workstations in order to accomplish ‘n’ tasks by using AGV in FMS. Czech and Czarnas [4] investigate the vehicle routing problem with time windows. Parallel-simulated annealing algorithm is proposed to solve routing problem assuming that there is a central depot of cargo and customers a particular distance far away from the depot. The effectiveness of the method is tested on some well-known instances of the problem. Lin et al. [5] apply an algorithm combining simulated annealing with local search approach to handle capacitated vehicle routing problem (CVRP) and test the algorithm on fourteen benchmark problems having different settings. Onoyama et al. [6] propose an algorithm to solve vehicle routing problem for a cooperative logistics network by using genetic algorithm. They use multistage GA and a method of multistage point evaluation to satisfy the
optimization of a cooperative logistics network. Here, they claim that the method of multistage GA gives a chance to obtain accurate solution under various conditions. The paper of Morhiro et al. [7] is about an online ‘Tasks Assignment and Routing Problem’ as called TARP. Their method is for an initial task assignment of autonomous distributed vehicle systems that uses finite buffer capacity. Also, the purpose of the method is to decrease the computation time of route planning by using initial task assignment. In other words, the importance of selecting initial task in a right way is emphasized. Wu and Zhou [8] propose an algorithm to find shortest time routes by controlling deadlock and blocking in AGV systems because they are undesired. Bouhafs et al. [9] propose a hybrid algorithm that uses tabu search and ant colony algorithm to solve ‘Capacitated Location-Routing Problem’ that is composed of ‘Facility Location Problem’ and ‘Vehicle Routing Problem’. The purpose of using tabu search is to find distribution centers with reasonable configuration. Also, the purpose of using ant colony algorithm is finding a route for configuration founding in tabu search step. Another tabu search method is proposed by Guan and Shi [10] for vehicle routing problem. They suggest that their approach is more intuitive and easy to understand client-direct-arrangement solution method coded with C language. Li et al. [11] improve the tabu search for the vehicle routing with fuzzy demands. The purpose is to minimize total distance. Traditional tabu search is compared with the proposed improved tabu search to see the effectiveness of the algorithm.

In this work, SA algorithm is combined with Dijkstra’s algorithm to improve the performance of SA algorithm. Then, SA and hybrid SA are compared in a table to show effectiveness of new algorithm. Details of the algorithm are given in the following parts.

III. IMPLEMENTED ALGORITHM

Implemented hybrid algorithm consists of both SA and Dijkstra. SA gives a route for each AGV and Dijkstra enhance the routes by shortening them. So, performance of the SA algorithm is increased by Dijkstra.

Before the implementation of algorithm, assumptions and constraints should be determined because of ease of coding.

Assumptions and constraints are given as the following:

- All nodes are connected with each other.
- There is one depot and more than one distribution center.
- All AGVs are capacitated and total demand must be smaller than or equal to the total capacity of AGVs.
- Collision between AGVs does not take into account, or in other words, there is a sufficient gap for passing through more than one AGV at the same time.

After the assumptions and constraints, giving information about SA and Dijkstra’s algorithm can be useful to understand hybrid algorithm.

A. Simulated Annealing Algorithm

Simulated annealing algorithm is a metaheuristic method that is used to find maximum or minimum of a function without trapping local maxima or minima. Algorithm starts with an initial solution and tries to find better solution by randomly changing some neighbors. However, some high-cost solutions are selected if the probability of it is greater than a probabilistic value [12].

Actually, this method can be associated with cooling process of metal. In thermodynamics, metals should be cooled carefully and slowly. When the metals are abruptly cooled, they will have fragile structure that is undesired. At the same way, if there are abrupt changes in simulated annealing algorithm, it may trap local values. Therefore, small changes are preferred for both.

Simulated annealing method is used in electronic circuit design, image processing, path finding problem, travelling salesman problems, scheduling problems [13]. In this paper, SA is used for routing of AGVs.

B. Dijkstra’s Algorithm

Dijkstra’s algorithm is used to find shortest path between nodes in a graph by using open list and closed list logic proposed by Edsger W. Dijkstra in 1956 [14]. In this paper, Dijkstra’s algorithm is used to make the distance found by SA shorter.

Pseudo codes of SA and hybrid SA are given in algorithm 1 and algorithm 2, respectively to show the difference between them.

Algorithm 1: Simulated Annealing Algorithm

1. Generate an Initial solution, S
2. Select a value for initial temperature, T
3. Select a value for minimum temperature, T_{min}
4. while (T < T_{min})
   - Generate a neighborhood solution S’ of S
   - Δ=DistanceCost(S)’ -- DistanceCost(S)
   - If Δ<0, S=S’
     - Generate a number r between 0 and 1.
   - End if
   - If Δ>0, S=S’ with exp (-Δ/T) > r
     - T=α*T
   - End if
5. end while

Initial solution in (1) of Algorithm 1 is found using nearest neighbor strategy. Each service node is firstly ordered minimum to maximum according to distance to depot. Then, each service node is assigned to each AGV respectively. This step continues until no service node is left.

Algorithm 2: Hybrid Simulated Annealing Algorithm

1. Generate an Initial solution, S
2. Select a value for initial temperature, T
3. Select a value for minimum temperature, T_{min}
The “DijkstraOrder” function is applied each route of AGV in neighborhood solution $S'$. This function is ordered the route of each vehicle considering the shortest path cost.

**IV. EXPERIMENTAL RESULTS**

The algorithms are coded in C#. The tests for hybrid algorithm are done on a laptop with Windows 7, Intel Core i7 CPU and 8 GB Ram.

Simulated Annealing (SA) and hybrid SA algorithms are compared in terms of best distance costs using problem set by Augerat et al [15]. The instances range from 32 to 80 service nodes. Number of AGVs is changed from 5 to 10 according to problem set. In addition, the capacity of each vehicle for all problem set is 100. The problem set description and best distance cost results obtained using SA and hybrid SA are given in Table I.

As seen in Table 1, hybrid SA gives better results except for three of 27 results in terms of distance. Visualization of first data set A1 is made with simulated annealing in Fig. 1 and with hybrid simulated annealing in Fig. 2 for better understanding.
This page contains a discussion on the application of autonomous AGVs in transportation and the evaluation of different algorithms for their routing. The text also refers to the use of Simulated Annealing (SA) and its effectiveness compared to other methods. The figures illustrate the routes of AGVs, showing how SA can be used to optimize these routes. The references section cites various studies on AGV systems, including those on Simulated Annealing and other optimization techniques.

**Fig. 1** gives the route of the AGVs as the following:

Route for AGV 1: 1-21-6-26-11-16-23-10-9-19-30-1
Route for AGV 2: 1-28-25-1
Route for AGV 3: 1-15-29-12-5-24-3-4-7-27-1
Route for AGV 4: 1-8-14-18-20-32-22-1
Route for AGV 5: 1-31-17-2-13-1

**Fig. 2** gives the route of the AGVs as follows:

Route for AGV 1: 1-21-6-26-11-16-10-23-30-1
Route for AGV 2: 1-28-25-1
Route for AGV 3: 1-19-9-12-5-29-24-3-4-27-1
Route for AGV 4: 1-15-7-18-20-32-22-14-1
Route for AGV 5: 1-31-17-8-2-13-1

As seen above, routes for AGVs are generally different in Fig. 1 and Fig. 2 but it is not important because algorithm is probabilistic and can give different results at each run. It is required to control whether total distance is getting smaller or not. Distance can be controlled with Table I and it can be said that SA is improved by using Dijkstra’s algorithm.

**V. CONCLUSION**

So many factories use automatic systems due to developing technology to minimize cost and maximize efficiency, quality, and reliability. FMSs are used to meet this need. AGVs play a big role in this for the duty of transportation. It is required to make route planning of AGVs to use them effectively due to costs. SA algorithm is the one of the common methods in literature to solve the routing problem of AGVs. In this study, it is combined with Dijkstra’s algorithm that is another common method in literature. Hybrid algorithm is tried on problem set by Augerat et al as mentioned before. Obtained results show that the hybrid approach gives better distance results. In the future work, the algorithms are planned to handle the problem for the autonomous AGVs.

Abstract— The use of B-spline curves has spreaded too many fields such as computer aided design (CAD), data visualization, surface modeling, signal processing and statistics. The flexible and powerful mathematical properties of B-spline are the cause of being one of the most preferred curve in literature. They can represent a large variety of shapes efficiently. The curve behind of the model can be obtained by doing approximation of control points, approximation of knot points or parameterization. It is obvious that the selection of knot points in B-spline curve approximation has an important and considerable effect on the behavior of final approximation. In addition to this, an unreasonable knot vector may introduce unpredictable and unacceptable shape. Recently, in literature, there has been a considerable attention on the algorithms inspired from natural processes or events to solve optimization problems such as simulated annealing, ant colony optimization, particle swarm optimization, artificial bee colony optimization, and genetic algorithms. This paper implements and analyzes a solution to approximate B-spline curves using Intelligent Water Drops (IWD) algorithm. This algorithm is a swarm based optimization algorithm inspired from the processes that happen in the natural river systems. The algorithm is based on the actions and reactions that take place between water drops in the river and the changes that happen in the environment that the river is flowing. Some basic properties of natural water drops are adopted in the algorithm here to solve B-spline curve fitting problem. Optimal knots are selected through IWD algorithm. The IWD algorithm was experimented by some benchmark functions. The proposed algorithm convergences optimal solutions and finds good and promising results.

Keywords— Intelligent water drops, natural water drops, evolutionary algorithms, B-Spline curves, knot points, optimization, reverse engineering.

I. INTRODUCTION

B-spline curves are usually used in computer aided design (CAD), data visualization, surface modeling and many other fields. B-spline curve data fitting is a challenging problem encountered in reverse engineering. However, B-spline curves are most preferred approximation curve because they are very flexible and have powerful mathematical characteristics. Because of this feature, they can offer a large variety of shapes efficiently. In literature, many approaches and methods have been developed for B-spline curve approximation. Tirandaz et al.[1] studied on curve matching and character recognition using B-spline curves. In this work, dominant points on the borders of the object calculated by Local Curvature Maximum (LCM) and control points are calculated by least square method. Consequently, similar characters are determined by utilizing data set of sample characters. Valenzuela and Pasadas[2] used simulated annealing method for cubic spline approximation for knot adjustment. Discrete curvature of data points was smoothed by low pass filters. Artificial immune system is used for optimization of the knots. Gálvez and Iglesia[3] calculated positions of the optimal knots using particle swarm optimization algorithm which was one of the most important metaheuristic approach in literature. They highlighted that parameters of the algorithm had an significant effect on the performance of the curve fitting problem. Finally, Gálvez et al.[4] studied elitist clonal selection algorithm for selecting optimal free knots. In their study, the focused on artificial immune system for the problem of knot adjustment. They mentioned that adjustment of computation time and parameters were basic limitation of the method but it was a matter of tuning parameters based on metaheuristic technical problems and they emphasized that this problem was inevitable. Standart problems solved by IWD algorithm are well known in literature such as vehicle routing problem, travelling salesman problem and robot routing problem. Differently, Dadaneh et.al[5] applied IWD algorithm to tackle the graph coloring problem.

This study focuses on the swarm based IWD algorithm which is inspired from natural colonizing behaviour of water drops in nature. Optimal knot points for drawing the curve are determined by applying proposed algorithm. We demonstrated the effectiveness of the proposed method using numerical studies on multiple representative functions.

II. B-SPLINE CURVES

B-spline curves can be determined for a collection of \( n + 1 \) control points. The first and the last control points intersect with curve. The degree of the curve is \( d \) and must be satisfy the equation \( 1 \leq d \leq n \). B-spline curves use blending functions which have local domain areas to overcome restrictions and disadvantages. These functions are equal to zero outside of own
parts. The mathematical definition of the B-spline curve is formulated as follows:

\[ P = \sum_{i=0}^{n} (p_i N_{i,d}) \]  

(1)

where \( p \) is the control points, \( d \) is the curve degree, \( n + 1 \) is the number of control points and \( N_{i,d} \) is the blending function which is calculated as follows:

\[ N_{i,d}(u) = \begin{cases} 
1, & t_i \leq u \leq t_{i+1} \\
0, & \text{otherwise} 
\end{cases} \]  

(2)

\[ N_{i,k}(u) = \frac{u-t_i}{t_{i+k}-t_i} N_{i,k-1}(u) + \frac{t_{i+k+1}-u}{t_{i+k+1}-t_i} N_{i+1,k-1}(u) \]  

(3)

where \( t \) is the elements of knot vector. The main framework of the B-Spline curve drawing is demonstrated as follows[6]:

1. When a point cloud \( (p_i, i = 0, ..., M_u) \) is given, some points \( Q_j, i = 0, ..., m \) and \( n \leq M_u \) are selected and Centripetal knots are calculated with these points. Here \( u \) shows each Centripetal knot:

\[ u_0 = 0 \quad u_m = 1 \]  

(4)

\[ u_i = u_{i-1} + \frac{\sqrt{Q_i - Q_{i-1}}}{\sum_{j=0}^{m} \sqrt{Q_j - Q_{j-1}}} \]  

(5)

\[ Q_i - Q_{i-1} = (x_i - x_{i-1})^2 + (y_i - y_{i-1})^2 \]  

(6)

2. Approximate B-Spline knots can be found by using calculated Centripetal knots. At this step, the following equation is used:

\[ U = [0, 0, ..., 0, u_{d+1}, ..., u_m, 1, 1, ..., 1] \]  

(7)

\[ u_{j+d} = \frac{1}{d} \sum_{i=j}^{j+d-1} u_i, \quad j = 1, ..., m - d \]  

(8)

3. Control points can be obtained by using the equation \( Q = P \times R \) which is the B-spline curve formula. In this equivalence, in order to obtain \( P \) (control points) matrix, at first, \( R \) matrix should be obtained by using blending functions. Matrix operations are applied over the equation \( Q = P \times R \) to left \( P \) alone. Accordingly, \( P \) is calculated using the equation \( P = Q \times R^{-1} \)

4. As a result, B-spline curve can be drawn.

5. The error value is calculated by using data estimated and data obtained. This approach is called Euclidean error sum which is expressed as follows:

\[ Error = \sum_{i=1}^{n} |S_i - F_i|^2 \]  

(10)

III. INTELLIGENT WATER DROPS

IWD is a swarm based numerical optimization algorithm inspired from natural colonizing behaviour of natural water drops in river. This algorithm contains a few essential elements of natural water drops and actions and reactions that occur between river's bed and the water drops that flow within. This IWD has two important attributes:

- The amount of soil it carries now, \( soil^{IWD} \)
- The velocity that it is moving now, \( vel^{IWD} \)

The values of the both properties may change as the IWD flows in its environment. This environment depends on the problem at hand. The goal of the problem is to find the best path from the source to the destination. One of the most important mechanism that exists in the behavior of an IWD is that it prefers the path with low soils on its bed. In this point, the probability of the next path to choose inversely proportional to the soils of the available paths. As a result; the lower the soil of the path, the more chance it has for being selected by the IWD. In the following, we will discuss the algorithm rules in details.

Path selecting rule: For each IWD, the probability \( p(i, j; IWD) \) of the choosing next location is given by Eqs. 11, 12 and 13 respectively[7]:

\[ p(i, j; IWD) = \frac{f(soil(i, j))}{\sum_{k\in\text{vic(IWD)}} f(soil(i, k))} \]  

(11)

\[ f(soil(i, j)) = \frac{1}{\epsilon_s + g(soil(i, j))} \]  

(12)

\[ g(soil(i, j)) = \begin{cases} 
soil(i, j) & \text{if } \min_{l}(soil(i,l)) \geq 0 \\
\epsilon_s - \min_{l}(soil(i,l)) & \text{else} 
\end{cases} \]  

(13)

where the set \( \text{vic(IWD)} \) represents the locations that the IWD should not visit to keep satisfied the constraints of the problem, \( \epsilon_s \) is a small positive number to prevent possible zero division,
the function \( \min(\cdot) \) returns the minimum value of its arguments.

**Velocity updating rule:** For each IWD that moves from current location \( i \) to next location \( j \), the velocity of IWD is updated as follows\[7\]:

\[
vel^{IWD}(t + 1) = vel^{IWD}(t) + \frac{a_v}{b_v + c_v \cdot soil(i,j)}
\]  

(14)

where \( vel^{IWD}(t + 1) \) shows the updated velocity of an IWD at the location \( j \), \( soil(i,j) \) is the soil on the path joining the current location \( i \) and the next location \( j \), \( a_v, b_v \) and \( c_v \) are constant velocity parameters.

**Local soil updating rule:** For each IWDs moving, the amount of soil \( (soil(i,j)) \) and the soil that each IWD carries \( (soil^{IWD}) \) are updated with the Eqs. 15, 16, 17 and 18 respectively\[7\]:

\[
soil(i,j) = (1 - \rho) \cdot soil(i,j) - \rho \cdot \Delta soil(i,j)
\]  

(15)

\[
soil^{IWD} = soil^{IWD} + \Delta soil(i,j)
\]  

(16)

\[
\Delta soil(i,j) = \frac{a_s}{b_s + c_s \cdot time(i,j; vel^{IWD})}
\]  

(17)

\[
time(i,j; vel^{IWD}) = \frac{||c(i) - c(j)||}{\max(e_v, vel^{IWD})}
\]  

(18)

where \( \Delta soil(i,j) \) is the soil which \( vel^{IWD} \) removes from the path between \( i \) and \( j \) and \( \rho \) is a small positive number generated from the interval \([0,1]\). In addition \( a_v, b_v \) and \( c_v \) are constant soil parameters and \( e_v \) is a small positive number to prevent possible zero division (According to original algorithm for finding the best tour we calculate the path with minimum length, however sometimes depending on the problem different measures can be used. For this study, we use error value between original curve and fitted curve instead of Euclidean error.)

**Global soil updating rule:** At the end of the each iteration, the amount of soil on the edges of the best tour (solution) \( (T_B) \) is updated via Eq. 19\[7\]:

\[
soil(i,j) = (1 - \rho) \cdot soil(i,j) + \rho \frac{2 \cdot soil^{IWD}}{N_c(N_c - 1)} \quad \forall (i,j) \in T_B
\]  

(19)

where \( N_c \) is the number of city that IWD visits on its path. According to obtained best solutions, total best solution is updated.

Taking into account four key rules described above, the steps of implementing standard IWD algorithm can be summarized as follows\[7\]:

1. The initialization of static parameter values.
   a. Representation of the problem in a graph format.
   b. Setting values for static parameters.

2. The initialization of dynamic parameter values.
3. Distribution of IWDs on the problem’s graph.
4. Updating the list of visited cities for each IWD.
5. Following of steps a-d for partial solutions:
   a. Selecting the next city for each IWDs.
   b. Velocity updating of each the IWD which moves from location \( i \) to \( j \).
   c. Calculation of soil.
   d. Updating of soil.

6. Finding the best of the solutions obtained by IWDs in the respective iteration.
7. Updating of soil amount of the edges which is on the best solution.
8. Updating of best solution.
9. Increasing the number of iteration.
10. Returning the best solution when the termination criterion is satisfied.

There are some improved versions of IWD method in literature. These adaptive IWD, improved IWD, modified IWD and neural IWD are examples.

**IV. B-SPLINE CURVE FITTING WITH IWD**

This paper focuses on the problem of selecting optimal knots for the best B-spline curve fitting. Data points have been accepted as a cities and all water drops start from the same point. When a water drop reaches predetermined point, it is accepted that this water drop completed its tour. At the end of the algorithm, the cities on the best path are accepted optimal points to fit data. Fig. 2 shows the optimal data points for the B-spline curve fitting.

In this study, some modifications have been made on the IWD method. The selection of some unnecessary points has been prevented by adding the concept of the radius of curvature. Neighborhood-based local search increases the probability of selecting better ways. Another concept that has been added to the steps of the algorithm is the diversity rate used in local search step. In this way, paths that water drops may follow are gone up. Experimental studies demonstrate that diversity rate prevents hanging out the local minimum. In the following section, some experimental studies were represented to demonstrate the effectiveness of the proposed algorithm.
V. EXPERIMENTAL STUDIES

In this section, numerous numerical simulations are performed to demonstrate the effectiveness of the proposed optimization algorithm. The scope of B-spline curve fitting, IWD algorithm is coded. On the knot prediction of curve in question, mentioned reverse engineering approaches and optimization process steps have been combined. Some parameters and values used in the problem are given in the following table:

<table>
<thead>
<tr>
<th>Parameter</th>

<td>1000</td>
</tr>
<tr>
<td>(b_v)</td>
<td>0.01</td>
</tr>
</tbody>
</table>

Table 3 shows their corresponding mathematical definitions and associated domains. Each function is evaluated at uniformly distributed values of \(t\) in its domain to generate a collection of 201 data points on the interval [0,1].

Table 2: Static parameters of the proposed algorithm

\[
SE = \sum_{k=1}^{N} (y_k - F(x_k))^2 \quad (22)
\]

where \(N\) is the number of data used in the approximation by cubic spline, \(N_{od}\) is the number of interior knots used for construction of B-spline, \(m\) is the order of the spline to be fitted for the given data, and \(SE\) is sum of squared error.

The reason why we used AIC and BIC as a fitness function is that they do not use subjective parameters such as error limits and smoothing functions. Therefore, these functions provide simple and straightforward procedure for identifying the best result[3]. According to these functions, lower values denote better fitness values.

Proposed method is compared with the elitist clonal selection algorithm. In that study, Galvez et. al[4] introduced an adopted elitist clonal selection algorithm for automatic knot adjustment of B-spline curves. In their study artificial immune system paradigm was applied to solve knot adjustment problem for B-spline curves. In this section, performance of the methods was compared by calculating AIC and BIC.

Our algorithm for B-spline curve fitting has been applied to several test functions and we consider here three of them, displayed in Fig. 1.

Table 3: Test functions used in this paper: mathematical definition[3]

All experiments in this paper have been performed on a 2.4 GHz, Intel Core i7 processor with 12 GB. Of RAM. The source code has been implemented by the authors in the programming language of the popular scientific program Matlab, version R2015a. The reason for selection of Matlab is that it is very fast, and it provides reliable, well tested routines for efficient matrix manipulations.

For this study we compute two fitness functions: Akaike Information Criterion (AIC) and Bayesian Information Criterion (BIC). AIC and BIC which are used to measure performance are defined as follows:

\[
AIC = N \log{SE} + 2(2N_{od} + m) \quad (20)
\]

\[
BIC = N \log{SE} + \log{N}(2N_{od} + m) \quad (21)
\]

Table 4 summarizes our simulation results of B-spline curve fitting. Here, best results are highlighted in bold. Fig. 3 demonstrates the approximated results of all function that we tested for the best solutions visually. Fig. 4 shows the effect of the diversity rate on the AIC and BIC values of the experimental result for function $f_3$ as an example.

Our comparative results reported in Table 4 confirm that our method outperforms in terms of the fitting errors for the knot selection problem. The number of iterations used to obtain best fitting is nearly ten times lower than other method. By using the AIC and BIC error functions we also provide efficient procedure to determine the optimal number of interior knots.

VI. CONCLUSION

We proposed the use of this algorithm for solving curve fitting problem. The points have been accepted as cities and a number of IWDs were placed on the cities randomly. At the end of the algorithm, the best path followed by IWD was determined. In this study, the points on the path were accepted the best points that represent the curve optimally.

Metaheuristic approaches frequently used in optimization problems are very strong but the convergence slows down when the generations approach to optimal solutions. Because of this, the cost of the problem rises up. Proposed method solves this problem in the local search step of the algorithm. In this step, diversity rate is used to prevent hanging out the local minimum.

In this paper, performance of IWD algorithm is demonstrated by representing numerous test functions and simulations. As a result, the proposed algorithm converges fast to optimal solutions and finds good, efficient and satisfactory results.

Abstract—Artificial sweeteners like MSG (MonoSodium Glutamate) model has been used anxiety-like behaviors on rats. The tracking of rat’s movements has broad applicability to questions in anxiety-like behaviors with different doses MSG injections (50 mg/kg/day, 100 mg/kg/day and 200 mg/kg/day) to rats. In this paper, in order to measure three types locomotor activity (line crossing, rearing, grooming), a video tracking software is used. The advantage of this type of tracking software is that it provides to give locomotor activity of rats in real-time. The experimental results obtained in this study have shown that learning and memory functions negatively affected in the brains of the rats an anxiety-like model. In addition, the visual tracking results demonstrate that video tracking system provides an accurate monitoring of rat’s behavior.

Keywords—Rat, locomotor activity, anxiety-like behaviors, MSG, computerized video tracking, animal tracking.

1. INTRODUCTION

The etiology of the behavioral disorders might be genetic, physical, developmental and also psychological or social as well. Neurological disorder appears mostly with anxiety disorder and depression. In animals, behaviors likely to anxiety can be identified through experimental open field test, light/dark test, elevated plus maze test, tail suspension test, forced swim test, social interaction task [1]. Open field test enables the evaluation of parameters such as line crossing, rearing, grooming and the defecation number in rats [2].

Studies in rodents have shown that the administration of MSG at the neonatal stage alterations in locomotor activity have been shown [3], [4]. Grooming duration and rearing counts can be used to assess anxiety-like and exploratory behaviors in rodents [5]-[7]. Following acute MSG administration, locomotor activity reduced, grooming increased, while rearing activity reduced at MSG doses [8]. Reduced locomotor activity can be considered a form of anxiety-like behavior [9].

The video tracking systems in open field tests (including mazes) has become a very popular technique for monitoring of anxiety-like behaviors on rats. The automated observation systems, which always work in the same way therefore behaviors are recorded more reliably, provide to researchers many behavioural information about animals. In literature, various types of the techniques can be found, including infrared photobeam detectors [10], [11], [12], [13], vibration detection [14], radio telemetry [15], radar [16] and computerized video analysis [17], [18]. However, video-based tracking systems using video cameras are currently the most common approach to achieve the task [19]. As video-camera technology has preferred to obtain the desired outputs, many automated video tracking methods have been developed [20]. In those methods, analog video signals are sent to video processing unit which detects peaks of the signal. The detected signals indicate contrast between the tracked animal and the background. Then the coordinates of the tracked animal are determined. Modern video tracking systems generally digitize analog video signals using frame grabbers. The digitized video frames is composed of pixels and each pixel has gray scale value [21]. The tracking procedure analyzes digitized frame in order to pick out the animal from the background. Then, the desired calculations are performed in order to explain the meaning of animal’s behaviour.

In this study, the anxiety-like behaviors are investigated using pharmacological activation model with MSG. The objective of this study is to evaluate the effects of neonatal exposure to MSG on locomotor activity with video tracking system.

This paper is organized as follows: In Section 2, material and method, which are designed here, are explained in detail. Section 3 presents the numerical results of the monitoring behaviors on rats with video tracking technique. The discussion and conclusions about the observation results are given in Section 4.
II. MATERIAL AND METHOD

In this study, in order to measure various locomotor activity (such as line crossing, rearing and grooming) an automated video tracking mechanism is designed.

A. Testing Procedure

The open field test setup consists of a square field with a dimension of $45 \times 45$ cm and it is lightened by 3 fluorescent bulbs. The top of the field is open to the ambient and the square field is bordered by white stripes each of 1 cm width, on a black colored background. Each of the experimental animals are brought to the center of the open field setup and released to move freely. Duration of the test is determined as 3 minutes during which the rats are observed closely and any of their behaviors are recorded as line crossing, rearing and grooming. Figure 1 shows the open field test area and the used video tracking mechanism is illustrated in Figure 2.

B. Experimental Animal Group

Rats that are included in the study, are subject to 8 sessions of MSG injections in total, in the order of 50 mg/kg/day (group number = 6), 100 mg/kg/day (group number = 6) and 200 mg/kg/day (group number = 6). Rats that are selected as the control group (group number = 6), are subject to the intraperitoneal serum physiologic.

C. Hardware and software equipment

Video data were processed with a PC (Windows 10 Pro platform, Intel Core i7-4600U CPU @ 2.10GHz 2.70 GHz processor). Video frames were obtained by Flaxes FC 1604 camera (30fbs/15fbs). The data processing algorithms were developed using MATLAB 2014b and Image Processing, Computer Vision toolboxes.

D. Data Analysis

To analyze the data, we used an analysis of variance (ANOVA) for multiple groups. More complex designs, such as one-way ANOVA with repeated measures or n-way ANOVA (additional factors: time, treatment, genotype, stress, etc), can also be used on behavioral studies of rats.

III. OBSERVATION RESULTS

In this section, the observed rat’s movements are illustrated separately in certain moments as shown in Figure 3. In addition, comparative tables related to locomotor activity are shown to discuss the behaviors of rats.

The video camera records the open field setup from the top where the rats are free in this area. Then, the camera signals synchronously are sent to a PC. The signals are digitized by frame grabbers. The video processing software analyzes each frame in order to distinguish the tracked objects from the background on the basis of their gray scale since the gray scaling is the fastest. The threshold values of the video signals, which are used to subtract rat’s image from the background, are set manually. Then, the coordinates of the animal are determined and recorded. Then, the monitoring of animal behavior is achieved in the open field maze.
activities such as rearing and grooming. The numerical results related to rearing are presented in Table 2.

</tr>
</tbody>
</table>

pi: pre injection, poi: post injection.
*p<0.05 (p-value is statistically significant).

Following post injection of MSG, grooming is increased significantly at doses of 50 mg/kg/day and 100 mg/kg/day, respectively. It is known that the following acute MSG administration, locomotor activity reduced, grooming increased, while rearing activity reduced at MSG doses. Reduced locomotor activity is considered a form of anxiety-like behavior.

IV. DISCUSSION AND CONCLUSION

In the literature, studies based on the anxiety model are achieved on animals through injections of artificial sweeteners such as MSG [22], [23], [24]. In the present study, characteristics of anxiety like behaviors of rats are determined through the injections of MSG at repetitive dosages. Following to the MSG injections, when we monitored the behavioral characteristics of rats resembling to anxiety, we determined a statistically considerable decrease in the roaming time of the animals in the open field and a decrease in the number of rearing behavior. However, the number of grooming is increased in a statistically considerable scale. Similar results is provided that a decrease in the motor activity is argued in [25], [26].
As an overall result, we have observed that in the anxiety modeling of rats, over activation of astrocytes has a certain effect on the motor neuron functions of the animals. Additionally, we have observed that the neuronal development, neuronal survival and the synaptic plasticity are also negatively affected by the over activation of astrocytes. Computerized video-tracking results of rat’s behavior confirm that the locomotor activities are negatively affected on rats an anxiety-like model.

A New Approach Based on Image Processing for Detection of Wear of Guide-Rail Surface in Elevator Systems

Orhan Yaman*, Mehmet Baygin*, Mehmet Karakose*

*Computer Engineering Department
Firat University Elazig, Turkey
{orhanyaman, mbaygin, mkarakose}@firat.edu.tr

Abstract—In this study, a system based on image processing has been developed in order to prevent wear on guide-rail surface in elevators. In the proposed method, real-time condition monitoring is performed by cameras using built-in system. The images of elevator guide-rail surface are captured via four digital cameras fixed onto elevator cab. The image-processing methods are applied on the images captured by cameras and hence the wears on the surface of guide-rails are detected. The surface of guide-rail is firstly detected in the proposed method. Then, image segmentation and mathematical morphology are applied on the image of guide-rail surface and the wears on the surface of rail are detected. The failure extent of the wear failures detected are calculated. By processing the images captured by four cameras during movement of elevator, the results for surface of guide-rails are obtained. Using these results, reporting is performed. An elevator prototype has been created in order to carry out tests for development of the proposed method. The tests have been conducted by fixing the built-in system and cameras onto this elevator prototype. It is considerably advantageous to detect the failures on elevator guide-rails through image-processing methods. Following a literature review, it is seen that the proposed method is a new approach.

Keywords—Elevator Systems, Fault Detection, Image Processing, Image Segmentation

I. INTRODUCTION

Elevators ensure transportation of people inside buildings and increase their life quality. High-rise buildings whose number is increasingly going up today has one or more elevator cabs to provide vertical transportation. A great number of people use elevators in many buildings such as business centres, hotels, hospitals and shopping centres daily. It is highly essential for the elevators used by many people daily to operate constantly. In the event of sudden failure of elevators during operation, people inside them face with a tough situation. Also, people have difficulty during the maintenance-repair period of elevators. Elevator system has counterweight system in order to balance the weight of elevator cab. A guide-rail system has been developed to limit the movements of elevator cab and counterweights on horizontal axis. When an elevator system is operational, cab and counterweight system move reversely. The common failures in elevators are usually seen in the components such as elevator guide-rail system, ropes and motors.

Today, when we take multi-storey buildings as an example, the fact that the elevator becomes out of service negatively affects the life of users and reduces the quality of life. In this study, it is aimed to repair the small failures that may occur in the elevator line without causing major failures through early detection. Thus, elevator companies will bring quality service to the elevator systems by gaining customer satisfaction. An elevator company with such a system will be preferred more by its customers. In this way, the fact that users are stuck in the elevator cages and the system becomes out of service will be prevented by eliminating the failures that may occur suddenly in elevators.

Today, most of the multi-storey buildings have elevator systems. Elevator systems are excessively used in the daily life. Elevators are used not only in buildings but also in dangerous places such as mines. In this study, a system has been proposed for the early detection of failures that may occur in the rail line, which is the most important component of the elevator. In the proposed system, it is aimed to produce accurate results by using digital cameras with image processing techniques without being affected by the environmental conditions. Elevator rail is fixed to the elevator shaft and is a unit which facilitates movement of the elevator. In the elevator system, the guide rails are used for the purposes of guiding the cage and counter weight separately in the vertical movements, minimizing its horizontal movements, protecting the vertical directions of the cage and counter weight and preventing its rotation. In this study, methods have been developed for the early detection of failures that may occur in the rails during the movement of the elevator cage.

The general structure showing the sample elevator system is given in Figure 1.

It is seen that similar studies are not available when a literature review is performed for the proposed method. When national theses are analyzed, we see how important the elevator guide rails are [1-4]. In the master's thesis, Serhat [1] carried out a thesis study about the stress analysis of guide rail consoles by mentioning the importance of the elevator guide rails. When we analyze the studies which have been carried out until today, studies have usually been carried out by elevator control and elevator component analysis [5].
Landaluze et al. [6] proposed the active noise control application for the elevator cages. They received results from the proposed algorithms by creating a sample experimental environment. Peiiliang et al. [7] proposed wavelet packet algorithm and fuzzy neural network based methods for the elevator brake systems. The proposed algorithms were applied for the different failures that occur in elevators. As a result of the experimental studies, successful results were achieved for the detection of the elevator braking failures. Zhang et al.[8] proposed a method based on failure detection in elevators. They created an information system for the failure events by explaining the elevator door failures. Zeng et al. [9] developed a elevator door control algorithm based on image processing. They created a system with a micro processor having camera on it, and they used it in the control operations of the elevator doors. Zhao et al. [10] carried out a study for detecting the failure in the elevator systems. They proposed a method for the detection of the failures by explaining the failures occurring in the elevator systems and the reasons for the emergence of these failures. Jiancan et al. [11] proposed a signal processing-based failure detection method for the detection of the failures in elevator machines. They performed failure detection by applying spectrum-based methods to the signals received from the elevator system. Hu et al. [12] developed a real-time knowledge-based detection system by using PLC controlled production systems. In the thesis study, Yimou [13] conducted elevator inspection and market research. Yimou developed a system for measuring the inspection and quality of the elevators in Deyang, China. In addition, various studies have been carried out in the elevator systems such as quality control, failure detection, inspection and condition monitoring. [14,15].

When the websites of the major elevator companies such as ThyssenKrupp, Klaemann, Otis, Kone and Schindler as well as the scientific studies in the literature were analyzed, it was seen that studies similar business idea were not available. When the existing studies in the literature are analyzed it is seen that the failure detection, control and condition monitoring methods are very important in the elevator systems. In this study, failure detection is performed by image processing techniques by developing much more different methods than the literature.

II. PROPOSED METHOD

In the studies carried out in recent years, about 152 thousand elevators have been inspected and nearly 63% of these elevators could not pass the quality level. These types of elevators often fail while using, endanger the life of users and lead to the disruption of their daily life. In the elevators used in hospitals, the lives of emergency patients are put at risk as a result of the failures that may occur while handling emergency patients. Besides, the failure of the elevators used in large businesses such as mines leads to disruption of the works and the people's lives are put at risk [16,17]. Early detection of the failures that occur in the elevators is very important to avoid such problems. In the proposed method, it is aimed to reduce the maintenance and repair costs by condition monitoring system, to prevent the major failures that may occur and to eliminate the user victimization. In addition, it is aimed to ensure energy saving by preventing the frictions that may occur in the rails as a result of monitoring the rails structures in the elevator lines by cameras. Sample images for the elevators rails are presented in Figure 2.

![Sample elevator rail images](image)

Fig. 2 Sample elevator rail images a) Robust rail image b) Curved rail image c) Rusty rail image d) Worn rail image

The robust, curved, rusty and worn rail image samples are presented in Figure 2. In this study, the detection of the failed parts of the worn ray images is performed. A sample elevator prototype was formed to detect the failed parts by image processing. The cameras were fixed on the elevator cage to monitor the rails on this prototype. The cameras fixed on the elevator cage are seen in Figure 3.
The images were taken by placing 4 cameras on the elevator cage as in Figure 3. The wear failures that occur on the elevator rails are detected by applying the proposed method on the image taken. A general flow chart of the proposed method is presented in Figure 4.

The opening operation is obtained as a result of applying the dilation processing right after the erosion processing on the image. The objects within the image and the gaps between objects are cleaned according to the size of the structural element. The mask matrix used for the opening operation in the proposed method is presented in equation 5 [20].

\[ X \oplus B = \{ p \in Z^2 : p = x + b, x \in X, b \in B \} \] (dilation)

\[ X \ominus B = \{ p \in Z^2 : p + b \in X, \forall b \in B \} \] (erosion)

\[ X + B = (X \ominus B) \oplus (B \ominus X) \] (opening)

\[ X \ast B = (X \oplus B) \ominus (B \oplus X) \] (dilate-erode) (5)

The flow chart of the proposed method is seen in Figure 4. Firstly, the rail surface is extracted as preprocessing on the image taken from the camera. A section with a size of 480x200 is taken from the image taken in 480x640 size. This section taken involves the rail surface image. The rail surfaces represent the same pixels on the continuous image because the cameras are fixed over the elevator cage. Therefore, the pixels belonging to rail surface are extracted in 480x200 size from the image. The obtained RGB rail surface image is transformed into gray format and then binary format [18,19].

The image was transformed into gray format and then binary format through the tests performed. The code particle given in Figure 6 is used for the estimation of the failure detection and the size of the failure.

The image in Figure 5.b was obtained by applying the opening operation to the normal image in Figure 5.a. In Figure 5.b, it is seen that small asperities on the rail surface were disappeared and the real failures appeared more clearly. After the opening operation, the failure detection and the size of the failure are estimated by taking into account the number of white pixels on the image. The code particle used for failure detection and the size of the failure is presented in equations 1, 2, 3 and 4 [20].

The image in Figure 5.b was obtained by applying the opening operation on the sample image taken in 480x200 size. This section taken involves the rail surface image. The rail surfaces represent the same pixels on the continuous image because the cameras are fixed over the elevator cage. Therefore, the pixels belonging to rail surface are extracted in 480x200 size from the image. The obtained RGB rail surface image is transformed into gray format and then binary format [18,19]. The image was transformed into binary format by using a specific threshold value. This threshold value was determined through the tests performed. The opening operation was performed as the mathematical morphology operation on the binary image. The mathematical expressions of the basic binary morphological operations are defined in equations 1, 2, 3 and 4 [20].

The flow chart of the proposed method is seen in Figure 4. Firstly, the rail surface is extracted as preprocessing on the image taken from the camera. A section with a size of 480x200 is taken from the image taken in 480x640 size. This section taken involves the rail surface image. The rail surfaces represent the same pixels on the continuous image because the cameras are fixed over the elevator cage. Therefore, the pixels belonging to rail surface are extracted in 480x200 size from the image. The obtained RGB rail surface image is transformed into gray format and then binary format [18,19]. The image was transformed into gray format and then binary format through the tests performed. The code particle given in Figure 6 is used for the estimation of the failure detection and the size of the failure.
III. EXPERIMENTAL RESULTS

Raspberry pi card having the features of “Broadcom BCM2836 ARMv7 Quad Core SOC (Quad-Core), 900 MHz processor speed and 1 GB RAM” was used in this study. The image processing was performed with "OpenCV" libraries by using "python" programming language on the Raspberry pi card. In addition, 4 cameras with 24 FPS speed were used to take the images. First of all, an experimental setup was developed to take the images and perform the test procedure. The developed experimental setup is presented in Figure 7.

Fig. 7 Development of the experimental setup

A system which was similar to a normal elevator structure was developed in Figure 7. This elevator structure has rails, ropes, elevator cage, counter weight system, control panel, asynchronous motor and sensors. The cameras were fixed over the elevator cage to take the images in the developed experimental setup as shown in Figure 8.

Fig. 8 Fixing of the cameras and the preparation of the test environment

As it is seen in Figure 8, the images are taken from the cameras fixed over the elevator cage. The erosion failures that occur on the rail surface are detected by applying the proposed method on the images taken. Two rail surface images including robust and failed are presented in Figure 9.

Fig. 9 Sample rail surface image a) Robust rail surface image b) Failed rail surface image

The robust and failed rail surface images are presented in Figure 9. The proposed method was applied to the robust rail surface image in Figure 9.a, and the obtained result is
presented in Figure 10.a. The proposed method was applied to the failed rail surface image in Figure 9.b, and the obtained result is presented in Figure 10.b.

In Figure 10.a, it is seen that the rail surface is robust and there is not any erosion failure. In Figure 10.b, it is seen that there is an erosion failure. The proposed method was tested for 4 cameras and the erosion failures on the rail surface were detected. The speed of the developed elevator prototype is about 0.60 m/sec. When the speed of the elevator was taken into account, the real time operation of the proposed method was evaluated as appropriate and it was seen that it was working successfully as a result of the tests performed. The real-time rail surface is monitored in the “Python Sheel” environment while the elevator is working. As in Figure 11, the size of the failure is monitored by performing failure detection in the “Python Sheel” environment while the elevator is working on a sample rail with erosion failure on the rail surface.

IV. CONCLUSIONS

Elevator systems have become an indispensable part of people in our day. Elevators are the means of transport which are beneficial to people regarding the transportation of loads and people. The fact that elevators are failed while working is one of the undesirable events. In particular, the fact that elevators are failed while people are using them reduces the quality of life. A new image processing-based method for the prevention of the elevator failures has been proposed in this study. The rail surface erosion failures that may occur on the rails, one of the critical components in the elevator systems, are detected. In this study, a sample elevator system was created and 4 cameras were fixed on the elevator cage. Whether the rail surface was robust or failed was detected and the size of the failure was estimated if it was failed, by applying the proposed method on the images taken from the cameras. When the proposed method is compared with the studies in the literature, it is seen that it is a new study and it can operate in real time. This study provides a basis for the future studies, and it is aimed to detect the erosion, cracking, warping and corrosion on the elevator rails in the future studies.

Abstract— In this work, we present a computer program that reads, manipulates, analyses and stores the mass spectra obtained by using Laser Time of Flight Mass Spectrometry (L-TOF-MS) system described elsewhere. This program allows users to record the characteristic parameters of experimental data such as vacuum pressure, voltages, laser power, sample name etc. both manually and automatically. Also, the obtained mass spectra can be used to investigate chemical substances (NOx, SOx, organic molecules etc.) or can be used to real time identification of the sample differences for given material database (metal oxides, alloys, paintings, healthy and cancerous tissues etc.) by using different mathematical and statistical procedures (PCA, LDA, kNN etc.). We have recently presented a simple chemical analysis procedure by starting from reading raw MS data from oscilloscope using TCP/IP protocol and following data processing steps. We have a great success to reduce the numbers of steps and time duration consumed for the following procedure.

Keywords— Mass Spectrometry, Data Acquisition, Data Processing, Statistical Analysis, GUI, MATLAB

I. INTRODUCTION

Mass spectrometry is an analytical method and has a wide applications including; industrial quality control [1-3], pharmacology [4-7], isotope ratio determination [7-10] and space exploration researches [11-13]. Mass spectrometers consist of three units, which are an ionisation unit, separation unit and detector. The obtaining and interpretation of the mass spectral data have a great importance to reveal the molecular structure and laser ionisation/dissociation processes [14, 15].

Data analysis is the most time-consuming processes and manual data processing can cause the unintended human error, such as, reading or writing ion intensities, workspace (time – mass to charge ratio) conversion errors. In this work, we have presented the reducing the numbers of steps and time duration spend for the mass spectral analysis procedure.

II. BACKGROUND AND THEORY

Recent years, multivariate data analysis methods have attracted great attention due to the large experimental data sets obtained from different experimental methods, especially in mass spectrometry. Researchers obtain thousands of ion peaks (mass to charge ratio) in different intensities for multiple repetitions for each experiment. Thus, dimension reduction and selection of the data analysis methods (PCA, LDA, kNN etc.) became an important problem. In order to overcome these problems, new software tools was created similar to MCR-ALS (Multivariate Curve Resolution–Alternating Least Squares) toolbox programmed in MATLAB environment [16]. A similar program (FlavonQ) was developed to simultaneously analyse ultra-high-performance liquid chromatography (UHPLC) high-resolution accurate mass spectrometry –mass spectrometry (HR-AMS) data and UV-VIS spectrometry data in order to profile the flavonoids [17]. Recently, a user-friendly program (SIM-XL) was developed for structural protein characterization by using peptide cross-linking analysis method for tandem mass spectrometric data [18]. In proteomics studies, a GUI program (IPeak) also presented for identification of the peptides data obtained from LC-MS/MS method [19]. To identify TLC (Thin Layer Chromatography) information from MSI (Mass Spectrometry Imaging) data sets, a program (DetectTLC) was developed [20]. Homemade software or package programs were used for biological tissue identification [21] or cancer detection [22] by using mass spectrometry data.

III. EXPERIMENTAL SETUP

Experimental setup consists of laser systems, time of flight mass spectrometer and electronics. In our experiments, we are using high-intensity femtosecond/nanosecond lasers. In the scope of this work, we have used a femtosecond laser system (Quantronix, Integra-C-3.5, NY, USA) as an ionisation source. TOF-MS system was designed and built by our group; background pressure of the vacuum chamber can be pumped down to 10^-8 mbar. Ion signals were collected by using an MCP detector (El-Mul Technologies LTD., Israel). The details of the experimental setup were presented elsewhere [23, 24].

Mass spectra were recorded remotely via TCP-IP protocol and real time by using a four-channel oscilloscope (LeCroy Corporation, WaveRunner 64 Xi, NY, USA).

IV. RESULTS AND DISCUSSION

GUI of the mass spectrometry program consists of the subpages that are Experiment, Setup, Connection, Laser Diagnostics and Database Control, as shown in Fig. 1. In the experiment section, the user can write sample name, number of sampling and perform plotting mass spectra. Setup section
(given as an inset in Fig. 1) provides the user to recording experimental parameters such as electrode voltages, vacuum pressure and laser power. In the connection section, the user defines IP number of the oscilloscope to connect using TCP-IP protocol. In laser diagnostics section, the user can obtain real-time UV-VIS spectrum of the laser pulses (Fig. 2.) by using UV-VIS-NIR portable fiber-optic USB spectrometer (0.1 nm FWHM optical resolution, USB 2000+, Ocean Optics). In database control section, the user can load a database file for given directory from local drivers. The user can control and plot mass spectra for desired rows and each row corresponds to a mass spectrum (Fig. 3).

MATLAB .mat file. After selecting and opening database file, the program record raw experimental data that contain mass spectra as an ion intensity (intensity corresponds to voltage value read by the oscilloscope) versus the time of flight of the corresponding ion peak. The user has to calibrate the system by using equation \((m/z)=at^2+b\) to transform time of flight spectrum to mass spectrum to use m/z ratio for further spectral analysis [25]. For calibration, the user has to select two known peaks (H\(^+\) and C\(^+\) or CH\(_3\)\(^+\) peaks) to calculate constant a and b to convert all time points to m/z ratio. The peak selection on the mass spectrum is shown in Fig. 4. The user select first hydrogen ion peak and then carbon ion peak in Fig. 4 by using mouse cursor (appearing crosshair).

In the database control section, the user firstly uses “Load Database” button to and then select database file stored as a MATLAB .mat file. After selecting and opening database file, the program record raw experimental data that contain mass spectra as an ion intensity (intensity corresponds to voltage value read by the oscilloscope) versus the time of flight of the corresponding ion peak. The user has to calibrate the system by using equation \((m/z)=at^2+b\) to transform time of flight spectrum to mass spectrum to use m/z ratio for further spectral analysis [25]. For calibration, the user has to select two known peaks (H\(^+\) and C\(^+\) or CH\(_3\)\(^+\) peaks) to calculate constant a and b to convert all time points to m/z ratio. The peak selection on the mass spectrum is shown in Fig. 4. The user select first hydrogen ion peak and then carbon ion peak in Fig. 4 by using mouse cursor (appearing crosshair).
Following the time of flight spectrum transformation to mass spectrum, the user can view all collected mass spectra by using “MS Viewer” button, the opening window seen in Fig. 5. On the other hand, the user can investigate statistical results by using PCA visualization tool as seen in Fig. 6.

As a result, the fs-TOF-MS data sets were acquired as raw electronic signals, converted to digital values by using oscilloscope via TCP-IP. The obtained spectra were in the time of flight space first and after calibration, spectra were transformed into mass space.

We have got a great success to reduce the numbers of steps and time duration spend for the manual data processing procedures of the mass spectra analysis from weeks to seconds. Thus, we can eliminate the possibility of the unintended human errors appears in these manual procedures.

Within the context of this work, we built a backbone of the flexible program, which can be manipulated by customs needs, changing experimental setup and/or new unused statistical procedures in laser TOF-MS.

Analysing fs-TOF-MS data using multivariate statistical method, which suggests a new opportunity to use this program in real-time cancer detection research.

A modified cuckoo search using different search strategies

Hüseyin HAKLI*

*Department of Computer Engineering, Selcuk University, Turkey

Abstract— Cuckoo search (CS) is one of the recent population-based algorithms used for solving continuous optimization problems. The most known problem for optimization techniques is balancing between exploration and exploitation. CS uses two search strategies to updating the nest: local and global search. Although cuckoo search are adequate for the exploration, it is not well enough the exploitation. Only one search equation is used for local search, this equation remains incapable and causes some deficiencies about the exploitation. To enhance the ability of exploitation and to balance between global search and local search, different search strategies were implemented in CS algorithm. The proposed method was compared with basic CS on well-known unimodal and multimodal benchmark functions. Experimental results show that the proposed method is more successful than the basic CS in terms of solution quality.

Keywords— Cuckoo search, continuous optimization, search strategies

I. INTRODUCTION

In the recent years, many novel nature inspired algorithm have been proposed to solve continuous optimization problems, alongside mostly known swarm intelligence algorithms such as particle swarm optimization [1], artificial bee colony [2], ant colony optimization [3] etc. The recent nature inspired algorithm was inspired by behaviours of animals in the nature. To illustrate, the firefly algorithm [4] was developed by flashing characteristic of fireflies, the bat algorithm [5] was proposed by being inspired behaviour of echolocation of bats. Yang and Deb [6] proposed the cuckoo search by being inspired breeding behaviour of some cuckoo species.

Cuckoo search (CS) is based on the obligate brood parasitism of some cuckoo species in combination with Levy flight random walk. Cuckoo search has been very popular in a short time and started to apply many engineering fields and optimization with promising efficiency and few control parameter settings. Due to these advantages, CS was used for clustering of web search results [7], hydrothermal scheduling [8,9], economic dispatch [10], multilevel thresholding [11], parameter estimation and optimization [12, 13], redundancy allocation problems [14], forecasting solar radiation [15] and so on.

The main problem of the optimization techniques is balancing between exploration and exploitation. The exploration is concerned the ability of autonomously seeking for the global optimum, whereas the exploitation is related to the ability of applying the existing knowledge to look for better solutions [16]. In other words, exploration represents global search and the exploitation stands for local search. CS has two search techniques and uses Levy flight rather than standard random walks for the global search. Thus, CS can explore the search space efficiently [17]. Although CS has local and global search capabilities, it opens to improvement about balancing between exploitation and exploration. In addition, due to some deficiencies about exploitation, strengthening the local search is more important for the CS. Many studies were performed to improve performance of cuckoo search. The cuckoo search parameters were properly tuned by Valian et al. [18] to enhance accuracy and convergence rate of the cuckoo search. Walton et al. [19] proposed modified cuckoo search which involves the addition of information exchange between the top eggs, or best solution. To improve refining ability and convergence rate of cuckoo search, Zhang and Chen [20] proposed the cuckoo search with adaptive method. This adaptive method was used to control the scaling factor and find probability to enhance the population diversity. A new cuckoo search algorithm based on the idea of opposition (OCS) algorithm is proposed by Zhao and Li [21] to increase the exploration efficiency of solution space. They merged the opposition-based learning in the CS and the proposed algorithm fully used beneficial information of the best solutions. In order to balance the exploitation and exploration of the cuckoo search algorithm, Li and Yin [22] proposed a new approach which uses two new mutation rules based on the rand and best individuals among the entire population. In addition, this new rules were combined through a linear decreasing probability rule. CS was used in hybridization with the other algorithm such as fuzzy c means [23], NEH heuristic algorithm [24].

To improve and enhance the performance of cuckoo search, we focus on ability of exploitation and some deficiencies of local search. CS uses only one search equation for the local search and this equation remains incapable and causes some deficiencies about the exploitation. To overcome this problem and balance between global and local search, different search strategies were implemented in the CS. Modified cuckoo search with the different search strategies (CSDSS) were compared with the basic CS on twelve benchmark functions. Experimental results show that the proposed method was more successful than the basic CS algorithm for both unimodal and multimodal functions. By virtue of different search strategies,
the CSDSS enhanced the efficiency of local search and improved the balance between exploration and exploitation.

The rest of the paper is divided as follows. In Section 2, the basic CS algorithm is presented. The proposed algorithm is detailed in Section 3. Section 4 gives the experimental results and comparison of the methods. As a final, the paper is concluded with the future works.

II. CUCKOO SEARCH

Cuckoo search was inspired by the interesting breeding behaviour such as brood parasitism of certain species of cuckoos by laying their eggs in the nests of host birds [6]. In the CS algorithm, there are mainly three principle rules as follows [6, 17]:

- Each cuckoo lays one egg at a time, and dumps it in a randomly chosen nest;
- The best nests with high-quality eggs will be carried over to the next generations;
- The number of available host nests is fixed, and the egg laid by a cuckoo is discovered by the host bird with a probability ps ∈ (0, 1). In this case, the host bird can either get rid of the egg, or simply abandon the nest and build a completely new nest.

For convenience, this last rules can be approximated by the fraction ps of the n nests are replaced by new nests (with new random solutions) [6]. Each egg in a nest stands for a solution and each cuckoo can lay only one egg. For the simplest approach of algorithm, each nest has only one egg. Thus, there is no difference between egg, nest and cuckoo. All of them represent one solution.

The CS uses two search strategies and two solution search equation to generate new solutions. One of them is local random walk and other one is global random walk. The global random walk is performed by the using Levy flights [17]

\[ x_{i}^{t+1} = x_{i}^{t} + \alpha L(s, \lambda), \]  
\[ L(s, \lambda) = \frac{\lambda \Gamma(\lambda) \sin(\pi\lambda / 2)}{\pi} \frac{1}{s^{\lambda+1}}, \quad (s \geq s_0 > 0) \]  

where \( \alpha > 0 \) is the step size of scaling factor and it is generally determined with \( \alpha = O(L/10) \), where \( L \) is characteristic scale of the problem of interest. On the other hand, the local random walk can be written as [17]:

\[ x_{i}^{t+1} = x_{i}^{t} + \alpha s \otimes H(p_s - \varepsilon) \otimes (x_{r}^{t} - x_{k}^{t}) \]  

where \( x_{r}^{t} \) and \( x_{k}^{t} \) are two different solution selected by randomly, \( H(u) \) is Heaviside function, \( \varepsilon \) represents random number drawn from a uniform distribution, \( p_s \) stands for switching parameter of controlling the balance between local and global random walk and \( s \) is the step size. The new nests are generated by the both of Eq. (1) and Eq. (3) in the every iteration. Detailed information about the cuckoo search, please refer to [6, 17].

III. MODIFIED CUCKOO SEARCH WITH DIFFERENT SEARCH STRATEGIES (CSDSS)

The CS can explore the search space efficiently thanks to Levy flights random walk. But one solution search equation is used for the local search and the best solution of nest is ignored by this equation. This causes lack of the exploitation. To strengthen and increase the efficiency of local search without losing the ability of exploration, different search strategies are implemented in the local random walk phase of the cuckoo search.

\[ x_{i}^{t+1} = x_{i}^{t} + \text{rand}(x_{i}^{t} - x_{j}^{t}) \quad i = 1, 2, ..., N, i \neq k \neq r \]  
\[ x_{i}^{t+1} = x_{i}^{t} + \Phi(x_{i}^{t} - x_{j}^{t}) \quad i = 1, 2, ..., N, i \neq k \neq r \]  
\[ x_{i}^{t+1} = x_{i}^{t} + \Phi(x_{i}^{t} - x_{best}^{t}) \quad i = 1, 2, ..., N, \]  
\[ x_{i}^{t+1} = x_{new}^{t} + \Phi(x_{i}^{t} - x_{j}^{t}) \quad i = 1, 2, ..., N, i \neq k \neq r \]  

Equation (4) is the same as local search update rule of the basic CS algorithm [17].In (4), (5) [25] and (7) [26], \( x_{i}^{t} \) and \( x_{k}^{t} \) are solutions randomly selected from the population at time step \( t \), and \( k \) and \( r \) are not equal to each other and \( i \). In (6) and (7), \( x_{best}^{t} \) in the equations is the best solution obtained by the population so far. Also, \( \Phi \) is a random number in range of \([-1,1]\] and produced for each cuckoo which is updated at the time step \( t \). To increase and protect the efficiency of exploration, the random neighbours are used in Eq. (4) and Eq. (5). Also, Eq. (6) and Eq. (7) are implemented to support the local search around the global best solution of population and enhance the ability of exploitation. The important point is how these equations are used together to obtain new solutions. Usage of these equations is explained by Fig.1.

\begin{verbatim}
for i=1: number of cuckoo
    if rand < ls_rate
        if rand < 0.5
            Generate new cuckoo with Eq. (7)
        else
            Generate new cuckoo with Eq. (6)
        end
    else
        if rand < 0.5
            Generate new cuckoo with Eq. (5)
        else
            Generate new cuckoo with Eq. (4)
        end
    end
end
\end{verbatim}

Fig.1 Usage of equations for the proposed method

In Fig.1, \( ls \_rate \) is the constant parameter in range of \([0,1]\) that controls the level of local search for the proposed method. If the \( ls \_rate \) is high, the proposed method searches the around of global best solution and makes more local search. The proposed method uses the algorithm in Fig.1 instead of the Eq. (3) in the basic CS to generate new solutions.
IV. EXPERIMENTAL RESULTS

In this study, all the experiments were run on a machine with Intel Core i7 2.40 GHz CPU, 8 GB RAM and the Windows 8 operating system and the codes were implemented in Matlab 2014 (8.3).

To examine the performance and accuracy of the CSDSS algorithm, the CS and CSDSS are applied to optimize 12 benchmark functions. The dimension is set 30 for all benchmark functions. Experiments are implemented with the population size of 40 for both algorithms. As a stopping criterion is used the maximum number of iteration and it is determined as 2500 in each run for each test function. While \( p_a \) parameter is set 0.25 for basic CS algorithm, it is determined as 0 for the proposed method. In addition, \( ts \) rate is used as 0.3 for the CSDSS as a result of the trials.

The determined benchmark functions are numbered \( f_1 \) to \( f_{12} \) given in Table 1. All the functions are to be minimized. Table 1 shows characteristic (C), search range (Range), and formulation of the functions. The cuckoos are initialized in the search range. The functions \( f_1, f_2, f_3, f_4, f_5, f_6 \) and \( f_{11} \) are unimodal and \( f_7, f_8, f_9, f_{12} \) are multimodal.

Table 2 contains a comparison of the original CS and the proposed method for the 12 benchmark functions listed in Table 1. Table 2 shows the mean result of 30 runs with 2500 iterations and dimension 30. The information about the mean optimum solution, standard deviation, minimum and maximum value and Wilcoxon test result by CS and CSDSS in 30 runs over benchmark functions are given in Table 2. The best mean result and the best standard deviations of the benchmark functions obtained by the algorithms are shown in bold. In the Table 2, in case Wilcoxon test was at 0.05 significance level, + mark was used, otherwise, - mark was used; NA was used in case all results showed the same value or optimum value.

**TABLE**

RESULTS FOR BENCHMARK FUNCTIONS (OPT:OPTIMUM STD:STANDARD DEVIATION, MIN:MINIMUM, MAX:MAXIMUM, SIGN: STATISTICAL TEST SIGN)
When examines Table 2, CSDSS algorithm acquires better results compared to CS algorithm for the all benchmark functions except $f_3$ and $f_8$ in terms of solutions. The proposed method is more successful for the all unimodal functions. While ability of local search of CS algorithm remains incapable on the unimodal functions, the proposed algorithm makes more sufficient local search and obtains the better result than the CS. The CS algorithm is better than proposed method for $f_3$ and $f_8$ functions. But, the CSDSS gives the optimum results for the function $f_3$. Experimental results show that not only the CSDSS enhances the ability of local search but also improves the balance between exploration and exploitation. The proposed method outperforms the basic CS on the unimodal functions, at the same time it obtains better results the most known multimodal functions such as Rastrigin, Griewank and Ackley.

Non-parametric statistical test has been implemented for statistically significant of between CS and the CSDSS. From the results in Table 2, it can be observed that the CSDSS algorithm’s performance is significantly better compared to CS algorithm for all benchmark functions.

When examines Fig.4, the CSDSS outperforms the CS algorithm and reaches the optimum result very quickly. So, with respect to overall assessment of convergence graphs, we can say that the proposed method converges quickly and accurately towards the optimum solution.

</tr>
</tbody>
</table>

In order to compare convergence rates of the methods, convergence graphs for CS and CSDSS algorithms are given in Fig. 2, Fig. 3 and Fig. 4 for Schwefel2.22, Rastrigin and Griewank functions. The convergence graphs show that the proposed method has rapidly convergence and also obtains successful results. Examining Fig.2, while the CS converges slowly, the CSDSS continues the improving solutions thanks to ability of local search. For the Rastrigin function, the proposed method has early convergence and then gets stuck the local minima in Fig.3. Although its early convergence, it obtains better result than the basic CS.

V. CONCLUSIONS

In the basic CS, one solution search equation is used for the local search and the best solution of nest is ignored by this equation. This causes lack of the local search. In order to overcome these deficiencies of the CS algorithm in local search, this paper proposed the CSDSS algorithm using the different search strategies. Not only the proposed algorithm strengthens the ability of local search but also it improves the balance between exploration and exploitation. The proposed algorithm was compared with the basic CS on twelve benchmark functions. The CSDSS performs better results than the basic CS for all benchmark functions except $f_3$ and $f_8$. The proposed method is more efficient and more effective than the basic CS algorithm especially on the unimodal and some of multimodal functions.

As future work, the proposed method will be implemented to optimization problems and different search strategies will be used for the other nature-inspired algorithms. Furthermore, different search strategies can be increased and varied to improve the success of the proposed algorithm.

Abstract—Internet of Things (IOT) and communication between machines (M2M), has emerged as an important concept in conjunction with the use of Internet technology in embedded systems. Thus, programmable remote control and the need for people with microcontrollers, it becomes possible to use the system are minimized. Given this device's web server hardware capabilities, also allows the use of technologies such as web sockets. In this study, a mini computer featuring Raspberry Pi 2 moving images received through the attached camera on, transmitting in real time with clients via the web browser and the ability to monitor the place where you have displayed to clients at the same time is designed as a system. The goal of this system, image processing and artificial intelligence methods using a remote place / region to create a hardware and software infrastructure for monitoring or monitoring. The target for the operating system that offers performance from the device with the use of minimal resources, non-graphical interface and development environment ARM-supported Debian Linux as the Node.js installation is preferred. Socket servers and HTTP server software made by users of a particular program without the need for mobile phone environment is installed the device in any environment with a computer or web browser to monitor in real-time, data retrieval, and has obtained the ability to check. Created this is the system to be monitored spaces regardless of the number of users, thanks to the web connector technology in the software encoded on the device in real time without requiring an additional operation in the browser monitoring displays alerts (voice, text, etc.) situation can be produced.

I. INTRODUCTION

Embedded systems, machines and the Internet of objects (IOT) communication (M2M) systems in the exercise, one of the problems is the ability of hardware and software of the card used. The card will be developed, based on powerful hardware of software capabilities and data directly to the success. Unlike the device used to this point IoT Raspberry Pi 2 stands out. Raspberry Pi 2 reminds of a small computer with its specifications [1],[2]. The features of the card:

- 900 mhz Broadcom bcm2836 armv7 quad core cpu,
- 1 gb sdram,
- 10/100 ethernet rj45 jack,
- 4 usb connector,
- hdmi video output,
- audio and video output,
- micro sd card slot,
- 45 gr weight,
- csi camera link ports,
- dsi display connector,
- general purpose input and output 40 pins,
- micro usb power input.

Raspberry Pi founded on the route that the operating system capabilities of the card and depending on the desired programming engine performance can be created. Thus, microcontroller’s language dependency, and programming language is a dynamic development environment which removes the version dependency is obtained. Therefore, the performance of the operating system to be installed on the card the Raspberry Pi card directly. Card will be selected according to the work to be done on the programming language of the work performed is a direct impact on the success and performance. Similarly in this study; Raspberry Pi 1 used to monitor traffic [3]. Raspberry Pi 1 Model B used for home automation system in another work [4].

II. OPERATING SYSTEM AND NODE JS

A. Operating System Selection and Installation

Raspberry Pi cards use ARM architecture processors. ARM processors are compatible with all operating systems can run on Raspberry Pi. But running compatible with hardware, card produced for Raspberry Pi operating systems is used more
libraries. Web socket technology used with a very available in the low to initialize language is created with the “WebSocket” objects with which new data exchange, a new connection must be created and a package is one of the Socket IO this work was used in the search over the package is used by adding to the project. as module. Node Js NPM. languages is the biggest advantage is the package m platform is easy to install. [7 of the nucleus so that it allo modular. Node Js in 2009 Joyent company by Google's V8 Javascript engine is produced with a typical run-time environment to be run by the server. Node Js is scalable, event-driven event-driven asynchronous, non-blocking I/O uses working model [6]. This also allows you to run with high performance. LinkedIn mobile server side after passing to Node Js Server dropped the number from 3 to 30 and up to 20 times faster in some operations in masterminding. Node Js are modular. As a module each Node Js library and shrink the size of the nucleus so that it allows applications to run faster [7]. Downloaded the file from the official website of Node Js platform is easy to install. According to other programming languages is the biggest advantage is the package manager Node Js NPM. Ask if you want to do what you want probably as module. NPM is located and easily the desired with the search over the package is used by adding to the project. This package is one of the Socket IO this work was used in the acquisition of data with the web socket.

B. Node Js

Node Js in 2009 Joyent company by Google's V8 Javascript engine is produced with a typical run-time environment to be run by the server. Node Js is scalable, event-driven event-driven asynchronous, non-blocking I/O uses working model [6]. This also allows you to run with high performance. LinkedIn mobile server side after passing to Node Js Server dropped the number from 3 to 30 and up to 20 times faster in some operations in masterminding. Node Js are modular. As a module each Node Js library and shrink the size of the nucleus so that it allows applications to run faster [7]. Downloaded the file from the official website of Node Js platform is easy to install. According to other programming languages is the biggest advantage is the package manager Node Js NPM. Ask if you want to do what you want probably as module. NPM is located and easily the desired with the search over the package is used by adding to the project. This package is one of the Socket IO this work was used in the acquisition of data with the web socket.

III. WEB SOCKET

When the HTTP protocol, web browser (client) from the server (web-server) an HttpRequest, HttpResponse from the server in return gets, the connection is closed. Again, for a new data exchange, a new connection must be created and a new request.HTML5 browsers that support Java Script language is created with the “WebSocket” objects with which to initialize the client-to-server, server-to-client-sided with a low-cost, persistent connections are created. In Java Script web socket technology used with a very available in the library [8]. One of them; “Socket IO” and “SockJs” libraries. In enterprise applications, has become widely used in the Java Spring Framework, STOMP protocol support with SockJs library. In this study, it has been the preferred socket IO library.

A. Socket IO

The socket IO's with almost every browser in real time (including mobile devices) in spite of different communication protocols to communicate study is preferred. On servers that have been created on the node Js platform Socket IO is used with ease. The socket IO library created from object is set to the specified port on the server is made ready for use by the rest.

B. Real Time Event Model

The Socket IO creates web socket objects. Sockets are created when request by client to the web server-side on the port opens a channel between the client and service (Fig 2).

Fig. 2 The socket IO client/server connection model

Connecting to a socket request pop-up web posted by all clients through data communications same channel (Fig 3).

Fig. 3 The socket IO client/server data exchange model

Depending on the socket, exchanging data between clients and the server, you can open the channel room performed. Data communication materializes “Unicast”, “Multicast” or “Broadcast” in channel (Fig 4).
1) **Multicast**: The message to be sent to clients only is desired.

2) **Unicast**: Exchange of messages between client-server only point-to-point.

3) **Broadcast**: The message is sent to all clients in the channel.

**Fig. 4** The socket IO client/server data exchange model 2

**IV. IMPLEMENTATION OF WEBSOCKET RASPBERRY PI 2 VIDEO STREAM**

The prepared implementation of the model split into two layers. Layers named “Hardware” and “Software” (Fig. 5). Raspberry Pi 2 Card and Raspberry Pi Pi Noir Camera used in hardware layer. Debian Linux OS, Node Js, Socket Io and Html 5 used in software layer.

**Fig. 5** Application Model

Pi Noir camera is different from a normally camera with some features. Pi Noir camera has not got infrared filter. Thus, light in different wavelengths of light environments detected by the camera [9]. Electronic pertinax card established consisting of infrared and rgb led for using features of Pi Noir camera (Fig. 6). Leds manage with Raspberry Pi gpio pins.

Led used on pertinax plate gives information about websocket communications.

**Fig. 6** Fritzing diagram which is used leds

The program is controlling open and closed status of leds used on the plate coded in Node Js platform. The means of types and colors of leds:

1) **Infrared led**: Use to capture at night.
2) **Rgb led blue light**: Use to display light’s purple and other rays
3) **Rgb led green light**: Websocket and informs that it expects clients in the operational position of the camera.
4) **Rgb led red lights**: It announces the formation of defects in the system

Debian Linux operating system boot (bootable) was written on an SD card that is compatible with the Raspberry Pi card. Pi Noir camera installed on hardware layer by Raspberry card’s CSI port (Fig. 6 and Fig. 7).

**Fig. 7** Hardware Implementation
Made and the installation of the card Node Js platform Raspberry Pi software development process was completed on the card. Images from a camera with software developed the web socket objects that were communicated to clients that connect to the so called html using (Fig. 9).

Fig. 9 Video stream

Written applications are listening for requests from port 8080. To access the application Raspberry Pi card is assigned a static "192.168.1.10" ip address. When you want to access the generated web application: between the client browser and the server establish socket connection called from a channel called "/jsws". The images from the camera push simultaneously to all clients. When the number of connections in the channel 0 application automatically adjusts the camera standby position. In night vision position by turning infrared leds provides image acquisition on the basis of sunrise and sunset times.

V. CONCLUSIONS

Raspberry Pi this system based on device that in terms of cost cheap and simple founded, without need for any additional software development it offers real-time video which can be monitored from any web browser or your mobile phone. Installed system image acquisition with the provision of day and night as well as used to monitor simultaneously zoology, science fields such as biochemistry. Adding to the installed system software image processing algorithms; scientific studies, in an environment that needs to be constantly monitored in everyday, the formation of unwanted alarm conditions occur. In our system operation of the infrared LED for darkness use of sunrise and sunset is the negative aspects of the work. This problem is solved by adding a light sensor in system. It offers flexibility improvements made on each layer of the work. The written application-layer architecture coding module provides convenience as the expansion of software. Image data obtained from this will be used in real-time face detection and identification operation

COMPARISON OF SIMULATED ANNEALING AND GENETIC ALGORITHM APPROACHES ON INTEGRATED PROCESS ROUTING AND SCHEDULING PROBLEM

Ahmet Reha Botsalı
Necmettin Erbakan University, TURKEY
Department of Industrial Engineering
rbotsal@konya.edu.tr

Abstract— Today flexible manufacturing systems are highly popular due to their capability of quick response to customer needs. Although the advantages of flexible manufacturing systems cannot be denied, these systems also bring new issues on production planning side. Especially assigning machines to production operations and scheduling these operations with respect to machine constraints turn out to be an NP-Hard problem. In this study, the integrated process routing and scheduling problem is explained, and the performance of two different meta-heuristic techniques, which are genetic algorithms and simulated annealing, are compared in terms of solution time and quality.

Keywords— Optimization, Integrated Process Planning and Scheduling, Job Scheduling, Simulated Annealing, Genetic Algorithms

1. INTRODUCTION

Today, as the flexible manufacturing systems get more popular, scheduling production activities becomes more complex. The production managers have to make decisions such as: “Identifying the production operations that the jobs should go through”, “Assigning machines to job operations”, and “Identifying the sequence job operations on the machines”. Some of these decisions are related to the routing of the jobs on the shop floor and some of them are related to machine scheduling. These multiple aspects of production planning make the decision making much harder. Although it is possible to make decisions sequentially, this approach leads to a sub optimal solution. In order to find the best solution that minimizes the completion time of all jobs (makespan), the solution algorithm should take into account all aspects of the problem. This integrated production planning problem is referred as integrated process routing and scheduling problem in the literature.

It is possible to solve integrated process routing and scheduling problem optimally using the following mathematical programming model given by Botsalı and Şeker [1]. The model is described as follows:

- There is a set of jobs \( N \) and each job \( i \in N \) has a set of operations \( O_i \) to be completed,

- Any operation \( j \in O_i \) of job \( i \in N \) can be processed by a machine \( k \) of machine set \( M_j \) with process time \( t_{ijk} \).

- One machine can only process one operation of a job at a time and no preemption is allowed.

- The precedence relationship between the operations of a job should be satisfied.

- The objective is minimizing the completion time of the last operation (makespan) of the schedule.

By introducing the following additional variables and parameters, this problem can be modeled as below:

\[ Q : \text{Set of all machines} \]

\[ P_{ij} : \text{Set of operations that precedes operation } j \text{ of job } i \]

\[ (i \in N, j \in O_i, P_{ij} \subset O_i) \]

\[ x_{ijk} = \begin{cases} 1, & \text{if operation } j \text{ of job } i \text{ is processed by machine } k \ (i \in N, j \in O_i, k \in M_{ij}, M_{ij} \subset Q) \\ 0, & \text{otherwise} \end{cases} \]

\[ y_{ijlm} = \begin{cases} 1, & \text{if operation } j \text{ of job } i \text{ starts before operation } m \text{ of job } l \ (i, l \in N, j \in O_i, m \in O_l) \\ 0, & \text{otherwise} \end{cases} \]

\[ S_{ij} : \text{Start time of operation } j \text{ of job } i \]

\[ (i \in N, j \in O_i, S_{ij} \geq 0) \]

\[ C_{ij} : \text{Completion time of operation } j \text{ of job } i \]

\[(i \in N, j \in O_i, C_{ij} > 0) \]

\[ C_{\text{max}} : \text{Makespan (} C_{\text{max}} > 0) \]

\[ M : \text{A very big number} \]

Objective function:

(1) **Minimize** \( C_{\text{max}} \)

Subject to:

(2) \( \sum_{k \in M_{ij}} x_{ijk} = 1 \quad \forall i \in N, \forall j \in O_i \)

(3) \( C_{ij} = S_{ij} + \sum_{k \in M_{ij}} t_{ijk} \quad \forall i \in N, \forall j \in O_i \)

(4) \( S_{ij} \geq C_{lm} \quad \forall i \in N, \forall j \in O_i, \forall m \in P_{ij} \)

(5) \( S_{lm} - C_{ij} \geq (y_{ijlm} - 1) \times M \quad \forall k \in Q, i, l \in N, j \in O_l, m \in O_i; k \in M_{ij} \cap M_{lm} \)

(6) \( y_{ijlm} + y_{lmij} = 1 \quad \forall k \in Q, i, l \in N, j \in O_l, m \in O_i; k \in M_{ij} \cap M_{lm} \)

(7) \( x_{ijk} + x_{ijk} - y_{ilmj} - y_{mlij} \leq 1 \quad \forall k \in Q, i, l \in N, j \in O_l, m \in O_i; k \in M_{ij} \cap M_{lm} \)
In the above model, the objective is minimizing the makespan that equals to the finish time of the operation completed latest as stated by constraint set (8). Constraint set (2) ensures that each operation is assigned to a machine. Constraint set (3) defines that the completion time of an operation is equal to the sum of its start time and processing time. Constraint set (4) states the precedence relationships. Finally, constraint sets (5), (6), and (7) guarantee that operations processed by the same machine cannot be processed simultaneously.

This problem is NP-Hard and it becomes more and more difficult to solve the problem at the optimal level as the problem size gets larger. Due to this fact, in the literature there are various studies ([2], [3], [4], [5], [6], [7], [8]) to find a good solution in a short time for this problem using heuristic methods. In this study, we compare the performance of two different heuristics based on genetic algorithms and simulated annealing algorithm using the data instances provided by [2]. In the next section, details of these heuristics are provided.

II. HEURISTIC ALGORITHMS

The genetic algorithm used in this study was developed by Botsalı and Şeker [1]. Basically, this algorithm assigns a gene for each job that will be processed on the job floor. If there are \( n \) jobs and each job \( i \) has \( O_i \) operations to be completed on a production scenario, then the total number of genes in the chromosome of the respective individual in the population is equal to \( \sum_{i=1}^{n} O_i \).

Each gene in the chromosome has nine fields and each of these fields carries specific information as given below:

- Field 1: Order of the gene in the chromosome,
- Field 2: Job id that contain the corresponding operation
- Field 3: Order of the corresponding operation in the job id’s schedule
- Field 4: Id of the corresponding operation
- Field 5: Machine id assigned to the corresponding operation
- Field 6: Order of the previous gene in the chromosome which has the same job id in its Field 2
- Field 7: Order of the previous gene in the chromosome which has the same machine id in its Field 5
- Field 8: Start time of the corresponding operation
- Field 9: End time of the corresponding operation

II. HEURISTIC ALGORITHMS

The simulated annealing algorithm uses a data structure that is similar to the one used in the genetic algorithms. Also, the modification of the solution during the simulated annealing algorithm’s iterations are similar to the mutation operations of the genetic algorithm. During iterations, any new solution with a shorter makespan is accepted. However, a new solution with a longer makespan is accepted with probability \( e^{-(\text{makespan old}-\text{makespan new})/T} \), where makespan old and new are the makespan values of old and new solutions, respectively. \( T \) shows the temperature parameter of simulated annealing algorithm and it gets smaller as more iterations are done.

The algorithms are tested on a data set provided by Kim et al. [2]. However, there is an assumption we made which is different than the work done by Kim et al. [2]. We assume that two or more operations belonging to a specific job can be processed at the same time by different machines as long as there is no precedence constraint between these operations. By this way, integrated process routing and scheduling problem analysed in this study contains some characteristics of the assembly line scheduling problem. Yet, it is still possible to cancel this assumption and apply our algorithms to the original problem by just modifying the fitness/objective value calculation functions in the coding. Our computational results are given in the next section.

III. COMPUTATIONAL RESULTS

The genetic algorithm population size and the number of iterations is set to 100 and 150, respectively. Tournament size is taken as 3 and at each generation of the genetic algorithm 20% of the population is replaced by new individuals. For the simulated annealing algorithm, the maximum and minimum temperatures are set to 300 and 0.001, respectively. The cooling rate is set to 0.9 and at each temperature 10 iterations are done.

Both algorithms are run on a computer with Intel Core i5-5200U CPU@2.20 Ghz with 8GB Memory. For each instance, the algorithms are run 10 times and 10 different solutions are obtained. In Table I, the best solution values and the average of all solution values are provided for each algorithm and instance scenario.

As seen in Table I, the simulated annealing algorithm outperforms the genetic algorithm both in terms of solution quality and solution time when best solutions are analysed. Out of 24 instances, only for instance 11, the best solution of the simulated annealing algorithm is \( 0.1 \) higher than the genetic algorithm solution. In two instances, best solutions of the simulated annealing and the genetic algorithm are same and for the rest of the instance runs, the simulated annealing algorithm solutions are better than genetic algorithm solutions.

When the algorithms are compared in terms of average solution quality, except three instances, again solutions of the simulated annealing algorithm are better than solutions of the genetic algorithm. For these three instances, the average of simulated annealing solutions are at most 1.8% larger than the average of genetic algorithm solutions. However, for the remaining instances, the average of the solutions given by the simulated annealing algorithm can be up to 7.1% better than the average of the solutions given by the genetic algorithm.
Finally when two algorithms are compared in terms of solution time, the simulated annealing algorithm’s solution time is in general 90% shorter than the solution time of the genetic algorithm. In fact this is something expected since the number of computations is higher in the genetic algorithm.

During genetic algorithm computations, it is observed that the population converges to final solution before the 150th generation, so it may be possible to shorten the solution time of the genetic algorithm a little bit by reducing the number of generation parameter value from 150 to a lower value. Yet, still it is not possible for the genetic algorithm to be as effective as the simulated annealing algorithm in terms of computation time.

Although both algorithms used in this study are heuristic algorithms and they do not guarantee the optimal solution in the end, it is interesting to see that the simulated annealing algorithm gives better results compared to the genetic algorithm in general. There may be several reasons behind this. The author thinks that one of these reasons may be the size of the solution space. Since the number of the variables is very large in an integrated process routing and scheduling problem, it is
difficult for a heuristic algorithm to explore the whole space. For this reason, the quality of the final solutions highly depend on the initial solution(s) that the heuristic algorithms start from. As stated in the previous section, the genetic algorithm starts with a set of solutions which contain 100 different solutions (initial population). These 100 solutions are at different quality levels. The tournament selection procedure of the genetic algorithm gives higher chance to good quality solutions to be involved in crossover process. However, it seems like this is not enough to explore the parts of the solution space containing good quality solutions. On the other hand, the simulated annealing algorithm, starts with the best solution chosen out of an initial solution set of 100 solutions. It is seen that searching the solution space starting with a good solution and putting all the computational effort on one promising solution lead the simulated annealing algorithm to be superior to the genetic algorithm.

IV. CONCLUSION

In this study, two different algorithms are compared for the integrated process routing and scheduling problem. These two algorithms are based on genetic algorithm and simulated annealing algorithm techniques. The algorithms are tested over the problem instances provided by Kim et. al. [2]. It is observed that the simulated annealing algorithm has better performance than the genetic algorithm in general.

It is possible to extend this study in various directions. Different assumptions such as the allowance of pre-emption on shop floor can be considered. Also the performance of different heuristic algorithms such as particle swarm optimization or tabu search can be compared.

Abstract—3GPP LTE-Advanced release-13 is now supporting the deployment of femtocells (HeNBs), which provide better connectivity to the users (UEs) at home, offices, shopping malls, and dense urban areas, where the macrocell (eNB) has weak signals strength or no signal. These femtocells cover short distance (10 ~ 20 m) with high throughput and increased capacity, while on the other hand the deployment of huge number of femtocells create co-tier and cross-tier interference issues. To mitigate the co-tier interference problem we propose a Transmit Power Control (TPC) Algorithm, which will establish and control the connection between femtocell and the users. In case of downlink and uplink scenarios the transmit power of femtocells and UEs will be monitored accordingly. As a result this data will help to manage the switching of users among femtocells, macrocells to femtocells and vice versa. In the end we show the simulation results to compare the SIR and Throughput of users.

Keywords—3GPP, LTE-A, Femtocell, Macrocell, RRM, UE, eNB, HeNB, SIR, Throughput

I. INTRODUCTION

3GPP LTE-A is a very promising 4G technology for the thirsty mobile cellular network. With the advancement of mobile communication and technology, the expectations for high data rates are also increased. Due to the huge growth of smart phones, tablets, and notebook etc. the quality of service (QoS) and ubiquitous connections are required. On the other hand the number of subscribers increasing every year dramatically. According to [1] Global LTE passed 1 billion subscriptions in 2015 and will reach up to 3.62 until 2020. Due to the explosive growth of users and multimedia services the main challenge for next generation cellular networks is to oblige mobile data traffic by improving the capacity of the networks [2]. The present LTE-A system is based on homogeneous network, where every single eNB cover the whole cell, and each eNB use similar transmission power levels, modulation techniques, access schemes, antenna patterns to offer QoS to the UEs across cell [3, 4]. However, such deployment degrades the coverage and capacity of the cell-edge users.

One approach to solve the above mentioned problem is to shrink the cells, it provide the high data throughput and can fulfill the increasing demand of cellular systems, which will also improve the interference and signal to noise ratio (SNR), but this approach is not economical and as a result its need lot of expenses [5]. Therefore, the deployment of heterogeneous network (HetNet) is more scalable and beneficial for both operators as well as users. This approach is expected not only to improve the broadband user experience but also increase the coverage and capacity of the cell in cost effective manner [3].

Fig. 1. Source: 3GPP Release 13 [6]

Small cells can support wireless applications for homes and enterprises as well as metropolitan and rural public spaces. Due to the smaller coverage area, the same licensed frequency band can be efficiently reused multiple times within the small cells in a HetNet (Figure 1), thus improving the spectral efficiency per unit area (and hence the capacity) of the network. In a HetNet, small cells are envisioned as traffic off-loading spots in the Radio Access Network (RAN) to decrease the congestion in macrocells, and enhance the users’ QoS experience [7].

There are different types of small cells included like femtocells, picocells, and microcells, in this paper we focus only on femtocells, which are denoted by Home evolved Node Base-Station (HeNB) in LTE-A, this low power device can be installed at Homes, Shopping Malls and Congested Urban Areas and managed by the user himself. It covers up to 20 to 30 meters distance of space; it is very useful for indoor communication where macrocell (eNB) coverage is not enough for customers. The main advantages of using HeNBs are low cost, IP backhauling and frequency reuse; provide high capacity. Low battery usage and seamless transition between wired and wireless connecting devices [8]. However, in order to successfully deploy the femtocell architecture several challenges need to be addressed. Interference management remains one of the major issues: femtocells which operate in the same spectrum of macrocell users produce a cross-tier interference which degrades their transmissions. Moreover,
neighbour femtocells which belong to same operators, which may interfere each other. The latter interference is known as co-tier interference [9]. In this article we propose an algorithm for co-tier interference management to avoid the interference between neighbour HeNBs and UEs.

In the preceding sections we discuss different approaches and techniques use for RRM; in Section III we proposed an algorithm, in Section IV we have simulation results and Section V is the conclusion.

II. RELATED WORK

These days the Radio Interference Management (RRM) in LTE-A femtocell is the most challenging issue for cellular network operators. This is also a very hot topic for wireless communication researchers. Some of the works done by researchers are discussed below.

The authors of the article [11] explained the orthogonal and co-channel frequency allocation schemes, compared them and also show the simulations results. According to the distance between HeNB and eNBs which are two coverage areas, where the spectrum of eNBs is different from the HeNBs. The [12] use the hybrid approach for both uplink and downlink interferences, in this article the use of shared spectrum is exploited only when this approach is favourable both to eNB and HeNB users; otherwise, the partitioned approach is chosen. A power control method are proposed in [13], the authors explain the uplink and downlink scenario, which limits the co-tier interference in, while the encroachment of co-tier interference is ignored. In [14] two possible solutions are highlighted, the first one is to use the separate spectrum for HeNB and eNB, this technique is said to be Dedicated Channel deployment, while the other approach is to use the same spectrum for HeNB and NBs, this is known as Co-Channel deployment technique. These solutions are good to sufficiently increase the overall capacity of the system, but the Co-Channel interference issue remains the same, and the deployment is costly for operators. Whenever HeNB and eNB share the same part of spectrum, they will interrupt each other. Article [15] proposed a systematic way to optimize the resource allocation for public femtocell networks, including three schemes of different stages: (1) long-term resource management, which is to allocate spectrum resource between eNB and HeNB networks; (2) medium-term resource management, which is to allocate radio resources to each HeNB; (3) fast resource management, which is to further enable multiple HeNBs to cooperate to improve the network’s coverage and capacity. As we know that cross-tier interference can also be minimize by interference cancellation, and this method is by [16] as the class of techniques that demodulate/decode desired information, and then use this information along with channel estimates to cancel received interference from the received signal. The key technique for interference avoidance is Transmit Power Control, especially when many HeNBs are installed very close to each other. One such approach is discussed in [17], where the transmit power of a HeNB can be utilized accordingly, while the outdoor eNB’s UE can be protected sufficiently. In article [18], the authors use a simple power control method to avoid the interference cause nearby eNB’s users.

III. EXISTING NETWORK AND ITS PROBLEM

According to [06], the users can install femtocells under a macrocell and share the same spectrum. In this paper, we studied the downlink and uplink co-channel interference when macrocell and femtocell share the same spectrum. The deployment configurations are CSG and co-channel. Specifically, the downlink transmissions from the femtocell will cause strong interference at a nearby macrocell’s UE and may cause the received macrocell signal at the macrocell’s UE degraded and become unacceptable. Hence, the co-channel interference is one of the major barriers for the successful co-existence of macrocell and femtocell. We address the downlink and uplink interference problem by considering the transmit power at both the macrocell’s UEs and the femtocell’s UEs in terms of their received SINR.

IV. PROPOSED ALGORITHM

As we discussed in above section many techniques are implemented in LTE-A femtocell networks to mitigate the interference problem, all these techniques are working very good but they have some limitations as well. In this paper we proposed Transmit Power Control (TPC) Algorithm, which would reduce the co-tier interference for uplink and downlink of the LTE-A femtocell system. The “Interference Avoidance” is used to reduce the system interference. Our proposed algorithm will avoid the interference based on the threshold value of Transmit Power of User Equipment (PT(UE)) and Home evolved Node Base-station (HeNB). PTUE represents Transmit Power of UE while PTHENB represents Transmit Power of HeNB and their values are pre-calculated. The PTUE of one specific HeNB is changing by the other HeNB which are deployed near to it, and these power levels are expressed in dbm. The uplink interference could be controlled and maintained by the HeNB Gateway Server, the UE under the particular HeNB should transmit the assign power as soon as possible, because the HeNB will connect on First Come First Serve (FCFS) basis. The HeNB uses pilot signal to detect the UE in its coverage area and set the Pilot bit (Pbit) to 1. After successfully established the connection the HeNB will instruct the UE to communicate at assigned transmit power level. In case of downlink, the HeNB power levels are registered on start-up in femtocell gateway (FG) center and the power within the power level assigned to each downlink channels of the particular HeNB it handles.

V. FLOW CHART

The backhaul of LTE-A femtocell and connections are explained in [19], the HeNB is initially connected with FG Server through ADSL or fiber optic and then it will further connect to ISP. The figure 2, explaining the algorithm how it works.

Step 1: When the femtocell (HeNB) is Switch ON. It will refresh/update its database and all values will set to “0”. At the same time the HeNB will be registered in FG, which will assign a unique identification number (ID) to the particular HeNB to recognize with its Transmit Power (PTHENB).

The HeNB will adjust the UE to set the specific transmit power level.
Step 2: The HeNB will set PTHeNB to 1, while in FG the (PTHeNB) will set on First Come First Serve (FCFS) basis.

Step 3: For Uplink there are many UEs i.e i=1,2,3,…,N and single HeNB. If the set value of PTHeNB is less than PTUEi, the connection will establish, otherwise the PTHeNB will be set according to new PTUE.

Step 4: If the new PTUEj is greater than PTUEi, then the PTHeNB will set according to new value, otherwise rejected.

Step 5: Downlink side, the FG will set the threshold value of HeNB in its database. If the PTHeNB is less than the threshold PTTH value, the connection will establish, otherwise rejected.

Step 6: We consider many HeNBs i.e (i=1,2,3,…,N) while single UE. If the new PTHeNBj is greater than PTHeNBi, then the database of FG will update according to new value, otherwise its value will remain the same.

Step 7: If the HeNB is Switched OFF, all the data will clear, otherwise it will repeat step 5.

VI. SIMULATION RESULTS

As for the 3GPP Release 13, we used LTE System Toolbox functions to generate a downlink Reference Measurement Channel (RMC) R.12. [20], to estimate the performance of the near and far femtocells UEs. The UEs which are near to HeNB receive high throughput while the far UEs receive low throughput in LTE femtocell system. To see the simulation results we assumed two different scenarios according to the transmitting power of the HeNBs.

The topology of the LTE-A femtocell system is shown in Figure 3. There are two femtocells (HeNB 2 and HeNB 3) under the range of one macrocell (eNB). These two HeNBs are very close to each other, which can be disturbed due to interference of the signals. To avoid the co-tier interference problem, we proposed an algorithm and can see the result of UEs and HeNB which are using different level of transmission power. There are four different users (UE 1, UE 2, UE 3 and UE 4) and they are using different transmission power. In the simulation we also use three different groups according to populations of the UEs, which are served by macrocell i.e (eNB). The three different groups are divided by Dense Populated (DP Group), Medium Populated (MP Group), and Less Populated (LP Group).

As for the HeNB-2 scenario is concerned, we have given high transmit power to UE 2 and low transmit power to UE 1, UE 3 and UE 4. In figure 4, the overall throughput is shown; where we can see the UE 2 throughput is higher than the rest of the other UEs. Which means the higher transmit power has high throughput and low transmit power has low throughput. On the other hand if there is less population then the throughput will be high, and vice versa. In the delay case, if the transmit power is high and population is less, then delay will also be less, and vice versa.

As for the HeNB-3 scenario is concerned, we have given less transmit power to UE 2 while on the other hand we have given high transmit power to UE 1, UE 3 and UE 4. Figure 5 showing the throughput result of the UEs of HeNB-3. We can
see in this figure, that the UE 1, UE 3 and UE 4 have high throughputs, while the UE 2 has low throughput. From these results we can say, that high transmit power has high throughput; while low transmit power has low throughput. Similarly DP Group has low throughput, while LP Group has high throughput. On the other hand if there is high transmit power and LP Group the delay would be quite low, and vice versa.

From the above simulation we can describe, that transmit power of femtocell (HeNB) is very important and will decide the communciation between HeNB to HeNB and UEs. The transmit power of both UE and HeNB will decide the connections between them. In our proposed algorithm, we use the transmit power of femtocell (HeNB) as a decider for both Uplink and Downlink scenarios. Higher the transmit power has higher chance of connectivity; lower transmit power will be rejected.

VII. CONCLUSION

The evolution in LTE-A, the deployment of femtocells (HeNBs) is of great improvement due its efficiency and low power consumption. In this article we proposed a Transmit Power Control (TPC) algorithm, which can work very intelligently to decide the connection between HeNB and UEs. Using this algorithm the co-tier interferences will eliminate and provide better performance. In the simulation section we discussed the importance of transmitting power of UEs and HeNBs in LTE-A femtocell networks; if the power is high the throughput is also good. In future we can propose some techniques (algorithms) for cross-tier interference which also affect the performance of femtocell network.

Abstract— Customers and products are the main assets for every business. Companies make their best to satisfy customers because of coming back to their companies. After sales service related to different steps that make customers are satisfied with the company service and products. After sales service covers different many activities to investigate whether the customer is satisfied with the service, products or not? Hence, after sales service is acting very crucial role for customer satisfaction, retention and loyalty. If the after sales service customer and services data is saved by companies, this data is the key for growing companies. Companies can add value their brand value with the managing of this data. In this study, we aim to investigate effect of 6 factors on customer churn prediction via data mining methods. After sale service software database is the source of our data. Our data source variables are Customer Type, Usage Type, Churn Reason, Subscriber Period and Tariff The data is examined by data mining program. Data are compared 8 classification algorithm and clustered by simple K means method. We will determine the most effective variables on customer churn prediction. As a result of this research we can extract knowledge from international firms marketing data.

Keywords— Data Mining, Customer Churn Prediction, Customer Satisfaction, Knowledge Discovery in Database

I. INTRODUCTION

Telecommunication companies maintain and store tremendous amount of data about the customer information, phone calls and the operations of their networks. Due to the improvement of computer systems and telecommunication technologies, this industry has expanded rapidly. Data mining helps to improve quality of service, detect the customer communication type, determine deceitfulness activities and make better use of resource in telecommunication industry.

One of the widely applied areas of data mining is Customer Relationship Management. Customer Relationship Management approach is focuses on retention, relationship development and increase satisfaction. From a business intelligence perspective, churn management process under the customer relationship management (CRM) framework consists of two major analytical modelling efforts: predicting those who are about to churn and assessing the most effective way that an operator can react (including ‘do nothing’) in terms of retention [1]. Previous studies have indicated that the cost of gaining new customers is much expensive than the cost of retention the existing customers [1], [2], [3], [4], [5], [6] Loss of customer causes negative effects on firms reputations and income reduction [7]. Companies are increasingly focused on accurate customer churn forecasting models. These models should be enhanced to identify the factors to churn and the developed needs to retain customers. Churn of customer is defined as the tendency of customers to interrupt doing business with a firm in the time process. Customer churn has become a significant problem today. In worldwide, one of the main challenges is determined to propensity of churn of customers. Geppert (2003) suggest another list of causes of churn: Price, Service quality, Fraud, Lack of carrier responsiveness, Brand disloyalty, Privacy concerns, Lack of features, New technology introduced by competitor, New competitor enter the market, Billing or service disputes [8].

High customer churn risk is one of the stringent challenges in telecommunication companies. Pareek has classified telecommunication industry challenges in four groups; Consolidation, Competition, Commoditization, Customer service. Telecommunication data which is very complex has needed many preprocessing for analyse. Data mining which is a useful tool, is extracting and exploring information from data. In this paper, we will provide an application to telecommunication companies. We want to have knowledge about customers that who are existing and loyal to company, who are going to leave or quitting from company products/services.

Customer churn probability is predicted by data mining algorithms analysing historical data. Data mining techniques used for this purposes typically utilize the average number of calls, billing data, the change in the average number of calls, call detail data, subscription and customer information [10].

In this paper, we investigate features of applying the data mining in customer churn prediction of a telecommunication data. First, we identify the variable of effecting customer
churn prediction of a telecommunication system. These variables are examined in data mining algorithms. Data mining algorithms are compared with each other. Proposed algorithm is also discussed and we conclude the paper with conclusions.

II. MATERIAL AND METHOD

Telecommunication data consist lot of interesting issues for analysing in data mining. Telecommunication databases include huge amount of data in worldwide. But raw data is not usually suitable for direct usage for data mining. For this reason researchers should examine data effectiveness and apply some of pre-processing operations to be usable. Our study include of data sampling, pre-processing, model construction, and model evaluation phases.

We have used open-source data mining tool Weka (version 3.8) for this study. We analyse our dataset performance of a comprehensive set of classification algorithms (classifiers).

A. Data Set

The dataset that we used obtained from a Turkey’s one of the biggest telecommunication company. Real time data was obtain on May 2016. Untreated data consisted of 6 factors, 66 sub factors and 498,866 instances. 38.36% of data were churners.

According to (Acker, et al., 2013), data pre-processing can be up to 80% of the total analysis work and analyzing the data, once joined, cleaned and transformed consumes just about 20%. The raw world data is usually noisy, inconsistent and incomplete due to their typically large size and their likely origin from multiple and heterogeneous sources. Dimensions of data quality; Accuracy, Completeness, Consistency Timeliness, Believability, Value added, Interpretability Accessibility.

Data sampling randomly selects a set of customers with the required information, according the definition of churn in designated telecommunication company. Evaluate factors and sub factors distribution as shown in Fig. 1.

![Fig. 1 Distribution of the data](image)

![Fig. 2 Major data pre-processing tasks and techniques](image)

In the study we used some of pre-processing techniques. In data cleaning step we clean some of the data, which are identifying incorrect information or incorrect. At the end of this step, we have 498.356 data. Ordered sub factors are converted to numeric values. We create some of groups of subscribe period for subscriber time.

B. Data Mining Techniques in WEKA

Data mining technique in CRM is usually apply in real world case because CRM on data mining have attracted both the practitioners and academicians. In CRM there are several
different functionalities, techniques and applications. as shown in TABLE II.

For churn prediction is used most popular ones are:
- Decision trees
- Artificial Neural networks
- Regression.

Weka (Waikato Environment for Knowledge Analysis) includes some of classifier algorithm such as Bayes, MISC, Functions, Rules, Decision Tree, Lazy etc. A good mix of algorithms have been chosen from these groups that include Naive Bayes and Bayes net from Bayes Classifier, Multilayer Perceptron from functions, JRip, PART, OneR from Rules Classifier and Random Forest and J48 from Trees.

III. RESULTS AND DISCUSSION

A total of 8 classification algorithms have been analysed in this study. We evaluate the features with 10-fold cross validation. In the classification process, we perform 10 times for training and testing.

The results from TABLE III have been analyzed the classifiers work better. The classifiers J48, Random Forest and PART have performed better in data set (up to %87). Errors and Kappa statistic seem to be same among 3 classifiers and are based on the accuracy of the prediction.

Customer clustering is very important issues in data mining methodologies for customer relationship management (CRM).

To segment customers by Customer Type, Usage Type, Churn Reason, Subscriber Period and Tariff as variables and used K-Means to model the customers into five clusters. To generate roughly the same number of subscribers in each of the seven clusters. Table IV is summarized the clustering results. Simple K-Means method is a common and effective method for clustering.

From this result, it is possible to generate some customer management strategies. Simple algorithm K means the results can be interpreted as follows.

- Cluster 0: Include %17 of all customers and these customers are active in system 0-5 year period. They use 4.tariff in telecommunication systems for their home.
- Cluster 1: Include %22 of all customers and these customers are active in system 6-10 year period. They use 14.tariff in telecommunication systems for their home.
- Cluster 2: Include %13 of all customers and these customers are churned in system 6-10 year period. They used 1.tariff in telecommunication systems for their business. Churn reason is 1 coded.
- Cluster 3: Include %17 of all customers and these customers are churned in system 6-10 year period. They use 14.tariff in telecommunication systems for their home. Churn reason is 5 coded.
- Cluster 4: Include %14 of all customers and these customers are active in system 16- year period. They use 7.tariff in telecommunication systems for their home.
- Cluster 5: Include %13 of all customers and these customers are active in system 11-15 year period. They use 7.tariff in telecommunication systems for their home.
- Cluster 6: Include %4 of all customers and these customers are churned in system 0-5 year period. They used 3.tariff in telecommunication systems for their business. Churn reason is 2 coded.
IV. CONCLUSIONS

With the strongly development of telecommunication industry, the service providers needs more knowledge of the subscriber. In today’s very hard competitive environment, holding of existing customers has become an enormous challenge. Churn analysis is used to predict of customer behaviours that are most likely to change provided service and to compose special marketing tools for them.

Churn prediction in customer relationship management is critical issues in telecommunication industry. For the purpose of competitive in this industry, service providers must be able to predict probability of churners and take proactive approach to retain existing customers. In this research, we use WEKA data mining algorithms for purpose of different classification techniques and clustering for churn prediction.

This study is inspected determinants of customer churn in the Turkish telecommunications industry service market using a sample of have 498.357 actual and churn customer data. The efficiency and the performance is compared of Naive Bayes and Bayes net from Bayes Classifier, Multilayer Perceptron from functions, JRip, PART, OneR from Rules Classifier and Random Forest and J48 from Trees.

The goal of the paper is define and explain the related factors in active and churn prediction modelling. On the other hand this study aims to cluster the application data with data mining simple k means clustered technique. Classified and clustered that uses for churn prediction in Data Mining.

ACKNOWLEDGMENT

The dataset were obtained one of the biggest telecommunication companies in Kayseri, Turkey.

A Fast Detection Approach for Road Defects Using Image Processing

Busra AKARSU, Koray Sener PARLAK, Mehmet KARAKOSE
busra.akarsu@hotmail.com, ksparlak@firat.edu.tr, mkarakose@firat.edu.tr
Firat University, Computer Engineering Department, Elazig

Abstract—Road defect is one of the most important factor for traffic accident. Therefore, this defects should be corrected as soon as possible. It usually occurs cracks, rutting, and potholes in road surface. There are various methods in the literature for the road defect detection. Traditionally these defects is tried to detected by the human eye are performed using image processing in recent years. However, there are deficiencies such as inability of real time application, slow work, and inability to identify with high accuracy in addition to being shortage of studies using image processing.

Aim of this study is defect detection at road by using image processing algorithm with images taken from a camera on a vehicle. In first step of this study, preprocessing is performed by utilizing median filter algorithm. Then, in second step essentially threshold values to detection process are obtained by performing feature extraction with mathematically morphological techniques. In final step whether road defect exist or not, and which level of defect are obtained by being classified in real time. To reveal the accuracy and performance of the proposed approach, comparative results are given by examining images obtained as experimentally.

Keywords—Road defect detection, image processing, morphological operation, decision tree, median filter

I. INTRODUCTION

Roads are the transportation method which is most widely used around the world at the present time. One of the most important causes of accidents on the roads is the road surface faults. The improper operations in the construction phase and the reasons such as pressure caused by heavy vehicles on the roads and weather condition lead to the deformations on the road surfaces over time. These deformations on the road surfaces are called Alligator Cracking, Block cracks, Linear Cracking, Transverse Cracking, Joint Reflection Cracks etc.

The elimination of the road defects is both a big work load and an organizational operation [1]. Today, road defect detection based on the fact that people see these defects. This method prevents the elimination of defects in a short time. Many researchers have proposed different methods about how to detect the defects in a faster way. The features such as being cheap, being fast and and applicable determine the effectiveness of a method [2]. Among these methods, one of the cheapest and fastest method is the algorithms developed using image processing methods.

The crack in the image taken and the contrast between the road are reduced due to the light on the road surface and the changes in weather conditions [3]. It is difficult to perform feature extraction from the road surfaces using image processing methods and to detect feature due to the plurality of the colour changes of the road surfaces [4]. Edge detection methods are very efficient for feature extraction in the other detection problems [5-7]. but performing feature extraction from the road surface is not only edge detection or texture analysis problem [8]. Color changes and noise in received image make difficult to defect detection. In this case, improvement of the image becomes an important duty in order to make an accurate prediction [9]. The road cracks constitute the continuous and darkest region of the image [10]. In the study carried out, the cracked structure was brought to the forefront to improve the image by using a median filter and collecting with an image on which no processing was performed. In the literature, productive results were also obtained by using median filter [12,13] to improve image. In addition to median filter, histogram equalization [8], calculate the threshold value [10], etc. were used for image improving.

Feature extraction defines the relevant shape information in the image [11]. In the literature, edge control [14] and various parameters such as slope, inertia [10] which can be removed through image were used for feature extraction. For instance, Guanqun Bao [12], proposed feature mapping method. This method was based on from vertical histogram and horizontal histogram values.

The usability of road defect detection applications depends on being able to achieve fast and good results. In accordance with this purpose, an attempt to achieve faster and better results was made in the study carried out. If deep cracks on the road are not repaired in a short time, the damage on the road is further increased. Therefore, it is necessary to make the distinction of superficial and deep cracks. In the study carried out, roads were classified as without crack, superficial crack, crocodile cracking, transverse cracking and longitudinal (linear) cracking.

II. PROPOSED METHOD

The proposed method is based on feature extraction and classification through the image obtained by bringing cracked structure into the forefront. The flow chart of the study carried out is presented in Fig. 1.
It is difficult to extract data through the obtained images. Because the received image may be noisy, low contrast etc. The road cracks constitute the continuous and darkest region of the image [10]. The operations required for the detection of the darkest region of the image are obtained more comfortably through the gray scale image. Median filter can be generally used to minimize the angular blurred degradations, soften the flat region and protect the edges [15]. Along with the synchronization algorithm, Median filtering can be used to improve the image contrast with the effects of the impulsive noise and white noise [12, 16]. Median filter is based on the recalculation of all pixel values in the image according to the neighboring pixels. Pre-processing with median filter is often used for preserving edge while removing noise. For the operations to be performed, median filter was used because it gives better results. The crack should be further brought into the forefront in order to find out whether there is a crack in the road images. Operation on rgb image leads to loss of time for road defect detection and it is more difficult than operation on grayscale image. Therefore, it is converted into a gray scale image for next steps as shown in Fig. 2.(b), the blurred image was obtained by applying the median filter. The cracked structure was brought to the forefront by collecting the blurred image and the gray scale image on which no processing was performed. Both fracture parts in the image obtained were brought to the forefront and noisy sections were reduced in the image obtained after the collecting process as shown in Fig. 2.(c).

Morphological operations were carried out in order to correct the sections which were seen as if they were disconnected on the image and to get rid of some undesired defects. The image was transformed into binary image in order to perform mathematical morphological operations and to achieve the cracked structure in a more accurate way.

Mathematical morphological operations are the commonly used methods in the operations of the geometrical structures. Morphological medians are hierarchically represented in similar dimensions among spatial areas [17]. Morphological operations are frequently exposed to scientific thinking and researches like morphological profiles, because Morphological operations are known to be useful for the classification of panchromatic and hyperspectral images with very high spatial resolution [18]. Erosion, dilation, opening and closing are the basic morphological operations. The input image and output image are generated in the same dimension. The pixel values in the processed image calculated by the
neighboring pixels. The mathematical morphological operations of erosion and dilation were applied in order to improve the images of the cracks. In erosion, it is performed by giving the smallest of the neighboring pixels. If the pixel is equal to ‘0’, it remains as is. In dilation, the biggest of the neighboring pixel values is given. If the pixel is equal to ‘1’, it remains as is. The results of morphological operations such as erosion and dilation operations are facilitated the detection of thin fractures in the image.

![Image of Mathematical Morphological Operations](image1.png)

Feature extraction process is based on performing operation over pixels through the image. The total number of pixels in the image is small because the surfaces without cracks are the points which are independent of each other. Therefore, the images below a defined value were accepted as without cracks. In the images with cracks, it was detected that there was a superficial crack if the value which was obtained by the division of the area of the cracked region to the entire area was below a certain value. For crocodile cracking in the images, whether there was crocodile image was detected by calculating the number of objects because more than one objects were obtained. Whether the crack was extended horizontally or vertically was found by detecting its direction. It was accepted horizontal if the obtained value was between -45 and 45, and it was accepted vertical in the other case.

The classification process was carried out with decision trees. Decision tree is performed by the hierarchical fragmentation of the object feature space [19]. A Decision Tree provides open relationship between input features and estimates [20]. Obtained of multiple data in feature extraction has made it’s possible to use decision tree for classification process. So road surface is usually without cracked structure. In the study carried out, whether the road surface is cracked in the root node is detected. If the path is faulty, whether there is a crack in the child node is detected. If the fault is deep crack, whether there is crocodile cracking is detected. If it is not crocodile cracking, whether it is linear or transverse cracking is detected. The operation steps in classification are given in Fig. 5.

![Decision Tree Algorithm](image2.png)

### III. EXPERIMENTAL RESULTS

The study was carried out on a computer with Intel(R) Core(TM) i5 CPU, 2.4 GHz, 3 GB RAM and 64-bit operating system. After the detection and classification algorithm of road surface defects was coded in Matlab on the computer, for the testing operation of the study carried out, the performance of the algorithm was evaluated using the required images which were obtained from both web environment and the camera with CMOS 13.0 MP resolution. The images were obtained by being positioned to be about 1 m above the road surface and 90° to the surface. Some examples of the study carried out and information about how long the operation was performed are given in Table I.

After the image was obtained, it was transformed into gray scale image. The gray scale image was dimensioned and prepared for the mathematical operations to be performed later. The cracked structure was brought to the forefront after blurring the image by median filter and the addition operation. As it is described in the proposed method, the image was transformed into binary image for the mathematical morphological operations after obtaining the cracked structure in the image. Mathematical morphological operations were used to improve the obtained image. An attempt to achieve better results was made by defining two different matrices for the morphological operations performed. In the feature extraction operation, the classification was performed by calculating the total number of pixels obtained through the image, solidity value, total number of objects and the slope of the object for the images consisting of single object. In classification, we found without crack structure because road surface is without cracked in generally. This situation gain time for find cracked structure.

Within the context of the application, to which of the five classes including without crack, superficial, crocodile cracking, linear cracking and transverse cracking the obtained image was belonged was detected. It was applied on various...
types of roads. The performance of the algorithm was evaluated by developing the algorithm developed on Matlab. The system can also detect the cracks about 1 mm in thickness.

The success of the system decreases on poor quality roads and in superficial cracks.

**IV. CONCLUSIONS**

The proposed algorithm is a new method used to perform the detection and classification of the road surface defects by image processing methods. In the first stage, operations were performed to bring the cracked structure into the forefront. The cracked structure has further come to the forefront by the mathematical operation performed because it constitutes the darkest part of the image. The roads were divided into five classes as without crack, superficial, crocodile cracking, linear cracking and transverse cracking. For these operations, in feature extraction, they were subjected to classification process according to the total number of pixels, solidity value, the number of objects in the image and the continuation angles of the cracks. The decision trees were used for the classification process.

The proposed method can also be used for the detection of very fine cracks. However, its performance decreases in the color changes that occur due to various reasons on the roads. The image taken by the camera should be obtained under appropriate lighting conditions in order to increase the efficiency of the algorithm.

The algorithm developed performs the classification operation between 0.940736 - 0.632034 sec. It has an average success rate of 80%. This also indicates that it is a system that can be used in real life.

A Vision Based Detection Approach for Level Crossing and Switch in Railway

Canan Tastimur¹, Mehmet Karakose² and Erhan Akin³
¹,²,³Firat University, Departure of Computer Engineering, Elazig, Turkey
{ctastimur¹, mkarakose², eakin³}@firat.edu.tr

Abstract—Railroad transportation is considered one of the safest means of transportation. Important components of this transportation are tracks, level crossing, turnout, and so forth. Detection of these component is critical for realizing centralized supervision, comprehensive evaluation, and accident prevention. Safety of railroad can be developed using intelligent systems which supply additional information about the exact location of the train, its speed and upcoming obstacles. Level crossings in railroad are significant safety points. Because there is the risk of collisions between motor vehicles and trains. Therefore it is necessary first to detection level crossings for detection of obstacles in level crossings. In this paper a vision based approach is presented that detects to level crossings and turnouts in railway. In the images of a camera that observes the area in front of a railroad vehicle the rail tracks are detected in real-time. These images are converted to HSV color format in first step of the proposed method. Then image normalization and gradient computing are performed. In the next step, the effect of illumination on the appearance of the image is removed with ratio of gradient magnitude and gradient the average of the gradients of all pixels in the image. Then to suppress the effects of pixels with large gradients, and noisy pixels, during illumination normalization, weights are calculated. In the next step the computation of the weighted average of V values of the pixels inside the rectangular windows with varied sizes is time consuming. Therefore to speed up the computation, Integral image which is an elegant technique for efficiently carrying out an averaging operation is applied to result image in the final step. In this way turnout detection is realized. While preprocessing, feature extraction, and image processing techniques is used in level crossing detection process.

Index Terms—Railroad Switch Detection; Level Crossing Detection; Integral Image; Image Processing; Image Normalization

I. INTRODUCTION

The importance of railway transportation has been increasing in the world. As the railway traffic are developing at a dramatically speed all over the world, the safety and comfort of the railway system are paid more attention than ever before. It is required that the railways are examined in more detail with the enhanced railroad technology. Trains are considered one of the safest means of transportation. Accidents still often happen due to driver’s tiredness, bad weather conditions or other factors. Safety can be enhanced using intelligent systems that supply additional information about the exact location of the train, its speed and upcoming obstacles [1]. Manual inspection of rails is slow and contact inspection methods harm the rails, rail analysis is performed with machine vision via non-contact, high accuracy and high speed methods [2]. Besides, manual inspection is expensive and cause to temporarily disable of railway [3].

Railway turnout systems are one of the most critical pieces of equipment in railway infrastructure. A turnout is used to transfer vehicles from one track to another track. As an important part of railway system, the turnouts have a strong relation to the comfort of the railway vehicles and severe turnout defects can lead to accidents [4]. Therefore, it is important to detect turnout defects timely. Switch is one of the three outdoor railway equipment [5]. It has many characteristics such as large quantity, complex structure, short using life, limiting the train speed, low driving safety, big investment for maintenance etc. [5]. It is also one of the three major weaknesses in rail.

To locate railway vehicles exact and reliably in railroad network, collision avoidance systems are required. In this systems it is vital to determine the direction a railroad vehicle turns at switches. Most of common driver assistant systems work on unstructured environments for detection of obstacles [6]. These environments include many non-planar surfaces which pose a big challenge for vision systems [6]. Alike problems exist for railroad environments which frequently contain complex shapes and surfaces like hills and vegetation along railroad tracks [6]. In railroad transportation, main task of train driver is carefully to focus on rail track. Therefore vision area of train driver is area between two rails in front of train and right and left sides of these rails.

Three important component of railway can be expressed as rails, switches and level crossings. Detection of switches and level crossings can be seen as possible accidents prevention tool and driver assistance system. The developed methods related with based contactless image processing switch detection are available in literature. Li et al. [7], enhanced line detection method for railway switch machine monitoring system. This method was based on image processing techniques. It was used to Canny edge detection, Zhang Suen Thinning method to reduce the thickness of the edges and Probabilistic Hough Transform to detect the lines in this study
Espino et al. [1] offered a method that detects railway track and turnout. And this method was not based on an empirical threshold. Railway track extraction was not based on an edge detection using the width of the rolling pads. This edge detection scheme was then used as an input to the RANSAC algorithm to determine the model of the rails. The turnout detection scheme was based on the Histogram of Oriented Gradient (HOG) and Template Matching (TM) [1]. To detect railway turnout, Support Vector Machine (SVM) was also used. Qi et al. [8] presented a novel railway tracks detection and turnouts recognition method by using HOG (Histogram of Oriented Gradients) features. Firstly, this method computes HOG features and defines integral images, and then extracts railway tracks by region-growing algorithm [8]. By recognizing the open direction of switch, this method finds path where the train will travel [8].

Wohlfeil [9] recommended a vision-based method that provides to determine the direction a railroad vehicle turns at switches. A camera observed area in front of railroad vehicle and images of this area were used to detect rail tracks in real-time. Switches were detected by tracking rail tracks in these images. It was shown that the followed track can be determined at branching switches [9]. Kaleli and Akgun [10] offered an algorithm to extract railroad track area in front of the train by utilizing Dynamic Programming. They utilized dynamic programming to compute the optimal path which gives the minimum cost to extract the railroad track space. This algorithm extracted the left and right rails through utilizing dynamic programming simultaneously.

Espino and Stanciulescu [11] improved a vision based algorithm which detects railway track and turnout and classifies turnout. In this algorithm, railway track detection was performed with edge detection using the width of rolling pads [11]. Then this edge detection scheme was used as an input to the RANSAC algorithm to determine model of rails knowing their gauge. Turnout detection process was based on Histogram of Oriented Gradient (HOG) and Template Matching (TM) in this study. The turnout classification process was based on Histogram of Oriented Gradient (HOG) in this study [11]. Ross [12] proposed the utilization of a monofocal video camera to enhance the localization quality. Ross’s algorithm estimated the track recursively in camera images.

II. RAILROAD SWITCHES AND LEVEL CROSSINGS

Switches, also called turnouts or points, are an important part of railroad. This component enables to orient from one track to another. Switches are a fundamental part of the railway infrastructure, given that they enable the creation of a real network. Turnouts are not only placed in the infrastructure to connect different lines, but also to connect parallel tracks of the same line [13]. So, this process give flexibility to track. The operational effect reasoned by a case on track is directly related to the number of crossover in the line [13]. Moreover turnouts offer a singular point in the track. When compared to plain track, switches have higher track toughness considering that they are supplied with altered sleepers dimensions and arrangements, additional rail elements, etc. Besides, according to adjacent rail track, the conditions of the wheel-rail interface change significantly given the rail geometry interruption of switch [13]. Components on the railway line should be monitored at regular intervals to ensure continuous transport security [14].

Switches must be kept in good condition in order to guarantee an enough running of the train through switch. If this situation is not properly maintained, the wheel-rail interface will be negatively affected. Because of safety and operational issues, switches are intensively examined and protected. In spite of high investment on maintenance, switches have a lesser existence than plain track be considering that they suffer higher stress. The switch consists of the pair of linked rails. There are a number of standard layouts or types of turnouts [15]. These types are Left Hand Turnout, Y Turnout, Diamond Crossing, 3-Way Turnout, Single Slip and Double Slip, as shown in following diagrams.

The term level crossing is also called are railroad crossing, railway crossing, road through railroad, train crossing or grade crossing. The level crossing is a crossing on one level of a railway line by a road, path, or another railroad [16]. Level crossings are high risk areas where rail traffic crosses paths with road and pedestrian traffic at the same level. In many countries, level crossings on less important roads and railway lines are often open or uncontrolled [16]. An example of level crossing is shown in Fig. 8.
III. THE PROPOSED METHOD

The rail tracks, switches and level crossings are vital components in railway. To be safety transportation in railroad, these components should be controlled and be examined whether defects or not. Determination of these components with contactless image processing techniques provides additional information such as exact location of train, its speed and upcoming obstacles.

A contactless vision based image processing algorithm is recommended in order to detect rail track, switch and level crossing. Block diagram of switch detection algorithm is as shown in Fig. 8. Steps of this algorithm are respectively acquiring the railway images, determining the region of interest with ROI segmentation, rail track extraction, and determination of switch crossing. Acquiring the images, first of these steps, is process of taking images from the camera that is placed on top of the train. Determining the region of interest is performed with ROI segmentation. Region of interest consists of rail track area in front of train. Using ROI segmentation has led to easier detection of the track. The next step is rail track extraction. Result image of this extraction process includes only rail track and small amount of noisy pixels. Switches in image are detected in final step.

Figure 8. Block diagram of switch detection algorithm

A. ROI Segmentation Method

The flowchart of ROI segmentation algorithm is shown in Fig. 9. To extract region of interest area, we compute to the railroad vanishing point \( \mathbf{p} \) and track width parameter \( W_{\text{max}} \) from an input image. Rail tracks are aligned parallel to each other and their width decrease linearly in the image from bottom to up. Vanishing point term refers to the intersection of the track lines defined as in Liang [18]. It is firstly performed color conversion from RGB to HSV color space in this algorithm. HSV color space consists of 3 channels. These channels are Hue (H), Saturation (S), and Value (V). Hue channel defines the dominant wavelength of the color such as green, blue, yellow, and etc. And this channel has a value between 0-360 angular. Saturation channel identifies the vividness of the color. High saturation reasons to vivid colors and low saturation ensures that the color approaches to shades of gray. While value channel defines white rate of within color. So it identifies the bright of color. In this study, ROI segmentation steps are performed on V channel image.

In gradient computing step, the gradient of input image is computed by using Sobel operator and thereby gradient magnitude image \( \text{Gradient}(i,j) \) is obtained. Then a given threshold value is applied to the bottom 1/5 of the gradient image due to the fact that this part of the image includes sufficient information to extract the features. Furthermore rail tracks are straight and their gradient magnitudes are high in the bottom of the image. This threshold process eliminates the points that have lower gradient magnitude from the threshold value \( T \). In the next step, a binary image \( \text{Binary}(i,j) \) is constituted from gradient image \( \text{Gradient}(i,j) \) by Equation 1.

\[
\text{Binary}(i,j) = \begin{cases} 
1 & \text{if Gradient}(i,j) > T \\
0 & \text{otherwise}
\end{cases}
\]

In the next step, Hough transform is carried out to binary image \( \text{Binary}(i,j) \) in order to detect rail lines. Hough transform returns lines that have different lengths. Hough transform is very helpful in order to detect straight lines. Lines returned include their end-point coordinates without line length information. The length of a straight line between its two end points \((x_1,y_1)\) and \((x_2,y_2)\) is computed by Equation 2.

\[
\text{length} = \sqrt{(x_2 - x_1)^2 + (y_2 - y_1)^2}
\]

This operation specifies many lines including rail track lines. But the lines expect for rail track lines are also available. Thus we extract the rail lines which are the longest lines on the left and right. Then the longest line on the left and right can be founded by calculating line lengths by Equation 3.

\[
y = mx + c
\]

After rail track lines are detected by using Hough transform [19, 20], the intersection of two straight rail lines in the image can be computed. To compute vanishing point, common form of a linear equation can be used. This equation is described in Equation 3. This equation is slope-intercept form, where \( m \) is the slope and \( c \) is the y-intercept of the line. The slope equation of a line which passes through two different points \( P_1(x_1,y_1) \) and \( P_2(x_2,y_2) \). This equation is shown in Equation 4.

\[
m = (y_2 - y_1)/(x_2 - x_1)
\]

The y intercept of a line which passes through two different points \( P_1(x_1,y_1) \) and \( P_2(x_2,y_2) \). This equation is shown in Equation 5.

\[
c = (x_2y_1 - x_1y_2)/(x_2 - x_1)
\]

The y coordinate of vanishing point \( p \) is computed by Equation 6.
\begin{equation}
\text{Point}_y = \frac{(m_1 c_2 - m_2 c_1)}{(m_1 - m_2)} \quad (6)
\end{equation}

In Equation 6, Point\(_y\) is the \(y\) coordinate of the intersection of lines. \(W_{max}\) can be computed by subtracting \(x\) coordinates of the rail lines at bottom of the image. So region of interest area in image is detected with \(W_{max}\) and Point\(_y\) obtained. And then this area is extracted from image by cropping. So ROI process facilitates in order to detect of rail track in image.

B. Rail Track Extraction Method

To determine of rail track in ROI area extracted from image, the flowchart of algorithm used is shown in Fig. 10. The rail track extraction algorithm consists of a few steps. These steps are respectively HSV color transform [37], V channel normalization, gradient image computing, and Integral image computing. V channel normalization is firstly applied within a range between 0 and 255, because RGB-HSV color transform was previously applied to ROI image in an earlier chapter. \(x\) and \(y\) axis gradients of image are computed. In the last step Integral image is computed and rail track image is extracted. And finally rail track is extracted from rail image by applying some morphological operations.

In the normalization step range of pixel values is exchanged. Normalization is expressed as histogram stretching or contrast stretching. The normalization returns a grayscale image and returns new values within range newMin and newMax with intensity values between Min and Max. Linear normalization of grayscale digital image is performed according to following formulation [21].

\begin{equation}
I_N = (I - \text{Min}) \times \frac{\text{newMax} - \text{newMin}}{\text{Max} - \text{Min}} + \text{newMin} \quad (7)
\end{equation}

In the Equation 7, \(I_N\) is normalization image, Min is minimum value of pixels, Max is maximum value of pixels, newMin is minimum value of new range values, and newMax is maximum value of new range values.

Gradient image is calculated using Sobel operator. The obtained gradient image is used to get Integral image. Gradient image is obtained with Equation 8 and Integral image is obtained with Equation 9.

\[ G_x = I_N \times 2 \quad 0 \quad -2 \]
\[ 1 \quad 0 \quad -1 \]
\[ G_y = I_N \times 0 \quad 0 \quad 0 \]
\[ 1 \quad 2 \quad 1 \]
\[ 0 \quad 0 \quad 0 \]
\[ -1 \quad -2 \quad -1 \] \quad (8)

\[ I_{II}(i,j) = \begin{cases} 
I_n(i,j) & \text{if } i = 0 \text{ or } j = 0 \\
I_{II}(i-1,j) + I_{II}(i,j-1) - I_{II}(i-1,j-1) + I_n(i,j) & \text{otherwise} 
\end{cases} \quad (9)\]

In the Equation 8, \(G_x\) is x-axis gradient image and \(G_y\) is y-axis gradient image. \(I_{II}(i,j)\) is integral image in the Equation 9.

C. Switch Detection Method

Tracking algorithm is used to detect whether there are switch crossings in image extracted rail track. To identify connection points of rail track in the rail image, tracking algorithm is applied to the rail image. Visual tracking is hot topic in the research areas of computer vision and multimedia processing [22]. In the past decades, there have been diverse visual tracking algorithms proposed for object tracking in video sequences in tracking conditions such as strong occlusion, complex background, quick movement, etc. [23, 24].

The object tracking is performed in two stages. First, the algorithm must seek in image for a known object of interest. The other, the algorithm can search the whole image again for the object movement [25]. In the field of Unmanned Aerial Vehicle (UAV) there are a few attempts on tracking landing pad. Most of them include of finding an ellipse using thresholding technique couple with finding connected components [26, 27, 28].

The proposed switch detection algorithm is shown in Fig. 11. The connection points of rail track is detected by using tracking algorithm in order to determine switches. Hence, rail object is followed by analyzing image from the bottom-up and connection points have been founded. With number and location of these points, direction of switch crossing is determined. Detected connected points are shown in Fig. 12 as an example.

Figure 11. The algorithm of switch detection
D. Level-Crossing Detection Method

Level crossings that are located between the rails in a vertical position are horizontal position. To determine level crossings some of image processing techniques such as preprocessing, feature extraction, Hough transform, etc. are applied to image. The pseudo code of level crossing detection algorithm is shown in Fig. 13.

In the first step of level crossing detection algorithm, the image in RGB color space is convert to XYZ color space. XYZ color space is expressed such that all visible colors can be defined using only positive values. And the Y value is luminance [29]. Red, green, and blue values are to be unwanted for creating a standardized color model that is suitable for all devices [29]. Because of this reason XYZ is used a mathematical formula to convert the RGB data. X, Y, and Z values can be obtained as shown in the following Equation 10.

\[
\begin{bmatrix}
X \\
Y \\
Z
\end{bmatrix} =
\begin{bmatrix}
0.41 & 0.35 & 0.18 \\
0.21 & 0.71 & 0.07 \\
0.01 & 0.11 & 0.95
\end{bmatrix}
\begin{bmatrix}
R \\
G \\
B
\end{bmatrix}
\]  (10)

In the next step of level crossing detection algorithm, Y channel image is obtained and this channel image is utilized in later stages of proposed algorithm. The reason for using this channel in later stages of the proposed algorithm, is to express luminance value in image. Then, gradient magnitude and x and y direction gradients of this image are calculated [30, 31, 32].

Algorithm: Level Crossing Detection

1. \( L \leftarrow \) Level crossing image
2. \( XYZ\_Image \leftarrow \) Obtained XYZ image
3. \( Y \leftarrow \) Obtained Y channel image
4. \( G \leftarrow \) Obtained gradient image
5. \( k \leftarrow \) The number of detected line on image
6. \( R, C \leftarrow \) The number of row and columns
7. For all i such that i≤C
8.   For all j such that j≤R
9.       \( XYZ\_Image\,(i,j) \leftarrow \) Converting \( L(i,j) \) from RGB to XYZ
10.      \( Y(i,j) \leftarrow \) Getting Y channel image
11.     \( G(i,j) \leftarrow \) Applying edge detection method to \( G(i,j) \)
12.   \( k \leftarrow \) Finding lines in \( G(i,j) \) image with Hough transform
13. endFor
14. endFor

In the next step, edge detection process is made on image. Prewitt edge detection algorithm is used to this. Prewitt mask is a discrete differentiation operator. This operator uses two 3×3 masks for calculating approximate derivative values in horizontal and vertical directions [32, 33]. Prewitt masks are shown in Fig. 14.

![Prewitt masks](image)

(a) X direction mask  (b) Y direction mask

Figure 14. Prewitt masks [33, 34, 35]

The Prewitt edge detection mask gives equal weightage to all pixels when averaging [35]. As seen in the mask the coefficients in the matrix kernel are all 1 [35]. The key idea is that of central differences. This mask when convolved with an image, it performs a two dimensional spatial gradient [35].

After done edge detection step, two different images are obtained by applying two filter which 0 and 90 degrees in terms of size. And difference process is performed by subtracting these images obtained from each other. In this way the level crossing that is horizontal position in the image, has become sharper. Then Hough transform is applied to detect line in image. The Hough transform is utilized in order to determine the straight lines and parametric curves in an image [36]. The pseudo code of Hough transform algorithm is shown in Fig. 15.

Figure 15. The algorithm of Hough transform [36]

IV. EXPERIMENTAL RESULTS

A computer which has Intel (R) Core (TM) i7-2400 M CPU, 2.5 GHz, 6.00 GB RAM under Windows seven 64 bits is used to perform the proposed method. The proposed methods are written in Matlab R2014b. In this study, switch and level crossing detection in railway are developed through using contactless image processing techniques.

ROI segmentation is made in the proposed algorithm to detect region of interest in the image i.e. rail track area. Images which are given to proposed ROI method as input and results of the proposed ROI method are respectively shown in Fig. 16.
Level crossing detection has been made in the railway image. And edge detection algorithms such as Sobel, Canny, Roberts, and Prewitt have been tried to detect level crossing. It has been observed that Prewitt edge detection algorithm has produced better results than other edge detection algorithms. Images which are given to proposed level crossing detection method as input and results of the proposed level crossing detection method are respectively shown in Fig. 19 and Fig. 20. Experimental result of level crossing detection algorithm is shown in Table III.

### V. CONCLUSIONS

An algorithm based contactless image processing has been suggested to detect switches and level crossings in railway. The switch detection has been performed by using ROI segmentation, rail track extraction and switch detection algorithm. With being performed ROI segmentation, both rail track has been extracted more easily and accurate rate of switch detection has been increased. So expressed step is very important for switch detection process. And also image used for switch detection is free of foreign objects such as trees, buildings, etc. by applying this step. To perform ROI segmentation, the image has been converted to HSV color space. V channel of this image has been used during the proposed method. With used this channel image, rail object could appear in clearer way and that has facilitated other image processing steps. Hough transform has been used to detect rail track line. The use of Hough transform has played an important role in determining the rail line. The Integral Image has simplified rail track detection. In the switch detection step, connection points of switches have been determined with tracking algorithm. The proposed methods have been written in Matlab 2014b. Average elapsed time of the proposed switch detection method has been 0.40 seconds and accuracy rate of the proposed switch detection method has been 89.66 %. Thanks to level crossing detection, while train travel it can be found that whether there are obstacles on level crossing. And thus train accidents can be prevented. With detection of level

![Figure 16. (a) Example railway input image (b) output image for ROI segmentation method](Image 64x612 to 225x742)

</tbody>
</table>

As seen in Fig. 16, with ROI segmentation process railway image is reduced to rail track image. And thus rail track has been identified more easily. In addition to this, success rate of rail track detection has been increased. Experimental result of ROI segmentation is shown in Table I.

Rail track extraction is performed in the proposed algorithm to extract rail track in the image. Rail track is identified in the image that is taken from ROI segmentation algorithm as an output image. Input and output images of Rail Track Extraction algorithm are given in Fig.17. And in addition to this, experimental result of Rail Track Extraction algorithm is shown in Table II.

As seen in Fig. 17, white pixels in the output image have been represented as rail track. Then rail track is extracted by applying mathematical morphological operations. After the rail track detection has been done, switch crossing has been identified with switch detection process. To detect switches elapsed time is 0.08 seconds and success rate of switch detection algorithm is 87%.

Abstract—Positioning systems have wide range of applications with the developing technology. Global Positioning Systems (GPS) is an efficient solution for outdoor applications but it gives poor accuracy in indoor environment. And, various methods are proposed in the literature such as geometric-based, WiFi fingerprint-based, etc. In this study, a hybrid approach that uses both clustering and classification is developed for WiFi fingerprint-based. Information gain based feature selection method is used for selection of the most appropriate features from the WiFi fingerprint dataset in the initial step of this approach. Then, Expectation Maximization (EM) algorithm is applied for clustering purpose. Then, decision tree algorithm is used as a classification task for each cluster. Experimental results indicate that applied algorithms lead to a substantial improvement on localization accuracy.

Keywords—WiFi fingerprint-based, indoor positioning, access point selection, clustering, classification, feature selection, expectation maximization, decision tree, received signal strength, WLAN.

I. INTRODUCTION

Positioning systems are becoming very important with the developing technology. These systems are used to determine the position of the mobile device and it is used by location-based services for navigating, or tracking etc. They are classified as outdoor and indoor positioning systems. Global Positioning System (GPS) is used for outdoor in our daily life. But, it cannot be used for indoor environment due to lack of GPS signals including multipath and signal blockage [1]. Therefore, different kinds of indoor positioning systems (IPSS) have been developed. WiFi-based indoor positioning systems have become an attractive solution in indoor area since WiFi access points (APs) can be found widely in indoor buildings such as airports, shopping malls, or office buildings, etc. WiFi-based indoor positioning is an inexpensive solution because they have not need any additional installation cost [2].

Fingerprinting technique is the most accurate technique that is based on Received Signal Strength (RSS) in WiFi-based indoor positioning systems [3]. In this technique, the RSS obtained from WiFi APs is used to determine the position of a mobile device. It contains two phases named as offline and online phases. In offline phase, RSS values are collected at known reference points (RP) in the experimental area and then are used to construct radio map. The dimension of the radio map is grown while including all the detectable APs in the region. But all these APs are not contributed positively to the accuracy of position. Therefore, the redundant APs will be removed from the radio map, since they increase the computational cost and also cause deterioration in the accuracy of position. For this purpose, the redundant APs are eliminated using feature selection methods. During the online phase, the radio map is used to estimate the location of a mobile device using a new RSS measurement using machine learning algorithms such as Decision Tree (DT), K-nearest neighbour (KNN), or Expectation Maximization (EM) etc. [4]

In this study, a hybrid approach that combines clustering and classification algorithms is applied. InfoGain based feature selection is firstly used to removed redundant APs in the radio map. Then, EM clustering algorithm is utilized to divide radio map into distinct groups or clusters. Finally, after assigning each test data to correct cluster, DT classifier algorithm is used as a classification task. In the experiments, DT and applied hybrid approach is compared in terms of positioning accuracy. In the experiments, WEKA open source machine learning toolbox and RFKON database [5] are used.

The paper is organized as the follows. Related works in literature for fingerprinting based indoor positioning is given in section 2. Section 3 focuses on applied hybrid approach introducing the algorithms using in this approach. Experimental area is given in section 4. Test results for proposed algorithm are given in section 5. As a result of this paper, conclusion part summarizes all written things in the paper with a short paragraph including future works in section 6.

II. RELATED WORKS

A large number of studies that adopt fingerprinting as the position estimation method are proposed in the literature. Fingerprint-based positioning algorithms can be categorized into two groups: deterministic algorithms [2, 6-8] and probabilistic algorithms [9-13].

Deterministic algorithms are used to find the minimum signal distance between the newly measured RSS vector and pre-measured fingerprints which are vectors of RSSs from detectable APs in the region (radio map). Each fingerprint in the radio map is associated with a known RP. In [2], KNN is used to estimate the position of a mobile WiFi-enabled device. A feature scaling based KNN (FS-kNN) algorithm is proposed in [6] to improve localization accuracy. In FS-kNN, different weights are assigned to signal differences at different RSS levels when estimating the similarity between two RSS vector. Artificial neural network (ANN) classifier is utilized to classify link quality patterns for each location in [7]. In [8], DT algorithm is used as the classification algorithm.
In probabilistic algorithms, the probability of the mobile device position to be each reference point is calculated and then maximum probability is returned as a mobile device position. In [9], particle filter, a Bayesian based method, is employed. Observed signal strengths are obtained using Bayesian inference in [10] and the estimated position is determined as the highest probability in the resulting distribution. An extended Kalman filter based approach is presented in [11], where the intra cell position of a cellular device is estimated using RSS readings from base stations. This estimate, movement pattern data and velocity vectors are combined in order to predict the next cell crossing. In [12], a Bayesian filter based approach is proposed. In this study, a posterior probability distribution over the target’s location is obtained by inverting Bayesian belief network. In [13], subset of the strongest APs is considered instead of all APs and target location is predicted using Bayesian estimate.

There are also various algorithms are proposed in the literature to reduce the computational cost by eliminating redundant APs in the radio map. In [14], according to strength of the signal a weight is assigned to each AP and then the APs with minimum weights are dropped from each fingerprint. Various AP significance measures such as average RSS, entropy, variance, maximum RSS are examined in [15]. Fast Orthogonal Search (FOS) and modified FOS (mFOS) algorithms are implemented in [16] in order to reduce the dimensionality of the radio map in an IPS.

III. APPLIED HYBRID APPROACH

In this study, a hybrid approach that combines clustering and classification algorithms is applied. Information gain based feature selection is firstly used to remove redundant APs in the radio map. Then, EM clustering algorithm is utilized to divide radio map into distinct groups or clusters. Finally, after assigning each test data to correct cluster, DT classifier algorithm is used as a classification task. These algorithms are described in the following subsections.

A. InfoGain-based Feature Selection

Information gain is the most commonly used feature selection method in the machine learning field that is based on the entropy [16]. Information gain of each feature is calculated using Eq. (1).

\[
\text{InfoGain}(f) = \sum_{c \in C} p(c) \log \left( \frac{1}{p(c)} \right) + \sum_{f \in F} p(f) \sum_{c \in C} p(c|f) \log p(c|f)
\]

where \( f \) is the feature and \( c \) is the class.

B. Expectation Maximization (EM) Clustering Algorithm

Clustering algorithms assign similar data to same cluster without the prior knowledge about the data’s characteristics. Since the data’s labels’ are not known, these algorithms are also called as unsupervised learning algorithms [17]. EM algorithm is a clustering algorithm that assigns data to particular clusters by computing one or more probability distributions. It then maximizes the overall probability of the data belonging to a certain cluster [18]. EM algorithm consists of two steps: determination of expectation and maximization of expectation iteratively. In this study, EM algorithm in WEKA is used for clustering purpose.

C. Decision Tree Classifier Algorithm

Decision Tree predicts an output by tracking the decisions in the tree from the root node down to a leaf node according to the outcome of the tests along the path [19]. In this study, C4.5 that is a benchmark tree (J48 in WEKA) is applied in the classification step.

IV. EXPERIMENT

Data were collected to construct our database for Eskisehir Osmangazi University Teknopark. It has two floors of area of 800m². This area was broken into grid squares (each of size 2.4m × 2.4m). We collect the data from the first floor of Teknopark and the center of each grid square was noted as seen in Fig. 1.

![Fig. 1 Experimental environment of floor 1.](image)

As seen in Fig. 1, red stars represent the reference points that are used for collecting sensor values from the APs and red squares represent sensor nodes in the test area. The database and the experimental area are briefly described in [5]. There are 5 sensor nodes and 20 reference points in the original RFKON database. And, WiFi RSS values of 80 are obtained from per reference point (RP). There are 1600 instances in the train data and 1600 instances in the test data. In experiments, we use mobile-based WiFi RFKON database that is obtained using Sony Xperia mobile device.

V. EXPERIMENTAL RESULTS

In experiments, we first apply “InfoGainAttributeEval” function in WEKA to determine the number of most important APs using both train and test data with Decision Tree classifier. These results are given in Fig. 2.
In the clustering phase, EM algorithm is applied. In experiment, different number of clusters are tried to select the best number of clusters. 5 clusters give best accuracy results after selecting 8 APs using Information gain based feature selection algorithm. This is an important improvement of reducing computational time.

In the clustering phase, EM algorithm is applied. As seen in Fig. 2, we obtain best accuracy results after selecting 8 APs using Information gain based feature selection algorithm. This is an important improvement of reducing computational time.

The accuracy result of DT classifier using all APs in the database is 42.25. However, we obtain nearly same result (42.375) when we select 8 APs after applying Information gain based feature selection algorithm. As a result of Table II, the hybrid approach increases the accuracy (66.42) about 25 percent using 8 APs. To demonstrate the applied hybrid algorithm improvement on the decision tree size, Table III is constructed.

VI. CONCLUSIONS

In this study, a hybrid approach that uses both clustering and classification is applied in WiFi fingerprint-based method. Redundant APs are eliminated from the WiFi fingerprint dataset using Information gain based feature selection method in the initial step of this hybrid approach. In the clustering step, Expectation Maximization (EM) algorithm is applied. In the last step named as classification step, decision tree models are constructed for each cluster. Experimental results indicate that applied algorithms lead to a substantial improvement on reduced the total computational time of classification process while increasing the accuracy results. The comparison of the applied hybrid algorithm with DT algorithm is given in Table II.

There are 19 APs in the database before applying Information gain based feature selection algorithm. As seen in Fig. 2, we obtain best accuracy results after selecting 8 APs using Information gain based feature selection algorithm. This is an important improvement of reducing computational time.

In the clustering phase, EM algorithm is applied. In experiment, different number of clusters are tried to select the best number of clusters. 5 clusters give best accuracy results among the attempted cluster numbers. The RPs are numbered as seen in Fig. 3 to illustrate the cluster assignments clearly.

![Fig. 2 Number of APs determination using both train and test database with InfoGainAttributeEval.](image)

![Fig. 3 The representation of each reference point.](image)

Each RP that illustrated with numbers in Fig. 3 is assigned to a cluster using EM algorithm as seen in Table I.

<table>
<thead>

Finally, DT classifier is applied for each cluster. In this step, cluster specific DT models are constructed. This step is

![Cluster specific DT models are constructed. This step is](image)
localization accuracy. In addition to this, by the help of the clustering phase of the applied approach and constructing cluster specific DT models reduce the size of the tree significantly.

In a future work, different clustering and classification algorithms will be evaluated in a hybrid approach to get better results in terms of accuracy and computational time.

Abstract— In parallel with the increase seen in the number of high-rise buildings, vertical transport systems are progressing. One of the results of this progress is the emergence of group elevator systems and their primary aim is to transport its passengers to the target floor the fastest way possible. Studies on this field are generally simulation and optimization based and they have an aim of minimizing the passengers’ waiting and traveling periods. In this study, a real time group elevator experimental setup was created and an optimization algorithm was applied on the setup. Genetic algorithm was chosen as optimization algorithm and this method was tested in an elevator prototype of 10 floors and 5 cabins. The results obtained revealed efficiency, performance and accuracy of proposed method.

Keywords— group elevator systems, optimization, genetic algorithm, average waiting time, real time control

I. INTRODUCTION

Elevator systems are of utmost importance in our daily lives. These systems are used in nearly all fields and they provide ease especially in vertical transport [1, 2]. In addition to this, when we take rising number of high-rise buildings of today’s world into account, importance of elevator systems increases [3].

In parallel with increasing number of floors in buildings, the population in the buildings also increases and single cabin elevator systems fail to meet the needs of this population [4-6]. Group elevator systems, which have emerged for satisfying this needs, are seen in many buildings and are in active use today. In general sense, group elevator systems are active usage of two or more elevator systems in the same building. Main aim of these systems is to ensure that people’s average waiting and traveling period is reduced [5-7].

In one of the studies in line with these objectives, group elevator systems are optimized using genetic algorithms. In the study, a system of 20 floors and 4 cabins were created and reducing people’s average waiting and traveling period is aimed. Directional calls were used and these calls were previously uploaded into the system. Obtained simulation results show efficiency of the proposed approach [8]. In another study on the same subject, hybrid optimization technique was proposed. In the study in which particle batch optimization and simulated annealing algorithms are used and a system of 16 floors and 4 cabins was preferred. Average waiting period, long waiting percent and process time was taken into account in the study. Proposed approach overcome the deficiencies of particle batch optimization algorithm and offered a new solution for timing group elevator systems [9].

In another study on group elevator systems, three different optimization techniques were used for process of timing. Genetic algorithm, artificial immune algorithm and DNA algorithm were used in this study and an estimation algorithm was proposed. In simulation processes, a 20 floor and 5 cabin system was considered and approximately 500 directional calls were created. In the system in which all methods are tested in line with these calls, a decrease in people’s average waiting periods was observed [10]. In another study for average waiting time, a simulation environment consisting of 16 floors and 4 floors was created. In this study, a numeric keypad was used for people to enter their destination floors. Therefore target floors could be known beforehand. In addition to this, an artificial immune optimization algorithm was used in the study in order to for the cabins to detect the optimal way [11]. In another study on the same field, a fuzzy group elevator control algorithm was proposed. In this study, there are five different control algorithms based on FPGA. An example of block diagram summarizing this structure which consists of four different modules is as seen in Fig. 1 [12].

![Diagram](image_url)

Fig. 1 The proposed approach in literature [12]

In another study which proposes a different point of view to analyse group elevators, the aim was to create double cabin elevator systems. In this approach, which was applied on group elevator systems, genetic network programming
technique was used and it was revealed that the proposed approach diminished waiting and traveling periods in different building traffics. The block diagram to summarize the system used in this study is given in Fig. 2 [13]. Another issue to take into account in group elevator systems is energy efficiency. In another study, in addition to minimizing cabins’ average waiting and traveling times, an adaptive control system with the aim of diminishing energy use was proposed. In this approach, genetic algorithm, clonal selection algorithm, DNA algorithm and estimating algorithm was used. Besides, in this system, a fuzzy structure was created to make effective use of these algorithms. The proposed system calculates average waiting and traveling periods and energy amounts to be used by the cabins to detect the optimal solution. An example block diagram of this paper is presented in Fig. 3 [14].

In this study, a genetic algorithm was used for time efficiency optimization of group elevator systems. Within the scope of the study, an experimental setup of 10 floors and 5 cabins was established and optimization algorithm was tested on this system. On the established experimental setup, people could enter their destination floors thanks to numeric keypad. Directional floor call keys were also used. Also, optimization algorithm was applied on both call types and system behaviour was studied. In line with these objectives, details of the optimization algorithm was given in part two. In part three, work patterns of the elevator control system was referred to and in part four, experimental results were included. In the fifth and the last parts of the study, results were presented.

II. GENETIC ALGORITHM FOR ELEVATOR CONTROL SYSTEM

Control and optimization of a group elevator system is an important issue. Using optimization techniques in these systems for usage of elevator cabins ideally and for the elevator to provide its services to the people is a must. In the study performed with this objective, genetic algorithm was used and minimizing people’s waiting period was aimed.

Genetic algorithm is an optimization technique which is commonly used in literature and applied in many fields [15, 16]. Pseudo code of this approach which aims best ideal solution in big solution space is shown step by step in Fig. 4.

One of the most important difficulties encountered in organization methods is specifying objective function. Objective function, which is of utmost importance in problem solving, is seen as in Equation 1 for group elevator system.

\[
Affinity = (|k - l|) \times T_R \times a_1 + T_D \times a_2
\] (1)

\[k = Elevator’s \ floor\]
\[l = Elevator’s \ target \ floor\]
\[T_R = Elevator’s \ average \ passing \ time \ between \ two \ floors\]
\[T_D = Elevator’s \ door \ openin \ closing \ time\]
\[a_1 = Equation \ weight \ (0.8)\]
\[a_2 = Equation \ weight \ (0.2)\]

Genetic algorithms are one of the most frequently used optimization techniques. One of the principle reasons for this is that genetic algorithms are able to offer really fast and effective solutions in big solution spaces. Therefore, this method was chosen for the study and used for control and optimization of group elevators.
III. PROPOSED ELEVATOR CONTROL APPROACH

In order to put the proposed approach into practice, an elevator prototype was developed which worked in line with the real elevators. This system has 10 floors and 5 cabins. Dial calls are designed both as directional and as in a way which destination floor can be entered. For this purpose, a numeric keypad is integrated onto the system. An example block diagram on the designed system can be seen in Fig. 5.

In the designed system there are seven segment displays on each cabin and these displays show the floor the cabin is on. There is also a 2x16 LCD screen placed on top of the system. In this group elevator system of 10 floors and 5 cabins, Can Bus communication standard is used. Communication of the system with the outer world is established with an RS-232 port via serial communication systems. Data is both transferred and read through this network. Various data polls were created on main computer line for measuring performance of the system and these calls are transferred to the processor controlling the elevator. Therefore performance tests could be made and statistical information could be obtained.

On the system, the tests are made through three different ways. These are elevator control approach using classical directional floor call, elevator control approach based on directional floor call based on optimization and elevator control approach using numeric keypad. The system receives calls from call pool, floor and cabin numbers, cabin position and direction information as an entry. Then it applies the chosen one of the 3 proposed methods onto the system. When this frame is considered, diagram for the proposed approach is as seen in Fig. 6. In addition to this, a block diagram to summarize the way the system works is shown in Fig. 7.
IV. EXPERIMENTAL RESULTS
In this study, group elevator systems’ control and optimization were performed. For this purpose, an elevator system of 10 floors and 5 cabins was established and optimization of incoming floor calls was performed using genetic algorithms. With this optimization process, minimizing people’s waiting period was aimed. Three different situations were taken into account in tests. First of them is the system using classical methods and directional buttons. In this application, the system works in line with the logic of closest floor. In other words, the cabin which stands closest to the floor from which the call is made is transferred to the floor. In the second scenario, optimization of these directional calls is managed with genetic algorithms. A call pool of random directions and these calls are optimized with genetic algorithm. In the third and last scenario, a numeric keypad integrated onto elevator prototype was used. This allowed people to enter the destination floor they want to be on. The most important advantage of this method is the capacity to know of destination floors beforehand. An image of experimental setup established within this framework is shown in Fig. 8 and 9.

Fig. 8 The experimental setup
Fig. 9 The cabinets, display and numerical keypad

There are basically three different traffic periods in elevator systems. These are respectively up-peak, down-peak and interfloor. Up-peak is the period which is encountered usually in the mornings, when people are keen to travel upstairs. Down-peak is the period encountered at the end of the shift, when people are keen to travel downstairs. Interfloor traffic is the type of traffic encountered between floors during the day. Interfloor traffic was taken into account in this study. In calls with random directions created in line with this situation, the number of downward and upward calls are approximately the same. Details of the building and the cabins are given on Table 1. In addition, starting locations of cabins are kept fixed and cabins’ location and direction information is given on Table 2.

</tbody>
</table>

As reported in the very beginning of the report, three different applications were developed on the system. Random calls created in the beginning phase are tested and system behavior was examined. In this process, average waiting periods were consistently measured and a graphic indicating the results of this change can be seen in Fig. 10.
As it can be seen in Fig. 10, the ideal solution of three different tests turned out to be the one in which numeric keypad and optimization were used together. Besides, classical method offered provided the worst performance. In the light of this data, Table 3 shows average waiting periods assessed for system performance as well as the percentage of CPU usage.

<tr>
<td>~CPU (%)</td>
<td>11</td>
<td>63</td>
<td>35</td>
</tr>
</tbody>
</table>

As it can also be seen on Table 3, the systems in which numeric keypads were used turned out 23.8% more efficient, which means these systems provided a 14.6% more performance level when compared to the approach in which the optimization technique is used. When CPU usage data is analysed, the reason that classical method is the most advantageous one is that it steers the cabins according to the closest floor principle. When optimized system and the system with numeric keypad are compared by means of CPU performance, numeric keypad system is on step ahead.

V. CONCLUSIONS

Group elevators were optimized with the study’s proposed approach. With this objective, a prototype of a group elevator system of 10 floors and 5 cabins was set up and tests progressed on this experimental setup in real time. A numeric keypad system was integrated into the elevator, different from classical elevator systems, and the people were allowed to enter their destination floor before they get on the elevator.

In this approach, genetic algorithm was chosen for the method of organization. This algorithm is fast and efficient, paving the way to its preferable. Three different approaches were taken in testing process. As a result of the studies, the control system with numeric keypad worked better. Thanks to this new approach, a 20% more efficiency could be get and a 14% gain could be managed when compared to the systems in which only optimization techniques were used.

Abstract— An electroencephalogram (EEG) is an electrical activity which is recorded from the scalp over the sensorimotor cortex during vigilance or sleeping conditions of subjects. It can be used to detect potential problems associated with brain disorders. The aim of this study is assessing the clinical usefulness of EEG which is recorded from slow cortical potentials (SCP) training in stroke patients using Deep belief network (DBN) which has a greedy layer wise training using Restricted Boltzmann Machines based unsupervised weight and bias evaluation and neural network based supervised training. EEGs are recorded during eight SCP neurofeedback sessions from two stroke patients with a sampling rate of 256 Hz. All EEGs are filtered with a low pass filter. Hilbert-Huang Transform is applied to the trails and various numbers of Instinct Mode Functions (IMFs) are obtained. High order statistics and standard statistics are extracted from IMFs to create the dataset. The proposed DBN-based brain activity classification has discriminated positivity and negativity tasks in stroke patients and has achieved high rates of 90.30%, 96.58%, and 91.15%, for sensitivity, selectivity, and accuracy, respectively.

Keywords— Deep Belief Networks, SCP, Slow Cortical potentials, Hilbert-Huang Transform, EEG

I. INTRODUCTION

An electroencephalogram (EEG) is a biomedical signal that records the electrical activity in the brain [1]. The neurons connect to each other by the dendrites and axons in the brain. The communication between the neurons is provided by the electrical impulses over the dendrites and axons. The electrical activity in the brain can be recorded and monitored placing the electrodes to specific areas on the head [2]. The placement of the electrodes and the channel names are seen in Figure 1. The EEG is used in several areas such as providing the interaction between human and machine [3], [4], determining the response of the brain to the visual and auditory signals [5], [6], allowing the diagnosis of psycho-physiological and neurological disorders [7]–[11], and helping doctors to make a quick assessment of normal and abnormal patterns using the peaks and valleys on the EEG for all age groups. Seizure disorders (such as epilepsy), a head injury, encephalitis, a brain tumour, encephalopathy, memory problems, sleep disorders, stroke, dementia, and etc. are the diagnosable brain disorders using an EEG. The normal electrical activity of the brain is disrupted in many neurological disorders and brain potentials [2]. The kind of the disorder can be stated by evaluating the shape and the interval of the disruptions on the EEG. EEG carries characteristic features that are helpful in the early diagnosis and early treatment processes of psycho-physiological and neurological disorders [11].

Slow cortical potential (SCP) is gradual changes in the cortical layer and the regulation of cortical excitability in cortical neuronal networks [12]. The SCP has a duration that varies between 300ms and 10s [13]. The SCP is a low-frequency EEG component and a non-invasive method. The electrodes are placed on the top center of the head and conditioned responses method used in giving feedback. Due to these characteristics, the SCP may include the contingent negative variation, readiness potential, movement-related potentials, P300 and N400 potentials [1]. Negative SCP is assumed to depolarization of cortical neuronal cells and
positive SCP shows neuronal complication [13]. The SCP has been correlated with a large number of cognitive processes in a systematic and topographically ways and has been determinately utilized in psychophysiological experiments to dissociate cognitive functions and motor performance of the brain [14], [15]. Ergenoglu et al. worked on determining the relationship between SCP and P300 amplitude [12], Khader et al. analysed the relations between the SCP and Blood-oxygen-level dependent (BOLD) signal changes [16], Devrim et al. investigated the detection of visual stimuli at sensory threshold using the SCP [6], Kotchoubey et al. used the SCP training in the research on epilepsy with analysis of influencing factors [7], [8]. Strehl et al. used functional magnetic resonance imaging and the BOLD signal in the SCP to reduce epileptic seizure frequency [17], Sniatchkin et al. evaluated the analysis of migraine [9], Schneider et al. determined the efficiency of the SCP training in psychiatric patients with alcohol dependency[10], Cosch et al. associated the SCP with the event-related potentials such as object, spatial, and verbal information [4], Hinterberger et al. suggested a robust and steady communication method between computer and brain for amyotrophic lateral sclerosis patients using the SCP and studied on developing a tough translation device [3], Pham et al. developed an auditory brain-computer stimuli for paralyzed patients using the SCP [5].

Stroke is a brain disorder that causes when the blood supply of brain cells is either cut off or reduced and the cells began to die. The abilities controlled by dead cells such as memory and muscle control are lost. The disorder affects the EEG and can be declared from the SCP and more potential.

Deep Learning (DL) is an invasive, effective and machine learning algorithm that has a growing popularity and attempts to model high-level abstractions [18]. In recent years, the DL is a new method of Machine Learning researches, which has been recognized with image processing, character recognition, speech recognition, frequently. Convolutional Neural Networks, Stacked Auto-encoders, Deep Boltzmann Machines and Deep Belief Networks (DBN) are the most effective DL algorithms [19]. The biggest advantage of the DL is representing handcrafted features with the efficient algorithms for unsupervised or supervised feature learning and hierarchical feature extraction [20]. In this study, the DBN algorithm is utilized as the classifier. The DBN is a robust and simple type of the DL algorithms which is comprised of both supervised and unsupervised learning stages. The experimental results that are obtained with the same number of hidden units and same structure of the DBN are compared with artificial neural network (ANN).

In the following section, the SCP training database, Hilbert-Huang Transform (HHT), the HHT-based statistical feature extraction processes, and the DBN classifier are described in detail. The proposed SCP training classification system is explained. The experimental results that are obtained using the DBN classifier are presented.

II. MATERIAL AND METHODS

In this section, the SCP training database, the pre-processing of the database, Hilbert-Huang Transform, and statistical feature extraction methods would be explained.

A. Database

The EEG is an electrical activity which is recorded from the scalp over the sensorimotor cortex during vigilance or sleeping conditions of subjects. It can be used to detect potential problems associated with brain disorders. EEG data were recorded during eight SCP neurofeedback sessions from two chronic stroke patients [21]. Neurofeedback sessions were conducted with an approximate interval of one week between sessions.

The EEG was recorded with a sampling rate of 256 Hz from channel Cz using a Nexus-10 MKII DC amplifier (Mindmedia, Herten, The Netherlands). Each neurofeedback session included trials in which cortical positivity had to be increased and trials in which cortical negativity had to be increased. The durational presentation of the trials is 8s and is seen in Figure 2. The feedback includes a circle with the different size and colour related with the subject set successfully to baseline activity. The brain activities are labelled successful as positivity, and success indicated to the participant as negativity, if the trials are evaluated according to the task correctly, or not, respectively.

![Fig. 2 Timeline of a trial from neurofeedback session](image)

All EEGs were filtered with a low pass filter (10 Hz). The negativity trials in SCP training sessions more frequent than the positivity trials. A total number of 8000 trials (500 trials for each session and each patient) with 2400 data points were segmented from 2 of EEGs. Distribution of the trials according to positivity and negativity situation in the database is given in Table I.

| TABLE I | STIMULI TRIAL DISTRIBUTION OF EACH STROKE PATIENT |
|---|---|---|
| Sessions | # Negativity Trials | # Positivity Trials |
| Session 1-3 | 250 | 250 |
| Session 4-8 | 375 | 125 |
| Total | 2625 | 1375 |

B. Hilbert-Huang Transform

Hilbert-Huang Transform is a method that has a frequently use for feature extraction, filtering the signals, and similar processes on nonlinear and non-stationary signals. The growing trend on analysis of non-stationary and non-linear has led to opportunities of the analysis to expand the technical requirements [22]. The HHT is one of the adaptive and extensive methods that can be considered as relatively recent.
The HHT has been applied to lots of fields such as biomedical signal processing and geophysics [23].

Due to the flexibility of the stoppage criteria of the HHT algorithm, mathematical description of the HHT algorithm could not be defined precisely and clearly [24]. The HHT has a two-step analysis. The first step is Empirical Mode Decomposition (EMD), and the second step is Hilbert Transform (HT), respectively. The EMD is pre-treatment of the original data and extracts \( n \) number of Intrinsic Mode Functions (IMF) and a residual signal. Each IMF is a signal which is based on a frequency modulation of the original data. The HT performs to obtain instantaneous frequency and amplitude values of each IMFs in the time-frequency domain [11], [24]. The HHT can perform more precise, distinctive and clear results than other methods in the presentation of time-frequency-energy for non-stationary and nonlinear signals [25].

1) Empirical Mode Decomposition: The EMD is a flexible analysis method which is used for extracting characteristic information obtained from non-linear and non-stationary processes. The most important characteristic of the EMD that is separated from other transformation algorithms is producing self-distinct oscillation of the original data by assuming that the signal consists of self-oscillations modes at the different frequency bands [26]. Each oscillation is symmetrical relative to local mean of local extrema. Each different oscillation in the signal is indicated by an IMF. The IMFs are extracted from the signal by following two basic conditions[24], [25]:

- The number of the local extrema and zero-crossing must be either same or difference must be equal to one
- The mean of the upper and lower envelopes which are obtained by the combination of the local maximum and local minimum must be equal at any time

The stated IMF extraction conditions are used for preventing negative frequency and keeping the instantaneous frequency of narrow-band signals in the frequency band while calculating the instantaneous frequency information [11].

The local mean is calculated taking the average of the local minimums and the upper envelope defined by local maximums. The local mean is subtracted from the original signal and the new form of the signal is controlled verifying if it is an IMF. If the new form of the signal does not satisfy the IMF extraction conditions, the local mean is recalculated using the local maximums and local minimums of new signal. This calculation is performed until an IMF is extracted. The residual signal is obtained subtracting the IMFs from last form of the residual signal. When the residual signal is a monotonic function or the residual signal has only one local extreme, it is not possible to extract another IMF and the EMD process ends [11], [23], [24]. \( r(t) \) represents for the last residual signal, \( x(t) \) indicates the original signal, and \( n \) is the number of the IMF.

\[
x(t) = \sum_{i=1}^{n} IMF_i(t) + r(t)
\]

2) Hilbert Transform: The foremost characteristic feature of the non-linear signals is the internal wave frequency modulation that shows the instantaneous frequency oscillation in a single period. The signal characteristics are indicated straightforwardly by the instantaneous frequency distribution. The HT is a decomposition which determines the amplitude-frequency-time distribution of the signal [23], [26]. The HT of a signal is defined as:

\[
x(t) = \Re \left\{ \sum_{i=1}^{n} a_i(t) e^{i \omega_i(t) t} \right\}
\]

\( a_i \) indicates the amplitude function of the signal, \( \omega_i \) represents for the instantaneous frequency function. The frequency-time distribution of the amplitude is called as Hilbert Spectrum and is shown as \( H(\omega, t) \).

\[
h(\omega) = \int_0^T H(\omega, t) dt
\]

The above equations show each IMF is amplitude and frequency modulated signals. The EMD proves its impact by analysing the non-stationary signals in the variable amplitude and frequency scales.

C. Deep Belief Networks

The DBN is a generative DL algorithm that consists of both unsupervised training and supervised training phases. The most important feature of the DBN is the idea of pre-training the weights, biases, and the other parameters using an unsupervised training algorithm such as Sparse Autoencoder or Restricted Boltzmann Machines (RBM) [18], [27]. In this study, the RBM is selected as pre-training algorithm in unsupervised training phase. The RBM is a stochastic ANN type that calculates the weights of the units according to the probability distribution over a set of inputs. The stacking of the RBMs can build up the DBN with gradient descent algorithm or contrastive divergence algorithms [28]. In the RBM, visible units that represent input data are connected to hidden units that learn to represent features using undirected weighted connections [19], [28].Considering the RBM with input layer activations \( v \) (for visible units) and hidden layer activations \( h \) (hidden units), bias of the visible unit \( b \), bias of the hidden unit \( c \):

\[
E(v,h) = -hWv - bv - ch
\]

\[
P(v,h) = \frac{e^{-E(v,h)}}{\sum e^{-E(v,h)}}
\]

\( P(v,h) \) indicates the joint distribution of the RBM and \( E(v,h) \) represents for the energy function of the distribution. The DBN used latent variables in the deepest layer easy to understand the deepest features using at least two hidden layers in network. Each adjacent two layers have a connection to evaluate the greedily layer-wise pre-training [18]. The parameters such as the weights and the biases obtained in
unsupervised learning phase are unfolded to a neural network structure. The pre-trained parameters are updated and fine-tuned in supervising training phase. The whole network can be optimized by gradient descent algorithm in this learning phase. The detailed formulation about the DBN is presented in [18], [29].

III. EXPERIMENTAL RESULTS

The brain computer interfaces allow setting a connection between the machines and the brain to control devices with the SCP and more. The SCP training neurofeedback sessions are used to make a quick assessment of normal and abnormal patterns in the diagnosis of psycho-physiological and neurological disorders using the peaks and valleys from the EEG. The aim of this study is classifying the brain activities from the SCP training in stroke patients and pointing out the negativity and positivity trails in the neurofeedback.

The SCP training trials have been related with a large number of cognitive functions, motor performance of the brain and many neurological disorders in literature. Ergenoglu et al. worked with the positivity and negativity SCP trials to getting a connection between the SCP trainings and P300 amplitude and experienced the P300 amplitudes of trials with the negative SCPs are significantly higher in comparison with the positive SCPs at Cz, Pz, Fz, P3, and P4 channels under normal and abnormal conditions of the brain [12], Khader et al. investigated the relations between the SCP and Blood-oxygen-level dependent (BOLD) signal changes and proposed the similar topographical specificity of the SCP trials and the BOLD signal under cognitive experiments [16], Devrim et al. investigated the detection of visual stimuli at sensory threshold using the SCP and the negative SCP trials have a better separation ability than the positive SCP trials at Oz, Pz, Cz, and Fz channels [6]. Kotchoubey et al. analysed the influencing factors in epilepsy using twenty sessions SCP training and detected the positive trials are more important than the negative trials [7], [8]. Strehl et al. used functional magnetic resonance imaging and the BOLD signal in the SCP and reduced epileptic seizure frequency [17], Siniaitchkin et al. evaluated the analysis of individual differences in migraine and experienced the negative trials from the SCP differed significantly between the individual habitat [9], Schneider et al. determined the efficiency of the SCP training with self-regulation task utilizing biofeedback and instrumental conditioning in psychiatric patients with alcohol dependency [10], Hinterberger et al. developed a tough translation device for ALS patients using the SCP trials [3], Pham et al. developed an auditory brain-computer stimuli for paralysed patients using the SCP and discussed auditory stimuli characteristics may have to be adapted to optimize brain-computer interface performances [5]. The studies based on cognitive functions, motor performance of the brain and many neurological disorders in literature are indicated the efficiency and the importance of the SCP training and classification of the brain activities from the SCP training such as negativity trials or positivity trials in stroke patients.

The HHT is an effective method on non-linear and non-stationary EEG signals. Huang et al. [25] proposed a communication between human and computer. They used the HHT and wavelet transform for extracting the features from the steady-state visual evoked potential and indicated the HHT is more accurately expressing the time and frequency characteristics ability than the wavelet transform. Li et al. [30] proposed a sleep stage classification method using the EEG. They achieved a classification mean accuracy of 81.7% using the HHT, Fourier transform and wavelet transform features and discussed that the HHT is more successful and faster response for extracting the EEG features and tracking the rapid changes. Ozdemir et al. [11] and Oweis et al [22] applied the HHT to EEG and used intra wave frequency modulation on the different frequency bands to diagnose epileptic seizure prediction and classification and achieved accuracy rates of 89.66% and 94%, respectively. Considering these achievements of the HHT on EEG, we decided to utilize the HHT in the feature extraction of the brain activity classification from the SCP training in stroke.

The proposed method consists of preparing EEG signal, analysing EEG using the HHT and the HHT-based statistical feature extraction stage and the DBN-based brain activity classification stage. To provide the different definitive and descriptive situations in patient and recording process of the SCP training, the dataset with eight of the SCP neurofeedback sessions that were conducted with an approximate interval of one week from two chronic stroke patients is selected. A low pass filter is applied to remove the potential noises and peaks in the EEG. 8000 of the SCP trials with 2400 data points were extracted from the stroke patient EEGs. The extracted EEG trials are labelled as cortical negativity and positivity in the dataset.

The EMD is applied to extracted trials with 2400 of data points. IMFs were obtained vary in the number from 5 to 8. Figure 3 depicts a random trial and the IMFs decomposed from the random trial. HT is applied to each IMF. The amplitude-frequency-time distribution of each IMF is determined. Statistical features such as standard deviation, correlation co-efficient, skewness, kurtosis, minimum, maximum, covariance, mode and mean, energy based features, high order statistical features such as moment and cumulants were calculated for each HT applied IMF and the feature set is created.

The half of the trials (1750 of the positivity trials and 2250 of the negativity trials) from all sessions of the neurofeedback is used for training of the DBN classifier model and the remaining trials are reserved for testing the proposed DBN system.
The proposed DBN has 2 brain activities in SCP (Positivity, Negativity) as outputs. Figure 4 indicates the structure of the proposed DBN classifier with visible and 3 hidden layers. The RBM based greedy layer-wise pre-training is used in this model at the unsupervised learning stages of the DBN with 100 epochs. The optimization parameters such as learning rate, activation function of the supervised learning phase, output function of the DBN, and the number of the hidden units of the RBM were denoted by iterations. The models were tested with a limited number of the parameters and the highest classification performances are given. The learning rate of the model is 2 and the softmax output function was utilized in the DBN. The sigmoid activation function is selected in the all validations and training sessions. The DBN has 3 hidden layers with 350-100-260 hidden units, respectively. The confusion matrix of the proposed classifier is seen in Table II.

The classification performances are statistical valuation functions: Specificity, Sensitivity, and Accuracy which are obtained from confusion matrix of the classification. The formulation of the performance measurements are described in detail by Allahverdi et al. [29]. The achieved classification performances using both the DBN classifier and the ANN with same number of hidden units in 2 or 3 hidden layers are presented in Table III. The DBN and the ANN classifiers used same optimized learning rate, epochs, activation and output functions and hidden layer structures. The DBN structure with 3 hidden layers presented the highest accuracy of almost 91.15% using features from all sessions in neurofeedback.

It is hard to compare the success of the proposed system because of there is no reported study yet that we could find in our detailed literature search on the SCP training in stroke. In this study, the classification of brain activity in stroke patients is an overcome process using the SCP training. There is a strong correlation between brain activity and the SCP trials in stroke. The DL algorithms with the HHT-based statistical features have achieved a high classification performance of 90.30%, 96.58%, and 91.15%, for sensitivity, selectivity, and accuracy, respectively.

IV. CONCLUSIONS
The communication between the brain and computerized methods provides identifying the electrical neural patterns as a thought - before the pattern has fully manifested in to a conscious feeling, allows paralysed people to control prosthetic limbs with their mind and helps to diagnose the psycho-physiological and neurological disorders to clinicians. The proposed technique is a DBN classification method to detect the brain activity using the trials from SCP training in stroke. The achieved results indicate the efficiency of the HHT-based statistical features and the DBN when used together on EEG. The proposed system bears classifying the positivity and negativity trials with high accuracy, sensitivity, and specificity achievements. The present results suggest that the DBN classifier is more successful when compared with ANN in the classification of the brain activity from the SCP training in stroke for the HHT-based statistical and high order statistical features.

Abstract— An electrocardiogram (ECG) is a non-linear and non-stationary diagnostic biomedical signal that has a great importance for cardiac disorders. The computer-assisted analysis of biomedical signals has become an essential tool in recent years. This study introduces a deep learning application in automatic arrhythmia classification. The proposed model consists of a multi-stage classification system in raw ECG using a Deep belief network (DBN) which has a greedy layer wise training phase. The multistage DBN model classified the MIT-BIH Arrhythmia Database heartbeats into 5 main groups defined by ANSI/AAMI standards. All ECGs are filtered with median filters to remove the baseline wander. ECG waveforms were segmented from long-term ECGs using a window with a length of 501 data points (R peak of the wave is located at the centre of the window). The proposed DBN-based multistage arrhythmia classification has discriminated five types of heartbeats with a high accuracy rate of 95.05%.

Keywords— Arrhythmia, Deep Belief Networks, Deep Learning, AAMI, Raw ECG Waveform

I. INTRODUCTION

According to the World Health Organization surveys [1], heart diseases are one of the most important reasons which cause death. Heart disease symptoms depend on what type of heart disease you have. An electrocardiogram (ECG) is a non-linear and non-stationary diagnostic signal that is important for cardiac disorders [2]. It is hard to assess a cardiac disorder using ECG because of long processes that need a control in detail and infrequent arrhythmias. In order to overcome these challenges, the computer-assisted analysis of biomedical signals has become an essential method in recent years. The computer assisted diagnosis and analysis systems achieve rapid and advanced assessments in long, and hard to identify processes. Arrhythmia and many cardiac disorders usually need to use long-term ECG in inspection controls [3]. Therefore, computer-based methods and diagnosis systems provide major simplicity and reliability in the diagnosis and treatment of the diseases for cardiologists.

Arrhythmia is a problem concerning the abnormal rhythm and rate of heartbeats. The heart can beat too fast, too slowly, or inconsistently in different types of arrhythmias, which may feel like antagonism affection or fluttering. Arrhythmia may be classified by rate of heartbeats, mechanism (automaticity, re-entry, triggered) or duration of the heartbeats [4]. Several types of arrhythmia are harmless, but some of them refer the cardiac disorders that may cause death. The ECG is a popular diagnosis tool which is of the primary importance for cardiologists [5].

There are many studies that are used for detecting arrhythmias, classifying them and diagnosing cardiac diseases that occur as a result of arrhythmias. These studies can be incorporated into two basic feature extractions: fiducial and non-fiducial methods. The fiducial methods contain the local features such as temporal, morphological, amplitude, duration, interval and segments between two selected waves which are extracted from ECG waveforms. These methods are based on the time-domain features on the ECG [6]. The non-fiducial methods are based on the frequency-domain features such as wavelet transformations, and the other digital signal processing techniques that extract new signal forms, sub-bands and coefficients from ECG waveforms [7].

Deep learning (DL) is an effective and high-performance machine learning algorithm which is gaining popularity. Frequently used analyses of the DL are used in image processing, speech and natural language processing processes. Actually, DL is a neural network structure which addresses the deeper feature levels using more hidden layers [8]. In this study, Deep Belief Networks (DBN), which is an adaptable DL algorithm, is utilized to classify the heartbeats from different classes of arrhythmia using ECG waveform as input of the structure.

The remainder of the paper is structured in the following manner. The database and the arrhythmia types are defined by AAMI standards, pre-processing, and feature extraction from arrhythmia heartbeats are described in detail. The proposed multistage classification system is explained. The experimental results that are obtained using the DBN classifier are presented.
II. MATERIALS AND METHODS

The general management of medical treatment and assessment systems has become effective and convenient processes because of the recent technological developments in integrated circuit systems and computer-aided intelligent monitoring and diagnosis systems. In this section, information about ECG waveforms and the DBN classifier are described in detail.

A. Database

There are several arrhythmia databases in the literature. In this study, the MIT-BIH arrhythmia database (MADB) is utilized [9]. This database has been used for evaluating arrhythmia detection and classifying the arrhythmia types. MADB contains 48 long-term ECGs from 25 men aged 32–89 years, and 22 women aged 23–89 years; each has 11-bit resolution with 360 Hz sampling frequency. The heartbeats are labelled as five main arrhythmia types defined by the Association for the Advancement of Medical Instruments (AAMI) standard. AAMI standardizations provide an objective, understanding, and individual assessments and monitoring processes of the arrhythmia types for clinical treatments and an increased capability of testing and training abilities for supervised learning phases [10]. AAMI classifies heartbeats into normal beats (N), supraventricular ectopic heartbeats (S), ventricular ectopic heartbeats (V), fusion heartbeats (F), and unknown heartbeats (Q). The testing and training dispersions of the heartbeats from the MADB are seen in Table I.

Long-term ECG signals can be contaminated by several types of noise, such as motion during ECG recording, electromyogram noise, contact noise, clinician artefacts, coughing, position of patient, baseline wandering, etc. All ECGs are filtered with two median filters to remove the baseline wander [11]. 6077 short-term ECGs were segmented from long-term ECGs using a window with a length of 501 data points (R peak of the wave is located at the center of window). All data points are normalized to a [0, 1] range.

B. ECG Waveform

The ECG is a method that finds out the regularity or irregularity of heart beats and heart rates using the electrical activity of the heart. The recorded electrical activities of the heart represent for a waveform on the clinical assessments. These waveforms may have different forms according to the lead of the ECG [11], [12]. The use of the ECG in medical assessment processes is very important in detecting the different waveforms and various cardiovascular heart diseases.

In the entire body only the heart muscle has the ability to contract spontaneously. Polarity is the event of discharge of electrical charge of heart tissue. Depolarization is the positive charging case of electrical activation in heart tissue [13].

The ECG has 0 mV to 5 mV amplitude and a frequency band between 0.5 Hz and 100 Hz [2], [13]. P, Q, R, S, T and U waves appear over the baseline in the signal, respectively. If the amplitude of Q, R and S waves is less than 5 mV, the wave is referred to using small capitals (q, r, and s). The remaining portion between the waves is a segment; the distance between the waves is an interval [12].

A P wave occurs as the result of the depolarization of the atrium. First, the right atrium then the left atrium, depolarizes. Therefore, the first part of the P wave occurs when the right atrium depolarizes; second part of the P wave occurs when the left atrium depolarizes. Although it depends on the time of the year, the duration of the P wave is about 0.11 seconds; the amplitude of the P wave is between 0.18 mV and 0.22 mV on a normal lead [2].

The QRS complex occurs as the result of the depolarization of the ventricles. One of the waves (R) forming the QRS complex is positive; the other two waves (Q and S) are negative. The Q wave represents the first negative wave after the P wave; the R wave represents the first positive wave after the P wave and the S wave represents the next negative wave after the R wave. The QRS monitored complex varied in different leads. The QRS samples show significant differences even among normal individuals. R and S waves refer to the contraction of the myocardium. The QRS complex indicates the current causing the left and right ventricle contraction [14]. The QRS complex has the maximum amplitude between the ECG forms. The duration of the QRS complex does not
exceed 0.11 seconds and has an amplitude value up to 2-3 mV [2].

The T-wave occurs as a result of ventricular re-polarization. The T-wave may have a pointed or flat view and positive, negative or biphasic value on various leads. The duration of the T wave that belongs to a normal subject is between 0.10 and 0.25 seconds. It takes place after about 300ms from the QRS complex. The positions of these waves vary according to the heart rhythm. The T wave is closer to the QRS complex when the heart rhythm accelerates [14].

C. Deep Belief Networks

This study introduces a deep learning (DL) application for automatic arrhythmia classification. The proposed model consists of a multi-stage classification system of raw ECG using DL algorithms. The DBN is one of the most effective DL algorithms which has a greedy layer wise training phase [15]. The DBN is composed of both Restricted Boltzmann Machines (RBM) or an autoencoder based layer-by-layer unsupervised pre-training procedure and neural network based supervised training [8], [16]. Considering RBM with input layer activations $v$ (for visible units) and hidden layer activations $h$ (hidden units), bias of the visible unit $b$, bias of hidden unit $c$:

$$E(v,h) = -hWv - bv - ch$$  \hspace{1cm} (1)

$$P(v,h) = \frac{e^{-E(v,h)}}{\sum e^{-E(v,h)}}$$  \hspace{1cm} (2)

$P(v,h)$ represents the joint distribution of the RBM and $E(v,h)$ represents the energy function of the distribution. RBM is used for calculating the conditional distribution of the visible and hidden units. Each adjacent two layers create an RBM. The first visible unit is the input feature vector and the other RBM parameters $\theta = (W, b, c)$ are denoted by depending on the first visible unit [17].

In the unsupervised training phase, the sub-network's hidden layer serves as the visible layer for the next adjacent layer applying contrastive divergence and the probabilistically reconstruction of the shared weights is implemented [8]. In the supervised training phase of the DBN, the calculated shared weights and the structure of the DBN are unfolded to a neural network structure for fine-tuning all the parameters of the deep structure such as the weights and the biases [15]. The DBN consists of at least two hidden layers (latent variables) in the neural network. The number of the hidden layers is related to the deep analysis of the input features in detail [15], [17].

III. EXPERIMENTAL RESULTS

The morphological features are the ones most used in clinical trials for the diagnosis of the arrhythmia types. The robust and steady detection of arrhythmia is a common need for all the cardiac diseases. Each arrhythmia type can be related to different types of cardiac and pulmonary diseases. That’s why detection and classification of the arrhythmia types are so important in the early diagnosis and early treatment processes. Considering the importance of the classification of the arrhythmia types, a computer-aided classification of the 5 arrhythmia types is implemented using a DBN-based multistage classification. Figure 2 depicts the structure of the arrhythmia classification model.

Two median filters are applied to remove the noise and the baseline wanders to raw ECGs. Analysis of the long-term ECGs is a demanding process for clinicians and also for computer-aided systems. Considering this situation, ECG waveforms were extracted from long-term ECGs using the moving window analysis technique. The R peak centred window with 501 data points was moved to extract ECG waveforms. 6077 of ECG waveforms were obtained from long-term ECGs. ECG waveforms with 501 data points were directly used as features. Having a great number of the feature dimensionality causes long and deceiving training processes for the supervised machine learning algorithms. Feature dimensionality reduction for the provides for the extraction of more meaningful classification rules, the elimination of the pointless feature vector for machine learning algorithms, the improvement of generalization capabilities using fewer parameters and reduced complexity and run-time and for the evaluation and prediction of accuracy for classifiers [18]. The sequential forward feature selection algorithm is utilized in the proposed method to reduce feature dimensionality [19]. The algorithm selects a subset of features which are not yet selected from 501 data points and the best predict the arrhythmia types by sequentially selecting features until there is no improvement in the prediction. The highest accuracy is achieved using 106 features from the ECG waveforms. The reduced feature vector is normalized to 0-1. The proposed DBN-based multistage classifier was trained using 106 data points. Selected data points on the ECG waveform are seen in Figure 3 with the red asterisk.
The proposed multistage DBN model separates N, S, V, F, and Q types of arrhythmias, respectively. 4 of the DBN models are used in the proposed system. The RBM based greedy layer-wise pre-training is used in this model at the unsupervised learning stages of all DBNs with 5 epochs. The parameters of the RBM were denoted by iterations. The models were tested with a limited number of the parameters and the highest classification performances are given. The learning rate of the model is 3 and the softmax output function was utilized constantly. The proposed multistage arrhythmia classification model consists of 4 DBN structures with various numbers of hidden units. The DBN1 has 2 hidden layers with 100-260 hidden units; the DBN2 has 3 hidden layers with 230-520-210 hidden units; the DBN3 has 2 hidden layers with 120-240 hidden units; and the DBN4 has 2 hidden layers with 70-190 hidden units. The four DBN structures are connected sequentially and have the ability to separate five classes of arrhythmia types defined by ANSI/AAMI.

The training set of the DBN-based automatic arrhythmia classification model includes 4,077 of ECG waveforms from various types of heartbeat classes distributed homogeneously. The DBN-based multistage model is tested using 2,000 of ECG waveforms. The confusion matrix of the classifier is seen in Table II.

Zhang et al. used inter-beat features, amplitude morphology and morphological distance features for separating 4 types of arrhythmias by the Support Vector Machines (SVM) classification algorithm with 86.66%, 93.81%, and 98.98% for accuracy, sensitivity, and selectivity, respectively [20]. Melin et al. utilized cycle features and fiducial features with an Artificial Neural Network (ANN) and Learning Vector Quantization based multistage classification algorithm and classified 15 types of arrhythmia with an accuracy rate of 99.16% [21]. Thomas et al. extracted wavelet based coefficients from 4th and 5th scale of Wavelet transform, high order statistics and fiducial features using the QRS complex from the ECG with ANN and presented an accuracy rate of 94.64% and a sensitivity rate of 94.60% for 5 classes of arrhythmia types [22]. Batra et al. utilized invariant features and Principle Component Analysis features using the SVM classifier with the cross validation technique and achieved an accuracy rate of 84.82% for 11 classes of arrhythmia types [23]. Leutheser et al. compared the Naive Bayes and k-NN classifier algorithms using statistical and high order statistical features, heartbeat features and template based features from segmented ECGs for the real-time classification of 2 types of arrhythmias on Android-based mobile devices with reported accuracies of 93.30% and 56.10% for k-NN and Naive Bayes classifiers, respectively [24]. Alajlan et al. extracted morphological features, high order statistical features and non-fiducial features applying the Discrete wavelet transform, S transform and classified arrhythmia types into 2 classes using the SVM machine learning algorithm with high performances of 93.49%, and 93.14% for accuracy, and sensitivity, respectively [25].

DL algorithms, especially the DBN, are being effectively used in ECG analysis. The DBN is utilized at both feature extraction [26], [27] and classification stages [16], [28]. Huanhuan et al. used the DBN-based learning features from complete waveforms and R-R timing interval features with a multi-stage (5 stages) SVM classifier model. They achieved an accuracy rate of 98.82% for 6 classes of arrhythmia types [27]. Rahhal et al. extracted temporal features, morphological features and DBN-based features using stacked denoising autoencoders. They fed all features to the SVM for training and classification. They classified 2 classes of arrhythmia types defined by ANSI/AAMI with an overall accuracy rate of 98.49% [26]. Yan et al. utilized R-R interval features, beat features and raw ECG signals from multi lead to feed the DBN classifier and achieved a high accuracy rate of 98.82% for 12 classes of arrhythmia types [16]. There are lots of studies based on different types of arrhythmia classification. We focused on the arrhythmia types defined by ANSI/AAMI and the considerable studies are compared in Table 3.

It is hard to compare the studies in a stable way, because of reasons such as the different number of subjects, different number of the arrhythmia types, different subjects, different databases and different classification types. High classification performances are reported in the literature. In this study, the efficiency of the DL algorithms has been proven with high classification performances of 95.05%, 93.87%, and 94.51% for accuracy, sensitivity, and selectivity, respectively.

IV. CONCLUSIONS

PQRST complexes and T waves plots a regular form in normal sinus rhythm. Any obvious changes occurring in the PQRS and T waves lines indicate the irregularity or arrhythmia in heartbeats. Since the determination of the features such as intervals, segment measurements, heart rate, and the frequency of R waves have great benefits for clinicians to identify the cardiac diseases and arrhythmias, the physiology and the morphology of the ECG waveforms have frequently been used in clinical trials [12], [14]. The meaningful data points for arrhythmia classification are thickened between S-T waves and P-Q waves for the proposed DBN-based multistage classification model.

The proposed DBN-based multistage arrhythmia classification has discriminated five types of heartbeats with a high accuracy rate of 95.05%. The achievements prove the success and efficiency of the DBN algorithm in raw ECG signals.

EFFECTS OF SPECTRAL CLUSTERING ON DOCUMENT CATEGORIZATION USING DISTRIBUTED TOOLS

Evren Pala*, Guray Yılmaz*
*Department of Computer Engineering, Turkish Air Force Academy, Yesilkoy, Istanbul, Turkey
{epala, gyilmaz}@hho.edu.tr

Abstract—Amount of text data being generated each day is so huge that it is impossible to keep track of. Clustering text documents is an important task to make use of information carried by plain text. In many text document collections, clusters do not form easily separable compact shapes. Spectral clustering is an efficient when clustering such datasets because algorithm considers connectedness of clusters rather than assuming a specific statistical model and optimizing parameters of that model. On the other hand, distributed data processing tools have been becoming more and more widespread. Running clustering algorithms with distributed tools is getting essential in big data environments. In this research, spectral clustering is executed on text data using big data analysis tools. Effects of algorithm on document clustering is discussed with respect to cluster quality measures. Moreover, existing works about scalability of spectral clustering is investigated. Results show that spectral clustering algorithm categorizes documents more accurately than $k$-means. In experiments, text documents in 20-newsgroups are used as dataset, Apache Mahout is used as distributed machine learning library, Rand Index and Mutual Information measures are used to evaluate clustering performance.

Keywords: Text mining, document clustering, distributed systems, spectral clustering, big data

I. INTRODUCTION

As information technologies become more widespread in many aspects of the life, amount of data produced is growing gradually. Applications producing data includes both enterprise and public applications. Stock management, enterprise resource planning, customer relationship management applications are examples of enterprise applications. Social network applications, forums, news portals and blogs are examples of public applications. One of the most important common characteristics of these two separate software application groups is the fact that data produced using these applications should be stored and analysed. Storing data is important when auditing and tracking past transactions. Unless these are required, storing data without analysing is nothing other than wasting storage units of machines.

Most of content & service providers analyse data generated by users of systems they provide. For example, CRM application logs are analysed for segmentation or labelling of customer, user actions in an e-commerce application will be logged for promoting right product to right customer, social network application logs are analysed for providing people and content that are closely related to users, search engine logs are analysed for listing web pages relevant to search terms in an acceptable time amount.

Leading motivation behind collecting and analysing data is reaching a higher level of profit. Effective analysis of produced data enables marketing products in a more proactive way and governing customers effectively. Another purpose of analysis of data is enhancing performance of system. For example, in a search application, it is important to reduce search space and prevent search operation in whole data store. Many search engines crawl and index whole pages existing in world wide web. Performing a user search operation on a related subset of web document collection can provide a quicker search to user and less overhead to the vendor. This concern gets apparent in most of applications providing services using big data.

Recently, users of the software applications tend to search specific information with several keywords. They expect search system to be intelligent enough to examine requested information and fetch relevant results even data entities are not free text documents. Moreover, important part of the data produced by world consist of text documents such as news, blog posts, comments, product descriptions, and so on. Mining text data is important because of these facts.

In text mining, there are several issues where discussions are focused. First of all, converting text documents into vectors. It is necessary to express instances in dataset to run learning algorithms in data mining. Data contained by text documents consists of terms and number of terms in common text data sets are so high that they can be expressed with tens of thousands. Second issue is distance / similarity measure to use. It is important to choose distance best fitting to data domain in order to get better results. Another issue is algorithm to classify / cluster dataset. Characteristics of data domain and shape of data are important factors to determine algorithm.

This study focuses on clustering of text documents using spectral clustering algorithm [1], which is one of the effective methods for clusters that can hardly be separated linearly. It regards affinity matrix of data. Entries of this matrix are pairwise affinities between data instances. Algorithm is composed around eigenvectors of this matrix and has successful applications in image segmentation, that is another domain where clusters frequently do not seem in linearly separable compact shapes [2]. Moreover, in big data environments distribution of computation is usually required. Therefore, when clustering big datasets, accuracy of the used method is not sufficient alone. It must also scalable in
order to be applied for such datasets. Therefore, distributed tools are used in the work in scope of this study. Methods and algorithms are evaluated based parallel and distributed execution.

In section 2, previous work on spectral clustering and text mining is introduced. Then, in the 3rd section, spectral clustering algorithm is described in detail and some issues about how to apply algorithm are discussed. In section 4, experiments are explained including methods, used tools, dataset and experimental results. Then, final remarks, concluding words and possible future work are expressed in section 5.

II. RELATED WORK

Text document clustering is a main branch of data mining so there exist some surveys about it. M. W. Berry published an extensive survey of text clustering [3]. In that study, effective vectorization of text passages, dimensionality reduction methods and term-to-term similarities are mentioned. In the survey prepared by Sathiayakumari et al. [4], pros and cons of several clustering algorithms on text data are revealed and they are compared. In the study of Anna [8], similarity measures are compared using experiments on several data sets. Aggarwal and Zhao made a comprehensive study about issues that should be overcome in text clustering [10]. In that study, feature selection, dimensionality reduction and algorithm choice are discussed topics.

Spectral clustering algorithm is based on spectral graph theory. The theory includes analysis of graphs using eigenvectors of the matrix representing pairwise similarities of vertices in the graph. Spielman’s lecture notes are one of the resources explaining theory well [15]. On the usage of spectral clustering for text data, Vempala and Wang assert spectral projection enhances clustering results on document collections [5]. Their assertion is based on experimental results. Chen et al. address scalability problem of spectral clustering [11]. They offer methods for approximating dense similarity matrix and parallelize computations in spectral clustering. Chennubhotla and Jepson proposes a hierarchical algorithm for efficiently compute largest eigenvectors of large matrices [12]. A parallel eigensolver algorithm is proposed by Bientinesi et al. [13] and empirical success of their algorithm is expressed by comparing with other well-known eigensolver algorithms. Strakova and Gansterer introduce a distributed eigensolver [14]. Their proposed method considers only nearest neighbour similarities and is efficient in loosely coupled networks that are distributed arbitrarily.

As the notion of “big data” become more widespread, more studies about distributed tools and algorithms to process big datasets are being done. Judith and Jayakumari prepared a review about recent work on distributed document clustering algorithms [17]. In this study, existing distributed solutions are compared in terms of speed, accuracy, cluster quality and scalability. In another work done by Li et al. [18], distributed k-means algorithm executing on MapReduce model is evaluated. Possible enhancements approaches like partitioning dataset with an effective hashing algorithm, effective center initialization and pruning unnecessary distance calculations are mentioned in this paper. The article prepared by Datta et al. provides an overview of distributed data mining algorithms and applications in peer-to-peer networks [16].

III. SPECTRAL CLUSTERING ON TEXT DATA

A. Representing text data

Data instances are required to be expressed in vectors in learning applications. In text documents, data information is carried by terms. Therefore, as well as size of document vectors, algebraic value of entries in document vectors is determined by terms that occurs in documents. Basically, document $x$ can be converted to vectors as follows:

$$x = \{t_1 : tf_1, t_2 : tf_2, \ldots, t_d : tf_d\}$$

and where $x$ is vector representation of document, $t_i$s are terms falling into document $x$, and $tf_i$s are the frequency (number of occurrence) of $t_i$ in $x$. This vector is called term frequency vectors. A more advanced and more efficiently used vector model for text document is tf-idf model:

$$x = \{t_1 : w_1, t_2 : w_2, \ldots, t_d : w_d\}$$

and

$$w_i = \frac{|S|}{|\{x_j \in S | t_i \in x_j\}|}$$

where $S$ is data set, $x_i$s are documents in data set. This model is called tf-idf model. In this model, lower scores are assigned to terms that are not distinctive for document. This model is one of the most common techniques used to transform text documents into vectors. Derivation of tf-idf vectors from plain text is done by Apache Mahout’s seq2sparse utility tool [7].

Learning algorithm executions require a distance/similarity measure to cluster dataset into groups. When deciding distance measure characteristics of the dataset domain is an important factor. There is no global right distance measure but there are effective distance measures for data type. Cosine distance measure is one of the best fitting ones when working on text data so it is used in experiments of this study. With this measure, distance between two data instances $x_i$ and $x_j$ is calculated in following way:

$$d_{ij} = \frac{x_i \cdot x_j}{|x_i| \cdot |x_j|}$$

As the name implies, cosine distance $d_{ij}$ is equals to the cosine of the angle between two data vectors $x_i$ and $x_j$. Calculating affinity from distance is another issue. Calculation of cosine similarity between text documents is as follows:

$$a_{ij} = 1 - d_{ij}$$

where $d_{ij}$ is cosine distance.
B. Spectral Clustering Algorithm

Spectral clustering algorithm is an effective way of data clustering because it considers pairwise affinities of data instances without making any statistical model assumptions. When dataset is composed of complex-shaped connected clusters rather than compact clusters, ordinary clustering algorithms like k-means are hard to perform well.

In Figure 1, dataset represented in the left hand side is composed of compact clusters. Most intra-cluster pairwise distances in between instances of this dataset is lower than inter-cluster pairwise distances. Clusters seem like compact structures and instance density increases towards cluster center . However, in the dataset visualized in the left hand side, clusters are connected but not compact. They are formed with instances that are successively close to each other. In this case, data instances in same cluster are not necessarily closer to the each other than instances from different clusters. However, they are connected to each other with a chain of close instances falling into the same cluster. This two nested circular clusters are just for exemplifying but clusters may have more complex shapes than circles. In such cases, clustering algorithms that assume some model and try to optimize parameters of that model may easily fail to group data into clusters.

Spectral clustering algorithm considers only data instead of making assumptions based on some statistical models. It takes affinity matrix $A$ of the dataset as input and operates on top eigenvectors of the Laplacian matrix $L$ of affinity matrix $A$. Affinity matrix is as follows:

$$A^{n\times n} = \begin{bmatrix}
a_{11} & a_{12} & \ldots & a_{1n} \\
a_{21} & a_{22} & \ldots & a_{2n} \\
\vdots & \vdots & \ddots & \vdots \\
a_{n1} & a_{n2} & \ldots & a_{nn}
\end{bmatrix}$$

where $n$ is number of instances in dataset $S$ and $a_{ij}$ is similarity between $x_i$ and $x_j$. Calculation of affinity is given in equation 5. When constructing affinity matrix, one approach is forming it by calculating all pairwise affinities and regarding dataset as a fully connected graph. In other words, each pairwise affinity is taken into consideration no matter it is strong or weak. In this case, each instance is assumed to be connected to every other instance. Another approach when creating affinity matrix is using a graph construction method. In that way, many weak connections between instances are pruned in order to relax calculation and promote strong local neighbourhoods. Two techniques are used for graph construction:

- $\epsilon$-neighbourhood graph: Affinity $d_{ij}$ between $x_i$ and $x_j$ is considered only if its value is higher than a predefined constant value $\epsilon$. Choosing parameter $\epsilon$ is important to determine which connections will exist and which will be pruned.
- k-nearest neighbourhood graph: For each data instance, connections to only k-nearest neighbours are considered. Other connections are ignored. Affinity matrix is created using k highest affinity values for each $x_i$.

Another issue in spectral clustering algorithm is calculation of graph Laplacian. When calculating Laplacian matrix, degree matrix is used besides affinity matrix. In fact, it is derived using affinity matrix. Degree matrix is a diagonal matrix whose $i^{th}$ diagonal entry is the sum of affinities calculated for instance $i$.

$$D^{n\times n} = \begin{bmatrix}D_{11} & 0 & \ldots & 0 \\
0 & D_{22} & \ldots & 0 \\
\vdots & \vdots & \ddots & \vdots \\
0 & 0 & \ldots & D_{nn}\end{bmatrix} \quad \text{(7)}$$

where

$$D_{ii} = \sum_{j=1}^{n} a_{ij} \quad \text{(8)}$$

There are two types of graph laplacians:

- Unnormalized Laplacian:

$$L = D - A \quad \text{(9)}$$

- Normalized Laplacian:

$$L = D^{-1/2} \cdot A \cdot D^{-1/2} \quad \text{(10)}$$

In our study, no graph construction method is used. Data is handled as fully connected graph. Then, spectral clustering algorithm is executed using normalized form of graph Laplacian matrix. Pseudocode is provided in algorithm 1 and [1] can be checked out for a more detailed explanation of spectral clustering.

Algorithm 1 Spectral Clustering

1: procedure CLUSTER-SPECTRAL($S$, $k$)
2: $A^{n\times n} \leftarrow$ affinity matrix of dataset $S$
3: $D^{n\times n} \leftarrow$ degree matrix of $A$
4: $L^{n\times n} \leftarrow D^{-1/2} \cdot A \cdot D^{-1/2}$
5: $E^{n\times k} = [e_1, e_2, \ldots e_k]$ (smallest k eigenvectors of L)
6: $Z^{n\times k} \leftarrow$ normalized form of $E$
7: cluster $Z$ into k clusters using k-means
8: assign each $x^i$ to corresponding cluster of $z^i$
9: return clusters

IV. EXPERIMENTS

A. Dataset

20-newsgroups dataset hosted by UCI Machine Learning Repository [6] is used in tests executions. It contains 18846 documents of 20 different groups. There are 93,560 distinct terms in dataset. No NLP method such as stemming or stop-word elimination is used. In other words, "play" and "playing" are accepted different terms for our algorithm. Topics in 20-newsgroups dataset are listed in Table I.

B. Tools Used

Apache Hadoops distributed file system is used for storing data and MapReduce is used for processing data. MapReduce is a distributed processing model that fits into many real world problems [9]. Hadoop is one of the most common scalable MapReduce vendors and it has proven success in many real time systems. Hadoop is run in pseudo-distributed mode in our experiments.

Machine learning library used in experiments is Apache Mahout [7]. It works on top of Hadoop. Machine learning tasks are submitted by Mahout to Hadoop and they are executed as MapReduce jobs. Mahout does not only provide machine learning algorithms but also perform some utility tasks such as creating tf-idf vectors from plain text documents or calculating distance between vectors.

C. Experimental Results

As stated earlier, k-means and spectral clustering algorithms are executed to cluster 20-newsgroup dataset in scope of experiments in this research. Experiments are run 10 times consecutively using Mahout’s command line interface. Some parameters passed required to clustering commands are as follows:

- convergence delta : 0.001
- max. number of iterations : 100
- initial clustering : Canopy
- distance measure : Cosine
- num. of clusters : 20

After executions of clustering algorithms, found cluster results are evaluated in terms of two cluster quality measures : adjusted rand index and adjusted mutual information.

Fig. 2 Adjusted Rand Index and Adjusted Mutual Information scores of k-means and spectral clustering algorithms

Figure 2 shows clustering results of k-means and spectral clustering algorithms. Spectral clustering apparently performs better than k-means algorithm in seen in the figure. Enhancement of score is obvious for both adjusted rand index and adjusted mutual information measures. Then, it can be said that spectral clustering has a more accurate clustering result on text data than k-means.

V. CONCLUSION AND FUTURE WORK

Clustering text documents is an important because text data constitutes an important part of the data produced each day. When running learning algorithms, data sets may not be easily separable. Text document collections usually exist in hardly-separable forms. In scope of this study, we focus our effort to apply spectral clustering algorithm on text data. Effects of spectral clustering algorithm observed on 20-newsgroups data set. Results show that accuracy of the spectral clustering algorithm is better compared to k-means. Solutions are prepared using distributed tools in order to make use it in big data problems.

For future work, a dimensionality reduction technique may be applied in order to get rid of high number of features in tf-idf vector form. Another enhancement may be using a graph construction method in order to prune unnecessary distance and affinity calculations. Experiments in this study are done without using any graph construction method.

The Classification of White Wine and Red Wine according to their Physicochemical Qualities

Yeşim ER*, Ayten ATASOY*

*Department of Electrical & Electronics Engineering, Karadeniz Technical University, Turkey
yesim.er@ktu.edu.tr
ayten@ktu.edu.tr

Abstract—The main purpose of this study is to predict wine quality based on physicochemical data. In this study, two large separate data sets which were taken from UC Irvine Machine Learning Repository were used. These data sets contain 1599 instances for red wine and 4898 instances for white wine with 11 features of physicochemical data such as alcohol, chlorides, density, total sulfur dioxide, free sulfur dioxide, residual sugar, and pH. First, the instances were successfully classified as red wine and white wine with the accuracy of 99.5229% by using Random Forests Algorithm. Then, the following three different data mining algorithms were used to classify the quality of both red wine and white wine: k-nearest-neighbourhood, random forests and support vector machines. There are 6 quality classes of red wine and 7 quality classes of white wine. The most successful classification was obtained by using Random Forests Algorithm. In this study, it is also observed that the use of principal component analysis in the feature selection increases the success rate of classification in Random Forests Algorithm.

Keywords—Classification, Random Forests, Support Vector Machines, k-Nearest-Neighbourhood.

I. INTRODUCTION

Today, varied consumers enjoy wine more and more. Wine industry is researching new technologies for both wine making and selling processes in order to back up this growth [1].

Physicochemical and sensory tests are used for evaluating wine certification [2]. The discrimination of wines is not an easy process owing to the complexity and heterogeneity of its headspace. The classification of wines is very important because of different reasons. These reasons are economic value of wine products, to protect and assure the quality of wines, to forbid adulteration of wines, and to control beverage processing [3].

Data mining technologies have been applied to classification of wine quality. The aim of machine learning methods similar to other applications is to create models from data to predict wine quality.

In the year of 1991, a “Wine” data set which contains 178 instances with measurements of 13 different chemical constituents such as alcohol, magnesium was donated into UCI repository to classify three cultivars from Italy [4]. For new data mining classifiers this data set has been majorly used as a benchmark because it is very easy to discriminate. For wine classification according to geographical region; principal component analysis (PCA) was carried out and reported [5]. The data they used in their study includes 33 Greek wines with physicochemical variables. Another work of wine classification depended on the physicochemical information. This information involved in wine aroma chromatograms as measured with a Fast GC Analyser [6]. In the latter study, three classification methods such as Linear Discriminant Analysis, Radial Basis Function Neural Networks and Support Vector Machines (SVM) are compared according to their performance in a two-staged architecture.

Some have proposed a few applications of data mining techniques to wine quality assessment. Cortez et al. [1] proposed a taste prediction technique. Their taste prediction technique, a support vector machine, multiple regression, and a neural network were applied to chemical analysis of wines. Shanmuganathan’s technique was about prediction the effects of season and climate on wine yields and wine quality [7]. The Wineinformatics system according to Chen et al. [8] idealized the flavor and characteristics of wine from natural-language reviews. They used hierarchical clustering and association rules.

II. MATERIALS AND METHODS

A. Wine Data

The data set is a wine quality dataset that is publicly available for research purposes from https://archive.ics.uci.edu/ml/datasets/Wine+Quality [9]. Both dataset contains 1599 instances with 11 features for red wine and 4898 instances and the same 11 features for white wine. The inputs include objective tests (e.g., PH values) and the output is based on sensory data (median of at least 3 evaluations made by wine experts). Each expert graded the wine quality between 0 (very bad) and 10 (very excellent). The two datasets are related to red and white variants of the Portuguese “Vinho Verde” wine.

The features include fixed acidity, volatile acidity, citric acid, residual sugar, chlorides, free sulfur dioxide, total sulfur dioxide, density, pH, sulphates, and alcohol. pH describes how acidic or basic a wine is on a scale from 0 (very acidic) to 14 (very basic). Most wines are between 3-4 on the pH scale. Chloride is the amount of salt in the wine. Alcohol is the percent alcohol content of the wine.

The goal of the data set is to predict the rating that an expert will give to a wine sample, using a range of physicochemical properties, such as acidity and alcohol composition. Due to privacy and logistic issues, only physicochemical (inputs) and sensory (the output) variables are available (e.g. There is no data about grape types, wine brand, wine selling price, etc.).
Table I and Table II present the 11 different physicochemical properties and data statistics (minimum, maximum, mean, and standard deviation values of all instances for each feature) of white wine and red wine sets respectively.

**B. Data Mining Approach**

To evaluate performance of selected tool using the given dataset, several experiments are conducted. For evaluation purpose, two test modes are used, the k-fold cross-validation (k-fold cv) mode, and percentage split (holdout) method.

The k-fold cv refers to a widely used experimental testing procedure where the database is randomly divided into k disjoint blocks of objects, then the data mining algorithm is trained using k-1 blocks and the remaining block is used to test the performance of the algorithm, this process repeated k times. At the end, the average value of the recorded measurement is found [10]. It is common to choose k as 10.

In percentage split mode, the database is randomly divided into two disjoint datasets. The first set, which the data mining system tries to extract knowledge from called training set. The extracted knowledge may be tested against the second set which is called testing set [10].

In this study, for k-fold cross-validation mode, different k values are tested for each method. The best classification results of each method are obtained when k value is chosen as 10.

Firstly, both datasets are separated into training and testing set by using 10-fold cross-validation method. Afterwards, both datasets are randomly divided into two groups called training and testing set. First set involves randomly 80% of dataset, and the other set involves the resting data.

**C. Data Mining Techniques**

In the original form of this datasets, two datasets were created, using red and white wine samples. The two datasets are related to red and white variants of the Portuguese “Vinho Verde” wine.

First, these two datasets have been combined into one dataset to classify wine samples as red wine and white wine. Three different data mining algorithms were used in our study. Those classification algorithms applied on the data set are k-nearest-neighbourhood (k-NN), random forests (RF), and support vector machines.

1) **k-Nearest-Neighbourhood Classifiers:** This method was depicted in the beginning of 1950s. Nearest-neighbourhood classifiers are depended on learning by analogy, this means a comparison between a test tuple with similar training tuples. The training tuples are described by n attributes. Each tuple corresponds a point in an n-dimensional space. All the training tuples are stocked in an n-dimensional pattern space. For an unknown tuple, a k-nearest-neighbourhood classifier searches the pattern space for the k training tuples that are closest to the unknown tuple. k training tuples are called as the k “nearest neighbours” of the unknown tuple [11].

“Closeness” is a metric distance, likewise Euclidean distance. The Euclidean distance between two points or tuples, say, X₁=(x₁₁, x₁₂, …, x₁n) and X₂=(x₂₁, x₂₂, …, x₂n), is

\[
\text{dist}(X₁, X₂) = \sqrt{\sum_{i=1}^{n} (x₁ᵢ - x₂ᵢ)^2}.
\]

2) **Random Forests:** This methodology uses a combination of tree predictors; each individual tree depends on a random vector. This random vector has identical and alike distribution for all trees in the forest. It was described by Breiman in 2001[12].

3) **Support Vector Machines:** This method was derived from statistical learning theory by Vapnik and Chervonenkis. It was first introduced in 1992 by Boser, Guyon, and Vapnik. This method is used for the classification of both linear and nonlinear data. It uses a nonlinear mapping to transform the original training data into a higher dimension. It searches for the linear optimal separating hyperplane in this new dimension. A hyperplane can separate data from two classes, with a suitable nonlinear mapping to sufficiently high dimension. The SVM uses support vectors and margins to find this hyperplane [11].

Then, the following three different data mining algorithms were used to classify the quality of both red and white wine samples: k-nearest-neighbourhood, random forests, and support vector machines.

Afterwards, principal component analysis in the feature selection was applied to the original both red wine dataset and white wine dataset for each method. Three data mining algorithms were used to classify the quality of both red wine samples and white wine samples.
III. EXPERIMENTAL RESULTS

In this study, firstly three classification algorithms were used to classify the wine samples as red wine and white wine. A model was built using each method and applied to the wine data set. The classification results of the three classification algorithms are evaluated both test modes which are 10-fold cross-validation, and 80% percentage split.

Also, some of the standard performance measures (statistics) are calculated to evaluate the performance of the algorithms. The standard performance measures are recall, precision, F measure, and ROC values.

Table III presents the correctly classified instances results of the classification of red and white wine samples.

<table>

<td></td>
</tr>
</tbody>
</table>

The most successful classification result of red and white wine samples was obtained by Random Forests Algorithm for both test modes. The accuracy of each cross-validation and percentage split mode with this algorithm is 99.5229%, and 99.4611% respectively.

Table III clearly shows that Random Forests algorithm outperforms from the other algorithms in two test modes.

Secondly, for the classification of the quality of both red and white wine samples, the classification experiment is measured by the accuracy percentage of classifying the instances correctly into its class according to quality features which are ranged between 0 (very bad) and 10 (very excellent) as 11 different classes and totally 22 classes.

Table IV and Table V present the correctly classified instances results of the classification of white wine sample qualities respectively.

For k-nearest-neighbourhood classifiers, different k values are tested for each test mode. When k value is increased, the achievement of the classification decreases. For this reason, k value is taken as 1.

</tbody>
</table>

The most successful classification result of white wine sample qualities as 11 classes was obtained by using Random Forest algorithm for both test modes. The accuracy of each cross-validation and percentage split mode with this algorithm is 70.3757%, and 68.6735% respectively.

The most successful classification result of red wine sample qualities as 11 classes was obtained by using Random Forest algorithm for both test modes. The accuracy of each cross-validation and percentage split mode with this algorithm is 69.606%, and 71.875% respectively.

Finally, for increasing of classification success in this study, the number of features was reduced by using PCA algorithm and the process wine quality classification was repeated by using SVM, k-NN, and RF algorithms.

Table VI and Table VII present the correctly classified instances results of the classification of white and red wine sample qualities after applying PCA respectively.

The most successful classification result of white wine sample qualities after applying PCA was obtained by using Random Forest algorithm for both test modes. The accuracy of each cross-validation and percentage split mode with this algorithm is 69.9061%, and 67.449% respectively.
The most successful classification result of red wine sample qualities after applying PCA was obtained by using Random Forest algorithm for both test modes. The accuracy of each cross-validation and percentage split mode with this algorithm is 71.232%, and 73.4375% respectively.

IV. CONCLUSIONS

For each classification model, we analyzed how the results vary whenever test mode is changed. The study includes the analysis of classifiers on both red and white wine data set. The results are described in percentage of correctly classified instances, precision, recall, F measure, and ROC after applying the cross-validation or percentage split mode.

Different classifiers like k-nearest-neighborhood, random forests, and support vector machines are evaluated on datasets.

Results from the experiments lead us to conclude that Random Forests Algorithm performs better in classification task as compared against the support vector machine, and k-nearest-neighbourhood.

After applying PCA, the success rate of quality classification for white wine has decreased from 70.3757% to 69.9061% for cross validation mode. The success rate of quality classification for white wine has decreased from 68.6735% to 67.449% for percentage split mode.

After applying PCA, the success rate of quality classification for red wine has increased from 69.606% to 71.232% for cross validation mode. The success rate of quality classification for red wine samples has increased from 71.875% to 73.4375% for percentage split mode.

Abstract: Connection-oriented network routing (CONR) is one of the NP-hard problems. In the recent years, to solve the problem of CONR it was using the heuristic methods such as minimum spanning tree methods (Kruskal and Prim Algorithms) and shortest path methods (A Star and Dijkstra Algorithms) and also metaheuristic methods (Ant Colony Optimization (ACO), Genetic Algorithm (GA) and Artificial Bee Colony (ABC)). But as the complexity of the problem increase, the guarantee to achieve the best results by heuristic algorithms decreases. Therefore, in large scale problems metaheuristic algorithms are preferred. In this study, it was applied CONR to provide internet and telephone lines for Kirkuk city and the near regions in Iraqi by using the fiber optical systems. Firstly, the locations of 56 fiber optic panels previously determined with particle swarm intelligence algorithm (PSO) are placed Kirkuk city. Then, it was aimed to wire all the panels by fiber optic cables in minimum cost, to raise the data transfer speed, to decrease the excavation process. As a result, two different metaheuristic algorithms (ACO and GA) were applied to achieve these targets and compared the results of them. After the experiments, the optimum distance between the panels were obtained with ACO and GA as 366100 km and 353400 km, respectively. The results show that GA is the best optimization algorithm for this problem.

Keywords— Connection-oriented network routing, Ant Colony Optimization, Genetic Algorithm, fiber optical systems, CONR

I. INTRODUCTION

When transmitting data through a network from one source to another the data follows a special path. In its way towards the target area the data passes through a chain of panels, this process is called network routing [1,2].

Whether the distribution path is reasonable, it has large impact on speed, cost and effectiveness in the logistics system, so it is very important to use a reasonable method to determine a reasonable distribution route. The exact solution is very difficult to study due to the NP-Hard nature of the problem, so heuristics may well be a viable direction [1,2]. One of the NP-hard problems is connection-oriented network routing (CONR).

In literature, different researchers dealt with the subjects of network routing and finding the shortest route. These researchers applied different kinds of heuristic algorithms and metaheuristic algorithms to solve the problem of CONR. Karakas [1] applied Dijkstra and Prim Algorithms to decrease the cost of creating network across Turkey to the half. Hardi [2] used the Genetic Algorithms (GA) to determine the shortest route that could be followed by the mineral water company in order to enable the distributors to get to their destinations through the shortest distance of all available paths. Mahia et al. [3] proposed new hybrid method to optimize parameters that affect performance of the ACO algorithm using Particle Swarm Optimization (PSO). PSO is preferred to detect optimum values of parameters which are used for city selection operations in the ACO algorithm and determines significance of inter-city pheromones and distances. Experimental results showed that the performance of proposed method by using fewer ants than the number of cities for the TSPs was better than the performance of compared methods in most cases in terms of solution quality and robustness. Kuzu et al. [4] used eight of the most common kinds of metaheuristic algorithms to solve the TSP problem which is considered one of the NP-hard problems. Dikmen et al. [5] applied the artificial intelligence techniques to solve the travelling salesman problem (TSP) in order to find the shortest ways to connect the Turkish cities. The results showed that the ACO method is better than the GA concerning the distance and time. Fong and Yuan [6] applied ACO to solve the TSP problem and reached the best results of network routing solution. İşçi and Korukoğlu [7] applied heuristic algorithms (prim & kruskal) and metaheuristic algorithm (GA) to decrease the cost of connecting network cables. The results showed that GA is better than prim & kruskal concerning this issue [7]. Kaya [8] applied Minimum spanning tree algorithms (Floyd & kruskal) to find the shortest path to provide gas pipeline to a particular area.

In this study, it was proposed CONR to provide internet and telephone lines for Kirkuk city and its near region in Iraqi using the fiber optical systems. The CONR consists a number of Panels, where each pair of panels has a definite distance. The purpose of this study is to visit all the panels such that the
total distance will be minimized. Also, it was aimed to wire all the panels by fiber optic cables in minimum cost, to raise the data transfer speed and to decrease the excavation process. As a result, two different metaheuristic algorithms, ACO and GA, were applied to achieve these targets and compared the results of them.

II. MATERIAL AND METHODS

A. Problem Description

In this study, connection-oriented network routing application will be made in order to minimize the cost of providing internet and landline telephone services to 9679 sq. km of Kirkuk city and its nearby regions in Iraq by using the fiber optical systems. The advantage of using fiber optical system is to increase the speed of transmission data. The panels were distributed in the city using PSO taking into consideration the required conditions. The locations of 56 panels are shown in Fig. 1.

![Fig. 1. Locations of panels in Kirkuk city](image)

The (graph theory) has been used to determine the distances between the panels. If it is assumed that each panel is a node and each fiber optic cable is an edge, then all the panels connected by fiber optical cables will form the following graph in Fig. 2. Each node has its direct path with the other nodes on condition of passing once from each one. In telecommunication science, this is called Hamiltonian path. Fig. 2 represents the fiber optics panels in the shape of a completed graph.

![Fig. 2. Fiber optics panels in the shape of a completed graph](image)

In order to solve this problem, it was determined the distances between these panels in a two-dimensional matrix as shown in Table 1, firstly.

B. Ant Colony Optimization Algorithm (ACO) For CONR

The ACO algorithm was developed by Dorigo et al [9]. This algorithm is inspired by the actual ant colony behaviors. By examine behaviors of ants in real life, it is observed that ants have the ability to find the shortest path between their nest and food source [9]. The most important issue in finding the shortest path is the ephemeral, chemical matter of pheromone that ants leave on the path they use. Ants in a colony usually choose a path where pheromone matter is concentrated. The amount of pheromone increases on a frequently used route [10]. The ACO algorithm suggests a solution for the CONR problem. The solution aims to form a closed tour of minimum length with the condition of visiting every panel at once. In this study, it is accepted that ants leave pheromones on inter-panel routes that they use and this pheromone becomes ephemeral in a certain ration. Selection of the panels to which ants will go is performed depending on the distance and the amount of pheromones between panels. This algorithm is operated iteratively and the shortest route found is regarded as the best solution. Selection of panel j, to which an ant in panel i in iteration t will go, is made according to Eq. (1) [3].

$$O_{t}(i,j) = \frac{(\tau(i,j))^\alpha \times (\eta(i,j))^\beta}{\sum_{m \in N(i)} (\tau(i,m))^\alpha \times (\eta(i,m))^\beta} \quad \text{when } j \in V_t(i) \quad (1)$$

In Eq. (3), $\tau(i,j)$ represents the amount of pheromones between i and j panel, $n_ij$ represents information (1/dij) pertaining to distance between i and j panel, and j display panel where kth ant can go. An ant chooses the panel with the highest ratio of $O_{k}(i,j)$ by making a greedy selection. Parameters $\alpha$ and $\beta$ are used for determining the importance between amount of pheromones and distance inter-panel. kth ant completes one total tour by using Eq. (1). The above mentioned operation is repeated in t iteration for all ants that are present in the colony [3]. The amount of pheromones left by an ant on a path that it has used is determined according to Eq. (2).
\[
\Delta \tau^k_i(t, t + 1) = \begin{cases} 
\frac{Q}{\sum_{r \in R^k} \tau^r_i}, & \text{if} (i, j) \text{ route performed by the } k \text{th ant} \\
0, & \text{otherwise}
\end{cases} 
\]

Where \( L^k \) represents distance of tour, \( Q \) represents a constant number and \( k \) represents \( k \th \) ant in the colony. Total amount of pheromones that ants, which are present in colony and use the path between panel \( i \) and \( j \) have left, is calculated by using Eq. (3).

\[
\Delta \tau^k_i(t, t + 1) = \sum_{t=1}^{n} \Delta \tau^k_i(t, t + 1) 
\]

Amount of pheromones, which will be found in inter-panel routes in iteration \((t+1)\), is determined as in Eq. (4) depending on the impact of evaporation as well.

\[
\tau_{ij}(t + 1) = \sum_{t=1}^{n} (1 + p)\tau_{ij}(t) + \Delta \tau^k_i(t, t + 1) 
\]

In Eq. (4), \( P \) is the degree of evaporation and receives a value at intervals \([0–1]\). When the maximum number of iterations is reached, the shortest tour length obtained is considered as the solution of the problem \([3]\).

C. Genetic Algorithm (GA) For CONR

- Coding and structure of a chromosome

In this study, it was used a code of some sort of permutation type. Fig. 3 was given as an example of the structure of a chromosome composed for 8 panels. It explains the idea of finding the cheapest round-trip tour a fiber optic cable has to take by starting from the center panel and visiting all the 8 panels.

![Fig. 3. Structure of a chromosome](image)

- The initial population generation

When composing the initial population generation for CONR problem, there are 57 genes for each chromosome and this number differs from one problem to another. These 56 genes represent one chromosome and each chromosome is considered as path for the fiber optical cable.

- Fitness Function

The fitness function could be applied to find optimum solution for solving the CONR Problem according to the following Eq.(5).

\[
\text{Min} = \sum_{i=1}^{n} \sum_{j=1}^{n} C_{ij} \times X_{ij} 
\]

The fitness function that characterizes each chromosome represents the total length of the route from the center panel to the last panel (gene) moving according to the order of the genes in the chromosome. The best chromosome is the one gives the minimum value of fitness \([11,12]\).

- Selection

The Roulette-Wheel method is applied to select the best parent in the CONR problem. In this method each individual is assigned a slice of a circular “roulette wheel”, the size of the slice being proportional to the individual’s fitness. The wheel is spun \( N \) times, where \( N \) is number of individuals in the population. On each spin, the individual under the wheel’s marker is selected to be in the pool of parents for the next generation\([11,13]\).

- Crossover Operation

Crossover is considered one of the effective elements in the performance of GA. The aim of this operation is to choose good parents (chromosomes with high-value) in order to create children chromosomes (with bigger-value). In CONR problem, the fiber optic cables were required to pass once from every panel. In order to avoid repeating the passage through the same panel, the one cut crossover type is preferred. Fig. 4 represents the example of crossover operation for CONR with 8 panels\([11,14]\).

![Fig. 4. Crossover Operation](image)

- Mutation Operator

Mutation operator is also considered of the effective elements in the performance of GA. The aim of mutation operator is maintaining the diversity within the chromosome that exists in the population. The mutation operator cannot be applied on all children (chromosomes), but only on a small percentage of them. In CONR problem, the mutation operator will swap the places of the panels in a single chromosome in random form\([11,14]\).

- Forming New Generation

According to the results on fitness function, the new population is compared with the previous population after selecting the initial population generation, selecting parent,
The obtained results from GA and ACO algorithms were shown in Table 4 and Table 5.

### III. RESULTS AND DISCUSSION

In this study, it was investigated CONR problem with minimum cost and excavation process and maximum speed to provide internet and telephone lines for Kirkuk city and the near regions in Iraqi using GA and ACO algorithms and the results of these algorithms were compared. To solve the Kirkuk’s CONR problem, the C#2013 platform was preferred for programming GA and ACO.

The number of iteration was selected as 3000 times for both GA and ACO. Other parameter values for ACO and GA were given in Table 2 and Table 3, respectively.

The obtained results from GA and ACO algorithms were showed in Table 4 and Table 5.

</tr>
</tbody>
</table>

The experiments showed that ACO algorithm gave the most optimal performance when the number of ants was equal to the number of fibre optic panels. Therefore, the shortest route obtained as 366100 km while the number of ants was selected as 56. Table 4 illustrates the optimum route distance and the shortest route for ACO.

As for GA when applying the same number of iterations 3000, it was seen that the results was better than ACO algorithm and the shortest route was obtained as 353400 km. From this results it concluded that the optimum solution for CONR problem is using the GA algorithm with value out of 353400 km. Furthermore, the shortest route obtained with GA was directly drew using actual locations of panels and this route is shown in Fig. 5 which has been taken by the fibre optical cables in Kirkuk city.

![Fig. 5. Shortest Route for Fibre Optics Cables in Kirkuk City](image)

### IV. CONCLUSION

Many techniques have been invented for distribution because of its great role in economic life. In this study, connection oriented network routing was applied in order to provide internet and telephone lines for Kirkuk city and the near regions in Iraqi using optic fiber systems. It was aimed to wire all the panels by fiber optic cables in minimum cost, to raise the data transfer speed, to decrease the excavation process. As a result, two different meta-heuristic algorithms (ACO and GA) were applied to achieve these targets and compared the results of them. After the experiments, the optimum distance between the panels were obtained with ACO and GA as 366100 km and 353400 km, respectively. The results show that GA is the best optimization algorithm for this problem.

Abstract—In many image-processing applications, image segmentation is an essential stage. In this stage, an image is partitioned into several regions according to the similarity of its pixels. In addition to the accuracy of the image segmentation, the speed is also very important for real-time image processing applications. Many computer applications take advantages of the multi-processor architecture to up to their running performance. However, to run an algorithm as parallel is very difficult in many cases. Due to using the same memory blocks, many conflicts might be happened between the processors. Moreover, each process of one processor may depend on those of another processor. For this reason, the algorithm to be parallelized must be suitable to parallel. In addition, the processing traffic that is pursued by the processors must be controlled within some parallel directives. In this paper, we provide a parallel implementation to a hierarchical graph-based image segmentation method by using its hierarchical processing steps. To achieve this goal, we utilize the OpenMP (Open Multi-Processing) Library to run the segmentation process as parallel on images of different sizes from the INRIA Holidays dataset. The experimental results show that the parallel implementation of the algorithm is more effective than the serial type according to processing time.

Keywords—Parallel programming; Image segmentation; Graph; OpenMP

I. INTRODUCTION

For many image processing application, the image segmentation is one of the low-level and mid-level image processing stages. During the image segmentation stage, the pixels of an image are grouped into regions according to the similarity in the regions and differences among the regions. This stage is one of the most difficult stages in the image processing applications [1]. The consequence of this stage affects all of the following stages and their results. Image segmentation reduces the large amounts of data for the analysis operations. In an image, the segmentation process inherently focuses on the homogeneous regions and the borders between them. It performs this task by using brightness, color, pattern (texture), or density differences, etc. [2], [3].

Many pattern recognition and computer vision applications take advantage of the global features of the images for more accurate segmentation. However, in this way, the processing time exceeds the allocated time for the input frame periods of the used camera in many real-time computer visions system. Due to the computational complexity of the methods that take into account the global features of the images, those that consider local features are mostly preferred in real-time applications [2].

Graph-based methods are some of the segmentation methods. Because of their representation relevance and ease of retention of images, the graph theory tools are utilized as prominent tools in computer vision [2]. In graph-based segmentation methods, the nodes (or vertices) of the graph refer the pixels of the image and the edges define the connections between the adjacent (or neighboring) vertices. Each of these edges generally has a numerical value, which is called weight [4]. The weights of the edges are considered the difference of the gray level values or color values (if the segmentation is performed on a color image) of the vertices that exists at the ends of the edge. The difference is generally computed by using Euclidean distance measurement [5].

Spanning trees are sub-graphs of a graph; such that they do not contain any loop and it is easy to make process on the graph via the spanning tree structure. The spanning tree of a graph that has the least total edge weight among the other spanning trees of the graph is called minimum spanning tree (MST) [4]. Image segmentation algorithms based on minimum spanning tree take advantage of the features of the MST, because it takes no account of most of the edges on the image-graph. Therefore, the cost of the operation is reduced significantly [6].

The segmentation process in MST-based segmentation algorithms comes true in two ways. The first way is the cutting procedure in which the edges to be cut are removed on the MST that covers all of the pixels of the image. The edges to be cut represent the borders on the image. By this way, a tree is separated into several sub-trees. The sub-trees represent regions in the image [5], [7], [8], [9]. The second way is the merging procedure in which the sub-trees that satisfies a homogeneity criterion are merged [10]. If two sub-trees do not satisfy the criterion, they are not merged, and in this case, the border between the two regions that the two sub-trees represent occurs. In this paper, we parallelize the merging procedure that is performed hierarchically.

Efficient Graph-Based Image Segmentation algorithm, which is proposed by Felzenszwalb and Huttenlocher, defines a merging criterion [10]. The algorithm employs the Kruskal’s algorithm [12], which is one of the most popular MST algorithms. In this algorithm, all of the edges of
the graph structured an image is sorted in ascending order according to their weight. Then, the edges are added to the MST structure by starting the shortest edge, such that the MST is empty at first. If the trees that are at the ends of the edge to be added do not satisfy the merging criterion, the edge is not added. By the way, the MST may be divided into more than one sub-trees. Haxhimusa and Kropatsch [13] used this merging criterion on Boruvka’s hierarchical MST algorithm [14]. In this algorithm, each node (vertex) assumed a sub-tree, and each merging process of these sub-trees actualizes independently from others. For this reason, this makes it suitable for parallelization.

Nowadays, the multi-core processors are prevalent; and therefore, the parallel programming has been a very popular issue. Scientific and engineering programs such as image-processing applications need to be fast to overcome the heavy processing load in limited times. In order to make use of this technology, parallelization of the applications reduces the process load. Obtaining the same or similar results with sequential execution and ensuring to not overlapping of the parallel operations is mostly important and difficult matters for parallel programming issue. In this paper, we organize the hierarchical graph-based image segmentation algorithm as appropriate for parallel execution [15].

II. The Hierarchical Graph-Based Image Segmentation

Let the graph \( G = (V, E) \) be the image-graph that is constructed from an image. \( V \) represents the set of the vertices in the graph \( G \), such that each vertex refers a pixel in the image and \( V \) contains all of the pixel-vertices. \( E \) represents the set of the edges that connects each vertex to its neighboring vertices. In this paper, 8-connected neighborhood is used as a neighborhood system. The edges are generally weighted and undirected. The weight of each edge is a numerical and positive value that indicates the degree of similarity between two vertices at the ends of the edge. As the degree of similarity two vertices is lower, the weight value is higher (Ters orantllar hocam). To figure out the similarity, the one-dimensional gray-scale values or multi-dimensional color values of the pixels can be used, and to compute the difference for both ways, the Euclidean distance measurement can be used. The edge \((u, v)\) connects the vertices \(u\) and \(v\), and \(w(u, v)\) is the Euclidean value of the edge. Let \(x_u\) be the one-level gray-scale value, and \(x_{u,i}\) be the \(i\)-th value of the \(z\)-level color vector of the vertex \(u\) where \(i = \{1, 2, \ldots, z\}\). The Euclidean distance as the weight value of \((u, v)\) is computed as in Eq. 1.

\[
w(u, v) = \sqrt{\sum_{i=1}^{z} (x_{u,i} - x_{v,i})^2} \frac{1}{z}
\]  

A. Boruvka’s Minimum Spanning Tree Algorithm

Boruvka’s MST algorithm constructs an MST structure from a graph, such that the graph must be a weighted, undirected, and complete graph (Fig. 1). According to the algorithm, each vertex is assumed as a tree at first stage and no one is connected to any other one. The union of multiple trees is called forest. At first, all of the vertices compose the forest \(F_0\), because each vertex is a tree such that \(F_0 = T_1 \cup T_2 \cup \ldots \cup T_n\), such that \(n\) refers to the number of the vertices on the graph \(G\). \(T_i\) refers to the \(i\)-th tree \((T_i\) equals to the \(i\)-th vertex at first stage\) and each tree \(T_i\) chooses the smallest edge \((u, v)\) where \(u \in T_i\) and \(v \notin T_i\), then the edge is added to the new forest \(F_1\) that is being composed for the next stage. At the begin of the next stage, the number of the trees will have been reduced by at least one-half, i.e., \(t\) will have been decreased by at least one-half. If any edge is not added in the current stage, on the other words, the last forest \(F_{last}\) has one tree, the algorithm ends.

B. The Graph-Based Segmentation Algorithm

In the MST of a graph representation of an image, the highest weighted edges represent the boundaries of the image (Fig. 1). Felzenszwalb and Huttenlocher have segmented the images by detecting the edges of the boundaries, which are called boundary edges [10], [11]. For the purpose of to detect the boundary edges to be excluded from the

Fig. 1. (a) A simple black and white image , (b) the graph representation of the image according to 4-connection neighborhood, (c) the MST of the image extracted from its graph representation and an example of boundary edge in the MST
MST, Felzenszwalb and Huttenlocher have used the merging criterion Eq. 2 in the Kruskal’s MST algorithm. According to the Kruskal’s algorithm, each vertex in the graph $G$ that is representation of the image seems as a tree. Firstly, all of the edges in $G$ are sorted in order to their weight in ascending order. The two trees at the ends of the smallest weight edge in the sorted edge queue are merged if the two trees are not the same tree, and the edge is removed from the queue. At last, only one single tree remains such that it is called MST [12]. If the merging criterion in Eq. 2 is applied on the algorithm, more than one MSTs might remain at the end of this process [10], because the edges that does not satisfy the criterion are not added to the MST to be formed, and thus, the MST that covers all of the vertices might not be created.

$$\text{Diff}(T_1, T_2) < \min(\text{Int}(T_1) + k/|T_1|, \text{Int}(T_2) + k/|T_2|)$$

(2)

In Eq. 2, $T_1$ and $T_2$ are the sub-trees to be merged. $\text{Diff}(T_1, T_2)$ defines the weight value of the shortest weighted edge that connects the trees $T_1$ and $T_2$. $\text{Int}(T_1)$ and $\text{Int}(T_2)$ defines the internal difference of $T_1$ and $T_2$ respectively. An internal difference of a tree is the weight value of the highest weighted edge in the tree. $|T_1|$ and $|T_2|$ defines the number of vertices in the trees $T_1$ and $T_2$ respectively. The constant value $k$ refers to a threshold value that controls how much greater $\text{Diff}(T_1, T_2)$ must be than the internal differences of the trees $T_1$ and $T_2$.

In this paper, Eq. 2 is utilized as a merging criterion in the Boruvka’s algorithm, because the Boruvka’s algorithm progresses in a hierarchical order. Due to this reason, this algorithm is more suitable for parallelization than the other popular MST algorithms [16]. The hierarchical graph-based image segmentation algorithm is sketched in Fig. 2.

In Fig. 2, the constructed graph $G = (V, E)$ is obtained from the image used, and then it is taken to the process as an input data. Firstly, each vertex seems as a tree. The number of trees $t$ is equal to the number of vertices $|V|$ initially. For each tree $T_i$, the smallest edge $(u, v)$, where $u \in T_i$ and $v \notin T_i$, is found. If the weight value $w(u, v)$ satisfies the criterion in Eq. 2, the tree $T_u$ to which the vertex $u$ belongs and the tree $T_v$ to which the vertex $v$ belongs are merged, and thus, the number of tree is reduced to one. After these processes are complete for each tree, this cycle is repeated iteratively. If no merging is happened, the algorithm ends.

### III. The Parallel Implementation of The Algorithm

#### A. OpenMP

Multi-core processors have become quite prevalent nowadays. Scientific and engineering programs such as image-processing applications need to be fast to overcome the high processing load in limited times. In order to make use of the multi-core processor technology, such applications need to be parallelized. Therefore, some libraries and tools, which are developed to take advantage of the multi-core processor architecture, should be used and the programs that will be parallelized must be coded suitable for parallelization. OpenMP (Open Multi-Processing) is a run-time program library that has routines and environment variables and includes a set of compiler directives. The directives can be embedded into C/C++ and Fortran programming languages using shared-memory platforms to run codes on more processors [17]. On the platforms like these, OpenMP provides an easier programming model. However, getting high performance from OpenMP sometimes might be a very difficult task. The acceleration rate of the program that use OpenMP directives depends on many factors, including the problem how the variables are used in the code, data layout, workload balancing and so on. OpenMP is especially useful for partitioning a loop and running the iterations of the loop on more processors simultaneously. For that, the loop dependencies need to be configured in accordance to parallelism [17].

#### B. Implementation of The Parallel Directives

The parallel computation is put into practice in three ways: general-purpose computing on graphics processing units, via a message processing interface, or using shared memory architecture (OpenMP) [18]. In a shared memory model system, threads, which are processes such that each runs as parallel, are communicated each other by reading and writing directly to the same memory. Since the OpenMP specification was introduced as a standard shared-memory programming model in 1998, there have been many studies to

![Fig. 2. The steps of the hierarchical segmentation algorithm](image)

![Fig. 3. A simple presentation of a shared memory architecture](image)
implement the OpenMP directives to their programs to run as parallel [19]. By using the OpenMP instructions, it is easy to solve the high processing load problems of the classic single pipeline program model, because OpenMP execute some calibrations automatically, and we do not need to consider which core should run in which part of the calculation [20].

OpenMP uses a fork-join model, which is a standard way to execute a parallel program on shared-memory systems (Fig. 3). Firstly, a parallel program begins to run on a single thread called master thread. Once the process flow encounters a parallel block, the process flow is separated to several threads (known as the fork) to run on additional processor cores [21].

OpenMP provides several mechanisms to run the code as parallel. Additionally, OpenMP provides an extra translator that analyzes the parallel loop and generate executor code before the OpenMP translation [19]. The translator determines the number of cores to run, separates the loop into sub-loops automatically according to the number of the cores, and employs each sub-loops to different threats. The example of its use is as below:

```
#pragma omp parallel for
for (i = 0; i < 1000; i++)
{
    x[i] = y[i];
}
```

OpenMP provides some directives as private and shared to define how the parallel regions use the data values. In parallel programming, synchronization is used to impose some order constraints and to organize to access to shared data. OpenMP also provides several mechanisms to synchronize the parallel threads, with critical, atomic, lock, ordered, flush, and barrier [15], [22].

To synchronize the parallel graph-based algorithm, we used the lock directive. In the block for merging clusters, if we embed the locking mechanism in the processes, the threads that each works on a different cluster will also wait to each other [23]. In this way, the flow would not be parallel. Therefore, we restricted to the threads that own the same index of lock array so that the index is the cluster number at the same time. The example of its use is as below:

```
mylock = new omp_lock_t();
omp_init_lock(&mylock);

lock_array = new omp_lock_t[size];
for (i = 0; i < size; i++)
{
    omp_init_lock(&lock_array[i]);
}
```

If a lock is set with the expression omp_set_lock by a processor, other processors that wants to set this lock must be waiting the processor until the lock is unset with the expression omp_unset_lock by the processor that has set the lock.

Another problem for synchronizing the processes is the mutual exclusion problem. In cases when two clusters chose each other as nearest cluster on different threads simultaneously, a crash may happen. To solve this problem, we get the related code into a critical block by the directive critical. By this way, only one processor employs the codes that are in the critical block as seen below:

```
#pragma omp critical
{
    omp_set_lock(&mylock1);
    omp_set_lock(&mylock2);
}
```

There is also another directive for getting the code into a critical block, which is called atomic such that it is used for only one variable to perform faster processing [17]. For example:

```
#pragma omp atomic
    a = a - 1;
```

The input is: Given image graph $G = (V, E)$
The output is: Tree set $T = T_1, T_2, ..., T_t$

```
lock_array = new omp_lock_t[V];
for (i = 1 to V) do
    $T_i \leftarrow v_i$
    omp_init_lock(&lock_array[i])
end for
counter $\leftarrow V$
repeat
    $t \leftarrow counter$
    #pragma omp parallel for private(i) shared(counter)
    for (i = 1 to do)
        $(u, v) \leftarrow T_i$.smallest_adjoring_edge
        #pragma omp critical
        {
            omp_set_lock(&lock_array[T(u).id]);
            omp_set_lock(&lock_array[T(v).id]);
        }
        if $w(u, v) \geq \min (Int(T(u)) + \frac{k}{|T(u)|}, Int(T(v)) + \frac{k}{|T(v)|})$
            omp_unset_lock(&lock_array[T(u).id]);
            omp_unset_lock(&lock_array[T(v).id]);
        continue
    end if
merge $T_u$ and $T_v$
#pragma omp atomic
    counter $\leftarrow counter - 1$
    omp_unset_lock(&lock_array[T(u).id]);
    omp_unset_lock(&lock_array[T(v).id]);
end for
until counter $= t$
```

Fig. 4. Parallel implementation of the algorithm in Fig. 2
The parallel implemented version of the algorithm in Fig. 2 is sketched in Fig. 4.

IV. EXPERIMENTAL RESULTS AND DISCUSSION

The system that has been used for the values in Table I has 32 bit Intel i5-2400 3.10-GHz Quad Core processor with 4 GB RAM. We used C++ programming language. To import and illustrate the images, we used OpenCV (Open Source Computer Vision) library [24].

In Fig. 5, the original versions of some images from INRIA Holidays dataset [25], their segmentation results and which processor has performed on which segments of the images in last iteration are presented.

We applied the algorithm on some images from INRIA Holidays dataset [25] in the different versions of the images as the sizes of $128 \times 96$, $256 \times 192$, $512 \times 384$, and $1024 \times 768$. We executed the program five times for each elapsed time

Fig. 5. Visualization of the segmentation results and the task sharing of the processors for some images
value in Table I, and put the smallest one of the five values to the table. The time unit is given as seconds (s) in Table I.

V. CONCLUSIONS

As seen in the results, parallel programming provides an important acceleration in processing speed. However, the processing time decreases no more in all cases, as the number of cores increases. The speedup of the execution relies on many factors, including compiler optimizations, runtime support, data layout, operating system noise, workload balancing and so on. Additionally, it may be dependent on the regions to merge in the structure of the graph of the image. In a parallel loop, even if the threads complete their process except one, they will have to wait for it. In these cases, the operating system might have executed another task on the thread in the meantime. Nevertheless, the parallelization saved a noticeable time for us.

{murataslan, nurdan}@selcuk.edu.tr

Abstract— Graph coloring problem (GCP) is getting more popular to solve the problem of coloring the adjacent regions in a map with minimum different number of colors. It is used to solve a variety of real-world problems like map coloring, scheduling, graph coloring is associated with two types of coloring as vertex and edge coloring. The goal of the both types of coloring is to color the whole graph without conflicts. Therefore, adjacent vertices or adjacent edges must be colored with different colors. The number of the least possible colors to be used for GCP is called chromatic number. As the number of vertices or edges in a graph increases, the complexity of the problem also increases. Because of this, each algorithm can not find the chromatic number of the problems and may also be different in their executing times. Due to these constructions, GCP is known an NP-hard problem. Various heuristic and metaheuristic methods have been developed in order to solve the GCP. In this study, we described First Fit (FF), Largest Degree Ordering (LDO), Welsh and Powell (WP), Incidence Degree Ordering (IDO), Degrees of Saturation (DSATUR) and Recursive Largest First (RLF) algorithms which have been proposed in the literature for the vertex coloring problem and these algorithms were tested on benchmark graphs provided by DIMACS. The performances of the algorithms were compared as their solution qualities and executing times. Experimental results show that while RLF and DSATUR algorithms are sufficient for the GCP, FF algorithm is generally deficient. WP algorithm finds out the best solution in the shortest time on Register Allocation, CAR, Mycielski, Stanford Miles, Book and Game graphs. On the other hand, RLF algorithm is quite better than the other algorithms on Leighton, Flat, Random (DSJC) and Stanford Queen graphs.

Keywords — Chromatic number, Graph coloring algorithms.

I. INTRODUCTION

Graph theory is a problem represented with vertices (nodes) and edges (arcs) [1]. Otherwise, graph coloring problem (GCP) is a problem where adjacent vertices or edges in graph must be colored by using different colors [2]. GCP was proposed by Francis Gutrie as the four color problem. Four color problem has described by F. Gutrie to solve the problem of coloring the adjacent regions in a map using the minimum number of different colors [3].

Graph coloring is associated with two types of coloring as vertex and edge coloring [2]. The goal of the both types of coloring is to color the whole graph without conflicts. Therefore, adjacent vertices or edges must be colored with different colors. If there is at least one link (edge) between two nodes, it is called adjacent vertices. If the Fig. 1 examines, it can be seen that there is no edge between $V_2$ and $V_4$ vertices. Therefore, these vertices are not adjacent vertices. However, the other vertices in the graph are adjacent because there is at least one edge between each other. In the context of this study we described vertex coloring problem in graphs. If an undirected $G = (V, E)$ graph is examining; $V$ is the set of vertices and $E$ is the set of edges. The graph which is given in Fig. 1, the set of vertices are $V = \{v_1, v_2, v_3, v_4\}$ and the set of edges are $E = \{e_1, e_2, e_3, e_4, e_5\}$. In addition, $R = \{1, 2, \ldots, k\}$ is the set of colors which are used for coloring the vertices. In this case, if the whole graph colored without conflicts is performed by utilizing the minimum number of different colors, it’s called “k-coloring graph” [4]. This minimum number of different colors is known as chromatic number. Chromatic number is indicated by $\chi(G)$ [5,6].

Graph coloring problem is mostly used for solving computer based applications and problems. Graph coloring algorithms are usable for solving the many engineering applications and real-world problems [2]. Some of the these problems are Map Coloring [7], Timetabling and Scheduling problems [8,9], Register Allocation problems [10,11], Sudoku problem [12] and Frequency Assignment problems [13].

As the number of vertices or edges in a graph increases, the complexity of the problem also increases. Because of this, each algorithm can not find the chromatic number of the problems and may also be different in their executing times. Due to these conditions, GCP is known an NP-hard problem [14]. Hence, for getting a better solution for GCP many heuristic and meta-heuristic algorithms are developed. Heuristic algorithms generally can be used for a problem with fewer numbers of vertices. On the other hand, for the complex graphs meta-heuristic algorithms can find better solutions [15].

Tabu Search (TS) Algorithm [16], Simulated Annealing (SA) Algorithm [17], Genetic Algorithm (GA) [7], Ant Colony (ACO) Algorithm [18], Cuckoo (COA) Algorithm [15] are some of the meta-heuristic algorithms used for graph coloring problem. When the vertices in a graph $G$ are colored by means of the greedy algorithms, the coloring issue is
performed with selecting and coloring methods of algorithms. These algorithms are called greedy algorithms because of the algorithms choice the best valid selection for every operation step. The greedy algorithms generally provide effective and sufficient results for vertex coloring [15]. In this study, we described First Fit (FF) [19], Largest Degree Ordering (LDO) [19], Welsh and Powell (WP) [5], Incidence Degree Ordering (IDO) [19], Recursive Largest First (RLF) [20] and Degrees of Saturation (DSATUR) [21] algorithms which have been proposed in the literature for the vertex coloring problem and these algorithms were tested on benchmark graphs provided by DIMACS [22]. The performances of the algorithms were compared with each other in terms of their solution qualities and executing times.

II. VERTEX COLORING PROBLEM

If the vertices in a graph are colored with different colors without considering their adjacencies, this graph would be colored utilizing the number of the different colors which are equal to number of vertices. However, this is not a good solution for GCP. Because, the purpose of the GCP is to find the minimum number of the colors for adjacent vertices colored with different colors.

As the number of vertices or edges in a graph increases, the complexity of the graph also increases. Because of this, coloring the entire graph is getting difficult by the least possible different colors. Therefore, we need some particular methods for coloring the graphs. Thanks to particular methods, the graphs can be colored with minimal different colors.

Algorithms in the literature use the adjacency matrix for coloring the vertices of graphs. Adjacency matrix is generated based on the condition that whether any edge exists between vertices [1]. For a graph, the set of vertices are shown in the set of \( V = \{v_1, v_2, \ldots, v_n\} \). The adjacency matrix of a graph is generated by the equation. \( A \) is represents the adjacency matrix.

\[
A = \begin{cases} 
1, & \text{if there is an edge between } v_i \text{ and } v_j \\
0, & \text{otherwise} 
\end{cases} \quad (1)
\]

Another important constraint for the selection of the vertex to be colored is vertex degrees. A degree of a vertex in an undirected and unweight graph is equal to the total number of edges connected to the vertex. It’s shown with \( deg(v_i) \) [1]. The graph given in Fig. 2 has seven vertices and nine edges.

![Figure 2. A graph with seven vertices](image)

Table I shows the adjacency matrix for the graph presented in Fig. 2 and and Table II shows the degrees of vertices for this graph.

III. VERTEX COLORING ALGORITHMS IN GRAPHS

At this section of the study we describe the steps of the some algorithms which have been proposed in the literature for the vertex coloring problem. Also these algorithms will be tested on the graph in Fig. 2. Then the selecting order of the vertices and the color of each vertex are given.

A. First Fit Algorithm (FF)

For the given graph, the set of the vertices is described as \( V = \{v_1, v_2, \ldots, v_n\} \) and the set of the colors is described as \( R = \{r_1, r_2, \ldots, r_k\} \). The steps of the algorithm:

**Step 1**: Create a color set. (initially the color set is empty).

**Step 2**: The first vertex in the set of \( V \) is selected as the starting vertex. The selected vertex is colored with first color and this color is added to color set.

**Step 3**: Next vertex in the set of \( V \) is selected for coloring.

**Step 4**: For selected vertex, find the adjacent vertices of it from the adjacency matrix. A color which is in the color set, but not color of the adjacent vertices of selected vertex is given to the selected vertex. If the colors in the color set unsuitable for coloring the selected vertex, a new color is defined. The new color is added to the color set and appointed to the selected vertex. If the uncolored vertex exists, it is returned to the next.

Table III shows the result for the graph shown in Fig. 2. Selected order of the vertices and their colors are given in Table III. According to Table III, the first colored vertex is \( A \) and the color \( r_1 \) is given this vertex. The last colored vertex is \( G \) and the color \( r_3 \) is given this vertex.

![Table I: Adjacency Matrix](image)

![Table II: The Degrees of Vertices](image)

![Table III: The Result of the Colored Graph Using the FF Algorithm](image)
B. Welsh Powell Algorithm (WP)

For the given graph $G$, the set of the vertices is described as $V = \{v_1, v_2, \ldots, v_n\}$ and the set of the colors of the vertices is described as $R = \{r_1, r_2, \ldots, r_k\}$ . The steps of the WP algorithm:

**Step 1**: The vertex degree of each vertex is calculated and the vertex degrees are added to the degree set $\text{Deg}(v_i)$, such that $i = 1,2, \ldots, n$.

**Step 2**: The uncolored vertex that has the largest degree in the degree set $\text{Deg}(v_i)$ is selected for coloring. Initially, the first color in the color set is selected as the active color.

**Step 3**: The selected vertex is colored with active color. After that, find the uncolored vertices from adjacency matrix which are not adjacent vertices of the colored vertex and these vertices are added to the $V'$ set ( $V' = \{v'_1, v'_2, \ldots, v'_n\}$).

- The uncolored vertex that has the largest degree in the $V'$ is selected for coloring. This vertex is colored with active color. After that, the adjacent vertices of this vertex are deleted from $V'$. This step is repeated until all vertices colored in the set of $V'$.

**Step 4**: If the uncolored vertex exists, next color in the color set is selected as active color and it is returned to the step 2. Otherwise the program is terminated, because all vertices in the graph are colored.

Table IV shows the result for the graph shown in Fig. 2. Selected order of the vertices and their colors are given in Table IV.

C. Largest Degree Ordering Algorithm (LDO)

For the given graph $G$, the set of the vertices is described as $V = \{v_1, v_2, \ldots, v_n\}$ and the set of the colors of the vertices is described as $R = \{r_1, r_2, \ldots, r_k\}$ . The steps of the LDO algorithm:

**Step 1**: Create a color set. (initially the color set is empty). The vertex degree of each vertex is calculated and the vertex degrees are added to the degree set $\text{Deg}(v_i)$, such that $i = 1,2, \ldots, n$.

**Step 2**: The uncolored vertex that has the largest degree in the degree set $\text{Deg}(v_i)$ is selected for coloring. Firstly, the selected vertex is tried to color with the colors in the color set. If the color set is empty or the colors in the color set are not appropriate (all colors int the color set used from the adjacent vertices) for color the vertex, a new color is defined. The new color is added to the color set and appointed to the selected vertex.

**Step 3**: If the uncolored vertex exists, it is returned to the step 2. Otherwise the program is terminated.

Table V shows the result for the graph shown in Fig. 2. Selected order of the vertices and their colors are given in Table V.

D. Incidence Degree Ordering Algorithm (IDO)

For the given graph $G$, the set of the vertices is described as $V = \{v_1, v_2, \ldots, v_n\}$ and the set of the colors of the vertices is described as $R = \{r_1, r_2, \ldots, r_k\}$ . The steps of the IDO algorithm:

**Step 1**: The vertex degree of each vertex is calculated and the vertex degrees are added to the degree set $\text{Deg}(v_i)$, such that $i = 1,2, \ldots, n$. Initially, there is just one color in the color set.

**Step 2**: The uncolored vertex that has the largest degree in the degree set $\text{Deg}(v_i)$ is selected for coloring. The selected vertex is colored with the first color.

**Step 3**: The number of the colored adjacent vertices is calculated for every uncolored vertices. After that, the uncolored vertex whose colored neighboring vertices are the maximum is selected. If more than one vertex provides this condition, the vertex which has the largest degree among them is selected.

**Step 4**: Firstly, the selected vertex with the colors in the color set is tried to color. If the colors in the color set are not appropriate to color the vertex, a new color is defined. The new color is added to the color set and appointed to the selected vertex.

**Step 5**: If the uncolored vertex exists, it is returned to the step 3. Otherwise, the program is terminated.

Table VI shows the result for the graph shown in Fig. 2. Selected order of the vertices and their colors are given in Table VI.

E. Degrees of Saturation Algorithms (DSATUR)

For the given graph $G$, the set of the vertices is described as $V = \{v_1, v_2, \ldots, v_n\}$ and the set of the colors of the vertices is described as $R = \{r_1, r_2, \ldots, r_k\}$ . The steps of the DSATUR algorithm:

**Step 1**: The vertex degree of each vertex is calculated and the vertex degrees are added to the degree set $\text{Deg}(v_i)$, such that $i = 1,2, \ldots, n$. 

**Step 2:** The uncolored vertex that has the largest degree in the degree set $\text{Deg}(v_i)$ is selected for coloring. The selected vertex is colored with first color.

**Step 3:** Firstly, calculate the number adjacent vertices which are colored with different colors for every uncolored vertex. After that, the uncolored vertex whose number of adjacent vertices colored with different colors is the maximum is selected for coloring. If more than one vertex provide this condition, the vertex which has the largest degree among them is selected.

**Step 4:** Firstly, the selected vertex is tried to color with active color. If the uncolored vertex exists, next color in the color set is selected as active color. Otherwise the program is terminated.

**Step 5:** If the uncolored vertex exists, it is returned to the step 3. Otherwise the program is terminated.

For DSATUR algorithm, Table VII shows the result for the graph shown in Fig. 2.

**F. Recursive Largest First Algorithm (RLF)**

RLF is used a recursive structure for coloring the vertices in graph. This recursive structure is the most important feature of the RLF algorithm [20]. According to this recursive structure, whole graph is colored with minimum different colors. For the given $G$ graph, the set of the vertices is described as $V = \{v_1, v_2, ..., v_n\}$ and the set of the colors is described as $R = \{r_1, r_2, ..., r_k\}$. The steps of the RLF algorithm:

**Step 1:** Vertex degree is calculated for each vertex and the degrees of vertices added to the set of $\text{Deg}(v_i)$. Initially, the first color in the color set is selected as the active color. Select the uncolored vertex which has the largest degree from set of $\text{Deg}(v_i)$ for coloring.

**Step 2:** The selected vertex is colored with active color. Adjacent vertices of the selected vertex can not color with active color. But the uncolored vertices which are not adjacent vertices of the colored vertex can be colored with active color. So RLF uses a recursive structure for select the uncolored vertices to color with active color. During this process the below steps should be followed:

- Adjacent vertices of the selected vertex $v_i$ are found from adjacency matrix. Adjacent vertices are added to the adjacent set $U$. ($U = \{u_1, u_2, ..., u_k\}$
- The vertices which are not adjacent vertices of the selected vertex $v_i$ are found from adjacency matrix. These vertices are added to the set of $V'$. Calculate the number adjacent vertices which are in the set of $U$ for every vertex in set of $V'$. After that, the uncolored vertex whose has maximum adjacent vertices (which are in the set of $U$) in the set of $V'$ is selected for coloring. The selected vertex is colored with active color.
- The colored vertex and the adjacent vertices of the colored vertex are deleted from $V'$ and added to the set of $U$.
- If the set of $V'$ is not empty, it is returned to the step 2. Otherwise move to step 3.

**Step 3:** If the uncolored vertex exists, next color in the color set is selected as active color. Otherwise the program is terminated.

**Step 4:** Calculate the number adjacent vertices for every uncolored vertex. After that, the uncolored vertex whose has maximum adjacent vertices is selected for coloring process. If more than one vertex provide this condition, the vertex which has the largest degree among them is selected. Then, it is returned to the step 2.

For RLF algorithm, Table VIII shows the result for the graph shown in Fig. 2. Selected order of the vertices and their colors are given in Table VIII.

**IV. Experiment Result**

FF, LDO, WP, IDO, DSATUR and RLF algorithms were tested on benchmark graphs provided by DIMACS [22]. The reason of preferring the DIMACS graph, it’s given a standard for performance comparison of the algorithms. The performances of the algorithms were compared as their solution quality and executing times. The edge density ($D$) of the benchmark graphs which are used in this study are calculated from equation 2. $E$ represents the number of the edges and $V$ represents the vertices number of the graph [23].

$$D = \frac{2 * E}{V * (V - 1)} \quad (2)$$

In this study we used Mycielski, CAR, Stanford Graph Base (SGB), Register Allocation, Leighton, Flat, Random (DSJC) and Random geometric (DSJR and R250) DIMACS graphs. $V$ represents the number of the vertices, $E$ is the number of the edges, $Den.$ represents density, $\text{Best}/\chi(G)$ means chromatic number or the best known number, $R$ represents the number of colors that algorithms are found, $T$ is computation time in seconds. The algorithms are written in the programming language Matlab R2010a. For experiments we used a Laptop.
Mycielski graphs are triangle free graphs. It’s mean that the edge connections in the graph must be free of triangle. For mycielski graph, if the vertices in the graph increases, the number of the colors for coloring the graph increases too [24]. Stanford GraphBase (SGB) graphs are created from Donald Knuth. SGB graph can be divided to books, miles, game and queen graphs [22]. For books graphs, a character in the book represents a vertex. So the books graphs are created for holds to relationship between characters. If the characters in the book have relationship to each other, an edge is generated between two vertex characters run across in the book. These books are Charles Dicken’s David Copperfield (david), Victor Hugo’s Les Misérables (Jean), Lev Tolstoy’s Anna Karenina (Anna), Homer’s Iliad (Homer) and Mark Twain’s Huckleberry Finn (Huck). For miles graphs the vertices represents some of the United States cities and if there is a road between two cities which provides the conditions, there is an edge generated between them. For game graph, any vertex in the graph represents a college team. There is an edge generated between for every two teams when the teams played to each other during the season. Table IX shows the results for algorithms which are used for this study. Except the FF algorithm all other algorithms find out the best χ(G) results. In addition, FF algorithm finds out the best χ(G) results for graphs which are used for this study except miles graphs and anna, David, Homer graph. On the other hand, if the algorithms compared to each other about their computation times, WP algorithm is reached these conclusions in a quite short time.

R: Result of the algorithm, T: Computation time (in second)

Queen graphs are n x n dimensional chessboard graphs. If two queens on the chessboard are in the same row, column, or diagonal, there is an edge generated between them. So, if two queens placed in same row, column or diagonal, one queen can eat the other one. Because of this, there is an edge between them for they don’t eat each other. For queens graph if only the graph is colored with minimum number n, two queens can move on chessboard. Table X shows the results for queens graphs. Experimental results show that while RLF and DSATUR algorithms are sufficient for the queens graphs, but the other algorithms are generally deficient. RLF algorithm finds out just only the chromatic number of queen5_5 graph and also it finds out quite better results for the other queen graphs. DSATUR algorithm generally finds out good results, but it is very slow according to the RLF.

CAR graphs are created from inspiration of the mycielski graphs. After the some new vertices inserted graph, the graph size increases, but the density of the graph is unchanging [25]. The CAR graphs are more difficult than the mycielski graphs. Table XI shows the results for CAR graphs. According to the Table XI; RLF, DSATUR, WP and LDO algorithms reach the best/χ(G) results. Furthermore the IDO algorithm generally finds out the best/χ(G) results. But FF algorithm is generally deficient. If the algorithms compare to each other about their computation times, the best algorithm for CAR graphs is WP algorithm. Because WP algorithm reaches the best/χ(G) results shortest computation times.

Random (DSJ) graphs which are created from David Johnson and R250_5 graph are difficult to solve benchmark graphs [15]. Flat graphs are created from Culberson. [26]. First parameter of the Flat graphs represents the number of the vertices and the second parameter represents the chromatic number. Table XII shows the results for Random and Flat graphs. According to the Table XII, RLF and DSATUR algorithms generally find out the best/χ(G) results. For the R250_5 graph, DSATUR algorithm’s computation time is further than RLF’s. But DSATUR finds out quite better result than RLF for R250_5 graph. On the other hand, RLF finds out quite better results for the other graphs and RLF is faster than the other algorithms.

fpsol2*, inithx*, zeroin* and mulsol* graphs are computer register allocation problem graphs which are generated from Gary Lewandowski [24]. These graphs are real-world problem’s graphs. The computer registers and the operations are defined as vertices. If a register and an operation have a relationship, there is an edge generated between them. Table XIII shows the results for computer register allocation graphs.

In the Leighton graphs, each graph consists of 450 vertices. First parameter of the Leighton graphs represents the number of the vertices and the second parameter represents the chromatic number [20]. Table XIV shows the results for Leighton graphs. Experimental results show that RLF algorithm finds out quite better results for Leighton graphs. Just for le450_25b graph, WP algorithm finds out the $\chi(G)$ result the better computation time. The other algorithms are generally deficient.

R: Result of the algorithm, T: Computation time (in second)
V. CONCLUSION

Experimental results show that while RLF and DSATUR algorithms are sufficient for the GCP, FF algorithm is generally deficient. WP algorithm finds out the best solution in the shortest time on Register Allocation, CAR, Mycielski, Stanford Miles, Book and Game graphs. On the other hand, RLF algorithm is quite better than the other algorithms on Leighton, Flat, Random (DSJC) and Stanford Queen graphs. As shown in the study, firstly it should be decided that the problems which we want to solve with graph coloring algorithms is similar to what benchmark graphs. After that, the optimum graph coloring algorithms must be applied to the problem for finds out the the best solution. Thus, it can be avoided to waste of times and it can be reached the best results a quite short time.

Design of an Interface for Genetic Algorithm Based Optimization of Function

Zeynep Batik†, Erdal Buyukbicakci‡

†, ‡Department of Computer Programming, Karasu Vocational School, Sakarya University, Sakarya/Turkey
zbatik@sakarya.edu.tr, erdal@sakarya.edu.tr

Abstract—Many analytical solutions for linear and nonlinear mathematical equations and equation systems have been developed and still continue to be developed. However, in some cases, difficulties may be encountered to achieve the results by analytical solutions. Quantitative analysis gained importance and their use has increased in parallel to developments in quantitative electronics especially in computer sciences. In recent years, the use of intuitive/evolutionary algorithms has become very common. In this study, a user-friendly graphical interface programme that works genetic algorithm-based for optimization operations is designed. Optimization of many test functions is performed by genetic algorithms, the results and properties are presented to the user both quantitatively and graphically.

Keywords—Genetic Algorithm, Optimization, Simulator

I. INTRODUCTION

Various analytical methods have been developed and still are being developed for the solution of mathematical equation systems (linear and nonlinear equations). The use of computer-based numerical methods that makes the iteration number fast which will be done many times, makes the solution easier instead of the use of classical methods for the solutions in the mathematical equations in real life. In recent years, computer-based genetically algorithms (GA) are used commonly in areas such as every kind of solution of optimization problems.

Many studies are present relative to solutions of equations with genetic algorithms in the literature. There are some applications such as simultaneous solution of linear systems of equations [1], finding the roots of algebraic equations [2], the solution of linear and nonlinear equations [3], the solution of quadratic equations [4], finding the roots of first, second, third, fourth and fifth degree polinom equations [5], the solution of Poisson equations [6].

In this study, a genetic algorithm-based graphical interface programme aimed to use for education was designed for optimizing processes. Optimizing of the selected functions is performed with genetic algorithms whose parameters (the number of variables, lower limit, upper limit) with designation entered. Obtained results are presented to user as both numerically (suitability value, roots etc.) and graphically (suitability depending on iteration or on cross rate etc.). Hence, the efficiency of genetic algorithms and parameters can be obviously seen.

II. GENETIC ALGORITHM

Genetic Algorithms are a part of evolutionary calculation. This area is a developing branch of artificial intelligence. This algorithm emerged as a result of adjusting the occurring biological events on genes to today’s problems. John Holland came up with genetic algorithms first, then his students and colleagues developed. Holland were studying on machine learning, and by having been effected by Darwin’s evolution theory, he thought about performing the genetic process of the living in computer environment and he saw a community could generate successful new individuals by passing genetic processes such as proliferation, mating, mutation etc. in such structures instead of developing the learning ability of only one mechanical structure. He performed his studies based on natural selection and genetic evolution to research and to find optimum; during the process, it was modeled by computer softwares in finding the optimum and machine learning by taking an individual adapting his/her environment and becoming more suitable in biological system, as an example [7].

Algorithm uses an initial density (population) that consists of the present solutions in research space. This initial density is developed repeatedly by natural selection and reproduction processes in every generation. The most suitable it means the most qualified individual of the last generation is the optimal solution for the problem. This solution, may not always be the optimum, but it is absolutely the nearest solution to optimum [8].

Genetic Algorithm, is effectively used in problems which are impossible to solve by classical optimization methods or in the solution of the problems whose solution time increases with the increase of magnitude, and its suitable structure for the computers capable of parallel processing provide it to be an attractive alternative for the solutions of time consuming problems to solve in short time. Some application areas of Genetic Algorithm are given below:

- General Application Areas
  - Optimization Problems
  - Automatical Programming and Information Systems
  - Mechanical Learning
  - Economical and Social System Models

2. Suitability: x-each chromosome in the population is evaluated in f(x) function. | Step 2. The function which finds how good chromosomes are, is named as suitability function. Finding the chromosome by operating this function is named as calculation. This function is the base of genetic algorithm. The only part that works specifically to problem is this function in genetic algorithm. Mostly, the success of genetic algorithm depends on the productivity and sensitivity of this function. |

3. New Population: Selection, crossing, mutation and acceptance steps are repeated until the new population generated. | Step 3. Chromosome matching is done according to suitability value of chromosomes. New chromosomes are produced after the processeses below. a. Selection: Two parent chromosome are chosen. To make this selection, Roulette wheel selection, tournament selection methods are present. b. Crossing: They are matched to generate new generations with crossing possibility. If there is no crossing, children will be the same as their parents. c. Mutation: new generation in every locus are mutated by the mutation possibility. d. Acceptance: New generation is added to new population. |

4. Substitution: It is used to operate new population algorithm again. | Step 4. A constant population is provided by removing the old chromosomes. |

5. Situation: If the new population is enough, it stops. This is the best solution found ever because of saving the best individuals during the calculating population. | Step 5. The success of the new population is found by calculating all the chromosomes. |

Flow of Genetic Algorithm is quite easy. Many parameters and adjustments are accomplished in different ways for different problems. The steps for solutions of Genetic Algorithms and description of them are given in Table I [9].
III. SIMULATIONS

In this study, a graphical interface is designed to calculate the optimization of function roots that were determined by using MATLAB [10]. This programme is opened from the panel named function selection, function is chosen from the menu and the function which will be optimized is selected. Roots of the function and suitability value are calculated by genetic algorithm method. The main screen of the application is shown in Fig. 1 The first running version of the programme is shown in Fig. 2. Also mathematical functions used in the operation of the simulation is shown in Table II.

In calculation with genetic algorithm, the number of variables, lower and upper limits of root intervals should be entered by keyboard. Also, parameters of genetic algorithm can be changed and then applied. The changeable parameters of genetic algorithm are size of population, scaling the suitability (fitness) function (rank, proportional, hill, linear changee), selection function (Stochastic uniform, increasing, uniform, roulette, tournament), mutation function (gaussian, uniform, adaptive), crossingover function (distributed, single-point, two-point, search, heuristic, arithmetic) and crossing over rate.

In the first simulation Rosenbrock function

\[
y = 100(x₂ - x₁)² + (1 - x₁)² \quad (1)
\]

optimization was occurred (Fig. 3). In the second simulation

\[
y = x₁ * exp(-x₁² - x₂²) \quad (2)
\]

roots of an exponential function were optimized (Fig. 3). These functions have two different roots. Research space was formed between [1, 10] interval to find the roots.
Parameters of genetic algorithms were adjusted as below:

- Population size: 20
- Scaling suitability functions: Rank
- Selection function: Stochastic uniform
- Mutation function: Gaussian
- Crossing-over function: Distributed
- Crossing-over rate: 0.8

The change in suitability function and roots can easily be detected in Simulator by changing parameters of genetic algorithm. The effect of the change in crossing-over rates on suitability value can be seen in Fig. 3. To obtain the values that would give the best result, the crossing-over rates were changed and its effects were investigated during the iteration. The best individuals are in the interval of 0.7 ve 0.9 of crossing-over rate.

![Fig. 3 Application examples](image)

**IV. CONCLUSIONS**

In this performed study, an interactive graphical interface programme which can optimize the functions by genetic algorithm was designed. With this education-aimed programme; functions optimization operations can be performed more easily and more effectively, effects of parameters can be investigated, and the results can be observed both numerically and graphically. As a next study, it is aimed to investigate the diversity of functions and algorithm type.

Abstract— This paper proposes an algorithm to solve the problem of path planning for a mobile robot in a static environment with obstacles. The proposed algorithm is a Hybrid Genetic algorithm (HGA) which includes Genetic and Dijkstra algorithms together. The genetic algorithm (GA) is preferred since the structure of robot path planning problem is very convenient to apply genetic algorithm’s coding and operators such as permutation coding, crossover and mutation. GA provides diversification while searching possible global solutions, but Dijkstra algorithm makes more and more intensification in local solutions. The simulation results show that the mobile robot can plan a set of optimized path with an efficient algorithm.

Keywords— Robot path planning, genetic algorithm, Dijkstra algorithm.

I. INTRODUCTION

Robot path planning (RPP) is a popular issue in mobile robotics. An intelligent robot must be able to move by itself from a start location to a target location without collision with obstacles. Therefore an important research subject in this field is navigation of autonomous mobile robots, which is to find a globally optimal path from a starting point to a target in a given environment and at the same time avoid collisions. Moreover, the “optimal” here means that the path must satisfy some criteria like length of the path is the shortest, or energy consumption of robot is the lowest or needed time to reach a target is minimum etc.

There are several search algorithms for the shortest path problem such as the A* algorithm, the Dijkstra algorithm and the Bellman–Ford algorithm [1], [2], [3]. These algorithms ensure to find a shortest path. However, these algorithms are not effective for large dimensioned problems because of with low searching efficiency and high computational time.

In recent years, many researchers have studied the robot path planning on various intelligent methods, such as particle swarm algorithms [4], immune algorithm [5], neural networks and ant colony algorithm [6], differential evolution [7], and so on. Additionally, genetic algorithm is one of the popular metaheuristic algorithm for RPP [8] problem.

The GA was introduced by Holland [9] in the early 1970s. It imitates the evolutionary processes such as inheritance, mutation, selection and crossover. Also for centuries, there is a biological evolution in the world and GA simulates it by using iterative process. The GA has a wide using area in many types of problem thanks to easy adaptation and high high-performance computing.

In this paper, a Hybrid Genetic algorithm (HGA) is proposed to solve RYP problem. The aim is to combine the global search capability of genetic algorithm and local exact solution capability of the Dijkstra algorithm to get faster solution for shortest path problem. In numerical simulations, 20x20 and 50x50 environments with obstacles are solved to get shortest distances and, Dijkstra, genetic and proposed hybrid genetic algorithms are compared in Table for iteration number and required time, respectively.

The paper is organized as follows. Section 2 describes the method of grid modeling, Dijkstra algorithm and genetic algorithm. Section 3 describes the proposed hybrid genetic algorithm for the robot path planning problem. Section 4 presents the numerical simulations on robot path planning. Section 5 presents concluding remarks.

II. PRELIMINARY WORKS

A. Grid modeling

The method was proposed by the Howden in 1968, and its primary task is to construct a path grid map according to the environment. Given environment is divided into small units and a robot goes one unit with one move. Two kind of grid can be described in method which are free and obstacle grid. In black grid’s mean is obstacle, white grid’s mean is free namely movable area. In real environment sizes of obstacles can be different and they can occupy lower one or more grids. A robot cannot enter an obstacle even if the obstacle is very small.

The grid can be divided into intermediate grid and boundary grid. For intermediate grid, robot may have eight directions for the next motion. Such as up (7), down (2), left
(4), right (5), right-up (8), right-down (3), left-up (6) and left-down (1). Fig. 1 shows the motion direction of the robot and Fig. 2 shows a 10x10 grid map. And for boundary grid, it has to subtract inaccessible directions. Robot must avoid obstacles to select an optimization motion path moving to the target position [10].

![The motion direction of the robot.](image1)

**B. Dijkstra Algorithm**

Dijkstra algorithm is introduced by W. Dijkstra in 1959 [1]. It is one of the most common used algorithm for solving the shortest path problem. It is possible to find a shortest path from starting point to any node by Dijkstra Algorithm. If the performance criterion is different from distance, it is also useful for measuring other criteria such as time, cost and energy. Dijkstra algorithm guarantees the shortest path which is generated. Dijkstra algorithm is a useful method for not only robot path planning but also network optimization, transportation, logistics, electronics and other fields. However, it takes much time while solving large problems and this is a disadvantage for this method.

![10x10 grid map](image2)

**C. Genetic Algorithm**

Genetic algorithm combines genetics and computer science. GA is biology inspired, population based, has memory, stochastic and greedy algorithm.

Here are a few basic concepts of genetic algorithm:

**Chromosome and Coding:** In order to use genetic algorithm, feasible solution of the problem needs to be coded into symbol string which have fixed structure. The string is called chromosome. Each bit of the string represents a gene.

**Population:** the total number of chromosomes in each generation is called population. A population contains a set of feasible solutions in current generation.

**Fitness:** Each chromosome corresponds to a feasible solution, and each solution corresponds to a function value. This function value is used to measure the environmental adaptability of a chromosome.

Select: Select operation can select adaptable individual in current population, so that adaptable individual has the opportunity to breed the next generation as a parent.

Crossover: Crossover operation can produce new individual, the new individual combines the characteristics of parents.

Mutation: mutation operation can change one or a number of genes in a fixed probability. The purpose of mutation is to create new chromosomes for next generation.

The process of genetic algorithm: determine the encoding rules, generate a population randomly, calculate fitness function and selection probability, select, crossover, mutation, loop all the operation above until it meet the terminate conditions [11].

**III. PROPOSED HYBRID GENETIC ALGORITHM**

In this section, proposed algorithm steps are explained in detail.

**A. Problem Description**

A road from starting node (S) to target node T is an (S, T) path, the length of a path is the sum of the length of the edges \(|p_{i+1}\|\) in one path. Ro bot path problem is to find the path from S to T, where the length of the path is minimum one at the same time avoid obstacles. A candidate path for robot path planning is denoted by \(P=\{p_1, p_2, ..., p_n\}\)

where \(p_i\) denotes the \(i\) th node of the planned path \(P\), \(n\) denotes the number of without obstacle nodes in a given environment and \(p_1=S\) and \(p_n=T\).

Total length of the path can be obtained by equation (1):

\[
f(p) = \sum_{i=1}^{n-1} |p_ip_{i+1}|
\]

where \(|p_ip_{i+1}|\) is the length of the path segment \(p_ip_{i+1}\) which is computed by Euclidean distance and it can take value \(\sqrt{2}\) or 1. Additionally \(f(p)\) is objective function of given path which we try to minimize.

**B. Chromosome encoding and initial population generation**

For a given graph, each node will be coded as a gene sorted by the node number. A chromosome includes path information and sequence of genes. In this paper, permutation coding is used for encoding. Nodes take place as combinatorics in a solution if a node is visited as an example shown below:

\[1\rightarrow 9\rightarrow 16\rightarrow 17\rightarrow \ldots \rightarrow 71\rightarrow 79\]

The first and end nodes must be in the solution, indicating the starting node S and target node T. There is no need to the test chromosome if the path is connected. Producing initial solution strategy guarantees that all the nodes which are included solution are connected. In other word, length of a
chromosome is equal to number of passed nodes. Therefore, there is a remarkable decreasing usage of memory for a chromosome and computation time. Cross-over and mutation operators are modified because of different length of chromosome which are shown next subsections.

While generating initial solution, a node is selected (initial gene of solution is starting node) and other neighbors are found which are connected to the selected node. Randomly selected a neighbor node is added to solution. This procedure is repeated until reached target nodes. Additionally, generating strategy checks if a node is visited before. Table 1 shows generating a chromosome for given map in Fig. 3.

<table>
<thead>
<tr>
<th>Exist Solution</th>
<th>Candidate Nodes</th>
<th>Randomly Selected Node</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>2, 9</td>
<td>9</td>

<td>16, 24, 25</td>
<td>25</td>
</tr>
<tr>
<td>...</td>
<td>...</td>
<td>...</td>
</tr>
<tr>
<td>1, 9, 15, 23, ... , 71</td>
<td>62, 79</td>
<td>79</td>
</tr>
</tbody>
</table>

For example:

\[ \text{intersect}(x_1, x_2) = 9,44 \] except for 1,79

For randomly selected node which is 44. The new chromosomes (children):

\[ x_1 = 1.2.9,17,18,19,27,36,44,52,61,68,76,77,78,79 \]
\[ x_2 = 1.9,16,25,33,41,42,43,44,53,54,62,71,79 \]

**Mutation:** The parental chromosome is chosen according to selection method. The parents start and target nodes are not mutated. The mutation operation is done by selecting a random node in the parent according to mutation probability. The two nodes which are coming before and after selected nodes are detected. Mutation operator tries to find a different node to connect these two nodes. If these two nodes connect to each other directly, selected node is deleted from the solution. An example for mutation operator can be shown as

\[ [1,2,9,17,18,19,27,36,44,53,54,62,71,79] \]

where selected node is 36, node 27 is coming before and node 44 is coming after node 36. Neighbor nodes are from 27 and 44 are:

27→19,20,26,28,34,35,36
44→34,35,36,43,52,53

where node 34 and 35 are common neighbors for nodes 27 and 44. Randomly selected one of these nodes is exchanged with node 36. The mutated chromosome is

\[ [1,2,9,17,18,19,27,35,44,53,54,62,71,79] \]

**C. Fitness function**

Fitness function must be calculated for each of chromosomes. The function is the sum of the length of the edges \(|p_{i_{start}}|\) in a path which is given equation (1).

\[ \text{Fitness function} = \sum |p_{i_{start}}| \]

**D. Select, Crossover and Mutation**

**Select:** For a given population \(X\) and fitness of each chromosome is \(f(X)\). The number of chromosome randomly selected in \(X\) is \(M\) and the best one is selected by using tournament selection for reproduction. In this work \(M\) is assumed 2 for the tournament selection.

**Crossover:** For the given chromosome \(x_1, x_2\) which are parent, their intersected nodes \(\text{intersect}(x_1, x_2)\) are found except for starting and target nodes (1,79) and one of the found nodes is selected randomly. This node is called as crossover point and single point crossover is used. A crossover is done at the selected node.

For example:

\[ x_1 = 1.2.9,17,18,19,27,36,44,52,61,68,76,77,78,79 \]
\[ x_2 = 1.9,16,25,33,41,42,43,44,53,54,62,71,79 \]

\(\text{intersect}(x_1, x_2) = 9,44\) except for 1,79

**E. Dijkstra Algorithm**

In this algorithm, after standard Genetic algorithm steps are applied in each iteration, Dijkstra algorithm is conducted to all individuals of current generation between two points (randomly selected) which are close to each other. Thus, the proposed algorithm is able to find rapidly a nearly optimum path for a mobile robot without collides with static obstacles.

After generating initial population, selecting, crossover, mutation and Dijkstra algorithm are applied to each generation until termination criteria is achieved.

---

Fig. 3 Grid map for initial solution procedure.
IV. NUMERICAL SIMULATIONS

Computer simulation environment includes a notebook computer with Intel® Core™ i7-4712 MQ CPU @ 2.30 GHz, 8 GB RAM. The planned path is shown in Fig. 4.

The simulations are conducted with 20x20 and 50x50 environments with random obstacles. The 20x20 grid map example, which includes 400 nodes and 318 of total nodes are free and 82 nodes are obstacles. At the same time the 50x50 grid map example, which includes 2500 nodes and 2080 of total nodes are free and 420 nodes are obstacles. The resulting paths with HGA are shown in Fig. 4 and Fig. 5, respectively.

The performances of the algorithms are given in Table II. These algorithms produce same fitness value for 20x20 and 50x50 environments as 59.8701 and 72.8112, respectively. However, the iteration number and required time change with the algorithm therefore they are given in Table II. According to the performances, the proposed HGA is always better than the conventional genetic algorithm. However, for small size problem, the Dijkstra algorithm provides the solution in a shorter time. Note that when the problem size increased, the Dijkstra algorithm requires larger time to solve which is seen in given Table.

V. CONCLUSION

In this paper, RPP problem is solved with a novel Hybrid Genetic algorithm (HGA). Simulation results show that the proposed method provided the same solutions with lower iteration number and required time for 50x50 environment. It is seen that the proposed method is especially suitable for the large dimensional RYP problems in future applications. The algorithm is planned to be used in real-time with a laboratory mobile robot.

Abstract—Stimuli types are very crucial for the performance of electroencephalogram (EEG) based brain computer interface (BCI) systems. This study aims to investigate methods for obtaining higher information transfer rate (ITR) through duty cycle and brightness variation of visual stimuli which have high frequency for steady state visual evoked potential-based BCI. Although previous studies were concentrated on either duty cycle or brightness of stimuli separately, our study focused on the change of duty cycle ratio and brightness of stimuli at the same time. Duty cycle values of 40%, 50%, and 60% were used. During the experiment, 16 flickering stimuli were used on liquid crystal display. Participants gazed to the flicker which had frequency of 15 Hz. Canonical correlation analyses (CCA) was used for channel selection and frequency detection. According to the CCA, the maximum average accuracy of the experiment was 92.54% when the frequency of flicker was in beta band and its duty cycle was 40% with a brightness tuning wave. Under the same conditions stated above, average ITR was improved 16.1% according to the most commonly used flicker model which is square wave and has 50% duty cycle.

Keywords—Brain Computer Interface, EEG, Human-Computer Interaction and Systems, Steady State Visual Evoked Potential

I. INTRODUCTION

Brain computer interface systems gives chance users to communicate with external devices without using peripheral neuromuscular systems. There are many brain imaging methods, such as electroencephalography (EEG), functional magnetic resonance imaging(MRI), magnetoencephalography (MEG), and and near-IR spectroscopy (NIRS) have been adopted BCI systems [1], [2]. In BCI systems, the commands are identified by extracting Electroencephalograms (EEG) which measures the electric field generated from brain. EEG based BCI systems is preferred for other BCI system because of practical use, low cost, good response, portability [3].

There are some most common approaches to EEG based BCI systems that are P300 potentials, event-related (de)synchronization (ERD/ERS), slow cortical potentials, oscillatory activity, and visual evoked potentials (VEPs) [4-7]. The Steady state visual evoked potential (SSVEP) is a brain response modulated by the frequency of repetitive visual stimulus [8]. SSVEP is known to be most prominent at the occipital location over the visual cortex.

The SSVEP-based BCI has been preferred due to high signal to noise ratio and high information transfer rate (ITR) according to other BCI approaches [9]. Moreover, the SSVEP has a short training and response time [10].

The term of Information transfer rate is a very significant unit that has been used to evaluate overall performance of BCI systems [11]. Types of stimulus have very important role for high SSVEP response that related on ITR that can be described as information transmitted in bits per minute (bpm).

Thus, there are many studies for investigate best stimuli type for SSVEP based BCI systems. Wu (2010) [12] proposed that %40 duty cycle ratio when the flicker was 10 Hz, SSVEP response reached highest value. Shyu et al. (2013) [13] made a SSVEP-based BCI system that using FPGA, which based on duty cycle ratio. Manyakov et al. (2013) [14] showed that sampled sinusoidal stimulation enabled for encoding more targets and elicited SSVEP response with a significantly better phase stability. Moreover, Chen et al. (2014) [15] presented sampled sinusoidal stimuli for SSVEP response. According to result of this study, ITR value was reached the highest one when the flicker was at low and high frequencies.

In recent years, researchers presented many approaches to make and develop SSVEP based BCI systems.

In this study we aimed to investigate effect the change of duty cycle ratio and brightness of stimuli at the same time, although previous studies were concentrated on either duty cycle or brightness of stimuli separately.

II. MATERIAL AND METHOD

Five healthy participants (males, mean age 29 years, corrected to normal vision) joined experiments in this study. Participants didn’t have any history of epilepsy and psychiatric disorders.
A. Experimental Structure

In the experiments, SSVEP stimulator software was created by C# programming language. This SSVEP stimulator software is portable and functional. As shown in Figure 1, according to the main menu of software, colour of flickers and background, size of flickers, frequencies of flickers, quantity of flickers, brightness of flickers, duty cycle ratio of flickers could be changed by users.

The EEG were acquired from the scalp of the participants via 19 Ag/Ag-Cl electrodes. EEG electrodes placed according to the international 10-20 system. During the study Nihon Kohden Neurofax EEG-1200 EEG device was used for EEG data acquiring.

The reference electrodes were placed over the left and right earlobes. Ground electrode was on the intercilium point (the space between the eyebrows). EEG data were sampled at 500 Hz.

B. Stimulation Types

In this study, we focused on the change of duty cycle ratio and brightness of stimuli at the same time. Duty cycle values of 40%, 50%, and 60% were used. As shown in Figure 2, we used a square pulse that was presented as Type I signal. \( T_{\text{period}} \) is denoted the pulse cycle duration which is total of \( T_{\text{on}} \) and \( T_{\text{off}} \) that are defined stimuli on and off cycle durations respectively. \( R_{\text{duty}} \) is denoted duty cycle ratio which is presented in Equation 1.

\[
R_{\text{duty}} = \frac{T_{\text{on}}}{T_{\text{on}} + T_{\text{off}}}
\]  

![Fig. 1 The SSVEP stimulator software setting menu](image1)

![Fig. 2 Type I signal: stimulation signal is at square pulse.](image2)

In this study, we presented a novel stimuli type that variation of brightness of pulse as shown in Figure 3. During the “on” status, flicker’s brightness was on the increase within the equal time span of \( T_{\text{on}} = 9 \) till it reached to the peak value of Type I signal, after increased, it was on the decrease till it reached to “off” status within the equal time span.

![Fig. 3 Type II signal: variable brightness when the flicker is on status](image3)

C. Experimental Steps

During this study, as shown in Figure 4, 16 flickering stimuli were showed on liquid crystal display (LCD). Participants were seated 50 cm away from LCD with a refresh rate of 60 Hz.

![Fig. 4 The 16 Flickers on LCD](image4)

16 stimuli were 150 pixels x 150 pixels arranged in a 4 x 4 matrix.

Participants gazed to the flicker which had frequency of 15 Hz. During the experiment, participant gazed to flicker 6 seconds, after that 4 seconds for resting time. 10 trials were
examined by each participants for every duty cycle ratio and signal types that include type I and type II signals.

D. Data Analysis

Canonical correlation analysis (CCA) is a multivariate analysis that presented by Lin[16]. According to the Equation 2 CCA investigates the maximum correlation between the two variables.

\[
\max \rho (x, y) = \frac{E[x^T y]}{\sqrt{E[x^T x] E[y^T y]}} = \frac{E[W^T_x X Y^T W^T_y]}{\sqrt{E[W^T_x X X^T W^T_x] E[W^T_y Y Y^T W^T_y]}}
\]

Equation 2

The weight vectors \(W_x\) and \(W_y\) to maximize the correlation between, linear combinations, \(x\) and \(y\) by Equation 2. \(\max \rho (x, y)\) denoted as the maximum canonical correlation of the \(W_x\) and \(W_y\). As shown in Figure 5, shows the CCA model was presented. According to the model, \(X\) denoted EEG signal, \(Y_f\) denoted the reference signal.

![Fig. 5 The CCA Model](image)

The reference signals were artificially generated with sinus and cosines waves of the flicker’s frequency and their harmonics by Equation 3.

\[
Y_f = \left( \begin{array}{c} \sin(2\pi f_t) \\ \cos(2\pi f_t) \\ \vdots \\ \sin(2\pi H f_t) \\ \cos(2\pi H f_t) \end{array} \right), \quad t = \frac{1}{F_s} 2 \frac{F_s}{F_s} \ldots \frac{N_t}{F_s}
\]

Equation 3

Sixth-order Butterworth band pass filter with 5 and 20 Hz cut-off frequencies was applied. After that CCA method was used.

\(CW_k\) showed that brain frequency map. According to the result, O2, O1, O2 EEG channels were used for data accuracy.

ITR is a very significant unit that has been used to evaluate overall performance of BCI systems.

ITR can be described by following Equation.

\[
Bits_{Command} = \log_2 N + P \log_2 P + (1 - P) \log_2 \left(\frac{1 - P}{N - 1}\right)
\]

Equation 4

\(ITR = \frac{Bits_{Command}}{CTI} \times 60\)

Where \(P\) denotes accuracy of classification, \(N\) denotes total stimuli, CTI denotes command transfer intervals.

In this study, CTI is 6 seconds because of gaze time during in one trial.

III. RESULT AND DISCUSSION

Experiments were completed without any problem. Table 2 shows that outcome of the experiment average accuracy and the average ITR.

Average ITR was improved 16.1% according to the most commonly used flicker model which is square wave and has 50% duty cycle. As shown in Figure 6, the highest average accuracy was reached when the flicker’s duty cycle ratio was 40% and type II signal.

![Fig. 5 The difference of average ITR and improved ratio](image)
improving the accuracy, and (3) decreasing the command transfer intervals. In this study, we aimed to improve ITR value by increasing the accuracy with a new created signal type for stimuli.

We applied statistical test to the results shown in Table 2 to examine whether the differences in the classification accuracy were significant depending on the duty cycle and flicker type. A one-way analysis of variance (ANOVA) was conducted on the classification of accuracy for each flicker models, indicating that the difference was considered significant at the p-value < 0.05.

CONCLUSION

It can be concluded that previous studies mainly focused on the effects of either duty cycle pulses ratio or brightness of stimuli separately. But, we aimed to investigate the effects of both parameters at the same time. We optimized signal type and duty cycle ratio.

Despite the fact that there is not enough knowledge for characteristic attitude of brightness and duty cycle parameters which are very important for ITR and accuracy in SSVEP-based BCI systems, in this study, for these parameters remarkable results have been accomplished.

Abstract—Topology control is a set of strategies and actions that aim to improve energy efficiency, lifetime and reliability of the networks. One of the most effective methodologies is topology reduction, which is a part of the overall topology control process. Topology control process is usually considered under two phases: construction and maintenance. This hard work would even be harder for mobile ad-hoc sensor networks, those consist of devices with limited capabilities and continual independent movement. In this work, we made our efforts to find out effects of mobility of the nodes in an ad-hoc wireless sensor network on network parameters, by using different pre-defined topology control protocols. Thus, we made simulations using an experimental simulator, called Atarraya. Furthermore, we measured the performance of each protocol and compared the outcomes in order to find the best topology control strategy. Lastly, possible solutions to the uncovered problems are proposed.

Keywords—Ad-hoc wireless sensor networks, mobility, topology control, wireless sensor Networks, simulation

I. INTRODUCTION

After conventional wide area and local area networks (LAN), nowadays, personal area (PAN) and body area networks (BAN) are becoming more and more popular in applications of industry, commerce and science [1]. Along with their abilities and advantages, these networks also have their own challenges [2]. For instance, they usually include nodes on the move or at least nodes that can be relocated. Hence, the newest solutions in the interconnecting network technologies have to deal with the mobility cases as well.

From that starting point, in order to build the rest of the work on it, we’ve presumed a set of use cases, called as scenario. Although the results wouldn’t be directly related to the scenario, it would help us to make some decisions. Our scenario based on an indoor working environment including unsynchronized moving people, who are representing BAN or PAN networks by holding or even wearing wireless sensor devices. Most applicable realization is hospitals, but also mines, schools, prisons, sport fields and in a wider point of view, zoos. Additionally, we suppose a continuous communication is required in our scenario.

II. PREVIOUS WORKS

While building our background, we found out several studies about topology control [3] and maintenance [4] in wireless sensor networks. And of course we used valuable information provided in these works. But we couldn’t find a comparative study to refer, which focuses directly on mobility case. For instance, in [5] authors present a comparative study similar to ours, however they used fixed nodes and totally excluded the mobility case, which is our main focus. In their work, Laré et al. [6] introduce a protocol (Cascading information retrieval by controlling access with distributed slot assignment - CICADA) designed for mobility cases and present a detailed analysis, but their study is not comparative. Reluctantly, we could not include CICADA and CICADA-S (a secure version proposed later [7]) in our work because of the limitations of the tool we have used.

The reason of that scarcity is that wireless sensor networks is a quite new area, and mobility in these networks is even a newer aspect. Most of the previous works in this area focused on higher layer architecture, like routing and forwarding protocols. Here, we worked on a lower level relationship between nodes by reducing the number of links between them.

The simulator we used, namely Atarraya, was also introduced in a previous work [8] and still under development with new features. A side note: Mobility wasn’t even included in our simulation tool Atarraya’s first version, here we used version 1.3.

III. ASSUMPTIONS & DECISIONS

To find key points, we had to choose optimum preferences and had to limit our angle of sight. Our very first assumption about the concept is a scenario as described in introduction. Before going on, we assume the undetermined smallest integer time unit in Atarraya as milliseconds.

A. Algorithms

For the evaluation, we wanted to choose topology control and maintenance algorithms, which have different approaches as possible and tried to avoid similar algorithms. So, we have chosen A3, energy efficient connected dominating set (EECDS) and Kneigh tree protocols for topology construction. Detailed descriptions of these protocols can be found in [9, 10]. Then we considered dynamic global time-based topology recreation (DGTTRec), static global time-based topology rotation (SGTTRot), and HGTTRec and rotation (HGTTRecRot) for
initialized by the sink. Excluded from that ratio. Here, core network means the network basically, the nodes out of the core network coverage are setting the topology time interval 1 s. This interval theoretically provides 600 m of moving field mentioned above, using Normal distribution with sigma = 100. When simulation starts, nodes can leave this initial deployment area and can move in the whole observation field, or even may leave that area.

Our test field represents a surrounded area like a hospital, a factory or an office environment. It can also be an open-air field but we mostly focused on an indoor environment. Hence, we placed 30 nodes (+1 initializer sink), which makes a sparse network. This number may be increased until around 100 without distorting the test outcomes. Numbers bigger than a few hundred may cause the simulator to slow down, stutter or act inconsistently.

We used a realistic communication range of 100 m, which is typical for ZigBee, Bluetooth Class 1 and Wi-Fi b/g/n [11]. We set sensing area to 20 m but, in this work, it wasn’t important in our point of view, so we didn’t take care of sensing range and sensed data.

As total simulation time for topology maintenance tests, we considered 60 seconds. It was enough to see effects of mobility, plus we had some limitations about our movement model (see below). This interval theoretically provides 600 m of moving range to each node (see below). Thus, we also decided resetting the topology time interval 1 s.

We assigned 1000 mJ total energy stock to each node and used simple energy model of the software. We also used simple communication model. Another assumption was 0 bit error rate (BER) value, means communication link is perfect. Effect of BER is subsequently analyzed.

Finally, a connectivity metric is defined to measure the performance of the protocols in the sense of physical and logical connectivity. This metric is considered as a percentage of nodes (directly or as multi-hop) connected to the sink node among all the nodes in the coverage of the core network. Basically, the nodes out of the core network coverage are excluded from that ratio. Here, core network means the network initialized by the sink.

\[
C(\%) = \frac{\text{# of nodes connected to network (t)} - 1}{\text{# of nodes in the range of network (t)} - 1}
\]

Obviously, this connectivity metric is a function of time (and movement), so it will also represent robustness and sustainability of the protocols. By the way, this metric can be the most important information to determine the usefulness of a topology control protocol depending on the scenario.

C. Movement Model

We designed a movement model in order to provide mobility to nodes in the simulation. There are two main limitations to consider: First, movement model should be realistic, thus results will be useful in further works and industrial applications. Second, simulation tool Atarraya is an (very useful but) experimental tool and has limited capabilities in this manner [8].

So, our movement model consists of these features: Simple random walk mechanism for each node with sleep time 100 ms and step size 1 m, without surrounding limits (fences) on the field. This makes 10 m/s and is 5 to 10 times faster than the average human walking speed, which is around 1 to 2 m/s [12]. We used that increased value to see the effects of mobility more clearly. By using randomness, movement of nodes is non-deterministic to each other and no predictions can be made besides the step size.

Another characteristic of the model is spreading. All nodes in a very long period of time, eventually, will leave the test field since there is no fence. This is not an intended behavior but due to program limitations, it is not possible to prevent this. Only the simulation time can be limited at an optimal time period. However, this behavior allows us to see what happens when some nodes leave the area, which can be a realistic scenario.

IV. RESULTS

We first evaluated the topology construction protocols, by starting the simulation without a time limit. 30 Nodes and 1 sink node are deployed in the field as described above. Simulation ended up after a successful topology creation. All values given in this section are average of 10 measurements.

![Fig. 1 Durations of the initial topology construction period](image)

Fig. 1 gives the time passed until the successful creation for each protocol. Here, it is very clear that, tree based A3 and Kneigh tree protocols are much faster than dominating set based EECDS and k-connected k-dominating set (CDS-K).
Due to the mobility of the nodes, it would be better to use faster protocols.

Total message traffic can be seen in Fig. 2, which stands for the total number of sent and received messages in the network, between all 31 nodes. Here, A3 and Kneigh tree produce significantly less traffic than EECDS and CDS-K. Lower values would be preferable because sending and receiving more messages will cost more energy, processing power and bandwidth.

Fig. 3 shows total energy consumed among whole network. These values are some of the consumptions of all 31 nodes. As expected from the message traffic results, A3 and Kneigh tree consume much less energy from EECDS and CDS-K. While Kneigh tree consumes least energy, EECDS becomes the last preferable with the highest consumption, which is 4 times more than A3 and 30 times more than Kneigh tree.

A very important statement; all these protocols complete their work by constructing the topology much faster than the movement speed of mobile nodes. Our movement model proposes a 5 m step size per 500 ms. But, here the slowest protocol, CDS-K, requires 58.42 ms. Even when we change our movement model (unless we set an unrealistic super speed like 100 m step size per 10 ms or so), the results are (almost) the same as stationary ad-hoc wireless sensor networks’ results.

So, information given until here, are not enough to uncover the effects of the mobility in that network. Because, if there were no mobility, results would be very close, and also network operating time should be much higher than construction time. Over and above, we have to check topology maintenance simulation results.

Fig. 4 represents total amount of energy consumed by all 31 nodes during 1 minute run of the protocols. Here we can easily say DGTT consumes 5, 12 and 3.5 times more energy than DSR, SGTT and HGTT respectively. Among the DGTT experiments, most energy-efficient choice is A3. This result is reasonable, because, from the previous experiments (Fig. 3) we found out that A3 is more effective than EECDS and CDS Rule K, moreover, ECDS and CDS-K were very close. Here the same.

In Fig. 5, total message traffic of the network is given. There is a huge difference between DGTT and the others. Actually, the number of sent messages is very similar, just HGTT is relatively higher. But, the number of received messages is very high in DGTT. It is 4 times higher than the runner-up HGTT. SGTT has the lowest total traffic in general. In fact, the reason of this big difference between the number of received and sent messages is broadcast style transmission and mass reception of
the broadcasted messages by all nodes in the range. This behavior artificially boosts the network traffic.

Probably the most important data is presented in Fig. 6: connectivity metric. It shows reliability and sustainability of the protocols via 2 different time intervals. Here, all DGTT combinations together get the highest value by %100 connectivity rate in both 1-minute and 5-minutes tests. Mobility (in the coverage area of course) does not cause impairment while using DGTT. Distinctly, if a node is in the communication range, then it will be included to the network via DGTT. The others have relatively lower values in 1-minute test and they become much worse by the time, as can be seen in 5-minutes test. In a 10-minutes test (which is not shown in the figure) ratios of SGTT and HGTT are below 25%.

![Connectivity levels during topology maintenance in 1 minute and 5 minutes of run](image)

Fig. 6 Connectivity levels during topology maintenance in 1 minute and 5 minutes of run

Manifestly, here, we discovered a clear tradeoff between energy spent plus message traffic and connectivity performance. There is no linearity, but the correlation is clear. Before evaluating the values given in Fig. 6, it wasn’t possible to say A3 or CDS-K or even EECDS can be a good choice. But after, we can say, for that type of a network, DGTT has the best results and preferable with A3, from the previous results.

So-called energy efficiency and traffic emptiness of SGTT and HGTT can be very deceptive. This is highly probable a paralogy, caused by the low connectivity and the link loss. Less links mean, less message receptions and less message receptions lead less energy consumption. Even so, this conjecture is valid for specific scenarios and could be different under variety of conditions.

All in all, although these values can give very valuable information and can provide guidance for related applications, the optimum decision is always application dependent. For instance, in a scenario that continuous communication is not as important as node lifetime (energy efficiency), DGTT should be avoided, while A3 could still be preserved.

We also evaluated the effect of BER on DGTT with A3, CDS-K and EECDS respectively. In Fig. 7, the relation between BER and connectivity is analyzed. It can be clearly seen that, a higher error rate lowers the connectivity metric significantly, but this relation is roughly logarithmical. While the error rate is $10^{-5}$, which is a de facto industry standard boundary, connectivity metric is very high; 97% to 100%. And until $10^{-3}$ values are acceptable. But one shouldn’t forget that, sensor data transfer is not included in this communication. It just represents topology control messagings. So, for higher level decisions about the architecture, level of the BER should be maintained no lower than $10^{-5}$ if the data sensed is time critical.

![Effect of the bit error rate on the connectivity ratio](image)

Fig. 7 Effect of the bit error rate on the connectivity ratio

![Effect of topology recreation time interval on connectivity and energy consumption based on 1 minute run using A3 + DGTT](image)

We discovered a clear correlation between connectivity and energy consumption, but this does not mean there is nothing to do to save energy. Figure 8 shows the effect of topology recreation interval during maintenance on both connectivity and energy consumption. First, please note that we used 500 ms movement sleep time and 1 s refreshing interval in previous experiments. Here we kept movement model as defined, but tested different time intervals. Hence, we exposed that, a refreshing frequency which is much higher than the movement speed (this also means physical deployment change frequency) causes extraordinary energy consumption and highly ineffective. We can also see that a frequency much lower, causes loss of communication links. Thus, a balance should be preserved to save energy and to protect connectivity at the same time. An interval 2 to 4 times longer than basic movement period looks acceptable in our case. As a final comment,
statistical information about the deployment environment and movement should be obtained to find a (sub-) optimal solution.

V. CONCLUSIONS & FUTURE WORKS

In this work, we aimed to show possible effects of the mobility to ad-hoc network performance and reliability in different aspects. Furthermore, we wanted to propose basic solutions.

In spite of the application dependability, we got some solid outcomes; first, unlike DGTT, SGTT and HGTT are not suitable for that type of a mobile network. One should better prefer a dynamic protocol, at least in a similar scenario like our presumption. Because of the connectivity level provided, we are not satisfied with the performance of static and hybrid methods. But in a different scenario, significant energy saving (we also found out that this is deceptive and caused by physical link loss) of these protocols can be exploited in a way.

Additionally, between the construction algorithms, A3 provides better values from the rest apart from Kneigh tree. But in long term, we showed that this advantage gained from construction phase becomes less significant by the time. Even so, A3 could be a reasonable choice for our scenario.

An impromptu (but predictable) observable (or solution) to the “connectivity-energy efficiency” problem is also given.

We got a strong impression about; building a cell-like structure by placing several stationary nodes in the deployment field could help us to reduce redundant traffic and to increase energy efficiency without downgrading the link quality. This hybrid network structure may give better results. This strategy should be researched and it can be a good extension to this work.

We still have no overall optimum choices, so search for a topology maintenance protocol that offers a better balance between energy consumption (or message traffic) and connectivity should go on.

Another point is super-speed mobility. We created a realistic human-like movement model; it can also be used for animals, or robotic structures. But super-speed mobility is not supported; in that case it is not even possible to construct a network. And even we deploy a cell structure, handovers would be a big problem. However, super-speed moving objects, including racing cars, satellites, missiles or so, rarely move randomly. They follow a track or orbit. This feature can be exploited. So, that aspect can also be another topic to investigate.

ACKNOWLEDGMENTS

We want to thank Dr. Qi Zhang from Aarhus University, Department of Engineering, for her valuable guidance. Most work is done using the simulator Atarraya and we would like to present our sincerest respect and recognition to creators of the program: Pedro M. Wightman and Miguel A. Labrador.

Big Bang-Big Crunch Optimization Algorithm for Solving the Uncapacitated Facility Location Problem

Ismail Koç

Department of Computer Engineering, Engineering Faculty, Selcuk University, Konya, Turkey

ismailkoc@selcuk.edu.tr

Abstract— The big bang–big crunch (BB–BC) algorithm has been proposed as a new optimization method based on the big bang and big crunch theory, one of the theories of the evolution of the universe. The BB-BC algorithm has been firstly presented to solve the optimization problems with continuous solutions space. If the solution space of the problem is binary-structural, the algorithm must be modified to solve this kind of the problems. Therefore, in this study, the BB-BC method, one of the population-based optimization algorithms, is modified to deal with binary optimization problems. The performance of the proposed methods is analyzed on uncapacitated facility location problems (UFLPs) which are one of the binary problems used in literature. The well-known small and medium twelve instances of UFLPs are used to analyze the performances and the effects of the control parameter of the BB-BC algorithm. The obtained results are comparatively presented. According to the experimental results, the binary version of the BB-BC method achieves successful results in solving UFLP in terms of solution quality.

Keywords— Big Bang-Big Crunch Algorithm, Population-based optimization algorithms, Binary optimization, UFLP, Modulo function

I. INTRODUCTION

Many swarm intelligence methods have been recently proposed in order to solve compelling optimization problems by reason of their simple structures and creation of influential solutions for problems [1]. Heuristics algorithms are the algorithms that employ a simple approach to produce an acceptable solution to search and are recently becoming powerful and getting more common. The reasons of that can be shortly given as follows:

In case of different decision variables, objective functions and constraints, they provide strategies of the general solution that can be practiced to the problem.

They independently operate from the type of solution space, the number of decision variables and constraints.

They utilize probabilistic random searches. They do not need excessive computation time because their computation power is in reasonable level.

The processes of their transformation and adaptation for different type of problems are simple.

They dictate fewer mathematical requirements and in addition, they do not need very well defined mathematical models.

They present impressive solutions for the large-scale combinatorial and non-linear problems.

They do not require the assumptions as done in standard algorithm.

They do not need the change on the given problem unlike the usual algorithms. They adapt themselves for solving different types of optimization problems [2].

In the last decades, different swarm-based evolutionary algorithms have been proposed for solving this optimization problem including Genetic Algorithms [3-6], Tabu Search algorithm [7, 8], Ant Colony Optimization [9], Particle Swarm Optimizer [10-12] and Artificial Bee Colony [13-15]. The random selection process and the information attained at the end of each iteration (cycle) are utilized in order to discover more optimal solutions in the subsequent iterations [16].

Big-Bang Big-Crunch (BB-BC) algorithm which is one of the swarm intelligence algorithms has been proposed by Erol and Eksin in 2006 for numerical optimization problems and was based on the big bang and big crunch theory, one of the theories of the evolution of the universe [17]. While in the Big Bang phase, the BB–BC method similarly produces haphazard points in solution space, in the Big Crunch phase it shrinks all of the points in the search space to a single agent point due to a centre of mass. It has shown that The BB–BC method outperformed the enhanced classical Genetic Algorithm on many benchmark problems.

According to the literature review, the basic BB-BC algorithm is a competitive algorithm in solving optimization problems with continuous solution space. If the solution space of the problem is binary-structured, the basic BB-BC algorithm must be modified in order to solve this type of optimization problems. Using modulo function that is one of the main mathematical operators, we propose a binary version of the BB-BC method for obtaining the reasonable solutions for binary optimization problems. The proposed method is investigated on a standard binary optimization problem by utilizing the uncapacitated facility location problem (UFLP). The UFLP is one of the most commonly used problems in combinatorial optimization. In this problem, the main objective is to minimize the total cost by providing the demand of customers under the given conditions that are a constant cost of setting up a facility and a shipping cost of satisfying the customer demand for the corresponding facility [10].
II. Basic Version of Big Bang Big Crunch Algorithm (BB-BC)

The BB-BC algorithm was firstly introduced for solving continuous optimization problems in 2006 by Erol and Eksin. This method is constructed on two main steps: the first phase is the Big Bang phase in which all of the candidate solutions are randomly distributed into the search space and the next phase is the Big Crunch where a center of mass is calculated considering individuals in the whole population [18, 19]. The initial population is randomly produced over the search space as done in the other swarm-based algorithms. All subsequent Big Bang phases are randomly distributed about the center of mass or the candidate with the best fitness value in a similar way. The most important feature of the algorithm is that it has high convergence speed but low computational complexity. For instance, while many evolution-based algorithms in the literature present near-optimal solutions at the end of too much iteration, BB-BC algorithm obtains solutions very close to the optimal solution of this problem on far less number of iterations in general.

After the Big Bang, a contraction procedure is implemented during the Big Crunch. In this stage, the contraction operator holds the available locations of each candidate solution in the population and its associated cost function value and calculates a center of mass. The center of mass is presented as follow:

\[ X^c = \frac{\sum_{i=1}^{N} \frac{1}{P_i} X_i}{\sum_{i=1}^{N} \frac{1}{P_i}} \]  

(1)

where \( X^c \) = position of the center of mass; \( X_i \) = position of candidate solution; \( P_i \) = value of cost function of candidate \( i \); and \( N \) = population size. The best fittest candidate solution can also be utilized as the starting point instead of the position of the center of mass.

After the second stage completes, new individuals are once again calculated for Big Bang stage according to the formula below.

\[ X_{\text{new}} = X^c + \frac{ir}{k} \]  

(2)

where \( X^c \), \( i \), \( r \) and \( k \) are respectively the centroid of mass, upper bounds of parameters, random parameter and number of iteration. The value \( X_{\text{new}} \) is calculated according to the following formula.

\[ X_{\text{new}} = \frac{\sum_{i=1}^{N} \frac{1}{P_i} X_i}{\sum_{i=1}^{N} \frac{1}{P_i}} + \frac{ir}{k} \]  

(3)

The steps of the BB-BC method are presented in Fig. 1.

III. Proposed Binary Version of BB-BC

Modulo base 2 is used to convert the continuous solutions to binary version. This conversion is presented in Eq.4.

\[ BS_{ij} = \text{mod}(|X_{ij} - \lfloor |X_{ij} | \rfloor)|, 2 \]  

(4)

where, \( BS_{ij} \) is binary solution obtained from \( X_{ij} \). \( \lfloor |X_{ij} | \rfloor \) is rounding operation to down, \( \text{abs} \) is a function used in order to obtain absolute value of \( X_{ij} \). When \( BS_{ij} \) is computed, first of all, rounding operator is applied to \( X_{ij} \), then absolute value of \( X_{ij} \) is obtained. As for last process, the modulo base two is applied to the obtained value.

\[ BS_{ij} = \text{round}(|X_{ij} - \lfloor |X_{ij} | \rfloor|) \mod 2 \]

An example of the solving Eq. (4) is presented as follows:

\[ BS_{ij} = \text{round}(|1 - 12.24|) \mod 2 \]

\[ BS_{ij} = \text{round}(12.24) \mod 2 \]

\[ BS_{ij} = 12 \mod 2 \]

\[ BS_{ij} = 0 \]

IV. Uncapacitated Facility Location Problem

In the basic formulation, UFLP consists of a set of customer location \( m \) that must be served, and a set of potential facilities \( n \) in which at least a facility must be opened and has not any capacity limitation. The main purpose (Eq. (5)) is to find a subset \( f \) of \( n \) facilities that is supplied request of customers \( m \). The objective function of the problem is to minimize sum of the transport costs. The mathematical formulation of the UFLP can be expressed as follows:

\[ f(UFLP) = \min\left(\sum_{i=1}^{m} \sum_{j=1}^{n} c_{ij} x_{i,j} + \sum_{j=1}^{n} f c_{j} y_{j}\right) \]  

(5)

subject to:

\[ \sum_{j=1}^{n} x_{i,j} = 1 \quad \forall i \in m \]  

(6)
where \( i = 1 \ldots m; j = 1, \ldots, n; x_{ij} \) represents the quantity supplied from facility \( i \) to customer \( j \); \( y_{j} \) expresses whether facility \( j \) is located \( (y_{j}=1) \); otherwise \( (y_{j}=0) \). The constraint in Eq. 6 ensures that demands of all customers must be satisfied by an open facility. The constraint in Eq. 7 provides the collectivity, as well.

The UFLP is one of the most crucial NP-hard problems in location theory [15, 20, 21]. In order to solve UFLPs, many exact methods, such as branch-and-bound [22], linear programming and Lagrangian relaxation [23], and dual approach [24], have been proposed. Despite the fact that these methods guarantee optimal solution, the computation time of these methods may be too much. For this reason, some approximate methods have been proposed in order to solve UFLPs. These methods cannot ensure the reaching of the optimal solution, but they can attain optimum or near-optimum solutions in a reasonable time.

V. EXPERIMENTAL RESULTS

The uncapacitated facility location test suite (12 test problems) obtained from the OR-Library was used in order to examine the performance and accuracy of the proposed binary versions of the BB-BC algorithm [25]. In the test suite, four problems (Cap71-Cap74) are small-sized, the four problems are medium-sized (Cap101-Cap104) the remaining four problems are large-sized problems (Cap131-Cap134) and the sizes and the costs of the optimal solutions for the problems are given in Table I.

In order to make a clear and consistent comparison each other, the population size is taken as 40. For the entire experiments, the termination condition is selected as the maximum number of function evaluations (Max_FEs) and it is set as 80,000 and each experimental study performed by using center of mass and best fit individual instead of Eq. 1 and different upper limit \((\bar{l})\), which is one of the control parameter of the BB-BC, is run 30 times in order to solve UFLP. The mean, best and worst values and the standard deviations obtained by the runs are reported in Tables II-VII. The accuracy and robustness values of the methods are compared in terms of the mean and standard deviation, respectively.

In Table II, the experimental results obtained using center of mass function for value \(l=1\) is presented. The mean (Mean), standard deviation (Std), best value (Best) and worst values (Worst) obtained at the end of 30 times run are given for each problem. When analyzed the mean values, any success could not be gained under these parameters. However, when the best values are examined, the optimal results were obtained for small-sized and medium-sized problems problem groups but not large-sized problems. Besides, when looked at Table II and the other tables, it is seen that as the size of the problem increased, the average deviation from the optimal solution increased.

The reporting results obtained using center of mass function for value \(l=2\) are given in Table III. When examined the mean values, it could not be reached to the optimal value for any problem under the given parameters. However, when the best values are examined, the optimal results could not be found for small and medium-sized problems problem groups except for large-sized problems. In addition, while the standard deviation values obtained from small-sized problems got lower, those of medium-sized and large-sized problem sets got higher. Therefore, it can be said that this method is more robust for small-sized problems than the other problem groups.
The experimental results attained utilizing center of mass function for value \( l = 3 \) are given in Table IV. When examined the mean values, the optimal value could not be found for any problem under the available parameters. However, when examined the obtained best values, it is seen that this method obtained optimal results for small-sized and medium-sized problems except for large-sized problems. In addition, while the standard deviation values obtained from small-sized problems got lower, those of large-sized problems got higher. Therefore, it can be said that this method is relatively more effective for small-sized problems rather than large-sized problems.

The final results obtained using best fit individual instead of center of mass function for value \( l = 1 \) are given in Table V. When investigated the mean values under these conditions, any optimal value for any problem could not be found. However, when analyzed the best values, it is seen that the proposed method reached to the optimal solution for small-sized and medium-sized problems problem groups but not large-sized problems. Besides, when analyzed the mean values in this table while this method obtained very near-optimal results for both of small-sized and medium-sized problems, it did not obtain good solution for large-sized problems. Therefore, it can be specified that this method is relatively more effective for small-sized and medium-large problem sets than large-sized problems.

A. Comparative Analysis between Centre of Mass and Best Fit Individual

To fulfill a fair comparison, the experimental studies have been conducted under the equivalent parameters. In the process of comparison, Table II, III and IV are compared to Table V, VI and VII, respectively. In other words, to make a comparison between center of mass and best fit individual, the results of the corresponding problems have been compared under the same \( l \) values. As seen from Tables II - VII, when the proposed BB-BC\(_{\text{center}}\) method with Center of Mass is compared with BB-BC\(_{\text{best}}\) method with Best Fit Individual, BB-BC\(_{\text{best}}\) method is quite better in terms of both of solution quality and robustness rather than BB-BC\(_{\text{center}}\) method, in general. In addition, BB-BC\(_{\text{best}}\) method reached the very near-optimal solutions for the corresponding problems in all of the different \( l \) values. Based on the standard deviations, the robustness of the BB-BC\(_{\text{best}}\) method is better than that of the BB-BC\(_{\text{center}}\) method for all of the problems. When \( l \) values were set as one, two and three, the similar results were obtained. Therefore, for the entire problem groups (small-sized problems, 100s, 130s), it is observed that utilizing of different \( l \) values does not affect the success of the algorithm.

VI. CONCLUSIONS

In this paper, we studied the modification of the BB-BC method for solving binary optimization problems. Modula-2 based binary version of the BB-BC algorithm has been proposed and their performance has been investigated on uncapacitated facility location problems containing small and medium sized problem. The performance of the proposed methods is analyzed under the different \( l \) values which are upper value of the BB-BC method. In addition, the experimental results have been individually conducted using both of center of mass and best fit individual instead of center of mass and in view of these results, the comparative analysis between the BB-BC\(_{\text{center}}\) and BB-BC\(_{\text{best}}\) methods has been also carried out in this study. In experimental results, it is shown that promising results are obtained by this proposed binary method. The results show that the BB-BC method proposed for binary optimization can be used for solving other binary optimization problems.

Image Mosaicing Based Condition Monitoring Approach for Multi Robots at Production Lines in Industrial Autonomy Systems

Hasan Yetis*, Mehmet Karakose*

*Department of Computer Engineering, Firat University
Elazig, Turkey
{h.yetis, mkarakose}@firat.edu.tr

Abstract—In today industry, manufacturing become big and serial as it never been before thanks to the autonomy robots. Hitches on such autonomy systems used in industrial production may cause production delaying. In this study, it is aimed to obtain alive bird's eye view map of full system in order to monitor manufacturing robots at production facilities that are big and impossible to be monitored with only one camera. Finding the similar scenes of input images, estimation of homography, warping and blending operations are applied respectively in order to mosaic the images by twos. Thus the robots in the facility can be observed in one screen. With observation of the obtained images, faults on cyber-physical systems that may cause damage in machines which are not cheap can be handled beforehand.

Keywords—Condition monitoring, Multi robots, Production lines, Image processing, Image mosaicing

I. INTRODUCTION

Accuracy and security of cyber-physical systems become crucial with growing up cyber-physical systems in industry. In today industry, manufacturing become big and serial as it never been before thanks to the autonomy robots whose cyber and physical layers are diverse. Monitoring physical layer from cyber layer is necessary for link the layers and integrate them more tightly. Furthermore, it will ease the control of big facilities. Hitches on cyber-physical systems used in industrial production may cause production delaying. Furthermore, these hitches may cause damage in hardware which are not cheap. So observation of the system and determination of possible accident are required for deduction the cost of delay in production and repair. With processing the obtained image by algorithms in cyber layer, the cyber-physical system would be more integrated and secure.

In this study, it is aimed to obtain alive bird's eye view map of full system in order to monitor manufacturing robots at production facilities that are big and impossible to be monitored with only one camera. With the created alive map, it will be possible to monitor positions of all robots instant and extract more detailed information about the facility. It is need that locate cameras each of whose angel of vision contain the small piece of neighbour one's. Finding the similar scenes of input images, estimation of homography, warping and blending operations will be applied respectively in order to mosaic the images by twos. After all steps done, only one stitched image will be obtained from all these images taken by cameras at the same time. Thus the robots in the facility can be observed in one screen and machines which could lead to accidents can be noticed early. The stitched image can also be used for image processing in cyber layer.

There are studies about image mosaicing in literature [1-5]. One of the studies, Divya et al. [1], implemented weighted average method in addition to the methods used in image mosaicing such as feature extraction, cluster analysing, dynamic programming to obtain wide angle panorama. Although the study is effective for illuminated images, it is not useful for dark images. Another study about this subject is Lin’s study [2]. Lin et al. use image mosaicing in order to obtain cylindrical panoramic image. Scale Invariant Feature Transform (SIFT) and Random Sample Consensus (RANSAC) are used in this study. Patel et al. [3] employ Speeded-Up Robust Features (SURF) for feature extraction and Sum of Squared Differences (SSD) for feature matching. They also used RANSAC to eliminate incorrect matchings. At the end of their study, they compare Harris and SURF and decide that SURF is more effective for multi-imaged image mosaicing problems. Huang et al. effort to mosaic frames in videos [4]. Instead of using all frames in a video, they used the frames that contain small piece of other frame to enhance video mosaicing performance. In their study, Lee et al. [5] employ SURF for feature extraction and Histogram of Gradient (HoG) for matching. They also utilize from Approximate Nearest Neighbour (ANN), RANSAC algorithms.

![General Image Mosaicing Steps in Literature](image.png)

Figure 1. General Image Mosaicing Steps in Literature [6]
Qui et al. aimed to stitch images and eliminate ghosts occurred while stitching images [7]. In this manner they used SIFT and RANSAC methods. In order to obtain optimal stitching line dynamic programming methods are employed. Larqui et al. [8] also employ SIFT for feature extraction. Difference of their study is that they use voronoi diagram to eliminate incorrect matches.

The paper continues with information about image mosaicing that is given in section 2. In section 3 simulation results are given. Conclusion is handled in section 4 and references are listed following conclusion.

II. IMAGE MOSAICING

Image mosaicing is the process of obtaining single image from more than one images that contain common view with corresponding of the matching points. It helps to obtain qualified images with not expensive cameras [9], take the image of scenes that can not be viewed with one camera, obtain panoramic images, delete moving objects in a video. It has a wide application area from smart systems to military systems.

Regardless the count of images that will be stitched, the images are stitched by twos as seen in figure 2. There are stitching methods in space and frequency domains. The methods in space domain can be grouped as area-based methods and feature-based methods [10]. In this paper, feature-based techniques are applied because area-based techniques are sensible for changes in size, angle and illumination. In feature-based image mosaicing methods, interest points that are characteristic points in image and their features are found first. With the help of extracted features, matching operation is applied. Mismatches that may be occurred are eliminated and homography is estimated. With the found homography matrices warping operation is actualized and blending is applied to make the stitching seamless [11]. General steps of feature-based image mosaicing process are given by Fig. 3.

A. Feature Extraction

In order to stitch images, it is required to determine common areas / objects first. Feature based methods use characteristic points called interest point instead of all pixels in an image in order to make algorithm more efficient. Interest points can be edges, corners or blobs. There are several edge and corner detection methods to identify the interest points [13,14]. In this paper, interest points are extracted by Difference of Gaussian (DoG) method which is a blob detection method.

In order to link between images, interest points are used. Some features must be extracted for calculating the similarity of interest points. There are various feature extraction methods in literature [15]. In this study, we used Scale Invariant Feature Transform method [16].

B. Matching

After extracted SIFT features, it is searched corresponding interest points from second image to interest points from first image according to similarity [17]. In this stage second nearest neighbour distance rate is used to prevent mismatches [18]. According to this method the distance between interest points from reference and target image are calculated. The nearest 2 corresponding interest points are selected for each interest point from reference image. If the first distance is smaller than the multiply of distance ratio and second distance, it means there is no confusion probably and the first one selected as matched point. Otherwise it means there is confusion and no matching is realized.

$$\text{matching} = \begin{cases} 1, & A < B \times \alpha \\ 0, & \text{otherwise} \end{cases}$$

where A is distance of first nearest point, B is distance of second nearest point and \(\alpha\) is tolerance of distance difference.
C. Elimination of Mismatches

Although the second nearest neighbour distance method reduce the count of mismatches, it can not completely eliminate them. When we try to superpose the matched interest points, the mismatches make a fuss. So, the count of mismatches must be minimized before homography estimation. In this study RANSAC is used to eliminate the mismatches.

According to RANSAC method [19], some of the data are selected randomly and a model is tried to fit the samples. After all data are tested by the model respectively. If the model gives the correct result within the tolerance defined before, the datum is marked as in-liner. If in-liner data is sufficient to verify the model, the model is added to solution set. This operation is actualized pre-determined iteration times. At the end of the iterations best model that fits the majority of data with minimum error is selected as solution. The diagram belongs to RANSAC algorithm is given by Fig. 4.

D. Homography, Warping and Blending

We aimed to fit a model whose input is the pixel coordinate of target interest points and output is the pixel coordinate of corresponding reference interest point. The model that help us to calculate the new position of target image pixels’ in order to superpose these images is called homography matrices. Homography matrices is 3x3 sized matrices and it is used to move the points in homogeneous coordinate system. The equation for calculating new position of point and and its extended version are given by respectively (1) and (2).

\[ \begin{bmatrix} h_{11} & h_{12} & h_{13} \\ h_{21} & h_{22} & h_{23} \\ h_{31} & h_{32} & h_{33} \end{bmatrix} \begin{bmatrix} X_o \\ Y_o \\ Z_o \end{bmatrix} = \begin{bmatrix} X_n \\ Y_n \\ Z_n \end{bmatrix} \]

(1)

\[ \begin{bmatrix} h_{11} & h_{12} & h_{13} \\ h_{21} & h_{22} & h_{23} \\ h_{31} & h_{32} & h_{33} \end{bmatrix} \begin{bmatrix} X_o \\ Y_o \\ Z_o \end{bmatrix} = \begin{bmatrix} X_n \\ Y_n \\ Z_n \end{bmatrix} \]

(2)

where H is homography matrices, P and P’ are former and new coordinates of pixel in homogenous coordinate system respectively. To transform 2 sized vector to homogenous coordinate system, \( Z_o \) is selected as 1; to transform homogenous coordinate system to X and Y values (3) is used.

\[ X' = \frac{X_n}{Z_n}, \quad Y' = \frac{Y_n}{Z_n} \]

(3)

where \( X' \) is new value of X and \( Y' \) is new value of Y. After found of new coordinates of target image, target image is transformed and coordinates of corresponding points be the same. With the displaying transformed image and reference image in one frame, image stitching process is done.

Stitched image may have visible colour transition because of the cameras whose angel of vision is not illuminated as same as the other one’s. At last, to extinguish the difference blending operations are used [20]. In order to remove blur that may be derived from stitching operation or derived due to the high speed of robots at production line, some blur removal methods in literature can be used [21].

III. EXPERIMENTAL RESULTS

In this paper, the image stitching operation is implemented on images that belongs to robots at production line. The diagram of desired system given by Fig. 5. Although the sample system shown by Fig. 5 includes 4 cameras with the same characteristics, the count of cameras can be increased. A computer with intel i7 6020M CPU, 6 GB ram, and Windows 7 64bit home premium is used to perform the proposed approach on the sample images belong to production environment.

Figure 4. Block Diagram of RANSAC Algorithm [22]

Figure 5. Desired system for grabbing images.
In order to test the effect of the images order, the four image given by Fig. 6 are stitched respectively first. The result of this process is given by Fig. 7. Then the same images are subjected to the process of stitching by twos. In Fig. 8, e is obtained by stitching of a and b, f is obtained by stitching of c and d, and finally g is obtained by stitching of e and f.

Although there is not much difference in point of the quality between final stitched images that are obtained in Fig. 7 and Fig. 8, we can see that the process given in Fig. 8 works faster than the process given in Fig. 7 when we look elapsed time given in table 2 and table 3.

IV. CONCLUSION

It is very crucial to monitor physical elements especially for cyber-physical systems that is trend of the industry of today, which is called industry 4.0. In this paper, it is proposed that use image mosaicing to monitor conditions of multi robots at production lines and the proposed method is tested by experimental. In order to test the method 4 images that belongs the same science are used, and no one of them contains more than 1/3 of another one in spite of the possible deflections. With the knowledge of this, only a part of image is used to search interest points instead of full image. Finding interest points, feature point extraction, matching, warping and blending operations are used respectively to stitch images. Since the order of images that are stitched are certain, sorting of images is not required for such camera array applications. The images are stitched by order and by twos respectively. The effect of image order is demonstrated by results given by table 2 and table 3. The results show that stitching by twos outperforms stitching by order for the camera arrays which occurred from NxN camera, N is even number. Furthermore, if N is not even or the size of camera array is not NxN, a sub array that provides the constraints and the operation is applied for sub array. After the remains may be stitched by orders. Little time consumption of this approach make it possible to be used in camera array problems. The feature-based method makes the solution more reliable in case of changing in position, angle or illumination.

Consequently, it is possible to get high quality reliable image using low quality cameras thanks to the method. Monitoring the condition of robots at production line, which is a requirement for today’s industry facilities, in a screen is achieved by the study.

Abstract—Smart surveillance systems developed in recent years have made enormous contributions to providing safety and management of crowds. The aim of this study is to observe and try to understand how crowd movements presented in a video sequence show behaviour. For this end, the motion data at pixel level among the consecutive frames is obtained using optical flow initially. Then, this motion data is associated using the particle advection method and stable as well as moving areas in the image are obtained. After, the moving areas clustered using Mean-Shift method are described and classified as parabola, in addition to the studies in the literature. At the end of the study, the method developed was tested over UCF as well as Pets2009 datasets and the results are presented.

Keywords Crowd Analysis, Particle Advection, Optical Flow

I. INTRODUCTION

The flow of the daily life, willingly or unwillingly, integrate people in crowds. Streets, shopping malls, political meetings, stadiums or concerts are centres where crowds are abundant. It is possible for a crowd in calm movement to become a crowd of people running in panic all of a sudden. Although this case would not last long, but it may cause stampede and may result in losses of lives. It is quite easy for a person with suspicious behaviour to disguise himself in the crowd. These are bad incidents that have a higher percentage of lethal possibility and realization. Humanity has already experienced such bad incidents. Such sorrowful incidents experienced have shown the need for making studies on the analysis of crowd behaviour. Different disciplines such as computer vision, sociology, and psychology have been doing research on this topic for many years.

In this respect, researches such as estimating the density of the crowd and observing the flow by developing algorithms on images obtained from surveillance systems; noticing the generation of a dangerous crowd or predetermining the abnormal conditions in the crowd; managing the crowd in panic; designing the open public spaces; and tracking a suspicious person or people throughout a series of images; have been the primary topics of crowd behaviour analysis studies. Some images where there are crowd scenes are shown in Figure 1.

Crowd analysis problems were tried to be solved by algorithms developed for object tracking in the first years (Object approach) but it was seen that tracking people in high density videos is fairly difficult and that this is a solution that needs burdensome and excessive calculations. In the following studies, it was tried to grasp the general features of the crowd rather than focusing on the people in the crowd as a whole (Holistic approach).

Through the survey based publications in recent years, the topic has been handled with different issues such as determination of moving areas, crowd analysis, crowd behaviour, tracking of people, and determination of abnormal conditions. Methods that are used under these topics and success results obtained from these are being compared and evaluated. Moreover, there are studies from the perspective of different disciplines. [1][2][3][4][5][6][7]

Segmentation of moving areas in crowd provides a general view of the image. By focusing on these moving areas, this process plays an important role in the solution of problems such as determining the abnormal conditions or tracking of people. Insufficient or erroneous results in the segmentation process have a negative effect on the preceding steps. Because of this condition, studies on determining the moving areas go on developing every day. [8][9][10]

Incidents, not occurring frequently except for the general flow of a crowd, are called Abnormal Behaviour in the literature. Another important study in which a solution is looked for through computer vision methods is the determination...
of abnormal condition or behaviour in crowd by systems. Using such systems in high density areas such as shopping malls, stadiums, concerts or passenger stations presents an alternative approach to providing the safety and management of crowds. [11][12]

Another important issue on the crowd analysis field is the tracking of a person or people in a crowd. It is a very difficult thing to keep a track of people in high density crowds. The main reasons are; I) the denser it gets, the less pixel representing the person there will be, and this makes tracking more difficult. II) It is difficult to differentiate people in crowds. III) There are psychological conditions having an influence on the change of people’s direction.

Problems such as tracking of a person or moving objects (vehicles in traffic) after being determined in the image during a series of images are specialized fields where academic studies deal with in private and create private algorithms (tracking algorithms). In such studies, problems are tried to be solved by an object based approach.[13][14]

Estimation of density of a crowd is an important topic in terms of providing the safety and management of the crowd. It is crucial to make these analyses and these controls dynamically at places where there are crowds and crowds show variability, such as stadiums, concerts, and shopping malls. By this way, it will be possible to prevent potential condensations. These analyses are performed on a single image. Conditions such as few pixels per person, the perspective, cluttering, occlusion, and low resolution are important problems that these analyses should find a solution for.

Our target in this study is to obtain the moving areas in an image using optical flow method and defining the moving areas as a parabola. Moving areas that are defined as equation will give us information about how the crowd behaves. We believe that the results that are obtained from these studies will help us understand and define the behaviour of the crowd in the preceding steps. At the end of the study, the developed method was presented as ground truth by being tested on the images from UCF and Pets2009 database.

II. METHODS

Some methods that were used in order to obtain some characteristics of the crowd and to observe how the crowd moves clearly will be explained in a priority order.

A. Optical Flow

This is a method used in order to obtain movement data in a video. In this method, the direction and the speed of object movements in consequent frames at pixel level can be obtained. This method is usually used for obtaining the movement data at lower speeds and at high density. It is seen that the method proves to return better results in videos with these qualifications.[15][16][17][18]

When we take the prerequisite that the light source does not change in time and that the change is not more than 1 pixel (in relocations more than 1 pixel, the pyramid method is recommended but this is not included in this article) into consideration, we can have this equation, provided that the pixel at (x,y) location in t time can relocate as much as (dx,dy) in t+1 time period.

$$\frac{dI}{dt} = 1 \Rightarrow I(x,y,t) = I(x + dx, y + dy, t + dt) \quad (1)$$

When the process is proceeded using Taylor series;

$$I(x, y, t) = I(x, y, t) + \frac{\delta I}{\delta x} dx + \frac{\delta I}{\delta y} dy + \frac{\delta I}{\delta t} dt + H.O.T \quad (2)$$

$$Ixu + Iyv = -It \quad (3)$$

The general formula of the optical flow is obtained. ($Ix = \delta I/\delta x, Iy = \delta I/\delta y, It = \delta I/\delta t, u = dx/dt, v = dy/dt$).

In equation (3) that is obtained as the movement data of a single pixel, there are known values such as $Ix, Iy, It$ and also known values but also unknown values such as $u$ and $v$ values. The aim of the optical flow is to find the $u$ and $v$ values.

At this level, a solution was developed benefiting from the method developed by Lucas-Kanade for optical flow. Lucas-Kanade calculated the velocity of a pixel taking into consideration of the fact that a pixel moves at the same velocity with neighbouring pixels. That is to say, when calculating the movement of a pixel that has a 3x3 neighbouring scheme, we obtain 9 equations in order to find the two unknowns of $u$ and $v$ in equation (3), thinking that all the neighbouring pixels move at the same velocity.

$$\begin{bmatrix} Ix_1 & Iy_1 \\ Ix_2 & Iy_2 \\ \vdots & \vdots \\ Ix_9 & Iy_9 \end{bmatrix} \begin{bmatrix} u \\ v \end{bmatrix} = \begin{bmatrix} -It_1 \\ -It_2 \\ \vdots \\ -It_9 \end{bmatrix} \quad (4)$$

The neighbouring window chosen as 3x3 in the sample can be chosen at different sizes depending on the condition of the problem.

While preferring a smaller size of window value can help us obtain the details in an image, these details might lead to image confusion and the load of the system might increase. Moreover, it may also lead to the loss of general flow data of the video. On the other hand, a larger sized neighbouring window can capture the movements at larger scale and helps us obtain the general flow of the movement,
yet the bottlenecks or small movements might not be noticed. There is a trade off in question. Therefore, the size of the neighbouring window is another problem to think about.

When the equation (4) is solved using minimum least squares method:

$$A^T A \mathbf{d} = A^T \mathbf{b}$$

$$2 \times 2 \quad 2 \times 1 \quad 2 \times 1$$

$$\begin{pmatrix} \Sigma I_x I_x & \Sigma I_x I_y \\ \Sigma I_x I_y & \Sigma I_y I_y \end{pmatrix} \begin{pmatrix} u \\ v \end{pmatrix} = \begin{pmatrix} \Sigma I_x I_t \\ \Sigma I_y I_t \end{pmatrix}$$

(5)

There are four basic steps to be taken in obtaining optical flow using Lucas-Kanade method.
- Noise reduction is applied in frames
- Ix, Iy, and It are calculated
- u and v values are found by calculating the equation (5).
- Due to the fact that optical flow values are independent from each other and that they might show differences from the general flow, the resulting values (u,v) are applied a median filter.

B. Particle Advection

Optical flow provides the data related to where a pixel will be heading to on the next frame. Particle Advection, on the other hand, is a method used in order to observe (understand) how a pixel moves throughout the video.[19][20][21]

At this level, particles that are located on every pixel in the first frame of the video are being directed by the time domain pixel level 3D movement data that is obtained by optical flow. At the end of the process, the time domain 3D optical flow data is obtained as 2D movement data. This process is called particle advection and the distance covered by each particle is called particle trajectories. [22][23][24][25][26][27]

A grid is located on 1th frame in video sequence, namely each pixel in the first frame and the particles are moved according to optical flow data. Ideally, a grid is made up as N=Width X Height. Particle advection can be formulized according to notation expressed above.

$$x_i(t+1) = x_i(t) + u(x_i(t), y_i(t))$$  (6)

$$y_i(t+1) = y_i(t) + v(x_i(t), y_i(t))$$  (7)

C. Clustering

Differentiating multiple actions on an image from each other successfully is directly related to the success of the cluster process. The particles animated with the help of Particle advection process in fact carry the motion data and at the end of the process particles representing any action gathers at a cluster point. It is expected from the system to differentiate these clusters from each other. We can think that each cluster represents an action. In this study, we tried to obtain clusters using mean-shift method.[28][29]

Some places on the image might not move and therefore the particles on these pixels do not move. In this case, particles not moving or moving at a value lower than the threshold value and clusters emerged under a definite number of particles are accepted as noise and they are not included in the evaluation. By this way, only clusters that have the capability to represent motion or define a significant motion can be obtained.

D. Define as Parabola

In this step, the moving areas in the image will be defined as parabola. In this way, these results will be helpful in terms of determining moving areas and understanding the crowd behaviour.

Determining as moving parabola can be as follows; particles representing an action or behaviour move as a group with particle advection. This information can be expressed as a curve using least squares method according to the location of each particle has along the motion.

$$f(x) = ax^2 + bx + c$$  (8)

$$a = \begin{cases} 
\text{line} & \text{if } a \approx 0 \\
\text{circle} & \text{others}
\end{cases}$$
For this study, when we express each movement as a quadratic equation, it can be said that proximity to coefficient \( a \) (8th equation) shows whether this movement is a line or circular movement.

III. CONCLUSION

As a result, this study is a preliminary study that can make it possible to achieve targets like understanding and defining the behaviour of a crowd during a series of images. Initially, moving areas are obtained through optical flow method and then these moving areas are defined as the movement of particles through particle advection method. Particles clustering at a point on the image are marked with mean-shift method and behaviour at different types are determined. The movement is represented through a quadratic equation according to the location of particles in each cluster. In the end, it is possible to achieve the information on what kind of route the co-efficient of these equations follows.

The methods were tested on some images that we took from UCF and Pets2009 database. The results were shown as ground truth in Figure 3.

Vibration Analysis for Induction Motors with an Expert System

Cuma TIPIRDAMAZ and Mehmet Resit TOLUN
Aksaray University, Faculty of Engineering, Electrical and Electronics Engineering Department, Aksaray, TURKEY

Abstract—This paper presents an expert system for induction motor fault detection based on vibration analysis by using corvid expert system. Vibration signals of induction motors on four different actuating mechanism are collected with a specific vibration measuring device. The device evaluates the values with three harmonics in frequency domain. Expert system provides the recommendations as maintenance activity or the reason of the vibration by using vibration values. This system is tested and validated on four type of actuating mechanisms. Obtained results show that this system can detect faults in early stages with high accuracy and reliability. Thus, it provides malfunction and failure prevention and improves overall performance and efficiency of industrial systems.

Keywords—fault detection, induction motor, vibration analysis, data analyse, expert systems.

I. INTRODUCTION

Induction motors play an important role as prime movers in manufacturing, process industry and transportation due to their reliability and simplicity in construction. Although induction motors are reliable, the possibility of unexpected faults. The issue of robustness and reliability is very important to guarantee the effective operational condition. Therefore, condition monitoring of induction motors has received considerable attention in recent years. Early fault diagnosis and condition monitoring can reduce the consequential damage with unexpected production stops. Faults can occur in the stator, rotor, bearing, or the external systems connected to the induction motor. Because of this reason, fault diagnosis of engineering plant has increased recently.

Expert Systems contain specialized knowledge elicited from a domain expert usually in the form of IF-THEN rules. Expert systems are widely used in fault detection and diagnosis applications [1]. The knowledge engineer usually extracts rules for the given domain, in this case, fault diagnosis system for induction motors, and the inputs of expert system are the measurements taken by sensitive instruments, i.e. sensors. The expert system then proceeds on to reasoning with rules and infer meaningful recommendations. The present research is based on using motor vibration data measured with a professional device and use these results obtained from the device for diagnosing faults in an induction motor.

II. VIBRATION ANALYSIS

Vibration is the cyclic or oscillating motion of a machine or machine component from its position of rest. Vibration is a repeated action and is continuous. Most vibrations are undesirable in machines and structures because they produce increased stresses, energy losses, cause added wear, increase bearing loads, induce fatigue, create passenger discomfort in vehicles, and absorb energy from the system.

The amplitude of the vibration can be measured as displacement, acceleration or velocity. Displacement is a distance for moved object. Its measurement unit is mm (millimeter). Acceleration is a difference the rate of the velocity and is measured as mm/s².

The amplitude of the vibration can be measured as displacement, acceleration or velocity. Displacement is a distance for moved object. Its measurement unit is mm (millimeter). Acceleration is a difference the rate of the velocity and is measured as mm/s².

Displacement accentuates the low frequencies. Acceleration accentuates the higher frequencies. Velocity is consistent across a larger range of frequencies as presented Figure 1.

Vibration data can be collected through the vibration sensors. Vibration sensors can be classified as accelerometers, velocity sensors, capacitive and eddy current sensors and laser displacement sensors. All these sensors have some advantages and disadvantages according to the application. After the values are collected vibration analysis should take place. Vibration analysis consist of some logical steps. These are detection, analysis and correction. Detection should be implemented by the devices or sensors then analysis occurs by software program or just like ours with an expert system. The last step is the correction through the analysis. A systematic vibration analysis can then be carried out to identify the more common machinery problems, including: Unbalance, Misalignment, Looseness, Defective Bearings, Resonance, Eccentricity, Worn Gears, Motor Electrical Problems, Drive Belt Problems,

Figure 1: Amplitude – Frequency Chart
Distortion (Soft-Foot & Piping Strain). Diagnostic Charts are implemented to make rules for expert system.

![Unbalance Diagnostic Chart for Fan Mechanism](image)

**Fig. 1**: Unbalance Diagnostic Chart for Fan Mechanism

Mass unbalance will be in phase and steady as shown in Figure 2. Amplitude due to unbalance will increase by the square of the speed below first rotor critical (a 3X speed increase = 9X higher vibration). 1X RPM always present and normally dominates spectrum.

### III. EXPERT SYSTEM DESIGN AND IMPLEMENTATION

Expert systems are computer programs that emulate the interaction that a person would have asking a human expert for advice or a recommendation. Most decision-making processes can be broken down into many small parts. The human expert often makes decisions almost automatically and does not consciously think about each small step to solve problems or reach conclusions. However, they become apparent when the reason for the decision is explained to someone else, or the decision process is taught to others. A decision may be based on various facts that individually would not be conclusive, but when combined together lead to a specific decision or diagnosis.

The kernel of an expert system has two main components. Namely the knowledge base and the inference engine. The knowledge base contains knowledge about the expert’s domain. It may be represented by simple facts, or by more complex representations like frames. There are also rules which explicitly represent the expert’s skills or knowledge about the domain under consideration. The expert system uses this knowledge by exploiting the second main component, that is the inference engine which has several roles including determining how the system reasons using the IF-THEN rules in the knowledge base. Once the knowledge base is built, the ES can begin making inferences. The most common forms of inferencing are forward and backward chaining. The process of moving forwards from known facts to conclusions that follow them is called forward chaining. Alternatively, the process of working backwards from an hypothesis to known facts that support it, is called backward chaining.

Various expert system building tools or shells exist to facilitate and speed up the development process. In the present study, the new generation Exsys Corvid tool has been utilized [3]. Exsys tools have traditionally been used a pure rule-based approach to logic and this has proven to be extremely effective with heuristic rules [2]. There are many ways of describing the heuristics for a decision-making process, but the one that has proven the most effective and efficient is the IF/THEN rule. This is a rule where there is an IF part that can be tested to be true or false based on the data for a specific case or situation.

When the IF part is true, the statements in the THEN part are also considered true.

A sample dialog for Motor – Belt – Fan Mechanism is as follows:

**IF**: Choose the actuating mechanism: Motor – Belt – Fan

**AND**: Choose measuring point: Horizontal Vibration

**AND**: Is there any pick vibration value before the [Vibration Value1X], Evet

**AND**: [Vibration Value2X] = 0

**AND**: Vibration value3X] = 0

**THEN**: ‘‘There is a misalignment at the center of motor side. Maintenance is necessary. ‘’

### IV. EXPERIMENTS AND RESULTS

Expert system for induction motor fault detection presented in this paper implements all previously stated phases of the detection process. The measurements have been taken on the Motor- Belt – Fan mechanism by vibration device as presented in Figure 3. There is a peak value on the first harmonic as shown in Figure 4 that means there is a misalignment on motor side as recommended at expert system forward chaining rule structure. The system has recommended to the maintenance team before the problem has occurred that means the system has prevented the production loss and has guaranteed production stability.

![Motor – Belt – Fan Mechanism](image)

**Figure 3**: Motor – Belt – Fan Mechanism

![Vibration Value of Motor – Belt – Fan Mechanism](image)

**Figure 4**: Vibration Value of Motor – Belt – Fan Mechanism
V. CONCLUSION

In this paper an expert system for induction motor fault detection is presented. Using programming software tool Exsys Corvid System and packages combined with appropriate hardware and implementing forward chaining rules, this system is intended to be used as a practical diagnostic tool for condition monitoring and fault, malfunction and failure prevention in industrial systems. The system is tested in real industrial environment and obtained results proved its accuracy and efficiency.

Further research could be conducted in several directions with new type of vibration sensors. First of which would be to extend the number of faults covered by the classification, such as unbalance, misalignment, looseness, defective bearings, resonance, eccentricity, worn gears, motor electrical problems, drive belt problems, distortion (Soft-Foot & Piping Strain) at four different actuating mechanism. This would enable more efficient fault detection based on more comprehensive feature sets, which would improve maintenance procedure and decrease total cost in production processes.

Abstract— In the race of smartphone operation systems, IOS and Android seem to have the big part of pie. Both platforms have grown more enterprise-friendly since about one decade. Their adaptable functionalities make people's lives easy and give them a reputation in the current competitive technology world. We all have our personal thoughts it comes to features, usability and design. However, what about security? Mobile devices, smartphone operation systems run on, hold valuable, sensitive and classified information or content. So, that increases their attractiveness as targets for cybercriminals. The security of these devices is a growing concern and focus point for smartphone users. Eventually, the security technology of the smartphones becomes one of the prime research and these smartphone vendors have increasingly focused on security in their design efforts. In this paper, factors that influence security within IOS and Android are studied to promote the discussion. Security technologies of IOS and Android are briefly presented. And, varies factors are considered such as methods of application distribution, reduced attach surface, privilege separation, permission-based access control, sandboxing, data encryption, data execution prevention and address space layout randomisation, geo-location and auto-erase. Then, brief information is given about malicious apps. Lastly, discussion is concluded to answer that tight question in the light of security models investigation and evidences collected from current life.

Keywords— mobile security, mobile device, mobile OS, IOS, Android

I. INTRODUCTION

Mobile devices are rapidly becoming the platform of choice for consumers and businesses. There is a wide range of functionalities provided to the users by the mobile devices such as fast connection to social platforms, personal data storing, financial processes, web browsing and tons of services. Therefore, the smartphones sales achieve high number of records worldwide and going on to suppress other electronic technologies like notebooks and tablets [1]. On the other hand, while the number of mobile devices increased, the security threats such as privacy violations, malicious code and exploits in smart environment increased. According to a recent report from Gartner, global smartphone sales are estimated to reach 1.5 billion units in 2016, a 7 per cent growth from 2015 [2]. Also, worldwide smartphone sales to end-users by operating system in 2014 and 2013 are shown in Table I [3].

As mobile platforms become increasingly popular, so do the incentives for attackers, especially when mobile payment transactions are projected to reach almost US$630 billion by 2014. Recent security surveys describe the rapidly increasing number and sophistication of mobile attacks. Mobile devices' prevalence and mobile threats' rapid growth have resulted in a shortage of mobile-security personnel [4].

The storing of sensitive personal data in the smartphones and the increasing popularity of smartphones, lead them to attract the hackers' attention [5]. Cybercriminals have found many sophisticated ways to perform malicious activities on mobile devices. Cybercrimes such as identity theft, information theft, distribution of malwares, and financial fraud have become a real threat to individuals, organizations, and service providers. Nevertheless, there are defences that can be put in place to minimize and mitigate these threats [6].

Although academic research in mobile device and smartphone security has been conducted for several years now, it's only recently—due to the explosion of mobile device deployment in the enterprise environment—that those
research activities have truly focused on solving real-world security challenges [7].

In this study, Security technologies of IOS and Android are briefly presented and considered. Then, brief information is given about malicious apps and exploits. Lastly, discussion is concluded to answer that tight question in the light of security models investigation and evidences collected from current life.

II. EVALUATION OF SECURITY FACTORS

In this part of study, security factors that have chosen for comparison are evaluated.

A. Application Distribution

App Store is the only place to distribute apps. Therefore, the apps must be uploaded that official marketplace for public. Before this process, developer must register with Apple and gets aware of license conditions. After registration, digital certificate can be obtained to sign app for distribution. Aim of digitally signing is to guaranty that both the identity of the app’s developer and the app are not modified, and that app is belongs to intended developer. Second important step to publish app is vetting process. Vetting process is process for checking application for privacy and security violations [8]. That process can be taken one or more weeks. Also, some other issues that may get developer into trouble are explored during this process. For example, the app that works with public web site in real time needs to be confirmed its own End User License Agreement (EULA) by users and web site moderator must check and decide the content that send over that app to publish or not.

For Android, users need to create account on Google Play as a publisher like Apple. But signing and vetting processes in Google Play are different! Android does not require the applications’ developers to sign apps with Google-issued signing certificates. Actually, developers who want to post their apps on Google are able to create as many self-signing certificates as they want without being monitored by Google [9]. That leads to some security vulnerability such as attackers can use famous company name to fasten their malicious app distribution. Also, vetting process in android is shallow and automatic means not checked by human beings. This situation gives easy way to put malicious apps on this trusted domain play.google.com. Also, there is more important issue here Google Apps (APK Files) can be published over anonymous web site or over e-mail. That totally leaves the decision to consumers for installation. But, one central problem is the inability of users to make good security choices and awareness [7].

B. Reduced Attach Surface

The attack surface is the code that processes attacker-supplied input. If app has vulnerability in some code, and either the attacker can't reach it, an attacker cannot base an exploit on this vulnerability. Therefore, a key practice is minimizing the amount of code an attacker can access, especially remotely [10].

For example, flash has a history of security vulnerabilities and not available on IOS. Android is still going on support it. In addition, there are vulnerability occasions reported about PDF viewer on Android such as some script in PDF performs dropper functionality. But, IOS render PDF files natively, only some features of it parsed. That reduces the number of potential vulnerabilities.

Also, security problem of WebView has been studied before and still exists [11]. Interestingly, research has shown that the WebView technology can be further exploited to break the sandbox protection mechanism in the underlying mobile OS. More mobile applications that integrate WebView, the broader the attack surface will become [7]. This problem is closely pursuing by these tow big companies.

C. Privilege Separation

Both IOS and Android kernel implements a privilege separation model like on UNIX system. In privilege separation model, mobile operation system requires every application run with its own group and users. Thus, this ensures that applications have no permission to access other applications. The most important system processes run as a root that is most important privilege. Usually, phone manufacturer use this root right for system apps. Applications you are downloading from store will run as mobile. An attacker who gets full control of the app such as the PDF viewer will be constrained by the fact the code she is executing will be running as mobile.

D. Permission-Based Access Control

IOS permission mechanism is quite different from Android. When application requires use of some other application or service feature at runtime, IOS asks the user about allowing requested access to intended resources. In IOS, predefined limited sets of permissions are given to third party apps. And, accessing to many of devices’ subsystems is blocked. In that, IOS don’t leave some important security sensitive decisions to user.

For Android, inside the application manifest there is a static list of permissions that is shown the user during installation process. Then, users decide to accept or deny of these permission requests. By the way, users cannot partially select permissions, in that all or not. If users don’t allow this permission request, installing will be stopped.

E. Sandboxin

IOS and Android sandboxing mechanism sometimes called isolation almost similar where each application is separated from other applications and system’s kernel. Isolation limits a process’s ability to access sensitive data or system resources from another process. Still, there is slight difference between them. In Android, each application is given permissions to access certain resources, and the isolation system prevents
accessing resources beyond the approved permissions. In IOS, developer himself can’t define permission mechanism. It is mean that there are certain access rules defined by IOS that takes over some responsibility from end users shoulders. IOS isolates some apps from the in-out email boxes and the SMS of a device. For instance, apps cannot send SMS without the users’ involvement. Of course, apps can still access some resources on the system. Thus, an attacker can use a malicious application to steal private information such as the device’s unique ID, sending email spam, or performing an off service (DoS) attack on the device [8]. In Android, some ways are also open for attackers. For example, app list can be retrieved by another app using certain permissions. And, files on SD (Secure Digital) card can be read and modified by an app without any restriction.

F. Data Encryption

The features of this dimension interest about how to protect the user data. In IOS, generally there are two-protection mechanisms that are hardware security and data protection. Every IOS device has a dedicated AES 256 crypto engine implemented in silicon usingUID and GID as key. Integrating these keys into the silicon helps prevent them from being bypassed or accessed. The UID allows data to be cryptographically tied to a particular device. For example, the key hierarchy protecting the file system includes the UID, so the files cannot be accessed if someone moves the memory chips from one device to another. In addition to the hardware encryption features built into IOS devices, Data Protection technology is used to further protect data stored in flash memory on the device. This feature use Hardware Key and Passcode Key. Data Protection is automatically enables by setting up a device passcode. In addition to unlocking the device, a passcode provides entropy for certain encryption keys. This means an attacker in possession of a device can’t get access to data in specific protection classes without the passcode. Besides, IOS keychain securely store passwords and other short but sensitive bits of data, such as keys and login tokens. Keychain data is protected using a class structure similar to the one used in file Data Protection [12].

For Android, data encryption likes IOS with a few missing. Android encryption mechanism is not powerful and sophisticated as IOS. Basically, there is no hardware level encryption and for file protection it uses 128-bit AES. Also, it is hard to guarantee that the file system encryption is enabled. So, this feature selected by the user.

G. Data Execution Prevention and Address Space Layout Randomization

DEP (Data Execution Prevention) is the another layer for security in IOS where a processor can distinguish which parts of memory can hold executable code and which parts are data. In that, DEP just allow execution of the code not the data. That hardens attacker mission. For example, when an exploit tries to run a payload that is injected into the process, DEP prevent data from execution. There are one way to bypass DEP is to use ROP (Return-Oriented Programming). In ROP, attackers harness existing valid code in memory to perform desired actions. However, to do this, they need to know where the code segments they want to reuse are located. Address space layout randomization (ASLR) makes this difficult by randomizing the location of objects in memory. Also, writing large payloads in ROP is very time-consuming and complex. This makes exploitation of IOS more difficult than just about any other platform [10].

In Android, before version 4.0 there is not this kind of special security layer. On the other hand, Android leaned on code signing and memory management unit to restrain attackers from reaching intendent memory location. But, after version 4.0 android implemented DEP and ASLR in its system core.

H. Geo-Location and Auto-Erase

Geo-Location is very useful feature to locate your phone in case of lost. Apple as a feature of its operating system and accompanying online service provides this feature. Our smartphones carry with them lots of sensitive data that, in the wrong hands, is capable of being used for identity theft and fraud. For this situation, auto erase come to help. If your phone is stolen or lost you can wipe your personal sensitive data from your phone. When this feature enabled 10-failed passcode attempts will automatically erase all data on the device.

For Android, there is not native solution. But there is third party apps on market.

III. MALICIOUS APPS

The cybercriminal motivations behind mobile malware may vary from collecting confidential data to financial gain. The three main motivations behind mobile malware include obtaining financial gain, collecting sensitive data without a user’s knowledge or approval, leave a security hole in the device and accessing private networks. Also, mobile-malware functions include activity monitoring and data retrieval, system modification, and unauthorized dialling [4].

As given in evaluation of security factor, Android is the most susceptible OS for threats and attacks. The authors in [14] stated three foremost explanations aspects for that: the shortage in reviewing for applications in Android official market, the openness and the compatibility with other smartphones Apps [5]. On the contrary, in Apps Store, there is a strict process to review and sign Apps before accepting it. Also, IOS is less openness and less compatible with other third parties Apps.

Malware has significantly increased, and writers of mobile malware are targeting mostly the Android platform. The most frequently targeted mobile platform in 2013 was Android with 79%, compared to 0% threats with IOS [15]. According to McAfee, a 30% increase in the number of attacks targeting the
Android operating system was detected. Moreover, out of a total of 8,000 mobile malware, Android threats make up 7,000 [16]. Of course, this statistic belongs to 2013-2014 years. As we consider the previous section, IOS and Android have been enhancing their security technology and adapting against new threats.

In sum, it can be said that most important malware attacks are related with social engineering, because user does not know what is really happening when installing new software. For this reason, Apple is making an effort to get this risky and heavy duty from user’s shoulders according to Android.

IV. DISCUSSION AND CONCLUSION

The growing popularity and sophistication of mobile platforms have made security and privacy a major issue for everyone, since these devices welcome every need that a PC offers. To cope with this concern, mobile operation system vendors have been improving new techniques and technologies. Majority of these are evaluated in this study. Operation system of two giant technology providers Apple and Google are almost same in case of technology. But, in approach manner Android have a few problem. Which are signing process, permission system drawback in case of social engineering and quick vetting process. For IOS, these concerns are handled very well. Besides, App store is only place to download app.

In this study, frankly it is not tried to answer which platform is more secure. Main goal here is to open a discussion for future works.

Abstract—With the development of technology, the usage of the internet via mobile devices are increasingly widespread. At the same time people generally use the internet to contact with their environment. So instant messaging applications operating with internet have become very popular, therefore they are in competition with each other. In this paper, Signal, Threema and Telegram among the most popular commercial instant messaging applications that allow users to messaging each other safely are handled in terms of security. Although these applications use telephone numbers as contact list, calls and messages use data connection, therefore both of the two users talking to each other must connect to internet. Thus, users can send messages without expose to fee of SMS or MMS. Although these applications are practice and fast, they have some security problems arising from the usage of the internet. So unauthorized users (attackers) can access user conversations by using fake identity. To prevent this situation, some authentication techniques are used in these applications. In this study, these authentication techniques are examined and when the user’s public key changed, what changes have occurred in the application are tested. Also whether these applications have vulnerabilities against the MitM (Man in the Middle) attack or not is detected, and also the shortcomings of these applications are evaluated from an ordinary user perspective.

Keywords—instant messaging applications, Signal, Threema, Telegram, MitM, Authentication

I. INTRODUCTION

Instant messaging (IM) is kind of an online messaging which offers users to communicate each other in real-time. IM has become very popular recently. It is used more than SMS worldwide. The number of IM accounts were over 3.2 billion in 2015 [1]. It is estimated that this figure will reach over 3.8 billion over the next four years [1].

When the topic comes to internet, IM applications bring some security problems. The users of IM applications don’t want anyone to read or modify their private conversations. There are some possible threats for these applications, the most important are government intelligence, curious family or friends or neighbors etc., analyzing messages for targeted advertisements etc. So, the instant messaging applications are divided into non-secure (not end-to-end) and end-to-end encrypted. The non-secure IM examples are Skype, Viber, Line, Telegram (it has both non-secure and secure form) etc. The end-to-end encrypted IM examples are Signal, Threema, Telegram (secret chat), WhatsApp (recently added) etc. In this study we compare Signal, Telegram and Threema among some popular secure IM applications in terms of security. Our main purpose is to detect which application is the most secure against the MitM attack. MitM is type of an attack based on the principle of seeing unencrypted data or data capture by entering between the victim computers and the other network tools [7].

II. INSTANT MESSAGING APPLICATIONS

A. Signal

Signal application supported by Android and IOS operation systems is free and open source software application allows users to send message to each other, to do encrypted calls, to send photograph and video with end-to-end encryption. After the application installed from the store of the device, in first step the screen of registration and phone number confirmation are seen as shown in Fig. 1.

Fig. 1: The registration screen and confirmation code in Signal application
When a phone number is entered and a button namely “Verify this device” is pushed, SMS-OTP consists of six digits is sent to user to confirm the phone number. After the confirmation code is entered to shown area, the user can start using Signal application. To use Signal as bilateral contacts, the application has to be installed in the devices of both sides. Encrypted and non-encrypted messaging can also be done in Signal. When messaging with persons exist in contact list or talking unauthentically, this application is not differ from the standard messaging application. For encrypted messaging, QR code is scanned. In this operation, a person’s identity verification is done through the barcode system. When clicked the user name which exists contact list, in upper right corner of the interface, “Conversation Settings” is exist as shown in Fig. 2. When entering the conversation settings, the option of “Verify identity” is located. Thus the user can be verified with this option.

As soon as clicking on the authentication section user’s self identity and identity of a person who wants to communicate with this user are listed and the user can reach to QR code from there (Fig. 3). After a user’s QR code as shown in Fig. 3 is scanned by the other user’s device, there is a unilateral authentication operation. Likewise when user select the option of “scan the QR code”, the QR code of the other user is scanned via the barcod reader. An example of QR code reading operation is shown in Fig. 4. If QR code is read truly, the user gets a confirmation message.

The other user confirms the opponent user’s QR code. If a user’s QR code confirms and one of the other QR codes is tried to confirm, Signal application gives "Conflict" alert to the user (Fig. 5).
After the confirmation operation, this users can messaging each other as encrypted. As well as the feature of encrypted messaging, another feature of Signal is that the feature of screenshot is not active as default. This feature is opened and closed as optional. According to us, this operation can be a security precaution against copying (phone number, the screenshot of any user’s QR code etc.). Also when a user suspects from the privacy of messages, he/she can do session reset easily (Fig. 6).

In an encrypted conversation, the most secure way of confirmation of the user’s identity is that co-words should be compared with a different confirmation way except from this communication traffic (in other words out of the communication band). Also if the user can recognize the voice of the opposite person, he/she can be done this operation by reading words an audible form through the phone.

**B. Telegram**

Telegram is a free application and it has both Android and IOS support. For it is faster than other instant messaging applications, Telegram has come to forefront when compared with others. Because it works cloud-based it is given right of access to last correspondences in seconds on any platform. As well as opportunity of setting up a group with 200 person by starting secure session, it enables to sharing videos in size of 1 GB. Telegram application has common usage because of these features is installed in a device to test. After the installation is completed, the user is verified with phone number and verification code (Fig. 8).
As the other chat applications, Telegram can be used in authenticated and unauthenticated form. In Telegram, secure messaging can be started as shown in Fig. 9.

In Telegram, users can only verify by sending screenshot of their symmetric encrypted keys (Fig. 10). When compared with Signal, ensuring this verification as a manual way raises doubts about the reliability of Telegram application.

C. Threema

Threema is a paid software presented by Kasper Systems GMBH. It has both Android and IOS support. After the installation of this application, it is clicked to “Set up Threema” button and the operation fingerprint generation is started as shown in Fig. 11.
When the application is installed, the first part of attracting to user’s attention is orange dots existing next to each user’s name (Fig. 12). By default, user which hasn’t any confirmation are shown as two orange dots.

According to confirmation level it changes to green in maximum security level. As in the other applications, it can be messaging in protected and unprotected form. Threema claims that messages between users are protected with end-to-end encryption. In Threema, the authentication is done with QR code identification asymmetrically. Users can see their QR code and have to be scanned by opposite user as shown in Fig. 13. This picture represents the QR codes of two different users. When these QR codes are scanned accurately by barcode scanner, the application sends user a confirmation info. Like in Signal, when different QR code is scanned for the same user, Threema sends user a conflict alert.

After the user’s identity is verified, the three dots which are located next to the user’s name in contact list are seen completely green. This view indicates that the user communicates with other users through encrypted line. In the same way after the other user performs verification, the authenticated user in his list and unauthenticated users are shown green and orange dots respectively. Thus the user can enabled to distinguish authenticated and unauthenticated user (Fig. 14).

III. SECURITY COMPARISON ANALYSIS OF THE APPLICATIONS

In this section we analyse these three applications in terms of security. With the purpose of observing that how the system reacts when one of the users changed his/her public key, one of the users removes his application and installs again. The opponent side doesn’t do any change. When the user (Isil) installed again the Signal application, her public key changes automatically. Previous encrypted conversation conducted with Ugur via his earlier authentication are saved in both devices of Isil and Ugur. When Isil sent message to Ugur with her new public key, this message isn’t delivered and some warning messages are sent to Ugur as shown in Fig. 15.
As seen in Fig. 15, the warning message about changing of Isil’s public key is notified in Ugur’s device. But in this point the missing part is that Isil doesn’t aware of this situation. She sees that he sent messages to Ugur are correctly delivered. Similarly the alert can be given to the user Isil, the opponent side until he verified new public key, the warning in the form of "this user hasn’t verify your public key yet" can be given.

In Signal, after mutual authentication has been done, the same users can not do unauthenticated conversation with each other. Therefore the messages of the user Isil changing her public key are not delivered without authentication by Ugur. Even except private messaging, encrypted group chat is opened and still Ugur doesn’t see the messages of Isil. This is a good way to prevent Man in The Middle (MitM) attacks.

After Ugur verified Isil’s identity, no longer Ugur’s messages are delivered to Isil in Signal. To be attacked by fake users in Signal is related to user’s attention. Because the message that is about Isil’s changing public key is delivered to Ugur but it is doubtful whether this user is real Isil or not. An attacker can copy the number of Isil and install Signal. In such a case to be sure Ugur should send e-mail to Isil to notify this situation, he need to confirm whether this user is really Isil or not.

From the perspective of both user authentication of Signal and giving warning message to user when the other user changes her public key, Signal is a secure chat application. Also the verification of the public key is realized by barcode scanner professionally. This is one of the superior aspects of the program. In addition, even if the user changes her/his public key (when she/he removed application and installed again), old messages are stored in Signal.

InTelegram application providing secure messaging with end-to-end encryption, because there is no authentication between users, the application works with the principle of trust to server. Encryption is performed between client and server, hence Telegram is imprudent against the MiTM attacks. Even the server has the potential to make this attack.

The negative aspects of Telegram application, when one of the user removed application and installed again, encrypted messages done with opponent side are deleted in both side. This situation doesn’t requested by clients. Secure session can be opened again without any authentication with the desired users and messages can be transmitted to the other side. So Telegram has not taken any precautions to prevent the imitation the client. Although this application is quick and practice, for there is no authentication between clients, we evaluate Telegram as an insecure messaging application.

In Threema, when one of the users changed her/his public key, a second user which has the same name is added to contact list to other side. The second user’s security level is low than the previous. The user’s old session stays as the same and the verification level of Threema id verified with the user’s old public key remains as green (Fig. 16).

The scenario in Fig. 16 while Isil has 482VCAHU id, the QR codes are scanned with Ugur mutually and the authentication process is completed. Then when Isil changed her public key, two different record in the same name which has different IDs has been seen in Ugur’s device. Isil’s new ID has changed as FS87P8H4. When Isil wrote message to Ugur with her new public key, the message transmits from insecure channel indicated with orange. So authenticated id and unauthenticated id coming from the same phone number are showed like two different users in contact list of the opponent side. We think that this application is secure against MiTM attacks because of these properties of the Threema. But for some features are not clear and due to be paid, Threema lost the feature of the interaction. A warning of changing the user’s public key should be given even one time but it shouldn’t allowed to automatic
verification. Another drawback is the lack of encrypted or unencrypted calls. The user’s public key exchange can be done by removing the application or reset the application with Delete ID option.

IV. CONCLUSION

In this study, we focus on Signal, Telegram and Threema among secure instant messaging applications, we evaluate usage patterns of these applications and we also test the applications by secure signing in or without adding security. Also when someone’s public key changed from two people during the communication, we examine occurring changes and make inferences about whether the application is safe against MitM attacks or not.

In Signal and Threema, thanks to QR codes, imitating any client is prevented but this precaution is not exist in Telegram. One of the disadvantages of Telegram is that uses symmetric key structure and any authentication is not performed between clients. If users want to share their encrypted keys with each other, they send the screenshot of their barcodes. The result of changing user’s public key Signal and Threema has taken security precaution by changing the user’s QR code. The information of the user’s public key exchange is delivered to opponent side in Signal, but such a warning message is not given and the messages of the user’s changing public key are transmitted from insecure channel in Threema. Also if the other user wants, the user’s new public key can be verified without re-matching QR code. Although this feature provides convenience in terms of the user, it can create sense of danger against copies phone numbers. For there is no such right in Threema, users need to meet face-to-face or via e-mail to re-verification their public keys of each other. They have to send their QR codes to each other. Due to this feature, there is slightly lack of user interactive in Threema. The balance between adding security and being user interactive is very important for such applications.

As a result, if we sort these applications according to security level, a free software Signal is evaluated in first rank when compared to the other two applications in terms of security and user interaction because of it’s secure group messaging, encrypted conversations and practice solutions presented to opponent user when another user’s public key changed. Threema is located in second rank, due to the situations of being paid software, the lack of calling feature and not giving a warning message to user as result of changing the public key. And finally Telegram is located in last rank in terms of security due to the lack of mutual authentication system and the use of symmetric key. Although the symmetric key is much faster than the public key, it can be broken more easily.

Preparing Diet List Suggestion with Fuzzy Expert System

Okan UYAR

Electric & Electronic Engineering
Selcuk University, Technology Faculty
Konya, TURKIYE
okanuyar@selcuk.edu.tr

Abstract— Proportion of disease is growing due to the malnutrition and sedentary life. In this work, a diet list is proposed to the user by calculating the necessary amount of calorie according to gender, weight, height, age and activity level. Diet list are prepared for seven days of a week as divided by six meals. Parameter assessment of users and offering recommendations are made via fuzzy expert system. Prepared diet list are constituted considering calories of nutrients and based on the dieticians’ general diet list proposals. Developed software also includes some functions such as nutrition advices, calculation of ideal weight, information about benefits of several nutrients and calorie evaluation of some daily activities. Thus, nutrition suggestion software carried out against for growing obesity and healthy eating problems in order that people would educate themselves about wellness.

Keywords— Diet list, fuzzy expert systems, nutrition, nutritional value.

I. INTRODUCTION

European office of World Health Organization (WHO) pointed out in “European Food and Nutrition Action Plan 2015–2020” that malnutrition, obesity and unhealthy diets lead to noncommunicable diseases (NCDs). Also, these cause economic and social costs for individuals, families and countries. In the same report, about %57.4 of people over the age of 20 are reported as overweight or obese. Action plan that further analyzes given in this report is about implementation of healthy diet and controlling the food productions with the aid of governments [1]. Besides all these, diabetes, hypertension and high cholesterol are among the top 10 causes of death in the world [2].

Every nutrition plays an important role for supporting daily activities of the people. Therefore, a balanced diet should be in proportion to the values of carbohydrate, protein, fat, vitamins and minerals. Values of these nutrients should be calculated by taking into account taken and consumed energy. Nevertheless, people do not prefer allowing time to go dietician because of their habits and busy schedule. To overcome this problem, web or pc based expert systems that have input parameters such as current diseases, activity level and age should be used.

There are many studies which are focused on diet planning for humans. Some of them are focused on a specific region or a situation. Kljusurić et al. [3] presented a nutrition planning system using fuzzy logic modeling method for boarding schools in Croatia. Daily menu price, meal preference, nutritional and energy value of foods considered input parameters. They take meal preference as input since nutrition habits are different in various places of Croatia. Their software is suitable for planning of menu which has optimal cost and adequate nutrient intake. Kurozumi et al. [4] proposed a Japanese diet evaluation system that uses Fuzzy Markup Language and food exchange list published by Japan Diabetes Society. Dietary healthy level is evaluated by calculating the nutrient percentages of foods selected for menu and proposed method according to the Japanese dietician database. Another region specific work is presented by Şahiner et al. [5]. They examined how to prepare a sample weekly menu for a young person who has a business environment that requires intensive physical activity and his revenue determined by Türk-İş (Confederation of Turkish Trade Unions) on the edge of hunger.

Faiz et al. [6] implemented an approach that gives diet and exercise recommendations for diabetes by using Web Ontology Language and Semantic Web Rule Language as a specific human case application. Similarly, Li et al. [7] proposed automated food ontology for diabetes that cares necessary nutrient values and limitations. They used Hierarchical Clustering Algorithms, Class Naming by intersection naming and instance ranking by granular ranking and positioning so as to construct various food groups (diet lists). Another work considers the diseases were presented by Chen et al. [8]. An diet recommendation was offered by using Fuzzy Rules and Knapsack Method that utilizes users’ height, weight, activity level, renal function, hypertension, high cholesterol and preference data. Mamat et al. [9] proposed Fuzzy Multi-Objective Linear Programming application that provides an optimum diet list includes enough nutrients for a day with reasonable price. Decision Support System also used in this work to recognize the type of disease according to the symptoms obtained from the users.

Main method used in the diet assessment systems is Fuzzy Logic and its derivatives. Lee et al. [10, 11] produced Type-2 Fuzzy Ontology based on Type-2 Fuzzy Food Ontology and Fuzzy Markup Language-2(FML2). Similarly, they presents to the user healthy level of the foods in diet with semantic expressions by developing FML2 based agent. Mamat et al. [12] made a balanced diet planning using Fuzzy Linear
Programing approach. In this planning, assessment of carbohydrate and fat amounts in the food that eaten every day, food prices and the amount of nutrients that required to take a day are for 30 years old sedentary woman considered. Mạ́k et al. [13] have presented an equation that define dietary and physical activity advisory problem. Proposed equation expressed as “Hierarchical Multi-Objective Dietary Menu Planning Problem with Harmony” allows the formalization of any diet and physical activity planning problem.

When we interpret the proposed works we deduced that there is a necessity for a software support to the diet list preparation. Another argument is usefulness of fuzzy logic based expert system since input parameters for diet and outcome presentation are verbal. Also, diet is a multi-parameter process should vary according to the individual and cultural characteristics. In this paper, we calculated adequate parameter process should vary according to the individual and cultural characteristics. In this paper, we calculated adequate calories in proportion to the person’s gender, weight, height, age and activity level parameters by using fuzzy logic. After calorie determination software presents one diet list that previously prepared. This diet list arranged according to the food culture and presence in related area.

II. NUTRITION AND BASAL METABOLISM

A. Nutrition

Nutrition is a conscious activity, taking nutrients needed by the body adequately and on time, to protect the health and improve the quality of life. Taking every item of the energy and nutrients that essential for growing-regeneration and working of the body and proper use of them in the body is called “Adequate and Balanced Nutrition” [14].

Nutrients that we need for healthy and balanced diet can be collected in 5 main groups as shown in Fig. 1.

When we examine the pyramid, we should say that grains are most preferred nutrient group. Hereinafter vegetables and fruits come. Milk and dairy products with meat group foods follows this group. We should consume fat and sugar group at least [14].

We can group the animal and plant nutrients according to the chemical properties as follows:
- Carbohydrates
- Proteins
- Fat
- Vitamin
- Minerals
- Water

There are similar or different features of each food group which are necessary for the body. Healthy eating achieved by taking these nutrient groups adequately and balanced as mentioned before.

1) Carbohydrates

Carbohydrates are used as primary energy source of body and it is important for brain functions and nervous systems. The building blocks of carbohydrates are glucose. It can be divided as monosaccharides, disaccharides and polysaccharides. Also while the most common dietary disaccharides can be divided as are maltose, lactose, and sucrose, the most common forms of digestible polysaccharides are amyllose and amylopectin. Monosaccharides and disaccharides are found in such food as fruits, vegetables, milk, milk productions, sugar and sugar products. And, as for polysaccharides, they are found in such food as cereals, bread, pasta, rice and potatoes. Glucose is stored as the form of glycogen in the liver and mostly skeletal muscle [15, 16].

2) Proteins

Proteins are related with all forms of plant and animal life and 20 percent of our body is composed of protein. Proteins form the structure of each cell of our body tissue, muscle, internal organs, tendons, skin, hair and nails. And it also used for energy productions as a fuel in such metabolic formation activations as growth, formation of new tissue and repairment of tissue damaged. Besides it is necessary for the production

![Fig. 1 A healthy eating pyramid [15]](image-url)
of many enzymes, hormones (adrenaline and insulin) and neurotransmitters. In addition to that it has important role in the protection of fluid balance in tissues, the transition of nutrients into cell sand out and making the blood. Protein is composed of 20 amino acids and these amino acids are grouped as essential amino acids and non-essential amino acids [15, 16].

3) Fat

Fat can provide more than twice the energy by weight compared to protein and carbohydrate and it is essential macronutrients which have most energy dense. Fat provides energy production, insulation against the cold, transportation of fat-soluble vitamins in the body and making the body tissue. Fat is grouped as saturated fat (butter, margarine), monounsaturated fat (olive oil, soybean oil, fish oil) and poly unsaturated fat (sunflower, corn). Especially, saturated fat increases the amount of fat in the body. There are a lot of fat in such food as meat, fish, milk, cream, eggs, nuts, chocolate, olive, coconut, cottonseed, corn, soybean, flax and peanut [15, 16].

4) Vitamins

Vitamins cannot be synthesized by the body, are required to support health and well-being. Vitamins are found in small amounts in foods and are designated as nutrients. They help catalyzing the numerous biochemical reactions and aren’t used for direct source of energy. Vitamins are grouped as Water-Soluble Vitamins and Fat-Soluble Vitamins. B group vitamins and vitamin C are the water-soluble vitamins. Unlike the fat-soluble vitamins, they leave the body after completing their task; they don’t accumulate in the body [15, 17].

5) Minerals

Minerals, occur naturally, are inorganic solid with a specific chemical composition. The properties of minerals can be listed as follows:

- It occurs naturally.
- It has the characteristics of any part of the whole.
- It has a specific chemical formula.
- It is solid but rarely fluid.
- Inorganic.

The chemical compounds obtained synthetically in the laboratory do not considered as mineral with the technological progress. These types of solid materials are named as artificial minerals. Each mineral have different features for the body and the features of some minerals are described. Iron is the necessary element for the delivery of oxygen to tissues and the use of oxygen at the cellular and subcellular levels. Magnesium is required in a variety of cellular activities that support diverse physiologic systems. Zinc is necessary for more than 300 enzymes activity. Chromium is the essential mineral for regulation of glucose, lipid and protein metabolism [17, 18].

6) Water

The water is abundant in the world, indispensable for life, odorless and tasteless compound. The amount of fluid we need to take daily is associated the calorie we spend. 1 ml water should be taken per calorie. Water is the essential element for life and it helps to control of body temperature, use of

| TABLE I       | CONTENT AND CALORIES OF SOME NUTRIENTS FOR 100 GR [19] |

Fluid intake must be increased to prevent dehydrations. Thirsty feel can be seen late in children and recommended amount of fluid are as follows to avoid of fluid loss for children:

- Up to 10 kg bodyweight → 100 ml / kg / day
- Up to 20 kg bodyweight → 50 ml (added for each kg) / kg / day
- Up to 30 kg bodyweight → 25 ml (added for each kg) / kg / day [15, 18].
Calorie, protein, fat and carbohydrate values of some nutrients can be shown in Table I.

B. Basal Metabolism

All the chemical changes that occur in the cell to sustain life is called “metabolism”. Metabolism covers all cell construction and demolition events. Mandatory energy expenditure for working of the organs, keeping body heat and keep living in the case of complete rest is called “Basal Metabolism” [20].

Several prediction equations were presented. Harris-Benedict equation created in 1919 was the most known. Mifflin St Jeor equation used for our work as follows:

\[ P = \left( \frac{10 \times m}{1 \text{ kg}} + \frac{6.25 \times h}{1 \text{ cm}} - \frac{5 \times a}{1 \text{ year}} + s \right) \]  

Where s is +5 for males and −161 for females, P is the total heat production at complete rest, m is the mass (kg), h is the height (cm) and a is the age (years).

Daily energy expenditure of individual determines his/her required energy intake for a day. Energy requirements for a normal person should be calculated by summing of the basal metabolism, need for daily physical activity and thermic effects of the foods. Energy need for sportive activities should be add this value for athletes. Thermic effect of the foods means that increase in the body’s metabolic rate that is produced by the consumption, digestion, metabolism, and storage of food. Increase in the body’s metabolic rate or energy consumption is about %3 for fat, %6 for carbohydrate and %16-20 for protein [15]. Energy expenditure of some activities can be shown in Table II.

III. DEFINITION OF FUZZY EXPERT SYSTEM

Expert system is software that provides solutions and suggestions by using knowledge and experience of an expert has skill in any area. Fuzzy logic is beneficial for taking linguistic values from the user. Expert systems have to include the 3 following units:

- Knowledge Database is an updatable structure which information is obtained from experts, books and other literature.
- Result Inference Mechanism should reach a conclusion by using rules in the knowledge database, facts and other whole information through the instrument of both forward and backward chaining method.
- User Interface uses the expert system and provide interaction between the user and system. Basic structure of a Fuzzy Expert System is shown Fig. 2.

IV. PROGRAM INTERFACE AND FEATURES

Main page of our software is shown in Fig. 3. Users input their personal information and desired values such as gender, workload, weight, height and age. According to this parameters required calorie determined and diet lists consonant with this value would be presented to the user. Software also includes enlightenments about several foods and vitamins. Additionally, user can calculate his ideal weight

and body mass index. Membership functions of female height which is one of the diet system inputs is shown in Fig. 4.

Diet list are prepared for seven days of week as divided by six meals. Diet list that previously prepared taking into account the calorie values of the foods and these are classified according to the fuzzy inference outputs. After required calorie calculation, relevant list proposed to the user.

V. CONCLUSION

Balanced diet should help users to prevent eating disorder such as anorexia nervosa, diabetes, and obesity. This study shows that application of fuzzy logic can be used to represent recommended energy and nutrient intake adequately, as well as to present acceptable price and preferences of menu selection for people in a specific region. Diet list is proposed to the user by calculating the necessary amount of calorie according to gender, weight, height, age and activity level. These lists are prepared for seven days as divided by six meals and constituted considering calories of nutrients and based on the dieticians’ general diet list proposals.

ACKNOWLEDGMENT

I would like to thank my undergraduate student Mustafa Oğuzhan MUSARA because of his valuable study in this project.

Switching Access Points on and off for an Energy-Efficient Wireless Communication

Mehmet Fatih Tüysüz
Harran Üniversitesi, Bilgisayar Mühendisliği
Osmanbey Kampüsü, Şanlıurfa
ftuysuz@harran.edu.tr

Abstract— IEEE 802.11 wireless network standard has become one of the most used wireless networking technologies for smart devices as it offers mobility support and low cost deployment. However, these devices deeply rely on the energy provided by their batteries, which results in limited running time. In addition, condensed deployment of Access Points (APs), which is essential to handle increasing demand of performance and coverage, has also been causing rise of network-side power consumption. In this context, this paper proposes an energy-aware Access Point switching procedure for smart mobile devices to increase overall energy saving of both APs and smart devices. In the proposed method, each channel is investigated, in terms of channel utilization, signal quality, probability of collision and deployed traffic types, making use of local and IEEE 802.21-based management frames. With the help of reputation and context-aware computations, Access Points inform the stations that are associated with themselves to maintain their connection or to handover to another network. The aim of the proposed scheme is to maintain desired QoS with minimum number of APs and optimal energy consumption. Widespread simulations have been executed to validate the efficiency of the proposed method. The results demonstrate that the proposed method dramatically increases overall throughput and reduces power consumption of stations over IEEE 802.11 WLANs.

Keywords— IEEE 802.11 WLANs, IEEE 802.21, Load balancing. Energy efficiency, Handover

I. INTRODUCTION

Nowadays, wireless local area networks (WLAN) and smart mobile devices have an enormous amount of usage in daily life. The IEEE 802.11 WLANs [1] are widely deployed all around the world. However, due to design choices and requirements, communication range of the IEEE 802.11 WLAN standard is limited and large wireless network coverage is provided using several APs [2].

Since smart devices are mobile, stations on the move may lose their signals from their associated APs. In this case, stations attempt to retain their wireless connectivity by connecting to other APs in vicinity. Therefore, AP selection, a.k.a. handover operation plays a key role for the optimization of the wireless connectivity over the WLAN environment.

Handover is the procedure of shifting an ongoing call or a data session from one AP to another. Conventionally, handover is activated according to the received signal strength (RSS), such that stations select an AP that has the strongest RSSI. If AP selection is activated only by observing the RSS, it results in many stations associate with one of the APs as shown in Fig. 1. As a result, throughput of the heavily loaded AP decreases due to the congestion, while there are other APs available but not used efficiently. Therefore, a new algorithm which balances the load among APs is required to choose possibly the best AP from an available AP list.

Current energy-aware handover approaches succeed energy savings either by diminishing channel scanning time or by connecting to the most energy-efficient AP according to the traffic type. Yet, an energy-aware handover approach must contain more local and network related metrics, such as battery and interface information, application-specific QoS requirements, user preferences, number of stations connected to each AP, channel utilization ratio per AP, and etc. [3].

In line with the above-mentioned clarifications, this paper addresses an energy-aware AP switching on/off procedure for smart mobile devices. In the proposed method, each channel is investigated in terms of channel utilization, signal quality, probability of collision and deployed traffic types by making use of local and IEEE 802.21-based management frames. With the assist of reputation and context-aware computations, APs inform stations that are associated with themselves to maintain their connection or to handover to another network. Widespread simulations have been executed to validate the performance of the suggested method. The results demonstrate that it dramatically increases overall throughput and reduces power consumption of stations over IEEE 802.11 WLANs.
II. RELATED WORKS

There have been some works in the literature that addresses AP selection for infrastructure based IEEE 802.11 WLANs. Some of these works are either centralized or decentralized, or even based on new network policies. For instance, authors in [4] propose an analytical approach to regulate efficiency of policies that trigger APs in dense wireless environments based on real consumer demands, and then measure the performance that is accomplished by such policies in terms of energy savings and QoS.

In [5], authors study the issues of: What kinds of information will help STAs to select the best AP? and How should STAs select APs based upon the available information? To achieve effectiveness and fairness among APs, they propose a decentralized scheme that requires some adjustments both for mobile devices and APs. They study both dynamic selection and one-time selection structures. They evaluate both cases through simulations and show the improvement of total throughput and fairness.

Additionally, authors in [6] suggest a decentralized fair AP selection approach both for recent associated mobile users and already connected mobile users. The proposed scheme is a heuristic algorithm and realized only by adding one additional field in current AP beacon and probe frames. Furthermore, authors also demonstrate steadiness of their scheme. Authors in [7] discuss potential bandwidth as a metric; mobile user is likely to receive connecting to a specific AP. They offer a procedure for the computation of potential upstream and downstream bandwidth between mobile users and APs depending on delay measurements experienced by beacon frames.

Authors in [8] propose another method called Virgil, a pre-programmed AP detection and selection scheme. Virgil scans for all available APs in a vicinity, associates to them one by one, and initiate a battery tests to evaluate the quality of each AP’s connection.

Additionally, in order to increase energy efficiency of APs, sleep mode procedure is discussed by the authors in [9]. Their proposed scheme makes use of an auxiliary low-power radio to carry out-of-band control information to maintain connectivity and wake up the APs when necessary. This work also details the software and hardware architecture as well as the prototyping results on Wi-Fi technology.

Authors in [10] addresses the multi-rate issue frequently seen in WLANs. Multi-rate elasticity may result in low bit rate mobile users to undesirably affect high bit rate ones and subsequently damage whole network throughput. In this context, authors first develop a decision metric the selection can be based on. Making use of this metric, they suggest two new selection mechanisms that are decentralized in the sense that the decision is achieved by each mobile user, by given proper status information of each AP.

III. PROTOCOL DESCRIPTION

In IEEE 802.11 WLANs, a station has the right to select an AP which it will associate with. However, a station does not know the channel utilization rate, the number of associated stations to an AP, transmission rates of other nodes etc. Additional information is required for stations to consider the network utilization and to select the most appropriate AP. Since an AP is capable of having information of all the stations it has, AP can transmit information to the channel to indicate its own conditions by installing a proper algorithm. Beacon frames or probe response frames transmit information that contains the channel utilization and the number of station connected to the AP. However, a station requires more than this information to select the most appropriate AP. Besides, channel utilization information that is transmitted from an AP can be calculated mistakenly in the existence of both real-time and non-real-time traffic.

To obtain fast and energy-efficient AP selection, the proposed scheme utilizes beacon frames and IEEE 802.21 Media Independent Information Service (MIIS). Beacon frame is one of the management frames in IEEE 802.11 based WLAN standard. It holds related information about the network and allows stations to initiate and maintain communications. Additionally, the aim of the IEEE 802.21 standard [11] is to progress mobile user involvement by providing a Media Independent Handover (MIH) which supports both mobile-initiated and network-initiated handovers.

The MIIS supports the distribution of the network information and provides as many information as possible to the APs, such as the available APs and their coordinates (or the connectivity graph), the services they can provide and channel utilization ratios of APs [3]. Fig. 2 shows a sample of a distance-based connectivity graph given by the IEEE 802.21 IS.

![Figure 2. Distance-based connectivity graph provided by the 802.21 IS](image)

where $r$ is the transmission range of each AP, $d(n)$ is the linear distance between the $AP_i$ and $AP_j$. Using this information, users are able to scan only the channels the IS provides. Therefore, users are also able to diminish total scanning time, reducing the channels that are not in the connectivity graph.

Decreasing total number of channels that will be scanned lets mobile users to enable fast and energy-efficient channel
scanning. Nevertheless, throughout the handover procedure, connecting to an AP that is expected to consume the least amount of energy among all APs is also as important as the fast handover. Therefore, we also propose an energy-efficient handover scheme, which calculates the expected amount of power consumption per AP, by utilizing the Channel Busy Times (CBTs) and the number of stations deployed in each AP.

CBT is the fraction of time that the wireless channel is busy within a given interval. CBT can be calculated by each mobile device distributedly through summing the time utilized by the transmission of all data, management, and control frames in the network. Consequently, CBT of a data frame that has a size of \( S \) bytes and a transmission rate \( R \) can be computed as follows, 

\[
CBT_{data} = \frac{T_{DIFS} + T_{data}(S)(R)}{T_{cy}}
\]

CBT of an ACK frame is computed as follows, 

\[
CBT_{ACK} = \frac{T_{SIFS} + T_{ACK}}{T_{cy}}
\]

CBT of a beacon frame is computed as follows, 

\[
CBT_{bf} = \frac{T_{DIFS} + T_{bf}}{T_{cy}}
\]

Finally, the total channel busy time \( CBT_{total} \) within a specific interval \( t \) can be calculated as, 

\[
CBT_{total}(t) = \left( a(t) \times CBT_{ACK} \right) + \left( b(t) \times CBT_{bf} \right) + \sum_{i=0}^{\infty} CBT_{data}(S_i)(R_i)
\]

where \( a(t) \), \( b(t) \) and \( c(t) \) are the numbers of ACK, beacon and data frames that are encountered within a specific interval \( t \), respectively. Accordingly, channel utilization percentage \( U(t) \) within a specific interval \( t \) can be computed as, 

\[
U(t) = \frac{CBT_{total}(t)}{t} \times 100
\]

With this computation, mobile devices can compute channel utilization rates of their APs within a specific interval distributively. Nonetheless, this computation is impractical for devices as it requires continuous processing overhead, prevents devices to be in the doze state and rises the power consumption. However, in the proposed method, APs are responsible for computing the CBT values within a specific interval. For instance, Atheros AR5212 chipset maintains 32-bit register counters to track the “medium busy time” and the “cycle time”. These counters give the fraction of time that the wireless channel is busy (CBT) per second [12]. Likewise, in the proposed method, we assume each AP computes and updates its CBT periodically with one-second intervals and then, delivers this information with the IEEE 802.21 IS. Whenever a device initializes its network discovery phase, the IS informs the station about the number of stations in available APs and their CBTs along with the connectivity graph. The information of the CBT and the number of stations per AP along with the RSSI values obtained in channel scanning are used to compute the expected amount of power consumption of the device for every possible association scenario with available APs in vicinity. Subsequently, the proposed method allows mobile devices to associate with APs that are expected to consume the least amount of energy among all APs.

Since unsaturated (e.g. UDP) delay sensitive stations have different characteristics and requirements, E-model conversational audio quality factor \( R \) is also used to estimate the perceived voice quality for real-time VoIP applications. Association of a new station to the AP affects the voice quality of other stations associated to the same AP. For an unsaturated station, there are many factors that may affect the selection of the right AP. R value, capacity utilization, transmission rate, fairness, hidden nodes and the number of associated stations to an AP are some of these factors. Existing beacon or probe response frames do not contain all of this information. A new algorithm that also considers all of these factors explained above is required for the best AP selection for unsaturated stations. Therefore, a few bytes of extra status information have to be added to the beacon and probe response frames. Since it is only a few bytes of information, it does not affect the overhead significantly but it improves the voice quality and overall throughput.

In this context, APs will transmit a beacon or probe response frame which contains three additional items; an average R value of the stations in AP, a new estimated average R value if the station selects the same AP and the possible R value of the station which is trying to associate with the same AP. Then, the station will receive the enhanced beacon or probe response frames from APs and consider the best AP selection by looking at the RSSI value as well. Besides, an AP which has less station due to different traffic types and frame sizes can be more loaded than other APs which have more stations. That’s why fairness is not only about the number of stations associated to the APs. The main point of this study is selecting an AP of a station to have a higher voice quality. Improving the voice quality also means better throughput, load balancing and fairness.

In the proposed algorithm, central algorithm first checks if there is a new association request from a station. If there is a new request, algorithm increases its request count by 1 to prevent hidden node effect. Then algorithm gathers MAC layer information and RTCP periodic frames to calculate channel utilization rate and R values of VoIP flows. RTCP feedback can be easily acquired from RTCP sender and receiver reports [13]. The proposed algorithm uses two one-second fast feedbacks. Our algorithm maintains a multi-dimensional control array that contains caller ID, \( T_{delay} \), \( Loss \), \( R_i \), \( R_j \), \( R_{mean} \) values to assist rapid computations and responses. After calculations, algorithm defines its \( R_i \), \( R_{new \_old} \) and \( R_{new \_new} \) values and responds this additional information with beacon frames.

Up until now, we have addressed energy-efficient wireless communication for mobile-side. In order to increase overall
energy efficiency, we will now discuss AP switching on/off procedure. Since dense deployment of APs, which is essential to handle the ever-growing demand of performance and coverage, has been causing to the rise of power consumption, an efficient solution must reduce overall energy consumption of both APs and smart devices. In this context, each channel is investigated by APs, in terms of channel utilization, signal quality, probability of collision and deployed traffic types, making use of local and IEEE 802.21-based management frames. With the assist of these messages, APs inform the stations that are associated with themselves to maintain their connection or to handover to another network.

In this context, APs shares their channel utilization ratios (through CBTs) and their locations (through IEEE 802.21 MIIS). If an AP has less than a pre-defined (that is set as 3 users) affiliations, and if it also has at least one neighboring AP that has not highly loaded (that is set as higher than %70 of its capability), then the AP informs its associated stations to handover to a particular AP. If more than one AP is available, then the AP selects different APs for stations to associate by considering load balancing and multi-rate WLAN environment. By doing so, whenever there are more than one APs in a vicinity and they are not highly loaded, one or more than one APs can be switched off and the users of these APs can be transferred to other APs in that vicinity. This way, energy efficiency will be further increased.

IV. SIMULATIONS

Performance of the proposed methods has been evaluated by widespread simulations using the OMNET simulator and a custom-made object-oriented event-driven simulator software written in C++. Some of the parameters used to calculate formulas and implement the IEEE 802.11 MAC layer are shown in Table 1 and Table 2. We implemented our own TCP/VoIP traffic generator and evaluation tool that creates realistic data and multimedia packet streams using the parameters in Table 1 and Table 2. During the simulations, TCP frames are implemented as saturated frames. Voice frames are implemented as unsaturated frames and queued in 20ms intervals. In order to reach saturation condition, offered load has been set greater than maximum achievable throughput [3].

Table 3. Channel Sc. time of a station for various scanning schemes

Table 3 demonstrates comparison of passive, active and proposed IEEE 802.21-aided channel scanning schemes in terms of the total interval spent for the scanning process. As it is seen on Table 3, regardless of the total number of APs in a vicinity, our proposed scheme lets mobile devices perform channel scanning in much less time compared to both passive and active channel scanning methods. It is because proposed channel scanning scheme is mainly based on unicast channel scanning, which means stations scan only the channels informed by the 802.21 MIIS protocol. Due to reduced channel scanning intervals, proposed scheme achieves faster and more energy-efficient handover operation.

In order to evaluate the impact of the proposed scheme on fairness, we set different RSSI values for various APs. In that case, when the proposed algorithm was off, stations generally associated to the AP which has the highest RSSI value. When the proposed algorithm was on, stations associated to the APs were balanced due to the proposed algorithm checks all of R values, load balancing, hidden nodes and RSSI values. Therefore, the proposed method also provides desired fairness.

Throughout the simulations, we also evaluated the impact of minimum number of AP deployment on the power consumption, throughput, delay and jitter. In this context, we initiated an environment that has 6 APs, each of which has one TCP and one UDP station. When the proposed algorithm was off, 6 APs maintained their communications. However, when the proposed algorithm was on, each channel was investigated in terms of channel utilization, signal quality, probability of collision and deployed traffic types. Afterwards, the proposed algorithm informed 8 of these 12 stations to handover. This way, only two of six APs maintained their operations. Other four APs were switched off for the energy efficiency. In this context, Table 4 shows the comparison of power consumption, throughput, delay, jitter and number of active APs when the proposed algorithm is on and off.

![Figure 3. IEEE 802.11 network communication scenario](image-url)
Table 4. Comparison of power consumption, throughput, delay, jitter and number of active APs when the proposed algorithm is on and off

As it is seen from Table 4, the proposed scheme increases the energy efficiency dramatically by switching some of the APs off. However, since the remaining APs have denser channel utilization, average throughput is slightly decreased due to increased probability of collision. Besides, delay and jitter are increased due to frequent contention compared to the scenario of the "proposed algorithm is off".

V. CONCLUSIONS

In order to reduce the overall energy consumption of both Access Points and smart devices, this paper proposes an energy-aware Access Point switching procedure for smart mobile devices. In the proposed method, each channel is investigated, in terms of channel utilization, signal quality, probability of collision and deployed traffic types, making use of local and IEEE 802.11-based management frames. With the help of reputation, historical and context-aware computations, Access Points inform the stations that are associated with themselves to maintain their connection or to handover to another network.

The aim of the proposed scheme is to maintain desired Quality of Service with minimum number of operating Access Points and optimal energy consumption. In this context, widespread simulations have been executed to validate the efficiency of the proposed method. The results demonstrate that the proposed method dramatically increases overall throughput and reduces power consumption of stations over IEEE 802.11 WLANs.

Clustering of Mitochondrial D-loop Sequences Using Similarity Matrix, PCA and K-means Algorithm

Can Eyupoglu
Department of Computer Engineering
Istanbul Commerce University
Istanbul, Turkey
ceyupoglu@ticaret.edu.tr

Abstract—In this study, mitochondrial displacement-loop (D-loop) sequences isolated from different hominid species are clustered using similarity matrix, Principal Component Analysis (PCA) and K-means algorithm. Firstly, the mitochondrial D-loop sequence data are retrieved from the GenBank database and copied into MATLAB. Pairwise distances are computed using p-distance and Jukes-Cantor methods. A phylogenetic tree is created and then a similarity matrix is generated according to the pairwise distances. Furthermore, the clustering is performed using only K-means algorithm. After that PCA and K-means are used together in order to cluster mitochondrial D-loop sequences.

Keywords—clustering; p-distance; PCA; Jukes-Cantor; k-means algorithm; similarity matrix.

I. INTRODUCTION

Mitochondrial DNA (mtDNA) sequences of mammals evolve more rapidly than nuclear DNA sequences [1], [2]. This fast rate of evolution generates more change between sequences. In order for research of closely related species and populations, this rate is a benefit [1], [3]. In animal mtDNA, there are four principal kinds for sequence changes. These are sequence rearrangements, additions, deletions and nucleotide substitutions [4], [5]. Nucleotide substitutions are the most important principal for the derivation of phylogenetic relationships [4], [6]. The fastest evolving part of the mitochondrial genome is the mitochondrial control region (Displacement or D-loop) [4], [7]–[9].

Principal Component Analysis (PCA) is a classical feature extraction and data representation method [10], [11]. In addition, it can be used to reduce the dimension of similarity matrix generated according to the pairwise distances and simplify the mitochondrial D-loop sequence data structure. The main features of the mitochondrial D-loop sequences can be extracted using PCA by means of mapping high dimensional space data into low dimensional space.

In phylogenetic analysis, distance measure is a significant matter [12]. Using p-distance and Jukes-Cantor methods, pairwise distances are calculated. Jukes-Cantor method is the simplest nucleotide substitution model which estimates the evolutionary distance between two sequences. Besides, it is called one parameter model in the literature [13]. This model can be applied to nucleotide substitution in alphabet (A, C, G, T) [14].

In data mining, the field of clustering has received significant attention in recent years and has become one of the important parts of machine learning research. Clustering is the process of categorizing a finite number of objects into groups where all members have common properties. Data mining is the process of using clustering algorithms in order to analyse data for patterns and relationships. K-means clustering algorithm [15] is one of the most used and popular clustering algorithms [16]. Furthermore, K-means is a simple unsupervised learning algorithm used to solve well known clustering problems.

The rest of the paper is organized as follows. In section II, the methods used for clustering of mitochondrial D-loop sequences are explained. Section III investigates the results of the methods used in this study. Finally, conclusions being under study are summarized in section IV.

II. METHODS

In this paper, in order for clustering mitochondrial D-loop sequences isolated from different hominid species, similarity matrix, PCA and K-means algorithm are used. To calculate pairwise distances, p-distance and Jukes-Cantor methods are utilized. K-means algorithm is used alone and then it is utilized with PCA for clustering. Clustering of mitochondrial D-loop sequences using Jukes-Cantor method is shown in Fig. 1. As seen in the flowchart, firstly, the mitochondrial D-loop sequence data are retrieved from the GenBank database. Secondly, retrieved sequence data are copied into MATLAB. After that pairwise distances are calculated using Jukes-Cantor method and then a phylogenetic tree is created. A similarity matrix is generated according to the pairwise distances. In addition, a dendrogram is drawn. Clustering is performed using K-means algorithm. Finally, K-means algorithm is used after applying PCA.

Clustering of mitochondrial D-loop sequences using p-distance method is shown in Fig. 2. As seen in the flowchart, unlike the first method, pairwise distances are calculated using p-distance method. Following steps are performed in the same manner.
In this work, 5 hominid species are utilized to cluster mitochondrial D-loop sequences. These are European Human, Russian Neanderthal, German Neanderthal, Chimp Trogloides and Mountain Gorilla Rwanda. When retrieving sequence data from the GenBank database, the accession codes for the mitochondrial D-loop sequences isolated from these 5 species are used. These codes are X90314, AF254446, AF011222, AF176766 and AF089820, respectively.

III. RESULTS AND DISCUSSION

In this study, to cluster mitochondrial D-loop sequences isolated from different hominid species, K-means algorithm is used and then it is used with PCA. Jukes-Cantor and p-distance methods are utilized in order to compute pairwise distances. The applications used for clustering of mitochondrial D-loop sequences are implemented using MATLAB R2014a. Phylogenetic tree created using Jukes-Cantor method is shown in Fig. 3.

Creating the similarity matrix according to the pairwise distances and drawing the dendrogram (Jukes-Cantor method) are shown in Fig. 4. Converting the pairwise distances to square form (Jukes-Cantor method) is shown in Fig. 4. Clustering using K-means algorithm (Jukes-Cantor method) is shown in Fig. 5. Performing PCA on square form (Jukes-Cantor method) is shown in Fig. 6. Clustering using K-means algorithm after applying PCA (Jukes-Cantor method) is shown in Fig. 7. Clustering using K-means algorithm after applying PCA (Jukes-Cantor method) is shown in Fig. 8.
Fig. 4. Creating similarity matrix and drawing dendrogram (Jukes-Cantor).

Fig. 5. Converting pairwise distances to square form (Jukes-Cantor).

Fig. 6. Clustering using K-means algorithm (Jukes-Cantor).

Fig. 7. Performing PCA on square form (Jukes-Cantor).

Fig. 8. Clustering using K-means algorithm after applying PCA (Jukes-Cantor).

Phylogenetic tree created using p-distance method is shown in Fig. 9. Creating the similarity matrix according to the pairwise distances and drawing the dendrogram (p-distance method) are shown in Fig. 10. Converting the pairwise distances to square form (p-distance method) is shown in Fig. 11. Clustering using K-means algorithm (p-distance method) is shown in Fig. 12. Performing PCA on square form (p-distance method) is shown in Fig. 13. Clustering using K-means algorithm after applying PCA (p-distance method) is shown in Fig. 14.
Fig. 9. Phylogenetic tree (p-distance).

Fig. 10. Creating similarity matrix and drawing dendrogram (p-distance).

Fig. 11. Converting pairwise distances to square form (p-distance).

Fig. 12. Clustering using K-means algorithm (p-distance).

Fig. 13. Performing PCA on square form (p-distance).

Fig. 14. Clustering using K-means algorithm after applying PCA (p-distance).
As seen in Fig. 3–Fig. 14, clustering of mitochondrial D-loop sequences isolated from different hominin species is successfully performed using similarity matrix, PCA and K-means algorithm. It is observed that both Jukes-Cantor and p-distance methods are practical for computing pairwise distances.

IV. CONCLUSION

In recent years, clustering has become a significant research topic in the area of machine learning. In this paper, when clustering mitochondrial D-loop sequences isolated from different homininid species, similarity matrix, PCA and K-means algorithm are used. First of all, K-means algorithm is used alone and then it is utilized with PCA in order for extracting features of the pairwise distances located in the similarity matrix. Besides, pairwise distances are calculated using Jukes-Cantor and p-distance methods. According to the study results, it is seen that the mitochondrial D-loop sequences are successfully clustered using similarity matrix, PCA and K-means algorithm.

Abstract—Image segmentation is the first step of image processing and image analysis. Texture segmentation is a challenging task in image segmentation applications. Neutrosophy has a natural ability to handle the indeterminate information. In this work, we investigate the texture image segmentation based on Gabor filters (GFs) and neutrosophic graph cut (NGC). We proposed an image segmentation approach, which applies GFs to gray-level images to extract image features matrix, and it segments them into regions. First, color images are transformed to gray level images as input images. Then, input parameters of GFs are adjusted, and GFs are performed on the input images to extract features. The NGC is employed for classification of input images. Finally, experiments are conducted on various natural images to evaluate the approach. Experimental results show that the proposed approach achieves desired performance of texture segmentation. However, it cannot segment the texture-free images as well as texture images. In future works, we will try to segment both texture images and texture-free images at the same time.

Keywords—Image segmentation, texture segmentation, Gabor filters, Neutrosophic Graph Cut.

I. INTRODUCTION

The goal of the image segmentation considered as dividing an input image into several sub-images. To do this, some predefined criterions should be accepted where the sub-images are disjoint, homogeneous and meaningful. Many researchers have been working on image segmentation, and a variety of works have been published [1]. Texture segmentation is a challenging and important task in image segmentation applications. For the texture feature extraction, there exist various texture descriptors such as gray level co-occurrence matrix, Gabor filters (GFs) and Markov random fields [2]. GFs have been successfully applied to many image applications such as texture segmentation [3–5], document analysis [6], edge detection [7], retina identification [8], fingerprint processing [9], image coding [10], and image representation [11].

Graph based methods are important for image segmentation applications [12]. A graph $G$ can be defined as $G = (V, E)$ where $V$ and $E$ are a set of vertices and edges, respectively. On an image, vertices can be either pixels or regions, and edges connect the neighbouring vertices [13]. A weight, which is a non-negative measure of dissimilarity, is associated with each edge based on some property of the pixels that it connects. Normalized-cut, Minimal-cut and Mean-Cut can be seen in some of popular graph cut methods [14–16]. Neutrosophic set (NS) was proposed as an extension of fuzzy set [17]. In NS theory, a member of a set has a degree of truth, a falsity degree and an indeterminacy degree [18]. Therefore, it has an ability to deal with the indeterminacy information, and has attracted much attention almost in all engineering communities and subsequently a great number of works have been studied [19], [20].

In this paper, we propose a texture image segmentation algorithm which uses GFs, NS and graph cut method. Firstly, various GFs are considered which constructs a texture feature volume. Constructed volume is then projected into 2d by using principal component analysis (PCA). The projected feature image is transformed into NS domain and indeterminacy degree is calculated accordingly. Then an indeterminacy filter is constructed using the indeterminacy value on feature image which is defined by combining the spatial information and global texture feature information. The indeterminacy filter is employed to remove the indeterminacy in the intensity and spatial information respectively. A graph is defined on the image and the weight for each pixel is represented using the value after indeterminacy filtering, and the energy function is also redefined using the neutrosophic value. Finally, the segmentation results are obtained using a maximum-flow algorithm on the graph.

The organisation of the paper is as following; in Section 2 we give the methodology of the proposed method. In Section 3, some experimental works are conducted. Finally, we concluded the paper in Section 4.

II. METHODOLOGY

Briefly speaking, the proposed approach composed of 3 main building blocks. Extracting texture features from input image by using GFs is the first building block. This block constructs a texture feature volume according to the number of considered GFs. The second block employs the NS and calculates the indeterminacy degree accordingly. Then an indeterminacy filter is constructed using the indeterminacy value on feature image which is defined by combining the
spatial information and global texture feature information. This filter aims to remove the indeterminacy in the texture feature and spatial information respectively. Finally, a graph is defined on the image and the weight for each pixel is represented using the value after indeterminacy filtering, and the energy function is also redefined using the neutrosophic value. Finally, the segmentation results are obtained using a maximum-flow algorithm on the graph. The flowchart of the approach is illustrated in Fig. 1.

The GFs theory was described in Jain and Farrokhnia [21]. GFs should be in array form and it is designed with different orientations and frequencies. The step of orientation angle can be 30, 45, etc. degrees and orientations are shown as below:

$$Orients = [0, a, 2 \times a, \cdots, 180 - a]$$  \hspace{1cm} (1)

where \(a\) is the step of orientation angle. Wavelengths have values in increasing powers of two start from minimum wavelength to maximum wavelength.

$$w_{\text{min}} = \frac{4}{\sqrt{2}}$$  \hspace{1cm} (2)

$$w_{\text{max}} = \sqrt{im_{\text{rows}}^2 + im_{\text{cols}}^2}$$  \hspace{1cm} (3)

where \(w_{\text{min}}\) is the minimum value of wavelength, \(w_{\text{max}}\) is the maximum value of wavelength. \(im_{\text{rows}}\) and \(im_{\text{cols}}\) are the size of rows and columns of the input image.

$$n = \left\lfloor \log \left( \frac{w_{\text{max}}}{w_{\text{min}}} \right) \right\rfloor$$  \hspace{1cm} (4)

$$Waves = [2^0, 2^1, 2^2, \cdots, 2^{(n-2)}] \times w_{\text{min}}$$  \hspace{1cm} (5)

The set of orientations and wavelengths are taken from [21]. Working GFs mean working with Gabor magnitude response of each filter. The size of the magnitude response is:

$$Orients_{\text{len}} \times Waves_{\text{len}}$$  \hspace{1cm} (6)

where \(Orients_{\text{len}}\) is the length of array of orientation \(Orients\) in Equation (1), and \(Waves_{\text{len}}\) is the length of array of wavelength \(Waves\) in Equation (5).

When using Gabor magnitude responses as features, some post-processing is required. Feature smoothing and normalization is applied as post-processing. In smoothing process, the Gaussian process and normalization is applied in order to get zero mean and unit variance. Smoothing is important because some local variations in each Gabor response are not suitable for the segmentation and they can be soften by using a low-pass filtering. In addition, spatial \(x\) and \(y\) axis properties of each pixel are added to the features matrix. Spatial location information improves the segmentation process to prefer groupings that are close together spatially. After the post-processing, we apply the PCA in order to reduce dimension size of the feature vector. PCA, is a procedure which uses an orthogonal transformation [22]. The transformation is carried out with the first principle component.

After PCA, the reduced feature matrix is fed into the NS domain. A neutrosophic image \(I_{\text{NS}}\) is interpreted using three subsets \(T_s\), \(I_s\) and \(F_s\). Based on the texture feature value and local spatial information, the true membership and indeterminacy membership are used to describe the indeterminacy among local neighbourhood as:

$$T_s(x, y) = \frac{g(x, y) - g_{\text{min}}}{g_{\text{max}} - g_{\text{min}}}$$  \hspace{1cm} (7)

$$I_s(x, y) = \frac{Gd(x, y) - Gd_{\text{min}}}{Gd_{\text{max}} - Gd_{\text{min}}}$$  \hspace{1cm} (8)

where \(g(x, y)\) and \(Gd(x, y)\) are the gray scale texture feature value and gradient values at the pixel of \((x, y)\) on the image, respectively. The algorithm also computes the neutrosophic membership values based on the global texture feature value distribution which considers the indeterminacy on texture feature value between different groups. To this end, NCM is used to obtain the indeterminacy values between different groups on texture feature value to be segmented [23]. Before calculation of the global texture feature value based NS memberships, the obtained local \(I_{\text{NS}}\) is filtered by indeterminate filter based on \(I_s\). After, constructing \(I_{\text{NS}}\), an energy function for graph model is determined and the \(I_{\text{NS}}\) is partitioned using maximum flow algorithm [24].

The algorithm of the proposed method is as following:

Step 1: Compute the GFs of input texture;

Step 2: Smoothing and normalization Gabor responses;

Step 3: Dimensionality reduction with PCA;

Step 4: Compute the local neutrosophic value \(T_s\) and \(I_s\);

Step 5: Filter \(T_s\) using indeterminate filter based on \(I_s\);

Step 6: Employ NCM algorithm on the filtered \(T_s\) subset to calculate \(T_n\) and \(I_n\);

Step 7: Filter \(T_n\) using indeterminate filter based on \(I_n\);

Step 8: Define the energy function based on the \(T'_n\) value;
Step 9: Partition the image using the maximum flow algorithm.

III. EXPERIMENTS

Experiments are conducted on various natural images from Berkeley Segmentation Dataset (BSD) to evaluate the approach. Four images are selected randomly to show the performance of the method. These images are “Cheetah”, “Lady”, “Plane” and “Zebra”, respectively. As shown in Fig. 2, each of figure which includes these images has four types of images. First image is original gray-level and second image is after Gabor filtered and PCA image. Third image is segmentation result of NGC of the first. Fourth image is border result of NGC of the first.

Fig. 2. Top-left: Cheetah image, top-right: result image after GF and PCA, bottom-left: segmentation of NGC, bottom-right: border of segmentation.

GFs are applied to the input images to extract texture features. To use GFs as features, the orientations and the wavelengths should be selected and calculated. We consider the “Cheetah” image in Fig. 2 to examine the process of feature extraction. As seen in Fig. 2, the input image is a gray-level image. Its size is 321×481 pixels. Minimum wavelength is mentioned at upper section and it is 2.8284. Maximum wavelength is calculated via size of the input image. Maximum wavelength is $\sqrt{321^2 + 481^2} = 578.2750$. The wavelengths that send to Gabor magnitude as input parameter, start in increasing powers of two from minimum wavelength up to maximum wavelength. For the “Cheetah” image, the wavelengths have six values: {2.8284, 5.6569, 11.3137, 22.6274, 45.2548 and 90.5097}.

Orientation angle called theta begins with 0 degree and continues with 45 degrees increase thus it has four values for the “Cheetah” image: {0, 45, 90 and 135}.

The related illustrations are given in Figs 2-5. As can be seen in these figures, the proposed method produced reasonable segmentation results. The objects in the input images are well segmented from the background. However, the boundaries of the object are rough and need further post-processing. Especially, for woman image, the head of the woman is not correctly segmented. In addition, several over-segmentations are clear.

Fig. 3. Top-left: Lady image, top-right: result image after GF and PCA, bottom-left: segmentation of NGC, bottom-right: border of segmentation.

Fig. 4. Top-left: Plane image, top-right: result image after GF and PCA, bottom-left: segmentation of NGC, bottom-right: border of segmentation.

IV. CONCLUSIONS

This paper presents a texture image segmentation using GFs and NGC method. Before the image is described in NS domain, GFs are applied on the image to extract texture features. The experimental results show that the NGC method can segment the images properly and the proposed approach achieves desired performance of texture segmentation. The disadvantage of the proposed method is rough segmentation. To overcome this disadvantage, in the future works, a boundary preserving filtering method will be adopted.

Abstract—Internet of Things (IoT) is a global infrastructure worldwide which links objects and enables data generation and sharing of this data. IoT is considered as one of the most important areas of future technology and gets attention considerably by researchers and practitioners in recent years. Applications presented by IoT makes possible a large number of developments, but very few can be used currently. With rapid advances in this system technology, successful implementations will continue to emerge to improve the quality of life in many areas. In this study, IoT is examined in general terms and its applications, advantages and disadvantages are reviewed.

Keywords—Internet of Things, RFID (radio frequency identification), Sensor, Smart objects.

I. INTRODUCTION

Internet has made a significant impact on the economy and society bringing exceptional network infrastructure and communication. It has been more persistent with the advent of the low cost wireless connection. With emerging technologies, billions of people are connected to the Internet via portable computers or mobile devices. After this stage, the expected big step is that interconnected computers exchange information with interconnected objects.

IoT is considered as a part of the Internet of the future and will comprise billions of intelligent communicating ‘things’. You can think of all the things / objects as from cars to books, from electrical appliances to foods, from refrigerators to water heaters, from intelligent buildings to shoes that are connected with each other will be a development waiting for us in the future. Products previously consisting of only mechanical and electrical components will return to hardware, sensors, electronics and complex devices which are interconnected in a variety of formats via the internet and even some platforms [1]-[4].

It is becoming more apparent, we stand on the threshold of new computer applications era that will radically affect our lives. But the oncoming wave of technological revolution will affect us more from all directions; it seems that our near future will be filled with small processors which communicate with each other simultaneously and these will be integrated into the majority of everyday objects when their small sizes and low costs are considered [5].

Internet of Things has emerged as new platforms in the Information and Communication Technologies revolution of the 21st century. This platform is used to provide (on demand) services and resources in different domains including education, commerce, healthcare, public sector and various governmental organizations [6]. Internet of things is a new world for connecting every object of the real world with the virtual space in the computer world. IoT is a type of network that links physical objects that surround us with the virtual world to perform information exchange [7].

When the literature is viewed, many of identification of internet of thing are seen;

The Internet of Things is the connection – via the internet – of objects from the physical world that are equipped with sensors, actuators and communication technology [8].

The Internet of Things is a novel paradigm that is rapidly gaining ground in the scenario of modern wireless telecommunications. The basic idea of this concept is the pervasive presence around us of a variety of things or objects – such as Radio-Frequency Identification tags, sensors, actuators, mobile phones, etc. – which, through unique addressing schemes, are able to interact with each other and cooperate with their neighbors to reach common goals [9].

The Internet of things is a things connected network, where things are wirelessly connected via smart sensors; IoT is able to interact without human intervention [4].

The internet of things is a network of objects equipped with radio frequency identification chips and similar technologies so that the objects could communicate and interact with each other [10].

The internet of things is a common worldwide network which in a unique way addressable things/objects created by them and the objects in the network are in contact each other with a specific protocol [2].

The impact of the IoT has influence on many areas in a short time. Especially, ability of IoT which adapts to any environment, in any conditions without restriction of place, time and object has made it popular [11]. IoT is currently going through a phase of rapid growth. Gartner, Inc. forecasts that 6.4 billion connected things will be in use worldwide in 2016, 30 percent more from 2015, and will reach 20.8 billion by 2020. In 2016, 5.5 million new things will get connected every day. Gartner estimates that the Internet of Things will support total services spending of $235 billion in 2016, 22 percent more from 2015. Services are dominated by the professional category (in which businesses contract with external providers in order to design, install and operate IoT systems), however connectivity services (through communications service providers) and consumer services will grow at a faster pace [12]. The evolution of IoT can be illustrated by several phases as shown in Fig. 1 [4].
In 1991, academics at the University of Cambridge share
the one coffee pot where they work. Researchers whose offices
on the lower floors of the building become uncomfortable to
find the coffee pot empty and they design a system which
captures three images of coffee pot in a minute and transfer to
their computer. After writing of protocols, image capture
software and with a video camera, each researcher could
see the quantity of coffee in the coffee pot on the screen in real
time and online. By 1993, this application moved web has
been watched millions of times a day and it was terminated
due to department move to another building in 2001. This
coffee pot was the first proof and example of the existence
of "Internet of Things"[2].

The term Internet of Things was firstly coined by Kevin
Ashton in 1999 in a presentation prepared for Procter &
Gamble Company. He sorted and proposed the benefits of
application of RFID technology in the supply chain and the
cost became popular through the Auto-ID Centre at MIT
[13]-[15]. Then, scientists and researchers have gradually
accepted the concept of IoT. The formal IoT concept was
given by International Telecommunications Union (ITU) in
2005 ITU released the report on the Internet, titled “The
Internet of Things”. The academic milestones in the brief
history of IoT are illustrated in Fig. 2 [10], [16].

Atzori et al. [9] reported different visions of Internet of
Things paradigm and surveyed the most important aspects of
the IoT. Kiritsis [17] studied on intelligent products in the era
of IoT.

Gu and Liu adapted Internet of Things applications to
information management in the reverse logistics in 2013.
Ondemir and Gupta proposed a mixed integer programming
model used IoT for minimizing remanufacturing, disassembly,
recycling, disposal and storage plans in a demand driven
environment in 2014 [13].

Tsai et al. [18] reviewed studies on basic concepts,
arichitectures, discussions and comparisons of IoT and Future
Internet of Things (FliOTr) and gived open issues and
challenges of IoT and FlOTr. Then they presented an intelligent
data management framework for the FliOTr. Also similar
review studies are found in [1], [4], [10], [15], [19], [20]. Lee
and Lee [21] presented essential IoT technologies and
identified three categories of IoT applications (monitoring and
control, big data and business analytics, information sharing
and collaboration). They also presented investment
opportunities and evaluation and discussed challenges of IoT.
Shrouf and Miragliotta [22] presented a framework for IoT-
based energy management to support the integration of
gathered energy data into a company's information technology
platforms and contributed to the understanding of energy-
efficient production management practices that are enhanced
by the Internet of Things technology.
Dijkman et al. [8] presented a business model framework for Internet of Things applications. Sicari et al. [23] presented the main research challenges and the existing solutions in the field of IoT security. Tao et al. [16] introduced the concept, characteristics, applications of IoT and analyzed energy consumption in product life cycle. Then they summarized the existing applications of IoT in product life-cycle energy management and analyzed the potential applications and challenges of IoT in product life-cycle energy management. Verdouw et al. [24] analyzed concept of virtual food supply chains with Internet of Things and proposed an architecture to implement enabling information systems. Then they verified the proposed architecture with a case study of a fish supply chain. Fang et al. [25] presented an integrated three-stage model based on IoT technology for the optimization of procurement, production and product recovery, pricing and strategy of return acquisition and proposed a novel particle swarm optimization algorithm based on two heuristic methods to solve the problem.

Aktaş et al. [3] suggested a system based IOT which allows viewing physiological data received from hospitalized babies in infant intensive care unit targeted realization within the scope of this technology both from the hospital environment and outside the hospital environment, referring to the IoT technology applications in the health field.

The aim of this study is to examine the concept of "Internet of Things" widely used in recent years and to determine the existing situation of IoT. Thus, it was strived to obtain more information about IoT that is a technology revolution. Following the introduction, the main components of IoT described in second section and current applications of IoT were discussed in the third section. Then the potential difficulties beside the opportunities of IoT were mentioned in the fourth section. And study is terminated with conclusion section.

II. FUNCTIONAL VIEW OF IOT

Internet of Things is comprised of three main components. These are;
1. Assets that represent portion of "Objects" of Internet of Things concept,
2. Networks that link these objects,
3. Computer systems that use data from the object [26].

Fig. 3 Three main components of Internet of Things [26]

Internet of Things is an interplay of smart objects and smart communication networks and include own system storage, computing, visualization and interpretation tools for data analytics [15], [22].

When objects equipped with sensors and electronic circuits, they begin to acquire properties “thinking”, "feeling" and "speaking". Thus, they have access the ability to update their own status information by contacting us [2].

Smart objects embedded device of IoT;
1. It has a unique identity.
2. It has the ability to communicate effectively with environment.
3. It has obtained and storage capability data related itself.
4. It deploys a language to show properties, production demands etc.
5. It has capable of making decisions about its own fate [27].

They can communicate and interact either among themselves, building networks of interconnected objects, or with end-users or other entities in the network [20].

Think of a cup that can access the Internet. It is able to detect what is the liquid put into it. Not only as a species; also in terms of the content-forming composition. This information can be transferred to a desired application or environment on the internet. Thus, you can examine the knowledge of fluid you drink throughout the day, for example through an application on your smart phone, at the end of the day. Cups, on top of that, can keep statistics. It can map your liquid consumption by determining what you drank in what time of day. It can suggest that you drink coffee when your coffee time. Even it can order instead of you at a nearby coffee shop [28].

Actualization of IoT into the real world is possible by the integration of several effective technologies [9]. These technologies are provided below.

A. Radio Frequency Identification (RFID)

Radio frequency identification allows automatic identification and data capture using radio waves, a tag and reader. RFID is key component of IoT system and also the newest identification technique among all IoT technologies. RFID as a technology for IoT is used to identify and track items. If objects (even people or animals) are equipped by identifiers, they can be managed and registered automatically; therefore, it is then possible to track the full transportation way of these objects [9], [14], [21].

Passive RFID are not battery-powered, therefore they use the power of the reader’s interrogation signal to communicate. Active RFID tags contain sensors and have their own battery supply and can communicate. Although passive RFID tags are sufficient for tracking, active RFID tags with embedded sensors can provide a lot more information about the usage/condition of objects. Sensor detects the changes in the value of various measures such as temperature, pressure, vibration and humidity and converts the signal to be recorded. RFID tag containing static information such as serial number, model, bill of materials, production and delivery date of the product is connected to the product and can be updated after
the operations such as each maintenance, improvement. Dynamic information such as environmental conditions occurring during use of the product, working time and frequency of the product is recorded with the help of sensors [13], [15], [21]. Fig. 4 shows building blocks of IoT.

![Fig. 4 Internet of Things](image)

**B. Wireless Sensor Networks (WSN)**

Wireless network which contains vehicles working independently and use sensors to monitor a cooperative manner physical or environmental conditions such as temperature, humidity, light, sound, pressure, pollution, soil composition, noise level, vibration, object moves in different places is called "wireless sensor network". Sensor networks play a crucial role in the IoT. Typical Wireless Sensor Networks consist of hundreds or even thousands of sensor nodes that connect via a wireless environment and exchange information with each other. Improvements in hardware and wireless system have enabled the production of low cost, low power consumption, multifunctional miniature sensing devices. Ad hoc networks can be created with the help of hundreds-thousands of these devices. For example, these devices create a wireless ad hoc network distributing over a wide geography. These sensors that distributed and formed the network generate a sensing network system by cooperating. A sensor network allows to access information easily at anytime, anywhere. It performs this function by collecting, processing, analysing and spreading data. [30].

The integration of WSN and RFID empowers IoT and makes possible to develop IoT applications [4].

**C. Middleware**

Middleware is a software layer between the technological and the application levels. Middleware architectures proposed in the last years for the IoT [9]. The complex distributed platform of the IoT requires simplifying the development of new applications and services, so use of middleware is an ideal option with IoT application development. More importantly, a centralized infrastructure to support storage and analytics is required. Storage and calculating tools for data analytics are included in middleware. The data have to be stored and used intelligently for smart monitoring and actuation. Many IoT applications require massive data storage, huge processing speed to enable real time decision making, and high-speed broadband networks to stream data. As of 2012, Cloud based storage solutions are becoming increasingly popular. Cloud computing provides an ideal back-end solution for handling huge data streams and processing them for the numerous number of IoT devices and humans in real time [1], [15], [21].

**D. Presentation**

Presentation is related to visualization and interpretation tools. These tools can be accessed on any platform and can be designed for a large variety of applications. Presentation allowed the interaction of the user with the object in real time anywhere, anytime is important for IoT systems [1], [15]. For example, IoT-enabled home appliances and devices can be monitored and controlled outside the user’s home through a computer, tablet, or smart phone due to presentations function of IoT [21].

**III. APPLICATIONS OF IOT**

Internet of Things that is called a new industrial revolution in the whole world finds itself in many fields of application possibilities. In recent years, it has attracted great attention and is used in various fields by researchers and practitioners worldwide.

Opportunities offered by the IoT make possible the development of a large number of applications [9]. IoT have been widely used in Transportation, Smart Home, Smart Factory, Smart City, Supply chain, Lifestyle Security, Retail, Agriculture, Emergency, Health care, Culture and tourism, User interaction, Environment and Energy, Library services, Food and restaurant industry and many other areas (Fig. 5). In the following subsections, a few typical applications examples are given.

**A. Smart environments**

A smart environment can be an office, home, industrial plant, city or any environment and it make our life more comfortable due to the intelligence of included objects [9].

Home appliances such as televisions, washing machines, refrigerators, air conditioners and many other devices can be controlled very efficiently, so, this smart system provide better home and energy management [1].

For example, rooms heating can be adjusted to our preferences and to the weather; lighting can change according to the time of the day; dangerous incidents can be prevented with suitable monitoring and alarm systems; and energy can be saved by automatically switching off the electrical equipments when not needed [9]. For communication between people and the smart environment a smart phone can be used. So far, there are several applications available for Apple iOS, Google Android and Windows Phone operating systems that measure various parameters [15].
B. Transportation and logistics

IoT really plays an increasingly important role in transportation and logistics. Intelligent transport systems that count vehicles on the road, calculate the travel time, determine the pits and calculate the using time of the parking place can be established with the help of sensors. Moreover, it is possible to realize better traffic management with data obtained from such a system [31].

Internet of Things means that the rich data and deep intelligence for all parties in the network from the manufacturer to the end user for supply chain. Real-time monitoring and object move tracking from an origin to a destination will be guaranteed with objects attached RFID tags or sensors so that transportation and logistics can be more efficient and accurate during the entire supply chain [16].

Some important benefits of internet of things related to the supply chain:
- The storage can be monitored in real time. Both the number of stored product and the costs can be reduced by eliminating redundant production and storage. In addition, turnaround time can be shortened; needless handling, loss and theft can be prevented.
- Prevents alteration of information enabling to store all kinds of information (Eg. Production date, expiry date, warranty period, after sales details) in objects and share by supply chain stakeholders in real-time.
- Business process optimization; smart objects used in the framework of business processes accelerate and facilitate the detection of potential problems and support the detection of a possible process optimization [32].

C. Health care

Healthcare is an important application area of IoT and in this sector, a number of applications containing IoT technologies can be found. Internet of Things offers a variety of solutions at the stage of take measures, monitories and diagnose depending on the health status. Devices can help individuals to control their own health status such as weight, body mass, sleep patterns and daily activity rate [31].

This systems include identification for reduce incidents harmful to patients such as wrong drug/dose/time/procedure. Tracking for identify of a person or object in motion. Data collection and transfer for reducing form processing time and medical inventory management. Sensing for diagnose patient conditions [9].

Patients carry medical sensors to monitor parameters such as body temperature, blood pressure, breathing activity. All
the healthcare-related information is collected by these sensors and managed efficiently and it can be able to perform advanced remote monitoring and can be capable of rapid response actions when needed. For example, fall detection application can help elderly or disabled people live more independently [16], [20]. It can be foreseen that the IoT with intelligent medical sensors will enhance the quality of life significantly and prevent the occurrence of health problems.

On the other hand, the rapid development of mobile devices and health applications creates a huge market for the application of IoT. Individual mobile health applications have been developed to serve healthcare tasks such as the measurement of blood pressure or recording of blood glucose [4].

D. Security and Emergency

Internet of Things can enhance security and help government in the emergencies. Devices that transfer information between each other quickly can be built in a condition of natural disasters or requires medical priority. Apart from that, ambient sensors can be used to monitor the presence of dangerous chemicals. Sensors monitoring the behaviour of people can be used to assess the presence of people acting in a suspicious way [20].

E. Agriculture

Internet of Things allows to establishment of smart fields that each step can be observed to increase agricultural production. The atmospheric, water, soil, and other information can be collected in real time and accurately with IoT technology to improve the efficiency and quality of agricultural production [16]. The smart irrigation systems provide ease about giving information about the condition of the soil and reducing water consumption with the aid of sensors. The system analyzes the data collected and realizes the irrigation process according to soil needs in the area where the irrigation system is installed. In addition, solutions based data offered by the Internet of things offers the option to be able to follow even the food which they eat to consumers in terms of food security [31].

Apart from these applications, many others may be envisaged many other applications that are define futuristic, because these base on some technologies that either is still coming or whose practice is still too complex[9].

IV. PROS AND CONS OF IOT

Internet of things feed on data in the continuous flow and composed of a variety of devices and millions of sensors is a technology that enables to facilitate our lives with many uses area and develop business processes. Data usability, continuous monitoring capability, time (money) savings are among the main advantages of the system. But, there are also challenges alongside opportunities that this system offers us. Although the success of IoT has confirmed the potentials, we have to confront with the challenges of IoT soon [18]. The disadvantages that are believed to be slowly eliminated result of the adoption of this technology;

A. Complexity

IoT is a very complex heterogeneous network included the connections among different networks through several communication technologies [4]. Data collected from sensors of IoT will become very large because of enormous amount of things connected internet. Current computer systems or sensors may not have enough storage to keep all this data [18]. The amount of data that will be occurred by billions of objects connected to this system will increase incredibly and this large data processing will become difficult and complex task.

B. Security and privacy

The system establishes on a huge of network system bring along the cyber security risks. Main security issues in IoT are illustrated in Fig. 6.

IoT will gather and store huge amount of personal information due to increase in connected devices. And so, this data is attractive to hackers and other cyber criminals [1]. There are many ways IoT system could be attacked disabling the network availability; pushing erroneous data into the network; accessing personal information; etc [15].

Although a number of projects have been developed for security and privacy protection, a reliable security protection mechanism for IoT is still in demand for data confidentiality, privacy, and trust [4]. This is the most important issue to prevent the use and become widespread of IoT. Therefore, valid security, privacy and trust models suitable for the IoT applications should be define and sensible solutions (such as intrusion prevention systems, firewalls) should be found in terms of technical to ensure customer privacy and security. Because, the run-up and acceptance of IOT technology will depend on the protection of users' privacy.

![Fig. 6 Security Challenges of IoT](image_url)
C. Convenience

Another concern for the Internet of Things is the problem of convenience. Since currently Internet of things is the initial phase of the idea and development, there are yet no convenience standards for labeling, monitoring equipment, providing data definition, capture and exchange, special software, end to end security and individual management etc. [10], [26], [33]. In recent years, a number of standardization activities focused tag-based technologies have been active and these standardization activities on the sensor and RFID [20].

V. CONCLUSIONS

Internet, indispensable of today, is highly effective in many areas such as education, business life, communication and daily life. But, traditional internet is not sufficient in capturing real-time data because it still depends on people. Internet of things is a technology that objects and creatures can transfer data connected to Internet without need for human-human and human-computer interaction [34]. Therefore, IoT is considered as part of the overall Internet of the future, which is likely to be dramatically different from the Internet we use today [9]. Given that humans advance and evolve by turning data into information, knowledge, and wisdom, IoT plays a very important role in the future emerging technology and it has the potential to change the world as we know it today for the better [1], [10].

If IoT that provides connection of any object, anyone, anytime and anywhere correctly applied, increase of things/objects that produce their data by themselves in real time will bring more reliable knowledge. Thus, the losses will be reduced, the waste will be prevented and after that costs will decrease. But unless required standards and rules of this system, the situations be encountered may blow innovativeness. For this, like all technological viewpoint innovations, the changes should be expected and accepted.

In conclusion, IoT represents the next evolution of the Internet and for a few years now, IoT has been developed dramatically and a great number of enabling technologies have been proposed. In this paper, some studies conducted up to this day were summarized mentioning the development of internet of things. Later, the main components of IoT described and current applications of IoT were given. Finally, the potential difficulties beside the opportunities of IoT were mentioned. It is expected that this survey will be useful for researchers and practitioners, helping them to understand enormous potential of Internet of Things and in addition this, to foresee the challenges of IoT which will be encountered.

An Expert System for Boring Tools Used for Machining Holes

Atakan Ugras * and Yunus Kayir*

Tavşanlı MYO, Dumlupınar Üniversitesi, Kütahya, atakan.ugras@dpu.edu.tr

*Teknik Eğitim Fakültesi, Gazi Üniversitesi, Ankara, yakayir@gazi.edu.tr

Abstract—Boring is a finish operation that widely used to machine the holes on the mechanical parts in manufacturing industry. The Boring also is a method that is usually preferred to size holes that can meet the appropriate tolerance. There are many tools for boring process in the world wide. Generally, Boring tools were parted two groups that are milling and turning. The boring tools especially for milling were packed in many set that include head, bars, etc. Decision of using any set in these packed is not easy exercise. For this reason, selection suitable head, bars, cutting tools and cutting conditions need long preparation time and good expertise for boring process in milling. Because of the quality of holes is depended by determining these parameters rightly.

In this study, an expert system that is called BT_expert was developed for using the boring tools in milling. BT_expert was built up by using an expert system shell that is called Kappa PC. Kappa PC is preferred because of programming with C++. BT_expert has a friendly user interface that is designed visual objects. A lot of rules about 70 are written for BT_expert. The system asks a few simple questions to user about boring process. And, BT_expert can make a decision by using forward chaining mechanism. Finally, BT_expert system determines the boring bars, cutting tools and ideal cutting parameters automatically.

As a result, BT_expert system makes easy to select boring and cutting tools, and cutting parameters correctly in many set without any expert. And, the system decrease the long preparation time of boring process.

Keywords—Boring, Boring tools, Milling, Expert System, Kappa PC

I. INTRODUCTION

Nowadays, computers’ hardware and software use easily for many applications in many areas. For example, machining is a very important area that is widely used computers and programs. Computers and programs provide a lot of advantages, such as speed, accuracy, lower costs, etc. Generally, computer programs have an algorithm. So, solutions of these programs are not enough for all application. Because, an expert decision require for some application. In addition, many years need to be an expert of a person in a sector. For this reason, a lot of expert systems were developed on the world. Expert Systems (ES) have very special programs. These systems solve a problem according to rules obtained from the knowledge of the experts. In other word, the ES evaluate knowledge, the classical programs that have algorithm evaluate evident data. Thus, ES provide to use expertise at any time without an expert person.

ES is a technique used in artificial intelligence discipline. Moreover, there are a lot of techniques such as neural networks, genetic algorithm, fuzzy logic, image processing, in artificial intelligence discipline. Especially, ES [1], [2] and neural networks [3] well as various programs are used in the process sequence. Also, ES is an intelligence program that uncovers an expert thinking and behaviour for a specific area [4]. ES can calculate the data and make inferences something by using about information in the knowledge base. Thus, they provide fast and reliable solutions for special problems. ES is an interactive system for experts in many areas.

Expert systems were improved with different capabilities for many areas since computers were invented. Especially, these systems rapidly climbed high level in 20th century. However at present time, new expert systems have been implementing to solve problems and select optimal parameters (boring tools, material, cutting tools and cutting conditions) in machining industry in the world. Some studies carried out in this direction are summarized below.

Tan, et al. [1] have designed a selection of cutting tools of expert and have checked the accuracy of the system for CNC turning. An expert system called EXTOOL developed by D. Mookherjee and Bhattacharyya [2]. The program stated that the process for the customer’s choice of material and types for cutting lathes and milling enables automatic determination based on geometry. An expert system for the selection of cutting tools and turning conditions were developed by Arezoo et al. [5]. Sapuan, et al. [6] were developed a system of specialist material election for tools and components for ceramic matrix composite. Er and Dias [7] were improved an expert system engineering components, based on which the selection rule for the production of casting system. Kayir, et al. [8] were built up an expert system by using Leonardo shell program for selection optimal cutting tools and operation for drilling holes. Poyrazoglu, et al. [9] were implemented an expert program to choose right operation from non-traditional machining methods.

In this study, an expert system called BT_expert was developed for machining of various size holes. BT_expert selects the optimal boring tools that are commonly used for machining holes desired with geometrical tolerances. The system was built up with KAPPA-PC expert shell program. BT_expert system contains 4 modules. They are database module, reasoning (inference engine) module, user interface module and knowledge base module. BT_expert makes a decision for selecting an optimum boring cartridge, cutting
tool (insert type and radius), cutting parameters (cutting speed, feed rate). It has user interface that includes screen pages formed menus, buttons. User can input or change data on these pages. The system can be used easily by any man (engineer, worker, etc.). BT_expert reduces planning time and improves product quality because of choice right boring cartridge and the insert and cutting parameters for boring operations.

II. BORING TOOLS

Boring machining can be referred as one of the difficult process in machining. Boring process is widely performed on the lathe and milling machine tools. Boring process is process of completing finished final dimensions and tolerances by upsizing parts of which first bore is drilled. The machining process is performed as a finish work. After performing the boring process, additional boring operations cannot be performed on the hole. Hole is ready to use. Boring process is similar to the hole turning on the lathe, but in this process boring tool rotates not workpiece. Hole is machined by performing an eccentric movement of the boring tool.

In boring process a lot of boring tools are used. Boring tools exist in different sets that include a lot of parts in the market. In addition to different types of boring tools in the market, boring tools are classified according to specialties of hole which will be processed. (rough and finish etc.). Classified boring sets (Fig.1) are capable of machining specific diameter hole in specific circumstances. It is required that a boring cartridge is determined according to first hole and final hole shown at Fig.1.

One of the subjects which have to be considered is that diameter of the selected boring cartridge is not too smaller than the first bore of workpiece.

The other subject is that the length of the selected tool is not too longer than the hole’s length. In this study by looking L/D rate, the determination of boring cartridge is done. L shows deepness of the hole and D shows the diameter of the final hole. Programme offers a higher level boring cartridge when L/D rate is higher than 2.5. If this case is not paid attention in Boring tool that will be used, chatters are observed over the hole surface. Abele et al., in their study, placed a damping system to shaft of boring tool for preventing chatters [11].

II. Boring Tools

Boring machining can be referred as one of the difficult process in machining. Boring process is widely performed on the lathe and milling machine tools. Boring process is process of completing finished final dimensions and tolerances by upsizing parts of which first bore is drilled. The machining process is performed as a finish work. After performing the boring process, additional boring operations cannot be performed on the hole. Hole is ready to use. Boring process is similar to the hole turning on the lathe, but in this process boring tool rotates not workpiece. Hole is machined by performing an eccentric movement of the boring tool.

In boring process a lot of boring tools are used. Boring tools exist in different sets that include a lot of parts in the market. In addition to different types of boring tools in the market, boring tools are classified according to specialties of hole which will be processed. (rough and finish etc.). Classified boring sets (Fig.1) are capable of machining specific diameter hole in specific circumstances. It is required that a boring cartridge is determined according to first hole and final hole shown at Fig.1.

One of the subjects which have to be considered is that diameter of the selected boring cartridge is not too smaller than the first bore of workpiece.

The other subject is that the length of the selected tool is not too longer than the hole’s length. In this study by looking L/D rate, the determination of boring cartridge is done. L shows deepness of the hole and D shows the diameter of the final hole. Programme offers a higher level boring cartridge when L/D rate is higher than 2.5. If this case is not paid attention in Boring tool that will be used, chatters are observed over the hole surface. Abele et al., in their study, placed a damping system to shaft of boring tool for preventing chatters [11].

II. BORING TOOLS

Boring machining can be referred as one of the difficult process in machining. Boring process is widely performed on the lathe and milling machine tools. Boring process is process of completing finished final dimensions and tolerances by upsizing parts of which first bore is drilled. The machining process is performed as a finish work. After performing the boring process, additional boring operations cannot be performed on the hole. Hole is ready to use. Boring process is similar to the hole turning on the lathe, but in this process boring tool rotates not workpiece. Hole is machined by performing an eccentric movement of the boring tool.

In boring process a lot of boring tools are used. Boring tools exist in different sets that include a lot of parts in the market. If this case is not paid attention in Boring tool that will be used, chatters are observed over the hole surface. Abele et al., in their study, placed a damping system to shaft of boring tool for preventing chatters [11].

II. BORING TOOLS

Boring machining can be referred as one of the difficult process in machining. Boring process is widely performed on the lathe and milling machine tools. Boring process is process of completing finished final dimensions and tolerances by upsizing parts of which first bore is drilled. The machining process is performed as a finish work. After performing the boring process, additional boring operations cannot be performed on the hole. Hole is ready to use. Boring process is similar to the hole turning on the lathe, but in this process boring tool rotates not workpiece. Hole is machined by performing an eccentric movement of the boring tool.

In boring process a lot of boring tools are used. Boring tools exist in different sets that include a lot of parts in the market. In addition to different types of boring tools in the market, boring tools are classified according to specialties of hole which will be processed. (rough and finish etc.). Classified boring sets (Fig.1) are capable of machining specific diameter hole in specific circumstances. It is required that a boring cartridge is determined according to first hole and final hole shown at Fig.1.

One of the subjects which have to be considered is that diameter of the selected boring cartridge is not too smaller than the first bore of workpiece.
So, there are a lot of parameters correctly determined for successful operation in boring machining. Especially, boring tools, insert cutting tools and cutting parameters must be chosen correctly to get precision and desired tolerance. Mistakes made in their selection cause faults on machined holes and used tools. In a study, Rao et al. try to estimate the occurred vibration, the surface roughness and the tool wear during the machining hole on AISI 316 material by using artificial neural networks [10].

III. BT_EXPERT SYSTEM AND BORING TOOL SELECTION

KAPPA-PC expert shell program was used to develop a system that is called BT_expert system for holes machining. BT_expert system was designed for two main objects that are boring tools, cutting tools and cutting parameters. There are several factors for preference the KAPPA_PC shell program to develop BT_expert. KAPPA PC expert shell program is suitable program to improve any application in field of machining sector [12]. In addition, KAPPA-PC is an object oriented program. In KAPPA-PC program all objects are connected each other with a tree structure form (Fig. 3).

To get the best solution, about 72 rules were written in this study. Generally, structure of rules consists of “IF” and “THEN” words. The word of “IF” is used to determine the conditions. All conditions in rules are linked with “AND” words. The word of “THEN” leads to the conclusion. A sample rule written in the BT_expert is given at Fig. 4.

Moreover, name of the rules and task, and numbers of each task about 72 rules written in the BT_expert rule base are shown at Table 1.

Rules defined in the BT_expert rule base automatically associated with each other. For example the connection of Barasecimi 1 with other rules in the BT_expert rule base is shown at figure 5. Generally, two methods are used to evaluate rules for solution of any problem in expert shell programs. These are forward chaining and backward chaining method. The BT_expert rule base was designed to use forward chaining method. The solution of the forward chaining method starts from condition (IF) sentence and ends conclusion (THEN) sentence. If the conditions are satisfied, conclusion is true in “THEN” part.

Several pages were designed to input and output data for BT_expert. Visual objects were used on these pages that interact with the user. These pages are named as SESSION. When the BT_expert runs, the first page named “Boring Tool” is shown on the computer’s screen. Boring tool page is used to determine boring tools (fig. 6). First holed diameter, final holed diameter (D) and length (L) of hole have to be defined on this page. The system determines suitable boring cartridge from boring bar set according these data.

In addition, the BT_expert decides insert radius by considering half of difference between the first diameter and the final diameter. An insert radius is determined according to an experimental rule. It is known that insert radius is not smaller than chip thickness in machining operations. Then, the “Material selection” page (fig. 7) is switched after entering first diameter, final diameter (D) and length (L) on the first page. Material type is selected from this page. Finally, The system automatically select a boring cartridge, an insert and cutting parameters after entering hole information and material (fig. 7). In BT_expert, L/D rate is used in determining of cutting parameters. L/D rate are also important for set of boring tools (boring cartridge).

For example, when the final diameter of hole is 25 mm and the length of hole is 64 mm (fig.6), the program determines boring cartridge of which number is B3.22 by using the information in figure 3. In this example L/D rate is 4 (fig.8). BT_expert offers lower cutting speed (m/min) and feed rate (mm/rev) when L/D is higher than 2.5. The cutting speed (m/min) and the feed rate (mm/rev) by considering material type, L/D rate and insert radius. The system gives different cutting speed and feed rate when the finish cut calculated for bore decreases and the material or L/D rate change. The BT_expert system performs quickly, easily and safely selection of required boring tools, insert, cutting tools and cutting parameters. According to material of which is bored, the system can determine optimum boring cartridge, cutting speed, feed rate, insert quality and insert radius. Material selection entered on the page, first and last bore diameters and bore length are shown in the conclusion page of the BT expert system (fig 8)
The solution of the BT_expert for user inputs is shown on the solution page (fig. 8). BT_expert’s solution page has many parts. And, this pages that interact user has many active buttons. In other word, user can use page’s output data (get solution from BT_expert) for boring machining or user can run BT_expert program for new solution with page’s buttons. The solution output data is automatically painted with red colour. Red colour data is the best results. The best results that are boring cartridge, cutting speed, feed rate, and insert type and radius are shown blow of the page. User accept these parameters and use for hole machining. Otherwise, user runs the program by pressing “Run” button. In this case, all operation of BT_expert restarts.

IV. CONCLUSIONS

For precision bore machining, BT_expert system that determines the boring tool, the insert and cutting parameters, were implemented. This study will assist technicians and engineers to determine boring tool that widely used in precision bore machining, insert and cutting parameters. The system that has a simple structure can be used easily. Some additional studies can be done to improve this system. More technical data and details can be added to the database. The improved expert system can be evaluated in the machining sector. New boring tool, insert, material datum and cooling type (dry, coolant) can be added to the database. The user interface can be improved by adding new page and buttons. The tool holder manufacturing firms can develop software similar with BT_expert system besides the catalogues.

Multi-Core Computing Application for Lyapunov Exponents Analysis of Chaotic Systems

Sezgin Kaçar*, Akif Akgül*, Burak Arıçoğlu*

* Sakarya University, Technology Faculty, Electrical – Electronics Engineering, Sakarya, Turkey

{skacar, aakgul, baricioglu}@sakarya.edu.tr

Abstract— The Lyapunov exponents analysis is one of the stability analyses of nonlinear systems. In addition, this analysis method is also used for obtaining information about chaos that is a behavior of nonlinear systems. In this study, it is explained by an example application that the chaotic behavior analysis of a nonlinear chaotic system based on the Lyapunov exponents can be performed faster by a Multi-Core CPU. For this application, MATLAB parallel processing toolbox has been used and the parallel computing performance of the application has been analysed by using obtained results.

Keywords— Chaotic systems, Parallel processing, Lyapunov exponents

I. INTRODUCTION

The models of nonlinear systems are used for modelling and assessing the behavior of the systems that we encounter. One of the behavior types of the nonlinear systems is the chaotic behavior. For a nonlinear system to show chaotic behavior, the system’s parameters and initial values must be appropriate to the chaotic behavior. The nonlinear systems which show chaotic behavior for the appropriate values are called chaotic systems. With the Lyapunov exponents analysis it can be determined that whether the system exhibits chaotic behavior or not for the given parameters values.

The Lyapunov exponent analysis is used widely to explain dynamical behavior of nonlinear systems [1-4]. The largest Lyapunov exponent to be positive means the system is chaotic. The algorithms that calculate the Lyapunov exponents from time series are available [5-9]. In addition to this, the programs or codes that use these algorithms are also available [10-14]. All these algorithms, programs, or codes calculate the Lyapunov exponents for a certain parameters values or as a function of a single system parameter.

For examining the behavior of the chaotic systems, analyses which employ the Lyapunov exponent spectra are commonly used. The calculation of the Lyapunov exponents for a single system parameter value does not take too much time. However to obtain the Lyapunov exponents spectrum, the Lyapunov exponents must be calculated for too many parameter values. For a precise analysis, the number of the system parameter values must be as high as possible. This makes obtaining better spectrum take much more time.

In this study which differs from studies in the literature, the Lyapunov exponent spectrum obtained faster via parallel computing application in a PC with multi-core CPU. For this application MATLAB Parallel Computing Toolbox was used. The performance of the application was assessed according to speed and efficiency.

In the next section of this article, the algorithm that uses Lyapunov exponent is introduced. In the third part, Lorenz chaotic system and its Lyapunov exponent spectrum is presented as an example. In the fourth part, the realized parallel computing application is mentioned. In the fifth part the performance of the parallel computing is assessed. In the last part, discussion and evaluation is given.

II. LYAPUNOV EXPONENTS ANALYSIS

The Lyapunov exponents are calculated analytically as in Equation 1 [6].

\[ \lambda_i = \lim_{t \to \infty} \left( \ln \frac{P_i(t)}{P_i(0)} \right) \]

(1)

Fig. 1. Divergence of two trajectories

Here \( \lambda_i \) and \( p_i \) represents the Lyapunov exponents and the vectors given in Fig. 1 respectively. As it can be seen in the equation 1, the values of Lyapunov exponents depend on the distance between chosen points that are at two infinitesimally close trajectories in the phase portraits of the chaotic system. Moreover, the number of the Lyapunov exponents also equals to the dimension of the chaotic system.

To calculate the Lyapunov exponents analytically the values of \( p_i \) must be determined. Determining the values requires many different processes [5, 6]. As an alternative to...
this, many algorithms for calculating the Lyapunov exponents from time series have been proposed. [5-9]. In this study, the MATLAB code that is proposed by [11] which employs the algorithm in [6] is used.

The signs of the Lyapunov exponents give information about the dynamical behaviors of the systems. For a 3-D system, the dynamical behaviors of the system according to the signs of the Lyapunov exponents are given in Table 1. If one of the Lyapunov exponent is positive, systems exhibits chaotic behavior. In this way, the chaotic systems can be determined with the Lyapunov exponent analysis.

Another usage area of the Lyapunov exponents analysis is calculating the chaotic dimension [5, 6]. The chaotic dimension gives information about how chaotic the system behavior is. The chaotic dimension is calculated as in Equation 2 [6].

\[
d_f = f + \sum_{i=1}^{j} \lambda_i / j^{j+1}
\]

Here the term \( j \) is determined according to \( \sum_{i=1}^{j} \lambda_i > 0 \) and \( \sum_{i=1}^{j} \lambda_i < 0 \).

III. PARALLEL COMPUTING APPLICATION OF THE LYAPUNOV EXPONENT ANALYSIS

Nowadays most of the PCs have multi-core CPUs. To use this feature to its full potential in Computer-aided computation, parallel computing techniques are required. There are two basic approaches in the parallel computing techniques. The first one is task parallel technique in which the different processes are done simultaneously and the other one is data parallel technique in which the pieces of a huge data undergo to the same process in parallel.

To obtain The Lyapunov exponents spectrum, the Lyapunov exponents are calculated for many different values of a parameter of the nonlinear system. The graph of the Lyapunov exponents is drawn with respect to the system parameter. By examining this spectrum, the chaotic behavior of the system is commented on.

In this study, faster obtainment of the Lyapunov exponents spectrum with data parallel technique in a multi-core CPU PC was realized. The realized parallel computing application is seen in Fig. 2.

![Fig. 2. The realized multi-core computing application](image)

The parallel computing application in Fig. 2, to obtain the Lyapunov exponents spectrum n core processor is used. Moreover the system parameter take m number values between a and b. Each processor calculates Lyapunov exponents for m/n number of system parameter values.

After this, these results are brought together to obtain the Lyapunov exponent spectrum. The parallel computing application mentioned above was realized with parfor loop in MATLAB Parallel Computing Toolbox.

A. MATLAB Parallel computing toolbox and Parfor Loop

MATLAB Parallel Computing Toolbox is developed for parallel computing problems by using multi-core processors, graphic processing units (GPUs) and computer clusters. By using parfor which executes loop iterations in parallel, special series types and parallelized numerical algorithms it is possible to developed parallel computing applications without programming CUDA or MPI [15].

Parfor (parallel-for) in MATLAB iterates statements in the loop over a specified range of values like standard for-loop but in parallel. The logic of operation of parfor is shown in Fig. 3 MATLAB Client runs the parfor loop code while the iterations are run on MATLAB Workers [15]. Each Workers are run on different core. MATLAB parfor structure is shown in Fig. 3. In this structure the parallelization can be done up to with twelve workers.
B. Obtaining Lyapunov Exponents Spectrum with Parallel Computing: Lorenz Chaotic System

In this section, the Lyapunov exponents spectrum of a common chaotic system, Lorenz system, was obtained via parallel computing. The Lorenz system is defined as in Equation 3.

\[
\begin{align*}
\dot{x} &= \alpha(y-x) \\
\dot{y} &= x(\beta - z) - y \\
\dot{z} &= xy - \lambda z
\end{align*}
\] (3)

The parameters of the Lorenz system in Equation 3 must be at certain values in order to the system exhibits chaotic behavior. To determine the parameters values the Lyapunov exponents spectrum is obtained. In Fig. 4, Lorenz system’s Lyapunov exponents spectrum in terms of \( \alpha \) is given. This spectrum was obtained for the parameter \( \alpha \)'s values are between 5 and 20, the parameters \( \beta \) is 28, \( \lambda \) is 8/3 and the initial values is 1,1,1 for \( x, y, \) and \( z \) respectively.

As it can be seen in Fig. 4, there is no positive Lyapunov exponent if the parameter \( \alpha \)'s value is between 5 and 5.6 or 18.4 and 20, and for these ranges two of the Lyapunov exponents are zero and the other one is negative \((0,0,-)\), thus the system shows two-tours behavior. When the parameter \( \alpha \)'s value is between 5.8 and 18.3 there is a positive Lyapunov exponent, hence the system shows chaotic behavior.

The time results in Table 3 was acquired by using sequential and parallel computing with 2, 4, 6 and 8 cores for the obtainment of the spectrum in Fig. 4. The specifications of the multi-core PC is given in Table 2. The performance assessment of the parallel computing application was done in section 3.3 by evaluating the results in Table 3.

C. The Performance Assessment of the Parallel Computing

In the parallel computing applications, the properties of the computer, the algorithm, and computing load and complexity have an impact on the performance of the application. For this reason, in a parallel computing with an n-process unit, the computing speed cannot reach n times of that of non-parallel computing. Hence, efficiency and cost are taken consideration, in parallel computing. Equations 4, 5 and 6 are used in assessment of the parallel computing to calculate speed, efficiency and cost respectively [16].

\[
S_p = \frac{T^*}{T_p} \quad (4)
\]

\[
E_p = \frac{S_p}{p} \quad (5)
\]

\[
C_p = T_p \times p \quad (6)
\]

In these equations, \( p \) is the number of processor unit, \( T^* \) is the elapsed time when single-core processor is used, \( T_p \) is the elapsed time when \( p \)-core processor is used and \( S_p, E_p, \) and \( C_p \) are defined as speedup, efficiency and cost respectively.

In Fig. 5, the graphs of the performance analysis of Table 3 is given. These graphs includes speedup, efficiency and cost analysis for 2, 4, 6 and 8 core process units.
When Fig. 5 is examined, the result is obtained faster with parallel computing. As the number of the core increases the speed of the calculation is increased. However, as the number of the core increases the cost and efficiency for the obtainment of the Lyapunov exponents spectrum with parallel computing does not improve like speedup. In fact, the efficiency decreases dramatically and the cost increases as the number of the core increases. This situation is encountered in most of the application in PCs. The reason for this the increase in the parallel overhead with the number of the core used and reaching the maximum capacity of PC’s data transmission rate. This leads to negative effect on both cost and efficiency. Another reason for low efficiency and high cost is the CPU has not real 8 cores but virtual 8 cores. Thus, the increase in speedup and efficiency is much more in the computing application with 2 and 4 cores.

In this study, faster obtainment of the Lyapunov exponents spectrum is realized. For more efficient result, more appropriate hardware and programs should be employed. Moreover, if the dimension of the computing program increases the efficiency and cost will be at an acceptable level.

**IV. CONCLUSIONS**

In the proposed study, an application of parallel computing for faster obtainment of Lyapunov exponents spectrum is realized with a multi-core PC. In the application, as the number of core used increases the speed of the computing application increases, but the cost increases and efficiency decreases dramatically because of the PC’s limitations such as parallel overhead and data transmission rate .However, employing parallel computing for obtainment of the Lyapunov exponents spectrum is a sound approach when considering the speed of the computing. For more complex systems, the number of values to be calculated and the dimension of the problem increases, hence the efficiency of the parallel computing increases. In a future study, the Lyapunov exponents analysis of more complex systems will be examined.
Estimation of Turkey Electric Energy Demand Until Year 2035 Using TLBO Algorithm

M. Fatih TEFEK*, Harun UĞUZ*

*Ahi Evran University, Kırşehir/Turkey, mftefek@ahievran.edu.tr
*Selcuk University, Konya/Turkey, harun_uguz@selcuk.edu.tr

Abstract— In this study, the estimation of Turkey primary electric energy demand until 2035 is tried to estimate by using Teaching-Learning Based Optimization (TLBO) Algorithm. Two models are proposed which are based on economic indicators TLBO algorithm linear energy demand (TLBOEDL) and TLBO algorithm quadratic energy demand (TLBOEDQ). In both of these two models the indicators used are Gross Domestic Product (GDP), population, importation and exportation. After a comparison of these two models with real values between 1979 and 2005 years, it is applied to the estimation of Turkey electric energy demand until 2035 by three different scenario. The estimation results are suitable with the estimation of Turkey total primary energy supply of 2013 Energy Report of World Energy Council Turkish National Committee (WEC-TNC).

Keywords— Teaching Learning Based Optimization (TLBO) Algorithm, Energy Demand Estimation, TLBOEDL Model, TLBOEDQ Model, Turkey Energy Report 2013

I. INTRODUCTION

Energy is the most important need of developed and developing countries. Energy is an indispensable fact which its importance has been growing gradually. It is the most important means in the development of countries. Energy consumption has been increased with the growth in world population. The economic growth leads to energy consumption and energy consumption leads to economic growth [1]. Therefore the energy demand has been increasing despite important nuclear power plant accidents and financial crisis. Foreign energy dependency of Turkey as % 70 percentage obliges the special policies and special behavior styles as society on energy subject [2].

To meet the electrical energy of society economically, supply, demand, transmission, contribution and pricing policies should be constituted effectively. Moreover, ease of use of electrical energy for consumers, non-storability of electrical energy increases the importance of demand studies on electrical energy area [3]. Energy demand estimation has a critical role in energy agreement between countries. The excessive deviation leads to the economical deficits.

Although demand studies on energy have been studies in Western countries for a long time, the studies have accelerated at the end of 1990s in our country. State Planning Organization, State Statistical Institute and Ministry of Energy and Natural Sources have been used the mathematical models for the energy demand at the last of 1970s [4].

Recently, many studies on the Turkey primary energy demand have been done. In these studies, different methods, different scenarios with various data and variables for many terms have been used [3]. Some studies on this research area are the energy demand estimation by Artificial Neural Networks (ANN) [8-10], energy demand by Ant Colony Optimization (ACO) [11] and energy demand estimation by hybrid Algorithm [12].

Generally, any event which is wanted to model in terms of estimation by mathematically, as the numbers of variables are getting increased, correct estimation possibility decreases [3]. In this study, the estimation of Turkey energy demand until 2035 is try to estimate by using some economical variable indicators such as Gross Domestic Product (GDP), population, importation and exportation.

II. TEACHING LEARNING BASED OPTIMIZATION (TLBO) ALGORITHM

TLBO algorithm is a social based optimization algorithm which depends on interaction between students and teachers in a class. At every step of algorithm, successful students are elected and the best students have been determined [13].

It has three parameters which is the number of students, number of classes and iteration number. TLBO algorithm has two phases which are teacher and student phases.

At teacher phase of the algorithm, students learn from the teacher by imitating. Teacher is the most experienced and the most informed person so the best student can learn as much as the teacher.
Between teacher and student’s learning capacity, there is an average difference called difference mean and it is defined as Eq. 1.

\[
\text{Difference Mean}_{i} = r_{i}(X_{j,best,i} - T_{M,i})
\]

(1)

where \( r_{i} \) is a random number between 0 and 1, \( X_{j,best,i} \) is the result of teacher (the best result) and \( T_{f} \) is teaching factor between 1 and 2.

\( T_{f} \) is defined as Eq. 2,

\[
T_{f} = \text{round}[1 + \text{rand}(0,1) \{1.2\}]
\]

(2)

If difference mean is better than present result, Eq. 2 is arranged as Eq. 4, the best function result is given by Eq. 3.

\[
X'_{j,best,i} = X_{j,best,i} + \text{Difference Mean}_{j,k,i}
\]

(3)

where \( X'_{j,best,i} \) is the best function result accepted.

After teacher’s phase, all best function values are kept to use at student’s phase. At this stage, students learn the knowledge by interacting and by discussing between them. If a student is more knowledgeable, the other is updating himself by interaction.

\[
P_{i} = \text{random between 1 and 2}.
\]

(4)

where \( X_{total-P,i} \) and \( X_{total-Q,i} \) are updated values of \( X_{total-P,i} \) and \( X_{total-Q,i} \).

If \( X_{total-P,i} > X_{total-Q,i} \) \( X'_{j,P,i} \) is obtained as Eq. 5

\[
X'_{j,P,i} = X_{j,P,i} + r(X_{j,P,i} - X_{j,Q,i})
\]

(5)

and if \( X_{total-Q,i} > X_{total-P,i} \) \( X'_{j,P,i} \) is obtained as Eq. 6

\[
X'_{j,P,i} = X_{j,P,i} + r(X_{j,Q,i} - X_{j,P,i})
\]

(6)

\( X'_{j,P,i} \) is accepted as the best function value [13].

III. ESTIMATION OF TURKEY ENERGY DEMAND WITH TLBO (TLBOED)

Economical variable indicators such as Gross Domestic Product (GDP), population, importation and exportation for energy demand estimation is try to estimate by using TLBO algorithm. TLBOEDL and TLBOEDQ models are proposed depending on economic indicators. It is seen from the literature that Linear and quadratic models have been studied commonly [11, 12, 14-16].

Economic indicators of Turkey between 1979 and 2005 are given in Table I [17, 18].

</table>

The linear model proposed by TLBO algorithm as in Eq. 7,

\[
E_{TLBOEDL} = w_1 X_1 + w_2 X_2 + w_3 X_3 + w_4 X_4 + w_5
\]

(7)

Quadratic model equation is given in Eq. 8,

\[
E_{TLBOEDQ} = w_1 X_1 + w_2 X_2 + w_3 X_3 + w_4 X_4 + w_5

+ w_6 X_1 X_2 + w_7 X_1 X_3 + w_8 X_1 X_4

+ w_9 X_2 X_3 + w_{10} X_2 X_4 + w_{11} X_3^2 + w_{12} X_4^2

+ w_{13} X_3 X_4 + w_{14} X_2^2 + w_{15}
\]

(8)

\( w_i \) and \( X_i \) coefficients are used in two proposed models. \( w_i \) coefficients are defined as design parameters. There isn’t any limitation for design parameters \((-\infty < w_i < +\infty)\).

\( X_1, X_2, X_3, X_4 \) are constants and these are defined as Gross Domestic Product (GDP), population, import and export
respectively. The objective function in energy demand estimating is given by Eq. 9,
\[ \min f(v) = \sum_{r=1}^{m} (E_f^{observed} - E_f^{predicted})^2 \]  
(9)

where \( E^{observed} \) and \( E^{predicted} \) are the actual and predicted energy demand, respectively, \( m \) is the number of observations.

We give the algorithm of our TLBOED method below:

Step 1. Define the optimization problem and initialize the optimization parameters.
- Initialize the population size \( (P_n) \), number of generations \( (G_n) \), number of design variables \( (D_n) \), and limits of design variables \( (U_1, L_1) \).
- Define the optimization problem as Eq. 10:
\[ \min f(v) = \sum_{r=1}^{m} (E_f^{observed} - E_f^{predicted})^2 \]  
(10)

Subject to \( w_i \in w_i = 1,2,\ldots,D_n \)
where \( f(v) \) is the objective function, \( w \) is a vector for design variables such that \( -\infty < w_i < +\infty \).

Step 2. Initialize the population.
- Generate a random population according to the population size and number of design as Eq. 11 variables.
\[ \text{population}= \begin{bmatrix} w_{1,1} & w_{1,2} & \ldots & w_{1,D} \\ w_{2,1} & w_{2,2} & \ldots & w_{2,D} \\ \vdots & \vdots & & \vdots \\ w_{P_n,1} & w_{P_n,2} & \ldots & w_{P_n,D} \end{bmatrix} \]  
(11)

Step 3. Teacher phase.
- Calculate the mean of the population column-wise, which will give the mean for the particular subject as Eq. 12,
\[ M_{i,D}=[m_1, m_2, \ldots, m_D] \]  
(12)

The best solution will act as a teacher for that iteration in Eq. 13,
\[ W_{teacher} = W_f(W) = \min \]  
(13)

The teacher will try to shift the mean from \( M_{i,D} \) towards \( W_{teacher} \) which will act as a new mean for the iteration. So,
\[ M_{new,D} = W_{teacher,D} \]  
(14)

The difference between two means is expressed as Eq. 15,
\[ \text{Difference},_D = r (M_{new,D} - T_F M_{i,D}) \]  
(15)

The value of \( T_F \) is selected as 1 or 2. The obtained difference is added to the current solution to update its values using Eq. 16.
\[ W_{new,D} = W_{old,D} + \text{Difference},_D \]  
(16)

Accept \( W_{new} \) if it gives better function value.

Step 4. Learner phase.
- Learner modification is expressed as
For \( i = 1 : P_n \)
Randomly select two learners \( W_i \) and \( W_j \), where \( i \neq j \)
If \( f(W_i) < f(W_j) \)
\[ W_{new,i} = W_{old,i} + r (W_i - W_j) \]
Else
\[ W_{new,i} = W_{old,i} + r (W_j - W_i) \]
End If
End For
Accept \( W_{new} \) if it gives a better function value.

Step 5. Termination criterion.
- Stop if the maximum generation number is achieved; otherwise repeat from Step 3.

IV. EXPERIMENTAL STUDIES

TLBOED algorithm is proposed for Turkey energy demand estimation between 1979 and 2005 years by using economic indicators taken from MENR. Minimum objective function is obtained by calculating for TLBOEDL model. In Eq. 17, population size \( (P_n) \) is taken as 25, number of design variables \( (D_n) \) are taken as 5 and the number of generations \( (G_n) \) is taken as 1000 and \( f(v)_{TLBOEDL} \) is obtained as 41,712.
\[ E_{TLBOEDL} = 0,003805955X_1 + 1,9122747919X_2 + 0,3735435225X_3 - 0,4835157988X_4 - 55,89091016 \]  
(17)
Minimum objective function is obtained by calculating for TLBOEDQ model. In Eq. 18, population size (P) is taken as 25, number of design variables (Dn) are taken as 15 and the number of generations (Gn) is taken as 10,000. Minimum f(v)TLBOEDQ is obtained as 19,32921.

\[
E_{TLBOEDQ} = -0.01833664807X_1 + 0.1271526268X_2
-0.7303814145X_3 + 1.5173167741X_4
+0.0057624768X_5 + 0.0118978356X_6X_7
-0.0079494952X_8X_9 - 0.0013078678X_2X_3
-0.0149756126X_4X_5 + 0.0365796927X_4X_6 (18)

TLBOEDL and TLBOEDQ estimation models were executed for 50 times and best results were considered by given parameters in Eq. 17 and Eq. 18.

TLBOEDL and TLBOEDQ models which are formed by taking the data from Table II are effective and successful according to data between 1996 and 2005 years.

In Table II, the biggest decrease in energy demand is in 2001. In Table I, a considerable decrease is seen for the same year 2001. This situation results from the economic crisis in 2001.

Three different scenario have been constituted for Turkey 2013-2035 energy demand estimation. Scenarios are made by utilizing the data from Turkish Standards Institute [17]. Scenarios are compared to 2006-2012 demand [18] and our estimation models in Table III, Table IV, and Table V. At later stage, estimations until 2035 is obtained.

Table V: Energy demand estimation of TLBOED between 2006 and 2012 years according to scenario 3.

From the Tables (III-V), the estimations by TLBOED model is close to the observed demand values. According to these tables,
decrease in the demand in 2008-2009 years shows that the crisis worldwide was affected the Turkey as little.

Scenarios are compared to Turkey primary energy supply and demand estimations according to World Energy Council Turkey National Committee.

Scenario 1: It is assumed that the average growth rate of GDP is 4.7%, population growth rate is 0.11%, import growth rate is 4.5%, and export growth rate is 2% during the period of 2013-2035. The obtained results are compared to WEC-TNC Turkey 2013 Energy Report in Table VI and Figure 1.

Scenario 2: It is assumed that the average growth rate of GDP is 5%, population growth rate is 0.12%, import growth rate is 5%, and proportion of import covered by export is 2.5% during the period of 2013-2035. The obtained results are compared to Turkey 2013 Energy Report in Table VI and Figure 2.

Scenario 3: It is assumed that the average growth rate of GDP is 4%, population growth rate is 0.09 %, import growth rate is 4%, and export growth rate 2% during the period of 2013-2035. The obtained results are compared to WEC-TNC Turkey 2013 Energy Report in Table VI and Figure 3.

In Table VII, energy demand estimations which was done in some years according to WEC-TNC Turkey Energy Report 2013 are seen [2]. The graphics in Figures (1-3) is obtained as a result of a comparison in Table VII.

Figure 1: Energy demand estimations realized between 2006 and 2035 years according to scenario 1 in MTOE.

Figure 2: Energy demand estimation realized between 2006 and 2035 years according to scenario 2 in MTOE.
Countries must balance the energy supply and demand. Therefore they make agreements between them. Our country is a foreign dependent country as energy sources. This dependency is obliged us to an appropriate and consistent energy policy with the other countries. Energy demands according to Country needs will contribute the savings to the national economy. Excessive deviations in estimating country demands will result the much more natural gas import so the dependency in energy will be risen.

In this study, TLBOEDL and TLBOEDQ models make a demand estimation in accordance with given scenarios and these models can be useful in estimation analysis. Especially scenario 3 with its two models is consistent with WEC-TNC Turkey Energy Report 2013.

V. CONCLUSION

Countries must balance the energy supply and demand.

Abstract — Nowadays, the author of the recognition process, the development of technology and is made to find solutions to some problems emerged with the spread of knowledge. Some of these problems, author unknown documents, e-mail the threat, and the author of the criminal investigation is to determine the author of the text can’t be sure who. Authors identification is the process of determining who is the author of a text written in any language. This document, based on the language made the last 15 years and regardless of the language, the author presents a review about the identification their work. The authors recognize the language-dependent work in the language of the syntax of specific words in the uses of the language by the author and the word of their arrangement with the order in which to do that by paying attention to the author of the text is the process of estimating different algorithms starting from here. The author of the independent study of the language of the unknown text with the character n-gram methods of machine learning is the process after the calculation of weight and estimating based on the text of the previous authors using artificial neural networks. Authors frequently used in the identification, used in the selected article, methods have been investigated and their authors compared the accuracy of the identification. Authors alone can’t fully identification the many methods used to give accurate results and language used by the author using some combination of these methods and it was emphasized that the words have to look at trends in the author's writings.

Keywords— Author identification, Writer Identification, Language-Dependent Studies

I. INTRODUCTION

Document classification and verification is a matter of in natural language studies. If our goal is to separate the types of documents. We use properties, properties that are used to find the author of a document, may be different from each other. Author identification work is a subject studied for many years, artificial neural networks, statistical methods and machine learning, such techniques are used for author identification. With the advancement of technology, who written by the unknown online text, author identification work has increased. The authors identify a lead in the other study authors are handwritten identification process [5]. In recent years, terrorist acts in the use of online messages, these events may be subject to messages, to distinguish, and made studies on the presence of the author, language-dependent studies, language syntax structure that makes identifying the author examines how writers use. We follow a columnist, without name and even when the article was published on a different page, we can guess who wrote it in writing. We have become used to the author's writing style because we follow. We could do this to separate, we can make the computer automatically? The answer to this question is yes, of course. Every writer has a unique style. This style is converted to a mathematical function author recognition process is realized. Turkish studies done on this subject is limited [1]. Author identification is classified into three different research areas which include authorship identification, authorship verification, and authorship characterization [2]. Authorship attribution determines the most probable author of an anonymous document by comparing it with the known available documents. Authorship characterization is helpful to determine the characteristics like gender, age etc. [3]. Author identification of physical and electronic documents, it is close to an area of research, and many researchers are currently working in this research field [4].

This paper consists of three parts. the first part will be released in the definition of author identification. In the second part, the author identification the field, made different studies. In the third part of the study measurements it is included.

II. AUTHOR IDENTIFICATION AND AUTHOR ANALYSIS

Author identification the unknown author of the document the author is no process. This process, artwork, criminal investigation, online messages and handwritten etc. It is working in the fields. However, the online documentation for writing verification can be used to solve various crime cases such as extortion and terrorist activities [9]. Online messages, there are difficulties to implement the writer identification. These challenges are; Length of Online document is short, an online message, there is less regular font style, knows the right words to be
written, Online documentation style and structure is different from the normal text format documents. The different languages spoken in the world, making it difficult to the fight against international cybercrime. along with the challenges mentioned, crime analysis of online posts by author analysis it can be used for various applications. [2]. authorship analysis has been applied to various cybercrimes. for example, malware [6,7], it is used in the web spam measures [8].

The author analysis two different machine learning algorithm is used as the basis. they are supervised and unsupervised machine learning. The supervised learning algorithms are also suitable when the information of both training and testing data that is the data’s label is known beforehand [3].

III. AUTHOR CLASSIFICATION

Today, a lot of sources of information is held in the form of unstructured text documents in electronic form. In this case, users can find what they are looking for them, an increasing number of documents from the documents research, analysis, revealed the deal requires the grouping. automatically parses documents to predetermined class system being developed to find solutions to this situation. Recently, Support Vector Machine, Naive Bayes, K-Nearest a machine learning method is used in the neighbour-hood, such as text classification work. Artificial Immune Systems is a method has not been tested before, and when appropriate work in text classification feature vectors used in the trials, particularly in species recognition system has shown that successful results. They are frequently used classification methods;

Naive Bayes (NB). Classic Naïve Bayes algorithm often used in the determination of a document with the word class and the class of the joint probability [35].

Support Vector Machines (SVM). Class biggest margin separating from each other, aims to set a distinctive linear function. Linear inseparable as examples for examples, moved to another higher-dimensional space could be divided and linear classification that is done in space.

Random Forests (RO). Breiman to produce a single decision tree Instead, each trained a large number of different training sets, He proposed the merging of the multivariate decision tree. Different sets of training boot (bootstrap) and random by selecting the feature created from the original training set. Very variable decision trees obtained by CART algorithm [36]. Before any decision tree gives its decision, forest in-class maximum votes, which considered the final decision it is and incoming test data is included in that class.

K-Nearest Neighboring (K-NN). class of data which will feature vector value is based on the principle of finding the closest feature vector k. Found nearest feature vectors, Euclidean distance is used. The vector k found that most of what class, the class label is defined as a class of data to be sorted.

IV. STUDIES ON AUTHOR IDENTIFICATION

Document classification and author identification studies so far, various features are used. Burrows [10] based on the word wealth characteristics, Stamatelatos and friends [11] various combinations of syntactic features of style, Fürnkranz [12] n-grams, Authorship analysis is the study of linguistic and computational characteristics of the written documents of individuals [14,15]. special article features extracted from text written in advance of individuals can be used to distinguish another person [16]. writing styles can be categorized in five different types, these namely lexical, syntactic, structural, content-specific, and idiosyncratic features [4,13]. Authorship analysis has been very successful for resolving authorship identification disputes over literary and conventional writings [17]. online document analysis is more difficult. [18]. There are many applications for plagiarism detection and similarity determination. advancing technology, facilitate their replication and spread [19]. Similarly, taking different user names of customers, protect the reputation of the company [20]. have developed techniques for detecting aliases in online systems (e.g., eBay) by analyzing the users’ feedback. Abbasi et al [21]. The first approach conducts verification using classifica-tion; three different classifiers are investigated, namely, Adaboost.M1, Bayesian Network, and Discriminative Multinomial Naive Bayes (DMNB). The second approach conducts verification by regression; three different classifiers were studied including linear regression, SVM with Sequential Minimum Optimization (SMO), and SVM with RBF kernel. The feature set was composed of 292 attributes, which included lexical (collected either in terms of characters or words), syntactic (punctuation and function words), idiosyncratic (spelling and grammatical mistakes) and content-specific (keywords commonly found in a specific domain). Experimental evaluation of the proposed approach, using the Enron e-mail corpus and by analyzing 200 e-mails per author, yielded EER ranging from 17.1% to 22.4% [22]. Canales et al. trained a K-Nearest Neighbor (KNN) classifier with 82 stylistic features including 49 character-based, 13word-based, and 20 syntactic features [23]. In addition, they combined stylometry and keystroke dynamics analysis for the purpose of authenticating online test takers. They experimented with 40 students with sample document size rang-ing between 1710 and 70300 characters, and obtained as performances (FRR=20.25%, FAR=4.18%) and (FRR=93.46%, FRR=4.84%) when using separately keystroke and stylometry, respectively. The combination of both
types of features yielded EER=30%. They concluded that the feature set must be extended and certain type of punctuations may not neces-sarily represent the style of students when taking online exams [23]. For the author analyzes explored the use of stylogy for online posts [24]. The technique was based on a combination of supervised learning and n-gram analysis. The experimental evaluation yielded an EER of 14.35% for 87 users for message blocks of 500 characters. The evaluation used real-life dataset from Enron, where the e-mails were combined to produce a single long message per individual, and then divided into smaller blocks used for authorship verification. Advanced Information Networking and Applications (ANE-2014) on 28 IEEE presented at the International Conference on the current paper, in an earlier version, feature set is expanded and Information Gain (IG) was used to rank the metric good features, also used for SVM classification. Corpus based on a data set used to evaluate experimentally. Mutual information (MI) called for an extra filter is added in the process of feature selection to take high correlation properties. SVM classification technique of the authors only, but also and SVM-LR with SVM as a hybrid method that combines research. The approach proposed two different data sets, based on a twitter feed, and other email-based Enron 140, consisting of 280 blocks and 500 characters of text are evaluated using a text message [25]. verbal elements extracted from a text (word or character) consists of a series [26]. This series of uppercase letters, lowercase letters, vowels, white space, digits, including the frequency of characters includes special characters [27], automatic recognition task, writer, author attributions, and has various practical applications for plagiarism detection. The author is a challenging area of recognition [28]. The structure of a document can be easily interpreted in the machine side. Each author's style, interpretation, natural language, is subjective general; it is more difficult to find an explanation that allows the machine to automatically tell a writer from another. Is reported in, a literature review on modern authorship attribution methods, usually coming from the fields of machine learning and statistical analysis [28,29,30,31,32]. To resolve the problem of identifying the author, with Canadian law enforcement agencies were identified in a joint project of writing analysis, three issues have been resolved [8].

A. Authorship identification with large training samples: A cybercrime investigator wants to identify the most plausible author of an anonymous text message from a group of suspects. We assume that the investigator has access to a large collection of messages that are previously written by suspects. In real-life investigation, the sample text messages can be obtained from the suspects’ e-mail archives and chat logs on the seized personal computers, or from e-mail service providers with warrants. An investigator wants to precisely extract the writing styles of each suspect from the sample messages, use such patterns to identify the author of the anonymous message, and present such patterns as evidence to support the finding. Most of the previous works on authorship identification [4,33,34,13,27] assume that every suspect has only one writing style. We argue that a person’s writing style may vary depending on the recipients or the topics. For example, when a student writes an e-mail, his writing style to a professor is probably different from his writing style to a friend. The challenge is how to precisely identify such stylistic variations and utilize the variations to further improve the accuracy of authorship identification.

B. Authorship identification with small training samples: Given a collection of anonymous messages from a group of suspects, a cybercrime investigator wants to determine the author of each anonymous message in the collection. Unlike the previous problem, this problem assumes that the investigator has access to only a few training samples written by the suspects. In real-life investigation, the investigator can ask a suspect to produce a sample of his writing by listening to a story or watching a movie, then reproducing the played scene in his own writing. Clearly, the number of samples is very limited. The major challenge is how to identify the author of the anonymous messages when there are insufficient training data to build a classifier [4,27] or to extract any significant patterns.

C. Authorship characterization: Given a collection of anonymous text messages, a cybercrime investigator sometimes has no clues about who the potential suspects are and, therefore, has no training samples of the suspects. Yet, the investigator would like to infer characteristics, such as gender, age group, and ethnic group, of the author(s) based on the writing styles in the anonymous messages. We assume the investigator has access to some external source of text messages such as blog postings and social network websites that disclose the authors’ public profiles. The challenge is how to utilize such external sources to infer characteristics of the authors of the anonymous messages.

Author identification studies, they often use the n-gram methods before learning machine. N-gram choices are important. Examples of studies in [37]. To extract the dominant character n-grams in a corpus modified the algorithm LocalMax introduced in [38]. Then, the dominant n-grams are selected according to the following rules:

\[
\text{if (C.length}>3) \]

365
\[
g(C) \geq g(\text{ant}(C)) \land g(C) \geq g(\text{succ}(C)), \text{ant}(C) \neq \text{succ}(C)
\]

In the framework of authorship identification task, only consider 3-grams, 4-grams, and 5-grams as candidate n-grams, since previous studies have shown they provide the best results [39]. To measure the glue holding the characters of a n-gram together various measures have been proposed, including specific mutual information [41], the φ2 measure [40], etc. In this study, we adopt the Symmetrical Conditional Probability (SCP) proposed in [42]. The SCP of a bigram \( |xy| \) is the product of the conditional probabilities of each given the other. A sample steps of author identification [37],

- An initial large feature set consisting of n-grams of variable length is extracted from the training corpus. This feature set includes the 1 most frequent n-grams for certain values of \( n \). That is, for \( L=5,000 \), the 5,000 most frequent 3-grams, the 5,000 most frequent 4-grams, and the 5,000 most frequent 5-grams compose the initial feature set. In some cases, the most frequent long words (length > 5) are also added to the initial feature set.

- A feature selection method is applied to this large feature set.

- A Support Vector Machine (SVM) is trained using the reduced feature set. In all experiments, linear kernels are used with \( C=1 \).

- The SVM model is applied to the test set and the micro average accuracy is calculated.

Regardless of the language by following these steps, the author identification made the process.

V. CONCLUSIONS

In this review, we have presented definitions, methods, approaches and studies about of author identification. We determined that we focus on, regardless of the language in the working document. author identification, language-dependent performance of the author’s style, the words used, the sentence structure etc. It is revealed. In studies for Turkish documents, it has 60% success rate health. We have detected that increases the weight of the working documents online.

Abstract—Neighborhood topologies are extensively used in Particle Swarm Optimization (PSO). The structure of the selected topology may affect the PSO algorithm behavior. Therefore, neighborhood topology plays a crucial role on the performance of PSO algorithms when the population moves with the guidance of the best particles. However, in Artificial Bee Colony (ABC) algorithms, new population members are generated based on information exchange between the base food source and a selected member among all population. From this point of view, ABC algorithms use fully-connected neighborhood topology defined as in PSO algorithms. In this paper, we will investigate the contributions of some well-known neighborhood topologies used in PSO on the performance of ABC algorithms. We have tested fully-connected, ring, four-cluster, square and random topologies on the original ABC and global-best ABC (GABC) algorithms on the 19 benchmark functions suite (SOCO) from a special issue of the Soft Computing journal. SOCO benchmark suite consists of 7 shifted unimodal and 4 shifted multi-modal and 8 shifted hybrid functions. Experimental results reveal that population neighborhood topologies influence the performance of ABC algorithms related to the tackling problem type.

Keywords Artificial bee colony; Particle Swarm Optimization; Swarm intelligence; Single objective optimization; Neighborhood topology.

I. INTRODUCTION

Particle swarm optimization (PSO) which is a population based algorithm for global optimization, is introduced by Kennedy and Eberhart [1]. It tries to find a solution with individuals called particles.

In Standard PSO, particles communicate with each other based on social network structure called topology [2], [3]. Accordingly, each particle in the swarm can exchange information with other individuals. But some particles have information that may be useless, or some particle of information may be more important. For instance, the best-so-far particle which called as global best particle (gbest) communicates with all particles in the neighborhood structure. In literature several research have been proposed for topology structure and various type of topology structure is recommended [4], [5], [6], [7]. Neighborhood Topology has a significant impact on the performance of the algorithm [3]. For example, gbest or fully connected topology converge more quickly but it may easily trapped in a local optima [8]. On the other hand; another topology which is lbest or the ring have slow convergence speed, but it can escape from the local optima [9].

Artificial bee colony algorithm (ABC) is another population based technique [10]. ABC uses individual which is given name as food source. Neighborhood structure of food sources in ABC algorithm is similar to gbest or fully-connected topology. It means, all food sources communicate with each others. In this study, we have adopted PSO topology mechanism to original ABC and global-best ABC algorithms. We have tested fully-connected, ring, four-cluster, square and random topologies on the original ABC and global-best ABC (GABC) algorithms on the 19 benchmark functions suite (SOCO) from a special issue of the Soft Computing journal.

II. BACKGROUND

A. ABC Algorithms

1) Original Artificial Bee Colony: Artificial Bee Colony Algorithm is proposed for numerical optimization. It imitates smart behaviors of the real honey bee. According to pseudo-code of ABC which is listed in Algorithm 1, ABC has one initialization step and three repeating steps. Until a termination condition is met, Employed bees, onlooker bees and scout bees steps continue. Further details about this regarding steps are given bellow.

ABC algorithm in initialization steps which uses equation 1 to create uniformly randomly initial population of SN (SN is the number of food sources) solutions where each solution \( x_i(i = 1, 2, \ldots, SN) \) is a D-dimensional vector (D is the number of parameters).

\[
x_{ij} = x_{j}^{\min} + \text{rand}(0, 1)(x_{j}^{\max} - x_{j}^{\min})
\]

(1)

where \( i = 1, 2, \ldots, SN, j = 1, 2, \ldots, D; i \) is the index of food source and \( j \) is the index of dimension. \( x_{ij} \) represents a solution, \( x_{j}^{\min} \) is lower bound value, \( x_{j}^{\max} \) is upper bound value of the \( j \)th dimension.

In the employed bee steps, algorithm searches new promised candidate solution. By using equation 2; ABC generates new food source and evaluates its fitness value. Between old and new solution, greedy selection is applied. If the new is better than the old one, the new source position is memorized and old one is forgotten. If not, position of the old food source is kept.

\[
u_{i,j} = x_{i,j} + \phi_{i,j}(x_{i,j} - x_{r1,j}),
\]

(2)
topologies that have a different structure [5], [9], [3].

B. Neighborhood Topologies

In the PSO algorithm, each particle has social link between other particles. The set of link creates graph which is called topology of PSO. Many researchers are proposed several topologies that have a different structure [5], [9], [3].

In this study, we adopt PSO neighborhood topology mechanism to ABC algorithms. We considered popular topology structures: fully-connected, ring, square and random topologies. Their peculiarities are given below:

- **Ring Topology**: is known as local best in PSO. All node is connected to two immediate neighbor. Thus, every node has 2 neighbor. Structure of the ring topology is shown in Figure 1-a.

- **Fully-connected Topology**: is also called global best. All nodes have a link between others and get information from them. Neighbor size of fully-connected is NodeSize−1. Figure 1-b illustrates the fully-connected topology.

- **Square Topology**: which is a neighborhood topology where each node has four neighbor. Figure 1-c shows how to nodes are organized in square topology.

- **Random Topology**: creates random neighbor for all nodes. Unlike from other topology, each node has a different neighborhood structure.

![Fig. 1. Topologies which are used in this paper.](image)

### Algorithm 1: The Pseudo-code of the Original Artificial Bee Colony Algorithm

<td>Employed Bees Step</td>
</tr>
<tr>
<td>3.</td>
<td>Onlooker Bees Step</td>
</tr>
<tr>
<td>4.</td>
<td>Scout Bees Step</td>
</tr>
</tbody>
</table>

where \( i = 1, 2, \ldots, SN \), \( j = 1, 2, \ldots, D \) and \( r1 \) is a uniformly distributed random real number. \( \phi_{i,j} \) is a real number which is generated from a uniform distribution in \([-1, 1]\). \( v_{i,j} \) is the \( i \)-th solution with \( j \)-th dimension. \( x_{i,j} \) is \( j \)-th dimension of the reference food source.

In onlooker bees step, equation 2 is used same as employed bees steps to produce a new candidate solution. On the other hand, selection of a solution is based on probability of food source which is obtained by equation 3.

In ABC algorithms, food sources communicates in employed bees and onlooker bees steps. In Equation 2, a food source \( x_{r1} \) is selected randomly within the entire swarm. However, when ABC algorithms with neighborhood topologies, randomly selected food source \( x_{r1} \) is selected from neighbors of the reference food source.

GABC algorithm modifies search equation of original ABC by adding global best information and offers Equation 5 [11]. All food sources is used to determine the global best position. After we have adopted neighborhood topologies, as in original ABC algorithm, a random neighbor is determined based on neighborhood structure.

\[ v_{i,j} = x_{i,j} + \psi_{i,j}(x_{i,j} - x_{r1,j}) + \psi_{i,j}(x_{Gbest,j} - x_{r1,j}), \quad (5) \]

where \( \psi_{i,j} \) is a uniform random real in range of \([0, C]\) and \( C \) is nonnegative constant. \( x_{Gbest,j} \) is \( j \)-th element of the global best solution.

B. Neighborhood Topologies

In the PSO algorithm, each particle has social link between other particles. The set of link creates graph which is called topology of PSO. Many researchers are proposed several topologies that have a different structure [5], [9], [3].

In ABC algorithms with neighborhood mechanism, we adopt PSO neighborhood topology mechanism to ABC algorithms. We considered popular topology structures: fully-connected, ring, square and random topologies. Their peculiarities are given below:

- **Ring Topology**: is known as local best in PSO. All node is connected to two immediate neighbor. Thus, every node has 2 neighbor. Structure of the ring topology is shown in Figure 1-a.

- **Fully-connected Topology**: is also called global best. All nodes have a link between others and get information from them. Neighbor size of fully-connected is NodeSize−1. Figure 1-b illustrates the fully-connected topology.

- **Square Topology**: which is a neighborhood topology where each node has four neighbor. Figure 1-c shows how to nodes are organized in square topology.

- **Random Topology**: creates random neighbor for all nodes. Unlike from other topology, each node has a different neighborhood structure.

![Fig. 1. Topologies which are used in this paper.](image)
IV. EXPERIMENTS

A. Benchmark Functions

To conduct experiments for the effect of the neighborhood topologies on the performance of the considered algorithms, we have used test suite of Soft Computing Special Issue on "Scalability of evolutionary algorithms and other meta-heuristics for large-scale continuous optimization problems", (SOCO) [12]. The suite has 19 problems which are separated into three categories: 1) shifted multi-modal (4 problems) 2) shifted unimodal (7 problems) 3) shifted hybrid (8 problems). For more detailed information about SOCO is listed in Table I.

B. Experimental Setup

We investigate the contributions of some well-known neighborhood topologies used in PSO on the performance of ABC algorithms. However, we have studied the question of which topology to be more efficient according to SOCO test suite.

ABC and GABC do not have too many control parameters. Parameter setting of algorithms are presented in Table II. These values are taken from [13]. Experiments are carried out with default parameter values of ABC and GABC.

Each algorithm with every topology is run for 25 times for each problems. Each run is terminated after the number of maximum function evaluations (FES) which is set as 250000. The error value can be calculated as $f(x) - f(x^*)$ where $f(x^*)$ is the optimum value of function $f$. Error values lower than $10^{-14}$ is assumed as $10^{-14}$. All results are listed are based on the mean error values in Table III and Table IV. All experiment have been conducted on 2 GB RAM and Intel Xeon E5-2620 2GHz CPU.

C. Experimental Results

In this section, contribution of four different topologies Ring, Fully-Connected, Square and Random on ABC and GABC are compared. SOCO results of four topologies adopted ABC algorithm is shown in Table III. We mark best results in bold for all problems.

When Table III is examined, it seems that there is no topology never reaches the optimum value. Random topology obtains best value of functions $f_1$, $f_2$, $f_3$, $f_4$, $f_5$, $f_7$, $f_8$, $f_9$, $f_{10}$, $f_{13}$ and $f_{14}$. Fully-connected topology is better than the others in $f_6$, $f_{11}$, $f_{17}$ and ring topology is better in $f_{12}$, $f_{15}$, $f_6$, $f_{19}$. However, square topology is not better than others for any case.

Random topology is the first who has been obtained the best value in 12 problem. Furthermore, fully-connected takes second place, ring and square gets third place.

Four topology structure is adopted to GABC and algorithm is tested with SOCO benchmark functions. Their results of mean values is illustrated in Table IV. All topologies obtain optimum value of problem $f_1$, $f_4$, $f_6$, $f_7$, $f_9$, $f_{10}$, $f_{11}$, $f_{12}$, $f_{15}$, $f_{16}$, $f_{19}$. In addition that, in $f_5$ random and fully-connected topologies also gets optimum value. Random topology acquire best value of functions $f_2$, $f_8$, $f_{17}$. In function $f_3$, $f_{13}$, $f_{18}$ Square topology and in function $f_{14}$ fully-connected achieve best value. Consequently, like as the original ABC case, random topology is superior to all other rivals for GABC.

In both algorithms, Random topology gains better results than other topologies. According to the that obtained from experiments, random neighborhood structure provide to algorithms to work more effectively. The reason for this, Random neighborhood structure contributes to exploration behavior of algorithms. Finally, the ABC and the GABC algorithm are compared with each other, GABC demonstrated superior performance according to ABC.

V. CONCLUSIONS

In this paper, four different neighborhood structures are adopted and test on original and global-best ABC algorithms. The tests have conducted on 50 dimensional SOCO test functions. The results show that overall performances of ABC algorithms with random neighborhood structure is better than others for the SOCO instances. However, for some functions other neighborhood strategies gives superior performance. As a conclusion, it is possible to say that neighborhood structures can influence the performance of the ABC algorithms directly.

For the future work, several ABC algorithms will be tested on different neighborhood strategies on other benchmark function suites such as CEC 2005, CEC 2015 and CEC 2015 test suites. On the other hand, another further work about the self-adaptation of neighborhood structure will be applied to ABC algorithms to find appropriate neighborhood structure for a given problem instance when the algorithm is running.

m.kaya@adiyaman.edu.tr

Abstract—In many different fields, there is a high demand for storing information to a computer storage disk from the data available in printed or handwritten documents or images to later re-utilize this information by means of computers. One simple way to store information to a computer system from these printed documents could be first to scan the documents and then store them as image files. But to re-utilize this information, it would very difficult to read or query text or other information from these image files. Therefore a technique to automatically retrieve and store information, in particular text, from image files is needed. Optical character recognition is an active research area that attempts to develop a computer system with the ability to extract and process text from images automatically. The objective of OCR is to achieve modification or conversion of any form of text or text-containing documents such as handwritten text, printed or scanned text images, into an editable digital format for deeper and further processing. Therefore, OCR enables a machine to automatically recognize text in such documents. Some major challenges need to be recognized and handled in order to achieve a successful automation. The font characteristics of the characters in paper documents and quality of images are only some of the recent challenges. Due to these challenges, characters sometimes may not be recognized correctly by computer system. In this paper we investigate OCR in three different ways. We first review the general phases of an OCR system such as pre-processing, segmentation, normalization, feature extraction, classification and post-processing. Then, we give a detailed overview of the challenges that might emerge in these OCR stages. Finally, we highlight development and main applications and uses of OCR. Therefore, this discussion provides a very comprehensive review of the state-of-the-art of the field.

Keywords—OCR; OCR Challenges; OCR Phases; OCR Applications

I. INTRODUCTION

Optical character recognition is an active research area that attempts to develop a computer system with the ability to extract and process text from images automatically. These days there is a huge demand for storing information to a computer storage disk from the data available in printed or handwritten documents to later re-utilize this information by means of computers. One simple way to store information to computer system from these paper documents could be to first scan the documents and then store them as image files. But to re-utilize this information, it would very difficult to read or query text or other information from these image files. Therefore a technique to automatically retrieve and store information, in particular text, from image files is needed. Of course, this is not a very trivial task. Some major challenges need to be laid out and handled in order to achieve a successful automation. The font characteristics of the characters in paper documents and quality of images are only some of the recent challenges. Due to these challenges, characters sometimes may not be recognized correctly by computer system. Thus there is a need of mechanisms of character recognition to perform Document Image Analysis (DIA) which overcomes these challenges and produces electronic format from the transformed documents in paper format.

Similarly, Optical Character Recognition (OCR) is the process of modification or conversion of any form of text or text-containing documents such as handwritten text, printed or scanned text images, into an editable digital format for deeper and further processing. Optical character recognition technology enables a machine to automatically recognize text in such documents. In real world example, it is like combination of mind and eye of human body. An eye can detect, view and extract the text from the images but absolutely the human’s brain processes that detected or extracted text read by eye [1]. Of course OCR technology has not advanced enough to compete with human’s ability. The performance and accuracy of OCR is directly dependent upon the quality of input documents. Again, when we think of human’s ability to recognize text, the performance of brain’s process directly depends upon the quality of the input read by eye.

Today, to solve the text recognition problem several different types of OCR software exist such as Desktop OCR, Server OCR, web OCR and so on. Since the OCR research is an active and important field in general pattern recognition problems, due to its fast progress, comprehensive reviews of the field are needed on a regular basis to keep track of the new advancements. One such review was published to discuss the challenges with text recognition in scene imagery [2]. This paper attempts to elaborate on these kinds of studies by providing a comprehensive literature review of optical character recognition research. We discuss major challenges
and main phases of optical character recognition such us pre-
processing, segmentation, normalization, feature extraction,
classification and post processing in detail which needs to be
considered during implementing any application related to the
OCR, and in the last section of our paper some OCR
applications are discussed.

II. OCR CHALLENGES

For good quality and high accuracy character recognition,
OCR techniques expect high quality or high resolution images
with some basic structural properties such as high
differentiating text and background. The way images are
generated is an important and determining factor in the
accuracy and success of OCR, since this often affects the
quality of images dramatically. Usually OCR with images
produced by scanners gives high accuracy and good
performance. In contrast, images produced by cameras usually
are not as good as an input as scanned images to be used for
OCR due to the environmental or camera related factors.
Numerous errors might emerge, which are clarified as follow.

A. Scene Complexity

In a regular environment, we can see large numbers of
man-made objects which are included in camera taken images
such as paintings, buildings, and symbols. These objects have
comparative structures and appearances to text which makes
text recognition very challenging in the processed image. Text
itself is regularly laid out to encourage decipherability. The
challenge with scene intricacy is that the surrounding scene
makes it hard to segregate text from non-text [2].

B. Conditions of Uneven Lighting

Oftentimes, taking images in natural environments results
in uneven lighting and shadows. This poses a challenge for
OCR as it degrades the desired characteristics of the image
and hence causes less accurate detection, segmentation and
recognition results [2].

This condition with uneven lighting is what distinguishes a
scanned image form one that is produced with a camera. The
lack of such disparities in lighting and shadows makes scanned images preferred over camera images for their better
characteristics and quality. Although using an on-camera flash
may eliminate such problems with uneven lighting, it
introduces new challenges.

C. Skewness (Rotation)

For optical character recognition systems, the point of
view for the input image that taken from camera of hand-held
device or other gadgets that used for taken image is not fixed
like a scanner input, which skewing of text lines from their
unique orientation might be observed. Great degree poor
results will be observed when such a skewed image is fed to
the OCR classifier. Many techniques available for the purpose
development the image documents, such as Projection Profile,
RAST algorithm, Hough transform, methods of Fourier
transformation, etc.

D. Blurring and Degradation

Since working over a variety of distances are intended to
numerous digital cameras, an important factor is the digital
camera’s focusing. For the best accuracy of character
recognition and character segmentation, character sharpness is
required. At large apertures and short distances, uneven focus
can be observed when a small point of view changes. For the
most part connected with photography, there are two kinds of
obscure which is: out of focus obscure and movement obscure
[3]. At the point for catching a moving item, when the shade
rate of the camera is not sufficiently high, the sensor gets
presented to a continually changing scene. Accordingly,
blurring will observed in parts in motion.

E. Aspect Ratios

Text has different aspect ratios. Text may be brief such as
traffic signs, while other text may be much longer, such as
video captions. Location, scale and length of text need to be
considered with search procedure to detect text, which
introduces high computational complexity.

F. Tilting (Perspective Distortion)

Document images obtained by scanners is constantly
parallel to the plane of sensor, but this cannot be observed all
times for recorded picture obtained by a portable camera, that
may not generally be parallel to the form plane. Accordingly,
lines of text that distant from the camera seem littler than
those that nearer to the camera which seems greater. This
situation causes tilted pictures. Observation of a perspective
distortion is clear if the recognizer is not perspective intolerant,
which causes lower recognition rate and accuracy [4].

Cell phones have an advantage with orientation sensors.
They can recognize whether the device is tilted and when
twisting happens they can forbid clients to take pictures.
Permitting the user to align plane of the form with that of the
camera is also provided by this feature. Orientation sensors
therefore may assure that produced pictures satisfy a certain
degree of evenness.

G. Fonts

Italic style and script fonts of characters might overlap each
other, making it difficult to perform some of the main OCR
processes such as segmentation. Characters of various fonts
have large within-class variations and form many pattern sub-
spaces, making it difficult to perform accurate recognition
when the character class number is large.

H. Multilingual Environments

Although most of the Latin languages have tens of
characters, languages such as Chinese, Japanese and Korean,
have thousands of character classes. Arabic has connected
characters, which change shape according to context. In Hindi
syllables represent by combining alphabetic letters into
thousands of shapes [5]. In multilingual environments, OCR
in scanned documents remains as a main research problem [5],
since text recognition in complex imagery is more difficult.
I. Warping

Content or text on objects of varying geometries can be another challenge for OCR to be recognized when images of such situation captured by hand-held cameras. A few circumstances may emerge with flatted scanners, wherein the twisted text observed when the content procured on picture, for example the content towards the binding of an extremely thick book.

For convention paper documents, a technique for image dewarping is proposed by Ulges et al. [6]. By expecting the way that content lines are equally separated and parallel to each other, they dewarp pictures.

III. OCR PHASES

In this section we describe the main important phases and architecture of optical character recognition. These phases include pre-processing, segmentation, normalization, future extraction, classification and post processing. For designing an effective application related to the OCR, we must be considering the difficulties that may arise in each phase to obtain high character recognition rate.

A. Pre-processing Phase

The aim of pre-processing is to eliminate undesired characteristics or noise in an image without missing any significant information. Preprocessing techniques are needed on color, grey-level or binary document images containing text and/or graphics. Since processing color images is computationally more expensive, most of the applications in character recognition systems utilize binary or grey images. Preprocessing reduces the inconsistent data and noise. It enhances the image and prepares it for the next phases in OCR phases.

Thus, since preprocessing controls the suitability of the input for the successive phases, a primary stage prior to feature extraction phase is the pre-processing phase. Most of the challenges we listed in OCR Challenges’ section need to be addressed in preprocessing stage. Some operations that we may consider to carry out can be listed as follows: binarization, noise reduction, skew correction, morphological operations, slant removal, filtering, thresholding, smoothing, compression, and thinning. Some important preprocessing issues with short description were illustrated in Table I.

<table>
<thead>
<tr>
<th>Processes</th>
<th>Description</th>

<tr>
<td>Skew Correction</td>
<td>Because of the possibility of rotation of the input image through captured image device, document skew should be corrected.</td>
</tr>
<tr>
<td>Morphological</td>
<td>Adding or removing pixels to the characters</td>
</tr>
</tbody>
</table>

B. Segmentation Phase

The critical and major component of an Optical Character Recognition (OCR) system is the segmentation of text line from images. In general, Text segmentation from a document image merges line segmentation, word segmentation and then character segmentation. Segmentation is the process of isolating text component within an image from the image’s background. For appropriate reorganization of the editable text lines from the recognized characters, firstly, segmenting the line of text, then the words are segmented from the segmented line and then from that the characters are segmented.

Document segmentation is a major pre-processing phase in implementing an OCR system. It is the process of classifying a document image into homogeneous zones, i.e., that each zone contains only one kind of information, such as text, a figure, a table, or a halftone image. In many cases, the accuracy rate of systems related to the OCR heavily depends on the accuracy of the page segmentation algorithm used.

There are three categories of Algorithms of document segmentation [7] As follows:

- Top-down methods,
- Bottom-up methods,
- Hybrid methods.

The top-down approach in a document segments large regions into smaller sub regions recursively. When criterion is met then the document segmentation process will stop and at that stage the ranges obtained constitute the results of final segmentation. But, approaches of bottom-up start by searching for interest pixels and then groups interest pixels. They then manage those interest pixels into connected components that constitute characters which are then combined into words, and lines or text blocks. The integration of both top-down and bottom-up methods is called hybrid approaches.

Regarding different aspects of OCR system throughout the last decades many approaches have already been proposed for segmentation.

A novel technique for Text Segmentation based on A Hough Transform, was proposed by Satadal Saha, Subhadip Basu, Mita Nasipuri and Dipak Kr. Basu [8].

Extracting Text line from multi skewed handwritten document images has been studied by S. Basu et al [9]. The proposed technique for extraction of text lines implements a water flow technique with high rate of success.

A. Khandelwal et al [10] proposed a technique by comparing neighborhood connected components on text line segmentation from unconstrained handwritten document images.

Shinde, Archana A., and D. G. Chougule also proposed a segmentation technique in their paper [11]. They presented...
that utilizing the traditional vertical and horizontal projection profile method makes text easily segmented into lines and words. They reported experimental results with 98% accuracy of line and word segmentation.

C. Normalization Phase

As a result of segmentation process isolated characters which are ready to move through feature extraction phase are obtained, hence the isolated characters are minimized to a particular size depending on the algorithms used. The segmentation process is crucial as it converts the image in the form of m*n matrix. These matrices are then commonly normalized by minimizing the size and eliminating the unnecessary information from the image without missing any influential information [12].

D. Feature Extraction Phase

Feature extraction is the operation of extracting the pertinent features from objects or alphabets to build feature vectors. These feature vectors are then utilized by classifiers to identify the input unit with objective output unit. It becomes effortless for the classifier to classify between dissimilar classes by glancing at these features as it becomes fairly easy to determine [13].

Several techniques are proposed for extracting features from the segmented characters in literature. U. Pal et al [14] have proposed directional chain code features and zoning and for handwritten numeral recognition considered a feature vector of length 100 and have presented a high level of recognition accuracy. But, the feature extraction process is time consuming and complex [13].

Dinesh et al [15] have proposed end points as the potential features for recognition and used horizontal/vertical strokes and for handwritten Kannada numerals obtained a recognition accuracy of 90.50%. But, this method uses the thinning process which results in some loss of features [13].

E. Srinivasan et al [13] for handwritten alphabets recognition system have proposed diagonal based feature extraction utilizing neural network.

Sharma, Om Prakash et al [16] for handwritten alphabets recognition proposed an improved zone based hybrid feature extraction model utilizing Euler number.

Following to Sue [17], there are two major classes of features: statistical features and structural features. In a character matrix statistical features are obtained from statistical distribution of every point such as zoning, moments, crossings, fourier transforms and projection histograms [18]. Statistical features are also notable as global features as they are usually averaged and extracted in sub-images such as meshes. Initially, statistical features are supplied to recognize machine printed characters. On the other hand, structural or topological features are concern to the geometry of the character set to be contemplated. Some of these features are convexities and concavities in the characters, number of holes in the characters, number of end points etc.

E. Classification Phase

OCR systems broadly utilize the methodologies of pattern recognition, which assigns each example to a predefined class. Classification is the procedure of distributing inputs with respect to detected information to their comparing class in order to create groups with homogeneous qualities, while segregating different inputs into different classes. Classification is conveyed out on the premise of put away features in the feature space, for example, structural features, global features and so forth. It can be said that classification isolates the feature space into several classes taking into account the decision rule. Choosing classifier depends on several agents, such as, number of free parameters, available training set and so forth. Various procedures for OCR are explored by the scientists.

Techniques of OCR classification can be categorized [19] as Statistical Techniques, Neural Networks, Template Matching, Support Vector Machine (SVM) algorithms, and Combination of classifier.

1) Template matching: This is the least complex method for character recognition, in view of matching the stored models against the word or character to be perceived. By gathering of shapes, pixels, curvature and so forth, the operation of matching decides the level of similitude between two vectors. A gray-level or binary input character is contrasted with a standard arrangement of stored models. The recognition rate of this strategy is extremely delicate to noise and input disfigurment.

2) Statistical Techniques: Hypothesis of Statistical decision is treating with statistical decision capacities and an arrangement of optimality criteria, which for a given model of a specific class can amplify the likelihood of the observed pattern. The main statistical methods that are performed in the area of OCR are Nearest Neighbor (NN), Likelihood or Bayes classifier, Clustering Analysis, Hidden Markov Modelling (HMM), Fuzzy Set Reasoning, and Quadratic classifier.

3) Neural Networks: Character classification issue is identified with heuristic rationale as people can perceive characters and records by their learning and experience. Thus neural networks which are pretty much heuristic in nature are greatly appropriate for this type of issue [19]. A neural network is an ascertaining architecture that includes enormously parallel interconnection of flexible node processors. Output from one node is reinforcing to the next one in the network and an official choice relies on the complicated collaboration of all nodes. As a result of its similar character, it can apply calculations at a rate higher contrasted with the traditional strategies. Feed-forward neural networks and feedback neural networks can be thought as categorization of neural network architectures. Table II, compares and discusses some recent proposed OCR applications based on Neural Network.

377
4) **Kernel Methods**: While the most imperative kernel strategies are support Vector Machines, techniques such as Kernel Fisher Discriminant Analysis (KFDA) and Kernel Principal Component Analysis (KPCA) also employ kernel method. Support vector machines (SVM) are one of the most widely used and most effective supervised learning techniques that can be used for binary or multi-class classification. In classification techniques, by convention the data set first is partitioned into training and testing sets. The objective of SVM is to deliver a model, which predicts the output of the test set [24]. Width of the edge between the classes is the enhancement rule, i.e., the unfilled zone around the decision boundary characterized by the interval to the closest training example [25].

5) **Combination Classifier**: Different classification strategies have their own particular advantages and shortcomings. Thus ordinarily various classifiers are consolidated together to solve a given classification problem. Matei, Olivia, Petrica C. Pop, and H. Vălean [26] by utilizing neural networks and k-Nearest Neighbor, proposed Optical character recognition in real environments such as electricity-meters and gas-meters.

**F. Postprocessing Phase**

It has been shown that people can read handwriting by context up to 60%. While preprocessing tries to clean the record in a specific sense, it might evacuate critical data, since the context data is not accessible at this stage. On the off chance that the semantic data were accessible to a specific degree, it would contribute a considerable measure to the precision of the OCR stages. On the other hand, the whole OCR issue is for deciding the context of the saved image. In this way the incorporation of context and shape data in all the phases of OCR frameworks is vital for meaningful upgrades in recognition rates. This is done in the Postprocessing stage with an input to the early phases of OCR. The least complex method for consolidating the context data is the usage of a dictionary for amending the minor errors of the OCR frameworks. The fundamental thought is to spell check the OCR yield and give a few distinct options for the yields of the recognizer that take place in the dictionary.

**IV. OCR APPLICATIONS**

Optical character recognition has been performed in a numerous of applications. We discussed some of these application areas in this section.

<table>
<thead>

**A. Handwriting Recognition**

Handwriting recognition is the capacity of a PC to get and translate intelligible handwritten data from sources, for example, paper records, photos, touch-screens and different gadgets.

**B. Receipt Imaging**

Receipt imaging [27] is broadly utilized as a part of numerous organizations applications to monitor financial records and keep accumulation of payments from heaping up. In government offices and autonomous organizations, OCR simplifies information gathering and analysis, among different procedures.

**C. Legal Industry**

Legal industry [27] is likewise one of the recipients of the OCR innovation. OCR is utilized to digitize documents, and to specifically enter into PC database. Legitimate experts can further search documents required from tremendous databases by basically writing a few keywords.

**D. Banking**

Another imperative use of OCR is in banking [27], where it is utilized to process cheques without human intervention. A cheque can be embedded with a machine where the framework filters the sum to be issued and the right measure of cash is exchanged. This innovation has been idealized for printed cheque, and is genuinely precise for handwritten checks diminishing the hold-up time in banks.

**E. Healthcare**

To process printed material, medicinal services [27] have likewise seen an expansion in the utilization of OCR innovation. Medicinal service experts continuously need to manage extensive volumes of documents for each patient, including protection frames and in addition general health forms. To stay aware of every one of this data, it is valuable to input relevant information into an electronic database. With OCR processing tools, we can extract data from structures and put it into databases, so that each patient's information is quickly recorded and retrieved when needed in future.

**F. Captcha**

A CAPTCHA [28] is a system that can create and grade tests that human can pass yet current software technology can't. Malicious programmer can make software to misuse personal information on websites. Dictionary attack is assault against secret word confirmed frameworks where a programmer composes a system to over and over attempt distinctive passwords like from dictionary of most regular passwords. In CAPTCHA, a picture comprising an arrangement of letters and numbers is produced with variety of size and textual styles, distracting backgrounds, arbitrary portions, highlights and noise so that text cannot be read via OCR. Current OCR frameworks can be utilized to evacuate the noise and portion the picture to make the picture tractable by such malicious users.
G. Automatic Number Plate Recognition

Automatic number plate recognition [29] is utilized as a mass observation method making utilization of optical character recognition on pictures to recognize vehicle registration plates. ANPR has additionally been made to store the pictures caught by the cameras including the numbers caught from license plate. ANPR innovation own to plate variety from place to place as it is an area particular innovation. They are utilized by different police forces and as a technique for electronic toll accumulation on pay-per-use streets.

V. CONCLUSIONS

Numerous algorithms, methods and techniques have been proposed to optical character recognition in scene imagery, yet there are not enough literature surveys in this field. In this paper, we have proposed an organization of these methods, algorithms and techniques. It is hoped that this comprehensive survey will provide insight into the concepts involved, and perhaps provoke further advances in the area. Firstly, we discussed major challenges of OCR, then we discussed in great detail the main important phases, architecture, proposed algorithms and techniques of OCR, we highlight that for designing any application related to the OCR, one must pay great attention to each phase to obtain high accurate character recognition rate, but still we cannot propose comprehensive algorithms for each phase because it depends upon datasets, application specifics, and parameter specifics. Finally major applications related to the OCR are discussed.

Although the state-of-the-art OCR enables text recognition with high accuracy, we think that there could be many more practical applications of OCR. As a future work we are planning to use OCR for such practical applications for daily personal use. We are planning to incorporate mobile devices with OCR in one OCR system. An automated book reader or a receipt trader constitutes some of our future OCR based applications.

Abstract—Today, every kind of text, audio and visual data, which are thought to be transformed into pieces of information, are stored for long periods of time for processing. The concept of Big Data is not only associated with the data stored, but also with the system involving hardware and software that collects, processes, stores, and analyzes the data. As the data grows bigger, their physical storage options must be provided in a distributed architecture.

Solr and Elasticsearch are among the most preferred tools which makes this storage process easier. As a part of Apache Lucene project, Solr is a software which was started to be developed in 2004 with the searching features of full text, multiple search, dynamic clustering, database-integrated, open source and elasticity. Similarly, Elasticsearch is a new open-source tool for real-time, full-text and distributed search, which was launched in 2010 using the Lucene library. Although Solr and Elasticsearch have similar features, there are many parameters that differentiates one from the other such as intended use, type of use, and query and indexing performances. This study researches and analyzes the differences between Solr and Elasticsearch with regards to their query and indexing speeds, ease and difficulties of use, configuration forms, and architectures in light of the literature, and the results are discussed regarding these tools’ performances.

Keywords—big data, elasticsearch, solr

I. INTRODUCTION

Huge amount of data stack which cannot be stored nor processed by traditional methods is called Big Data [1]. Based on the fact that most of the smart devices communicate on the Internet and the technological devices and computers will communicate through cloud computing, it is easy to predict that much bigger data is to be produced in the future [2]. It is impossible to store, process, and analysis this big data by conventional tools. Therefore, many tools were developed for the data which can be regarded as Big Data. It was observed that Big Data tools and techniques that are used in processing this data provided better performance results in comparison with traditional tools and techniques [3].

One of these tools is Solr which is an open source, Java-based tools that uses Apache Lucene search library and it can be used on servers such as Tomcat, Jetty, etc. [4]. According to July, 2016 figures of DB-Engines Ranking of Search Engines, Solr is the second most popular search engine software [5]. With its 5th version, Solr has become a separate software instead of being a Java package [6].

Elasticsearch is one of the other tools that is used in analyzing and process Big Data. It is an open-source, Lucene-based content search and analysis tool that was developed in Java. This tool, which began to be developed in 2010, is used by many domestic/foreign organizations. It is also a tool that can be set up in Cloud servers purchased through Google For Works, and it is in a sense supported by Google [7]. According to July, 2016 figures of DB-Engines Ranking of Search Engines, Elasticsearch is the most popular search engine software [5].

Because of the fact that both of Solr and Elasticsearch tools are based on Apache Lucene library, and they have similarities between the intended use and methods, supported protocols, and coding languages, today they are compared and contrasted by users in different categories. Users try to decide which one is the best tool for them based on their own needs and system requirements.

This study, therefore, collects comparative data conducted so far between Solr and Elasticsearch. These collections involve technical configurations, performance tests, etc. This study is thought to contribute to software developers in using Solr and Elasticsearch.
II. SOLR

Solr is an open source enterprise search platform, written in Java, from the Apache Lucene project and its major features include full-text search, hit highlighting, faceted search, real-time indexing, dynamic clustering, database integration, NoSQL features and rich document (e.g., Word, PDF) handling [6][8].

A. Technical Specifications of Solr

Each data in Solr is named as Document. A simple analogy between Solr and Java Database is as follows:

- Java Class = Solr Document
- Java Class Attribute = Document Field
- Database table = Solr Document
- Column in the database table = Document Field

A Solr Document can be generated by method of creating a table in a database or building a Java class.

Data indexed by Solr provides a fast response based on query type through Request method on HTTP. In addition that query results can be instantly listed on the screen, one can also print out in XML, JSON, CSV, etc. formats.

Solr uses Lucene library in indexing, analyzing, and searching processes, which involves filtering on existing structures, faceting, caching, and distributed architecture support. While Solr can be used as an API server similar to REST, it can also operate on protocols that are supported by HTTP/XML or JSON coding languages. Additionally, it supports libraries that work independently in Java and enables specifications.

Rules regarding the Documents designed in Solr are stored in Schema.xml file. There are <field> settings in Schema file which corresponds to “column” in traditional databases. These settings are composed of the parameters of field name, whether it is indexed in Solr search, whether it is stored and responds to findings, whether it is multi-valued, and what type of data it includes [9].

A sample schema file involves the following data:

```xml
<field name="id" type="string" indexed="true" stored="true" required="true" multiValued="false"/>
<field name="sku" type="text_en_splitting_tight" indexed="true" stored="true" omitNorms="true"/>
<field name="name" type="text_general" indexed="true" stored="true"/>
<field name="manu" type="text_general" indexed="true" stored="true" omitNorms="true"/>
```

B. How to Use Solr

After the installation of Solr, some sample data sets in “exampledocs” file can be used. A sample data file is as follows:

<table>

Data in Table 1 can be listed by the following methods on sonar browser after indexed in Solr.

Request:

```
http://localhost:8983/solr/select?q=*:*&wt=json
```

- Lists all data
- wt=json Listed in JSON format

Request:

```
http://localhost:8983/solr/select?q=id:VS1GB400C3&wt=json &fl=id,name
```

- Lists data with VS1GB400C3 id parameter value
- wt=json Listed in JSON format
- fl=id,name Lists only id and name information in results page.
III. ELASTICSEARCH

Elasticsearch is also another distributed and open-source analysis and search tool which was developed using Lucene library. It was designed for Scalability, security, and easy management. By means of its query language that indexes structural and non-structural, and time-based data, provides rapid search and powerful analysis capabilities.

A. Technical Specifications of Elasticsearch

Elasticsearch is a document-based tool. Each entry in Elasticsearch is a structured JSON document. In other words, each data sent to Elasticsearch for indexing is a JSON document [10]. It is necessary to know some basic concepts to understand the structure of Elasticsearch. These are as follows:

Index: An index is like a database in a relational database. Each Elasticsearch index is a structured JSON document.

Type: A type is like a table in a relational database. Elasticsearch indexes can include more than one type.

Mapping: This is the process of managing how the data transferred types on indexes should be handled. It is equal to identification of data type (string, integer, double, boolean) before adding the data in the traditional databases. Elasticsearch automatically realizes mapping based on the data, and however this can also be done manually.

Shard/Sharding: It is the horizontal distributing of data to other machines on the network in database technologies. Thanks to sharding technology, data can be divided into pieces based on the existing physical facilities. Elasticsearch divides indexes into 5 shards by default to store them.

Replica: A replica is a copy of the primary shard. It is mainly used to prevent data loss in index documents as well as to distribute the load of the indexes in distributed database architectures. Elasticsearch indexes creates one copy of each shard document when they are created at first.

Schema: Being schema-free, Elasticsearch automatically realizes index, type, filed type descriptions and does not require the users to do so.

Elasticsearch can be managed by JSON commands over HTTP with RESTful API. Thereby, it can operate on many coding languages with no problem.

B. How to Use Elasticsearch

Elasticsearch can be used in computers with JVM installed after downloading. It does not require configuration for first use. Data adding/query can be conducted on curl (client URL library) as it is for RESTful API.

}

While using Elasticsearch indexes, curl library can be used in addition to “Sense” plugin in Google Chrome.

Elasticsearch provides client support for many platforms including Java, Ruby, PHP, Python and .NET, and it can be managed through coding languages of these platforms.
IV. TECHNICAL COMPARISON BETWEEN SOLR AND ELASTICSEARCH

A. Overview
Table IV provides a general overview for the features of Solr and Elasticsearch tools.

V. PERFORMANCE COMPARISON BETWEEN SOLR AND ELASTICSEARCH

One of the issues that Solr and Elasticsearch tools are compared most is their performance figures. Even though these tools are quite similar to one another in terms of being Lucene-based, different figures can be obtained related to their performance. In studies on performance comparisons, it was found out that Solr and Elasticsearch do not greatly have superiority over each other [12][13]. However, sometimes Solr had better performance over Elasticsearch based on intended use, place of use, and changes in some parameters, and vice versa. In this part of this study, some of the performance results conducted so far on Solr and Elasticsearch are listed.

A. Flax.co.uk Tests
Flax.co.uk design, build and support open source powered search applications based in Cambridge U.K. Flax has completed many performance tests on Solr and Elasticsearch. Cluster specifications used in a test are as follows:

- Two machines, each with 96GB RAM
- Two instances of SolrCloud or Elasticsearch on each
- Each instance has 24GB JVM heap
- Four shards
- No replicas

In the first stage of this test, a data consisting of 40 million pieces with 5 to 20 words was created. The results of Solr and Elasticsearch indexes are listed below:

- Elasticsearch indexed them in 30 minutes
- Total index size was 8.8 GB (easily cacheable)
- Solr indexed them in 43 minutes
- Total index size was 7.6 GB

Then, a data consisting of 40 million pieces with 200 to 1000 words was indexed. The results of Solr and Elasticsearch indexes are listed below:

- Elasticsearch indexed them in 179 minutes
- Total index size was 363 GB (not completely cacheable)
- Solr indexed them in 119 minutes
- Total index size was 226 GB

Based on these results, it can be concluded that Elasticsearch performs better with short documents, while Solr had better performance with long documents.

B. Search Test with Indexing
In another study, the first test was designed for conducting a search on servers with similar features (4 nodes, 4 index shards, no replication, 16 GB per node) with 20 million documents. In this process, no extra procedure was followed regarding Solr and Elasticsearch nodes. As seen in Figure 1, it was found out that most of the Elasticsearch queries were completed between 0.10 sec and 0.22 sec as a result of 1000 search inquiries sent to nodes. The same test provided the results of 0.12 sec and 0.54 sec for Solr tool [13].

C. Search Test with Indexing Load
In the second test, servers were requested to operate search inquiries while engaged in indexing process. These tests were also conducted with 20 million entries on servers with similar features. As seen in Figure 2, Elasticsearch had results varying between 0.14 sec and 0.34 sec, Solr completed search inquiry between 0.24 sec and 0.68 sec. Elasticsearch was slightly better than Solr in search tests with indexing load.
D. QPS Test

Queries per second (QPS) is a common measure of the amount of search traffic an information retrieval system, such as a search engine or a database, receives during one second [14].

In QPS test conducted between Elasticsearch and Solr, indexing was continued as a continuation of the previous test. QPS figures were measured for both tools while indexing process was active. As seen in Figure 3, Elasticsearch reached at 30 QPS speed, while Solr was remained at 15 QPS speed when sent similar search requests.

In another QPS test conducted with 40 million pieces of data (between 200 and 1000 words), it was observed that Solr had better performance (Figure 4) [12].

Taking a look at the July 2016 figures published by most-respected DB-Engines web site by database users, Elasticsearch use/liking has increased compared to the previous year, and it moved ahead of Solr (see Table VIII).

Considering the previous studies in literature and the technical data and performance tests of this study, it is seen that Solr and Elasticsearch were better than one another on different tests. These comparison results obtained through this study and the other studies conducted in literature are as follows:

- They are similar tools in terms of technical features.
- Elasticsearch supports more coding language than Solr.
- Solr uses less disk space considering the size of data after indexing.
- Regarding the indexing duration, Elasticsearch had better performance in short data, while Solr was better in long data.
- Both tools are rapid search tools.
- Close performance results were obtained in many different studies.
- Solr and Elasticsearch may have quite different performance characteristics in certain cases [12]
- QPS speed might vary depending on the type of data.
- It is quite hard to predict which one will have higher performance before the tests.
- If a choice shall be made between these two search engines, it is necessary to conduct a test based on the purpose of work.

VI. CONCLUSIONS

Solr and Elasticsearch are two similar search platforms which are both Lucene-based, has similar coding languages, intend use and styles. Solr is one of the search tools that could maintained its popularity even in today’s world.

Elasticsearch, one the other hand, was developed as a way of completing the deficiencies of Solr, and it had a significant place in markets in such a short span of 6 years (2010-2016).
ACKNOWLEDGMENT

We deeply send our regards and thanks to DB-Engines.com, www.solr-vs-elasticsearch.com, and www.Flax.co.uk web sites for the information they shared with us regarding the collection of technical data and performance tests about Solr and Elasticsearch.

Abstract—The User Knowledge Modelling dataset in the UCI machine learning repository was used in this study. The students were classified into 4 class (very low, low, middle, and high) due to the 5 performance data in the dataset. 258 data of 403 data in the dataset were used for training and 145 of them were used for tests. The Weka (Waikato Environment for Knowledge Analysis) software was used for classification. In classification Multilayer Perceptron (MLP), k Nearest Neighbour (kNN), J48, NativeBayes, BayesNet, KStar, RBFNetwork and RBFClassifier machine learning algorithms were used and success rates and error rates were calculated. In this study 8 different data mining algorithm were used and the best classification success rate was obtained by MLP. With Multilayer perceptron neural network model the classification success rates was calculated when there are different number of neurons in the hidden layer of MLP. The best classification success rate was achieved as 97.2414% when there was 8 neurons in the hidden layer. MAE and RMSE values were obtained for this classification success rate as 0.0242 and 0.1094 respectively.

Keywords— Machine learning, Weka, MLP, kNN, J48

I. INTRODUCTION

Data mining is an interdisciplinary subfield of computer science. It is the practice of automatically searching large stores of data to discover patterns and trends that go beyond simple analysis. Data mining uses sophisticated mathematical algorithms to segment the data and evaluate the probability of future events. Data mining is also known as Knowledge Discovery in Data (KDD) [1].

Educational data mining (EDM) is defined as the area of scientific inquiry centered around the development of methods for making discoveries within the unique kinds of data that come from educational settings, and using those methods to better understand students and the settings which they learn in [2]. Many studies in the literature have been proposed to explore the relationship between successes of the students and his/her culture, habits, life style, family structure etc.

Superbý et al. (2006) have search a relation between Academic failures and increase the number of debates among first-year university students. They aims to classify, as early in the academic year as possible, students into three groups: the ‘low-risk’ students, who have a high probability of succeeding, the ‘medium-risk’ students, who may succeed thanks to the measures taken by the university, and the ‘high-risk’ students, who have a high probability of failing (or dropping out). The fact that the most significant variables correlated to academic success have been provided among all the questions asked to 533 first-year university students during the month of November of academic year 2003-04. Finally, it presents the results of the application of discriminant analysis, neural networks, random forests and decision trees aimed at predicting those students’ academic success [3]. Vera et al. (2012) have proposed a genetic programming algorithm and different data mining approaches for solving these problems using real data about 670 high school students from Zacatecas, Mexico. They also propose to use a genetic programming model versus different white box techniques in order to obtain both more comprehensible and accuracy classification rules. They have shown that some approaches such as selecting the best attributes, cost-sensitive classification, and data balancing can also be very useful for improving accuracy [4]. Sen et al. (2012) developed models to predict secondary education placement test results, and using sensitivity analysis on those prediction models using a large and feature rich dataset from Secondary Education Transition System in Turkey. The Support Vector Machines, Artificial Neural Networks and Logistic Regression models have been used for prediction and results were presented [5].

In this study, the User Knowledge Modelling dataset obtained from UCI Machine Learning Repository have been used for classification. In this dataset, there are 5 attributes that used for determining the students’ educational status in 4 class as very low, low, middle, high. For classification 8 machine learning algorithm have been used. The obtained success rates and error values by those algorithms, have been compared.

II. MATERIAL AND METHODS

Software—WEKA

Weka (Waikato Environment for Knowledge Analysis) written in Java, developed at the University of Waikato, New Zealand [6]. Weka supports several standard data mining tasks, more specifically, data pre-processing, clustering, classification, regression, visualization, and feature selection. All techniques of Weka's software are predicated on the
assumption that the data is available as a single flat file or relation, where each data point is described by a fixed number of attributes (normally, numeric or nominal attributes, but some other attribute types are also supported) [7].

**K-Nearest Neighbour Algorithm**

kNN is the supervised learning algorithm, solving the classification problems. Classification is to analyse of features of image, and to belong it to the class which named in advanced. The important thing is determination the features of each category in advance [8]. According to kNN algorithm that was used in classification, characteristics which extracted from classification process, viewing the entire distance among new individual which should be classified and earlier individuals and then the nearest k category is used. As a result of that process test data belongs to the nearest k neighbour category that has more members in certain class. The most important optimization problems in kNN method are identification of neighbour’s number and method of distance calculation algorithm. At the study identification of the optimum k number is done by experiments and Euclidean Distance Calculations method was used as distance calculations method.

Euclidean calculation method [9]:

\[ d(x_i, x_j) = \left( \sum_{x=1}^{n} (x_{ij} + x_{i2})^2 \right)^{1/2} \]

\(x_i\) and \(x_j\) are two different points, and need distance calculation process in between.

**Multilayer Perceptron**

A multilayer perceptron (MLP) is a feed forward artificial neural network model that maps sets of input data onto a set of appropriate outputs. A MLP consists of multiple layers of nodes in a directed graph, with each layer fully connected to the next one. Except for the input nodes, each node is a neuron (or processing element) with a nonlinear activation function. MLP utilizes a supervised learning technique called back propagation for training the network. MLP is a modification of the standard linear perceptron and can distinguish data that are not linearly separable [6].

**RBF Network**

It is an artificial neural network that uses radial basis functions as activation functions. The output of the network is a linear combination of radial basis functions of the inputs and neuron parameters. Radial basis function networks have many uses, including function approximation, time series prediction, classification, and system control [6].

**BayesNet**

It is probabilistic graphical model (a type of statistical model) that represents a set of random variables and their conditional dependencies via a directed acyclic graph (DAG). For example, a Bayesian network could represent the probabilistic relationships between diseases and symptoms. Given symptoms, the network can be used to compute the probabilities of the presence of various diseases [6].

**Naive Bayes**

Naive Bayes classifiers are highly scalable, requiring a number of parameters linear in the number of variables (features/predictors) in a learning problem. Maximum-likelihood training can be done by evaluating a closed-form expression which takes linear time, rather than by expensive iterative approximation as used for many other types of classifiers [6].

**J48**

J48 algorithm of Weka software is a popular machine learning algorithm based upon J.R. Quilan C4.5 algorithm. All data to be examined will be of the categorical type and therefore continuous data will not be examined at this stage. The algorithm will however leave room for adaption to include this capability [6, 7].

**KStar**

K-star or K* is an instance-based classifier. The class of a test instance is based on the training instances similar to it, as determined by some similarity function. It differs from other instance-based learners in that it uses an entropy-based distance function. [10].

### III. RESULTS AND DISCUSSION

403 sample data at User Knowledge Modelling dataset were processed by using Weka program. The classification success rates at different neurons numbers in the hidden layers and MAE, RMSE error rates were determined. The diagram demonstrating the changes in MAE and RMSE error values based on the number of neighbours in the hidden layer is demonstrated in Figure 1.

</tbody>
</table>

In this study, students have been classified about their success in the school as very low, low, middle and high by using their daily habits. By this intention, popular data mining algorithms like kNN, MLP, J48, NaiveBayes, RBFNetwork, RBFClassifier, BayesNet and Kstar, have been used and compared with each other. At obtained classification success rates, success rates made with kNN algorithm is seen to be higher. At classification success rates obtained with kNN algorithm, highest classification success was obtained for 3 neighbour values and this value is 87.5862%. At this neighbour value, MAE error value is 0.1037 and RMSE error value is 0.2324. It is seen that classification success rates obtained by using Multilayer perceptron model is too low for kNN classifier. While the number of neurons in the hidden layer is 8, highest classification success was obtained and this value is 97.2414%. At this neurons number in the hidden layer, MAE error value is 0.0242 and RMSE error value is 0.1094.

The success rates obtained using J48, NaiveBayes, RBFNetwork, RBFClassifier, BayesNet and Kstar classification algorithms were found as 91.0345%, 84.8276%, 93.7931%, 71.0345%, 86.8966% and 81.37935 respectively.

Estimation of Credit Card Customers Payment Status by Using kNN and MLP

Murat KOKLU 1, Kadir SABANCI 2

1 Selcuk University, Faculty of Technology, Computer Engineering, Konya, TURKEY, mkoklu@selcuk.edu.tr
2 Karamanoglu Mehmetbey University, Faculty of Engineering, Department of Electrical and Electronics Engineering, Karaman, TURKEY, kadirsabanci@kmu.edu.tr

Abstract—The Default of Credit Card Clients dataset in the UCI machine learning repository was used in this study. The credit card customers were classified if they would do payment or not (yes=1 no=0) for next month by using 23 information about them. Totally 30000 data in the dataset’s 66% was used for training and rest of them as 33% was used for tests. The Weka (Waikato Environment for Knowledge Analysis) software was used for estimation. In estimation Multilayer Perceptron (MLP) and k Nearest Neighbour (kNN) machine learning algorithms was used and success rates and error rates were calculated. With kNN estimation success rates for various number of neighbourhood value was calculated one by one. The highest success rate was achieved as 80.6569% when the number of neighbour is 10. With MLP neural network model the estimation success rates was calculated when there are different number of neurons in the hidden layer of MLP. The best estimation success rate was achieved as 81.049% when there was only one neuron in the hidden layer. MAE and RMSE values were obtained for this estimation success rate as 0.3237 and 0.388 respectively.

Keywords—Data mining, Weka, MLP, kNN

I. INTRODUCTION

Credit card is a payment card issued to users (cardholders) as a method of payment. It allows the cardholder to pay for goods and services based on the holder's promise to pay for them [1]. The issuer of the card (usually a bank) creates a revolving account and grants a line of credit to the cardholder, from which the cardholder can borrow money for payment to a merchant or as a cash advance. For the banks the most important thing during credit card marketing is the payment capability of customers. In this study a payment status estimation have been proposed for credit card customers. For this purpose data mining algorithms have been used.

Data mining is a computational process that reveals patterns in data sets by using such methods like artificial intelligence, machine learning, statistics etc [2]. The methods used in data mining are investigated in two groups as predictive and descriptive. In predictive methods, a model is created by using a dataset whose results are known. For example in a bank, the properties of customers who pay their credits back can be revealed and a model can be created by using previous data sets about funding of them. Afterward this model can be used on new customers for determining the possibility of pay their credits back. In descriptive methods, a relationship can be searched between two data sets. For example, the shopping habits of two different culture may be investigated for similarity [3].

Data mining methods can be divided into three groups due to their function.
1. Classification and Regression
2. Clustering
3. Association Rules

Data mining methods are used to classifying the data set. In classification, training examples are used to learn a model that can classify the data samples into known classes. The classification process involves following these steps: creating a training data set, identifying class attributes and classes, identifying useful attributes for classification, relevance analysis, learning a model using training examples in the training set and using the model to classify the unknown data [4].

In this study, an estimation about whether the payment for next month is going to be done or not by the credit card clients in the default credit card clients data set with 23 attributes obtained from the UCI Machine Learning Repository, have been done. For estimation kNN and MLP algorithms have been used. The success rates and error values have been presented and compared with each other.

II. MATERIAL AND METHODS

Dataset

In this study the default of credit card clients data set obtained from UCI Machine Learning Repository have been used. This data set have been obtained from Credit cart customers’ default payments in Taiwan. In this data set there are 23 attributes and a binary type class. These attributes and descriptions are as follow [5].

X1: Amount of the given credit (NT dollar): it includes both the individual consumer credit and his/her family (supplementary) credit.
X2: Gender (1 = male; 2 = female).
X3: Education (1 = graduate school; 2 = university; 3 = high school; 4 = others).
X4: Marital status (1 = married; 2 = single; 3 = others).
X5: Age (year).
X6 - X11: History of past payment from April to September, 2005. The measurement scale for the repayment status is: -1 = pay duly or number of the delayed month.
X12-X17: Amount of bill statement (NT dollar).
X18-X23: Amount of previous payment (NT dollar).
X24: Class (0 = No; 1 = Yes)

Software-WEKA

Developed by Waikato University in New Zealand, WEKA is an open-source data mining software with a functional graphical interface which incorporates machine learning algorithms [6]. WEKA includes various data pre-processing, classification, regression, clustering, association rules, and visualization tools. The algorithms can be applied on the data cluster either directly or by calling via Java code [7][8]. They are also suitable for developing new machine learning algorithms.

Machine learning algorithms

K-Nearest Neighbor Algorithm: The k-NN is a supervised learning algorithm that solves classification problems. Classification is the examination of the attributes of an image and the designation of this image to a predefined class. The important point is the determination of the features of each category in advance [9]. According to the kNN algorithm used in the classification, based on the attributes drawn from the classification stage, the distance of the new individual that is wanted to be classified to all previous individuals is considered and the nearest k class is used. As a result of this process, test data belongs to the k-nearest neighbour category that has more members in a certain class. The most important optimization problems in the kNN method are the identification of the number of neighbours and the method of distance calculation algorithm. In the study, the identification of the optimum k number is performed with experiments, and the Euclidean Distance Calculations method is used as a distance calculation method.

Euclidean calculation method [10]:
\[ d(x_i, x_j) = \left( \sum_{p=1}^{P} (x_{ip} + x_{jp})^2 \right)^{\frac{1}{2}} \]

xi and xj are two different points, and we need distance calculation process in between.

Multilayer Perceptron: It is a feed forward type artificial neural network model which maps input sets onto appropriate output sets. A MLP is composed of multiple layers of nodes where each layer is connected to the next. Each node is a processing element or a neuron that has a nonlinear activation function except the input nodes. It uses a supervised learning technique named back propagation and it is used for training the network. The alteration of the standard linear perceptron, MLP is capable of distinguishing data which are not linearly separable [8].

III. RESULTS AND DISCUSSION

In the study, WEKA software was used in order to estimate the payment for next month is going to be done or not by the credit card. Using the kNN algorithm, the estimation success rates of payment were obtained for different k-neighbour values. Also, root mean square error (RMSE) and mean absolute error (MAE) values were obtained. The estimation success rates obtained with kNN algorithm, and MAE and RMSE values can be seen in Table 1. The diagram demonstrating the changes in MAE and RMSE error values based on the number of neighbours in the estimation performed with the kNN algorithm is shown in Figure 1.

Fig. 1 Variation of error rate based on the number of neighbourhood

The data in the same dataset were processed using the MLP model, and the estimation success rates of credit card payments. The estimation success rates of different number of neurons in the hidden layer, and MAE and RMSE error values were obtained. In the MLP model, the training was performed by
taking the learning rate value as 0.3, momentum value as 0.2 and iteration number as 500. The estimation success rates, and MAE and RMSE values obtained using the MLP model can be seen in Table 2. The diagram demonstrating the changes in MAE and RMSE error values based on the number of neighbours in the hidden layer is demonstrated in Figure 2.

IV. CONCLUSION
In this study, credit card clients’ behaviours about payment have been estimated. For this purpose machine learning algorithms like kNN and MLP have been used. The estimation success rates and error values of kNN and MLP were calculated. It was observed that the success rate was higher for the estimation performed by using the MLP algorithm. The highest estimation success rate was achieved when the number of neurons in the hidden layer was 1 and the success rate was 81.049%. The MAE error value was 0.3237 and the RMSE error value was 0.388 when there is only one neuron in the hidden layer. For the estimation success rates obtained using K-Nearest Neighbour Algorithm, the highest estimation success rate was achieved for 10 neighbourhood values, and it was 80.6569%. For this neighbourhood value, the MAE error value was 0.2743 and the RMSE error value was 0.3897.

**Abstract**—Blind Source Separation (BSS) is one of the most important and challenging problem for the researchers in audio and speech processing area. In the literature, many different methods have been proposed to solve BSS problem. In this study, we have compared the performance of three popular BSS methods based on Independent Component Analysis (ICA) and Independent Vector Analysis Models, which are Fast-ICA, Kernel-ICA and Fast-IVA. We collected experimental data by recording speech from 13 people. Three different scenarios are proposed to compare the performance of BSS methods effectively. Experimental results show that the Fast-IVA has better performance than the ICA based methods according to performance metrics of Source-to-Artifact Ratio, Source-to-Distortion Ratio and Source-to-Noise Ratio. But ICA methods give better results than Fast-IVA according to the Source-to-Interference Ratio.

**Keywords**—Blind source separation, Independent component analysis, Independent vector analysis

**I. INTRODUCTION**

Blind Source Separation (BSS) is one of the most important problems in speech processing area. The better description of this problem can be represented by this question: How can we accurately determine what a particular person talks among several speakers at the same time? Figure 1 shows an illustration of BSS problem. This problem describes the situation of focusing on one speaker in case of several persons talking simultaneously in same room. To separate the mixed speech signals to obtain just a speech signal which belongs to a particular speaker is very challenging and complicated problem [1]. In the literature, many different methods based on signal processing and statistics were proposed to solve BSS problem.

**Fig. 1. BSS Problem**

BSS was firstly addressed by Herault and Jutten in 1985 [2]. In their work, the sound is directly transmitted to the microphones without any delay which known as standard blind source separation. Then Bell and Sejnowski in 1995 developed the Independent Component Analysis (ICA) method to solve BSS problem when the sources are mixed simultaneously [3]. Also some different algorithms based on ICA such as Fast-Fixed Point ICA [4], the Jade-ICA [5], the EGLD-ICA, the MS-ICA [6], and the Kernel-ICA [7] were proposed in literature.

As a result, BSS problem becomes more complicated for real room environment and this speech propagation problem is called convolutive blind source separation (CBSS) [8].

In the literature, some solutions were proposed in the time domain. Due to the complicated calculation caused by convolution, Parra et al [15] suggested another method based on frequency domain. In frequency domain, the convolution is replaced with multiplication to have low cost in terms of execution time. However, the frequency based methods still have scaling and permutation ambiguities. To prevent permutation problem, an advanced method named Independent Vector Analysis (IVA) was proposed by Kim et al [9].

In this study we have compared the performance of two ICA based algorithms and Fast-IVA according to performance measurement metrics commonly used for BSS problem. This paper is organized as follow: Section II contains the standard ICA method and its properties, ICA based algorithms (Fast-ICA and Kernel-ICA). Section III explains details of Fast Fixed Point IVA algorithm. Section IV gives brief information about the commonly used performance measurement metrics. Experimental results obtained by using different proposed scenarios are represented in Section V. Finally the conclusion is presented in the last section.

**II. INDEPENDENT COMPONENT ANALYSIS**

Independent Component Analysis (ICA) is one of the most popular BSS methods. ICA was used extensively for many applications in various field of science and engineering. ICA, which is a statistical computational method, was employed to find underlying hidden factors among set of random vectors. The main aim of ICA method is to obtain the independent components (ICs), which are linearly independent or as independent as possible, by finding a linear representation of non-Gaussian data.
A. ICA MODEL

Suppose that we have two persons talking simultaneously in a room and two microphones were replaced in different places for recording their talking. In this way, two speech signals are recorded by these microphones. These signals can be represented as \( x_1(t) \) and \( x_2(t) \) where \( t \) is the time index. The signals from the speakers can also be represented as \( s_1(t) \), \( s_2(t) \), so the linear combination of the speech signals can be expressed as:

\[
\begin{align*}
  x_1(t) &= a_{11}s_1(t) + a_{12}s_2(t) \\
  x_2(t) &= a_{21}s_1(t) + a_{22}s_2(t)
\end{align*}
\]  

Where \( s_1 \) and \( s_2 \) are the original speech signals, \( a_{11}, a_{12}, a_{21} \) and \( a_{22} \) denote the parameters that depend on the distance between the speakers and the microphones. Assume that \( M \) is the number of observed mixture signals and \( L \) is the number of independent source signals. Then the model will be as follow:

\[
x_i = \sum_{j=1}^{L} a_{ij}s_j, i = 1 \ldots M
\]

Since instead of summations like in (2), using vector-matrix notation is more suitable to, the ICA model can be rewritten as:

\[
x = As \quad (3)
\]

where \( A \) is an unknown matrix called the mixing matrix, \( x \) is a vector of the observed signals and \( s \) is a vector of the source signals. The challenge in the ICA method is the estimation of both \( A \) and \( s \) by using only the observed random vector \( x \). It is assumed that the unknown mixing matrix should be invertible or pseudo-invertible. After the matrix \( A \) estimation, its inverse denoted by \( W \) can be computed. As a result ICs denoted by \( y \) is obtained simply by using following equation.

\[
y = Wx \quad (4)
\]

ICA requires some assumptions related to the sources and the mixing process. These assumptions make this method different from the other source separation approaches [10]. The first assumption is that the sources being considered are statistically independent. The other one is that the sources must have non-Gaussian distribution. The last one is to have invertible mixing matrix [10].

Two inherent ambiguities are hold in ICA framework. One of them is magnitude and scaling ambiguity, and the other is the permutation ambiguity [10].

Some preprocessing steps can be performed to improve the performance of ICA based methods. Some useful preprocessing techniques are Centering and Whitening[10].

There are several kinds of algorithm based on ICA. In this study we have performed two of them, which are widely used.

B. FAST FIXED-POINT ICA

The Fast Fixed-Point ICA (Fast-ICA) algorithm based on mutual information utilizes higher order statistics for the retrieval of independent sources [4]. Fast ICA has two estimation approaches:

(i) deflation approach to estimate ICs one by one and (ii) symmetric approach to estimate ICs simultaneously[4].

Fast-ICA uses fixed-point algorithm of ICA as follow:

\[\text{Algorithm} \quad \text{Fast fixed-point ICA [4]}\]

1. Take a random initial vector \( w(0) \) of norm 1, Consider \( k = 1 \).
2. Let \( w(k) = \text{Ex}(w(k-1)T \cdot x)^3 w(k-1) \). Estimate the expectation using a large sample of \( x \) vectors.
3. Divide \( w(k) \) by its norm.
4. if \( |(w(k)T w(k-1)| \) is not close enough to 1, consider \( k = k + 1 \) and go back to step 2, otherwise return the vector \( w(k) \) as output.

C. KERNEL INDEPENDENT COMPONENT ANALYSIS

The Kernel Independent Component Analysis (Kernel-ICA) is a different version of ICA model that based on the minimization of a contrast function based on kernel ideas. Kernel-ICA rely on an entire function space of candidate nonlinearities. In particular, Kernel-ICA works with the functions in a reproducing kernel Hilbert space using canonical correlation based functions. The Kernel trick is used to make the search over this space efficiently. Some new modifications were proposed to make the algorithm more robust and efficient to different source distributions [7]. In short, Kernel-ICA use optimization methods for canonical correlations to reproduce kernel Hilbert space.

III. INDEPENDENT VECTOR ANALYSIS

Independent Vector Analysis (IVA), which is one of the most advanced method, show better performance in the field of BSS. Theoretically this method overcomes the permutation problem that inherent from ICA. It is designed to remove the dependency between different source vectors while keeping the dependency within individual source vectors. The problem is transformed into frequency domain to reduce computational complexity of the time domain. The noise free model in the frequency domain can be defined as follow:

\[
X(k) = H(k)s(k) \quad (5)
\]

\[
\hat{S}(k) = W(k)x(k) \quad (6)
\]

Where the index \( k = 1, 2, \ldots, K \) indicate the k-th frequency bin, and \( K \) is the number of frequency bins, \( x(k) = [x_1(k), x_2(k), x_m(k)]^T \) represent the observed signal vector in the frequency domain, \( s(k) = [s_1(k), s_2(k), s_m(k)]^T \) denotes the original source vector in the frequency domain and \( \hat{s}(k) = [\hat{s}_1(k), \hat{s}_2(k), \hat{s}_m(k)]^T \) represents the estimated source vector in the frequency domain. And \( (.)^T \) is the vector transpose. The number of microphones and the number of sources are represented by \( m \) and \( n \), respectively. \( H(k) \), which is a \( mn \) dimension matrix, denotes the mixing matrix and \( W(k) \), which is a \( nm \) dimension matrix, denotes the unmixing matrix.

In this study, we assume that the number of sources and the number of microphones should be the same. The main goal is that the sources should be estimated by using only the observed (mixed) signals.

An objective function is defined to separate multivariate sources from multivariate observations. Kullback-Leibler di-
vergence between two functions as the measure of dependence is employed in IVA. These two functions are the joint probability density function \( p = 1, \ldots, n \) and the product of probability density functions of the individual source vectors \( \Pi q(\hat{s}_i) \). This function can be defined as follow:

\[
J = kL(p(\hat{s}_1, \ldots, \hat{s}_n) || \Pi q(\hat{s}_i)) = \text{const} - \sum_{k=1}^{K} \log|\det(W)| - \sum_{k=1}^{n} E[\log q(\hat{s}_i)]
\]

We can keep the dependency between the components of each vector, and remove the dependency between the source vectors if the cost function is minimized [11].

In literature, there are different version of IVA such as NG-IVA, Fast-IVA and Aux-IVA [11]. In this study Fast-IVA algorithm is employed for BSS.

A. FAST FIXED-POINT INDEPENDENT VECTOR ANALYSIS

This algorithm utilizes Newtons method to update the original IVA method, which converges quadratically and select an efficient learning rate. In order to apply Newtons method in the update rules, polynomial approximation of a quadratic Taylor series is produced in the notations of complex variables. In this way, it can be used for a contrast function of complex-valued variables [11]. The contrast function used by Fast IVA is as follows:

\[
J = \sum_{k=1}^{n} E[G(\sum_{k=1}^{K} |\hat{S}_i(k)|^2) \sum_{k=1}^{K} \lambda_i^{(k)} (w_i(k)w_i(k) - 1)]
\]

where, \( \lambda_i \) is the ith Lagrange multiplier, and \( w_i(k) \) denotes the ith row of the unmixing matrix \( W \), \( G() \) is the non-linearity function, which can take on several different forms as discussed in [11]. The learning rule can be defined as follow with normalization:

\[
(W_i^{(k)})^H \leftarrow E[G(\sum_{k=1}^{K} |\hat{S}_i(k)|^2) + \sum_{k=1}^{K} |S_i(k)|^2 G''(\sum_{k=1}^{K} |S_i(k)|^2)] x(W_i^{(k)})^H - E[\hat{S}_i(k)^* G'(\sum_{k=1}^{K} |S_i(k)|^2)^x K]
\]

where \( G'(\cdot) \) and \( G''(\cdot) \) represent the first and second derivative of \( G(\cdot) \), respectively. And if we use that for all sources, we can construct an unmixing matrix \( W(k) \) to be decorrelated with

\[
W(K) \leftarrow (W(K)(W(K))^T)^{-1/2} W(K)
\]

IV. PERFORMANCE MEASUREMENT

There are several performance measurement metrics to evaluate the quality of estimated signals obtained by BSS methods. The performance of BSS algorithms can be measured by comparing each estimated source \( j \) to a given true source \( j \). The measuring processing includes two successive steps [12].

The first step involves decompose \( j \) as:

\[
\hat{s}_j = s_{\text{target}} + e_{\text{interf}} + e_{\text{noise}} + e_{\text{artif}}
\]

Where \( s_{\text{target}} = f(s_j) \) denotes the version of \( s_j \) modified by an allowed distortion, and the interferences, noise, and artifacts error terms are represented by where, \( s_{\text{interf}}, s_{\text{noise}} \) and \( s_{\text{artif}} \), respectively.

The second step involves computing the energy ratios in order to estimate the relative amount of each of these four terms either on the local frames of the signal or the whole signal duration. The way of decomposing into four terms are given in [12] in detail. Relevant energy ratios between these terms are defined.

After the decomposition of \( j \) following the procedures given in [21]. Numerical performance criteria was defined by computing energy ratios expressed in decibels. Definition of source-to-distortion ratio (SDR), the source-to-interference ratio (SIR), source-to-artifact ratio(SAR) and source-to-noise ratio(SNR) are given below, respectively

\[
SDR := 10 \log_{10} \frac{||s_{\text{target}}||^2}{||e_{\text{interf}} + e_{\text{noise}} + e_{\text{artif}}||^2}
\]

\[
SIR := 10 \log_{10} \frac{||s_{\text{target}}||^2}{||e_{\text{interf}}||^2}
\]

\[
SAR := 10 \log_{10} \frac{||s_{\text{target}} + e_{\text{interf}}||^2}{||e_{\text{artif}}||^2}
\]

\[
SNR := 10 \log_{10} \frac{||s_{\text{target}} + e_{\text{interf}}||^2}{||e_{\text{noise}}||^2}
\]

V. EXPERIMENTAL RESULTS

The performance of Fast-ICA, Kernel-ICA and Fast-IVA methods for separating mixing speech signals was compared. We collected 13 speech signals recorded in real room, each record long 10sec in Arabic language with 16 kHz. These records are mixed by using random parameters.

In our experiment, three different scenarios are proposed to compare performance more effectively. The first scenario includes measuring and comparing the performance of Fast-ICA, Kernel-ICA and Fast-IVA for separating mixing speech signals without noise, as shown in Figure 2. Figure 3 illustrates the second scenario which shows the performance of these methods for separating mixed speech signals with Gaussian noise added to signals before mixing. In the third scenario, we add Gaussian noise to the signals after mixing as shown in Figure 4. Since Gaussian noise is added to the sources or mixtures in the second and third scenarios, Savitzky-Golay smoothing filter [13] is performed to enhance the signals before the separation.

![Fig. 2. Illustration of Scenario 1 for the experiment](image)

![Fig. 3. Illustration of Scenario 2 for the experiment](image)
In each scenario, we have created 77 different mixture signals from 13 original sources using different mixture parameters. The Fast-IVA use the Short time Fourier Transform of length 1024, and the sampling frequencies were 16 kHz. The results of our experiment for each scenario show that: the Fast-IVA has better performance comparing with Fast-ICA and Kernel-ICA according to SAR, SDR and SNR performance metrics. But we notice that Fast-ICA and Kernel-ICA methods have better performance than Fast-IVA according SIR as shown in Table 1, Table 2 and Table 3.

In this study, We have implemented Fast-ICA algorithm in MATLAB. A different version of Fast-ICA algorithm can be downloaded from http://research.ics.aalto.fi/ica/fastica/code/dlcode.shtml. For the other BSS methods (Kernel-ICA and Fast-IVA), we have used the shared codes. The kernel-ICA package is Copyright (c) 2002 by Francis Bach [14], and Fast-IVA can be implemented and compared using different scenarios.

VI. THE CONCLUSION

Blind source separation (BSS) is one of the most important and challenging problem for the researchers in audio and speech processing fields. In this study, we have implemented and compared three popular BSS methods, which are Fast-ICA, Kernel-ICA and Fast-IVA. Three different scenarios were proposed to measure the performance of BSS methods extensively using four different commonly used performance metrics. According to experimental results Fast-IVA shows better performance than the other methods according to SDR, SAR and SNR metrics. But Fast-ICA and Kernel-ICA methods have high performance than Fast-IVA according to SIR metric. In future, some advanced BSS algorithms will be implemented and compared using different scenarios.

Note Recognition from Monophonic Musical Signals
By Using Neural Network

Mürsel ÖNDER¹, Özkan İNİK²
¹ Department of Mechatronic Engineering, Gaziosmanpaşa University, Tokat, Turkey
mursel.onder@gop.edu.tr
² Department of Computer Engineering, Gaziosmanpaşa University, Tokat, Turkey
özkan.inik@gop.edu.tr

Abstract— In this work, note recognition from monophonic musical signals is studied. It is aimed to achieve a musical note from the fundamental frequency. Artificial Neural Networks (ANN) is used in order to estimate the fundamental frequency. Firstly, around 6-10 seconds audio recordings for each musical notes are taken with the flute. Certain number of frames are taken from these audio recordings and used for training of the ANN. After training, any parts that are played on the flute are tested. The musical notes was found correctly on the tested parts that are played on the flute.

Keywords — Artificial neural networks (ANN), Signal processing, Monophonic music signals.

I. INTRODUCTION

Music note recognition is one of the most important part of some music applications. This fact is emphasized on [1] and in more specific works such as music transcription [2,3], song retrieval [4,5] and others [6,7,8].

ANN is one the useful techniques to overcome the drawbacks of classical signal processing and filtering techniques. It is claimed [3] that no work that refers to ANN for music note recognition has ever existed prior to their work [1].

Monophonic means the production of musical signal from single source in a time interval. Sound produced by a variety of sources in different time intervals does not disrupt the monophony. Sound received in the same structure from the group consisting of multiples wires can be considered as monophonic at the stringed instrument. But as in the Turkish instrument “baglama”, produced sound by a thick (bam) wire and one or two thin wires cannot be regarded as monophonic. In the polyphony, multiple voices are produced in the same time range [9].

Based on the physiological relationship all the sounds in music can be handled four variables in a very simple way [10]:
1. Repetition rate of the audio signal is related to the fundamental frequency.
2. The amplitude of the audio signal associated with rotundity
3. The shape of the audio signal associated with the timbre of musical instruments
4. According to the sensors location of the sound source are associated with the position of the sensors different detection.

The last parameter is not taken into account in the existing systems. But making recordings with people's ideas will give healthier and more productive results. These peoples are musical instruments producers, users, recorders and listeners.

The frequency content of a note is made up of a fundamental frequency and its exact multiples. As in Figure 1; if fundamental frequency is f0 then first harmonic is 2f0 second harmonic is 3f0 and so on [9].

Because of overlapping of fundamental frequency and harmonic content, sound produced by a group of artists or instruments is percepted as same note.

Fig. 1 Frequency content of monophonic musical signals [11]

The fundamental frequency relationship of two consecutive notes f0 and f1 is given in Equation 1.

\[ k = \frac{f_0}{f_1} = 2^{1/12} \approx 1.05946 \] (1)

A4 (440 Hz) is accepted La note other fundamental frequency values is calculated according to the Equation 1. This means that each octave is divided into 12 equal intervals [9].

II. MATERIAL AND METHOD

In this work, due to the simplicity of the harmonic structure recordings from the musical instrument called “block flute” is studied. Recordings are obtained by Sound Recorder in Windows Operating System, in 21.05 kHz sampling frequency and .wav format.

Flut is a musical tool designed to produce sound in equal order. Samples notes (do, re, mi, fa, sol, la, si, do) are taken of
the notes that are played on the flute. For each note 6-10 second audio file is saved. The audio recording of file belongs to do note, and its zooming part around 200 samples are shown in Figure 2. Periodic structure in the zoomed image can be seen very clearly. Frames containing 200 samples are obtained from these recordings performed separately for each note. Values are normalized to the range -1 to 1 and placed on a column of the data matrix. This procedure is repeated 400 times for each note. As a result, 200x400 sized matrix is created for a note. For 8 notes, by concatenating these 8 matrices, finally 200x3200 sized data matrix is formed.

A. Artificial neural networks (ANN)

One efficient way of solving complex problems is following the lemma “divide and conquer”. A complex system may be decomposed into simpler elements, in order to be able to understand it. Also simple elements may be gathered to produce a complex system [12]. Networks are one approach for achieving this. There are a large number of different types of networks, but they all are characterized by the following components: a set of nodes, and connections between nodes. One type of network sees the nodes as ‘artificial neurons’. These are called artificial neural networks (ANN). An artificial neuron is a computational model inspired in the natural neurons [13]. In other Words, Artificial neural networks are an attempt at modeling the information processing capabilities of nervous systems [14]. As shown in Figure 4, Biological Natural neurons receive signals through synapses located on the dendrites or membrane of the neuron. When the signals received are strong enough, the neuron is activated and emits a signal though the axon. This signal might be sent to another synapse, and might activate other neurons [13].

Figure 5 shows the structure of an artificial neural neuron with \( X_1, X_2, X_3, \ldots, X_n \) inputs. Each input channel i can transmit a real value \( x_i \). The input channels have an associated weight, which means that the incoming information \( x_i \) is multiplied by the corresponding weight \( W_{1j}, W_{2j}, W_{3j}, \ldots, W_{nj} \).

The sum function \( \text{net}_j \) computed according to the Equation 2.
The output of the processing element is calculated by netj value passed through the activation function (Equation 3).

\[ \theta_j = f(\text{net}_j) = f\left(\sum_{i=1}^{n} x_i * w_{ij}\right) \] (3)

The task of neural cells briefly is that controlled in response to the output value of the input value Xn. Until obtaining the desired output value is updated weight Wnj. Learning neural network takes place with updating Wnj weight.

III. EXPERIMENTAL STUDIES

This work describes the design of the ANN is performed with software MATLAB R2015a. 200 neurons in the input layer, 40 neurons in the output layer and 8 neurons in the hidden layer is used for Multi-layer ANN. traincgf (Scaled conjugate gradient backpropagation) is used as a training algorithm. The neuron that has highest value is selected from 8 neuron at the output of ANN. Each note (do, re, mi, fa, sol, la, si, do) is represented by numbers from 1 to 8 which are the the highest value of the output of the ANN.

Designed and trained ANN is tested with consecutive played notes by the flute. When notes are played at low frequencies to high frequencies, it is expected as a result of stairs as shown Figure 5. Figure 6 illustrates of achieving the expectations. Consecutive played do, re, mi, fa, sol, la, si and do notes are overlapped with the corresponding numbers.

![Fig. 5 Consecutive sort of musical notes](image)

Trained ANN was tested *Twinkle Twinkle Little Star* song for a second test. This song is an international song. The melody of the song and even music are taught in basic education institutions by many people. The song notes are given in Figure 9. Figure 10 shows very clearly that the values are assigned to the notes correctly. The persons who know the melody can see the accuracy of the results.

IV. RESULTS AND CONCLUSIONS

In this study 2 different tests are made after training ANN with the flute musical notes. Firstly, estimation of the note from melody which playing consecutive notes. The second forecast *Twinkle Twinkle Little Star* song notes. Accurate estimates were obtained in both studies.

![Fig. 9 Twinkle Twinkle Little Star song notes](image)

During the creation of the data matrix for ANN training, the used preprocessing methods, such as avoid repeating each window and take into account phase information can improve the performance.

It is observed that ANN is more suitable techniques than classical signal processing and filtering techniques [3, 9]. In future, the workings comparing classical and ANN techniques are advised. These workings are especially meaningful for generally Eastern music and Turkish music and musical instruments because of more detailed structure of their musical temperament.

Abstract—The predictable and deterministic world of the past has been replaced by the uncertain, random, and disorderly world of today. Different attributes represent different dimensions of alternatives, which may not be easily represented on a quantitative scale, may not be directly measurable, and may be stochastic or fuzzy. Wide range applications of building performance evaluations are based on numerical grading, which have been conducted for comprehensive building analysis. However, expert evaluation, as a nature of human knowledge, tends to be vague or imprecise. Moreover, human decision-making needs a quick-response analysis based on the decision-maker’s intuition, judgement, and experience. In this study, in order to insert uncertainty and human knowledge to building performance evaluation systems, fuzzy logic method is proposed for vulnerability evaluation of building characteristics. For the first part of evaluation, fire safety performance evaluation model is proposed, and critical building components in terms of passive fire safety are identified including numerical and linguistic input variables.

Keywords—fuzzy logic, fuzzy expert system, construction project evaluation

I. INTRODUCTION

From the earliest periods of architecture and building, performance evaluations have been conditioned by rules, regulations, standards, and governance expert grading, which have been contradicting the creative basis of their practice [1]. On the other hand, new construction methods, resulting from new and unfamiliar materials, new organizations of functions and occupancy classes, new equipment in the buildings, or different activities facilitated within building occupancy introduce new complex interactions. As the interactions get more complex, existing building performance guidelines remain too generic to understand the relationships and they become less competent in evaluating performance of buildings. Moreover, rapid increase in the complexity and embedded information in building systems drastically limits the time available for making decisions. The inherent nature of construction projects tends to be uncertain and depends on a subjective judgment of decision makers [2]. Therefore, the single-criterion and simple decision-making requirements of the guidelines have given way to highly complex decision problems involving multitudes of variables, which may be stochastic, fuzzy, or at worst unknown [3]. On the other hand, human decision-making needs a quick-response analysis based on the decision-maker’s intuition, judgement, and experience. However, when the complexity of a system increases, the ability of human beings to make precise, but significant statements diminishes [4]. Therefore, the human reasoning usually gives results in approximate ranges [5]. In addition, the decision making in real-world situations is a complex subject with uncertainty and vagueness [2]. In order to insert human reasoning in building performance evaluation systems, fuzzy logic system is used as a decision making and evaluation method. Fuzzy logic helps to integrate uncountable, undefined, and uncertain information into the decision-making process by converting hidden information into workable algorithms.

II. PERFORMANCE EVALUATION OF BUILDINGS

The evaluation methods used in traditional occupational hazards in the construction industry were mainly qualitative or statistical approaches. In addition, construction experts tend to use a single crisp value during risk assessments, which may lead to inaccurate assessment results [6]. By the time knowledge is being transformed into their digital representations in all fields, performance evaluation of building parameters imported into automated code compliance checking systems. Computerized checklist systems have advantages for detecting building vulnerabilities faster, however, in terms of reflecting the diversity of evaluation methods, they are dependent to deterministic [7]. The deterministic approach of evaluation is the disadvantage of accurate performance evaluation in the uncertain nature of construction. Hence, the single-criterion evaluation prevents the integration of design objectives.

In integrated building design, architects and engineers develop building specifications together from an early stage of the project. Therefore, various key design objectives as performance evaluation determinants are needed to be assessed to take prevention measures in preliminary design stages. The multi-objective structure of building performance evaluation need to be analyzed and prioritized with respect to multiple attributes. The decision-making process consists activities of:

- studying the situation,
- organizing multiple criteria,
- assessing multiple criteria,
- evaluating alternatives based on the assessed criteria,
- ranking the alternatives,
- incorporating the judgements of multiple experts.
In multi-attribute evaluation system attributes are referred to as goals; and different attributes represent different dimensions of evaluating the alternatives [3]. Due to the dependency of evaluation system to expert opinion, the multi-objective performance evaluation systems are suitable to be expressed by linguistic variables. When people are asked to do subjective decision making on a subject in verbal categories rather than numerical categories, the consistency is improved and more accurate results are achieved [8]. Most words are inherently vague and depend on some arbitrary qualification for crisp application. Considering the operational and stochastic characteristics of construction projects and the fuzziness of multiple-objectives need to be considered for appropriate evaluation model [9]. Fuzzy logic, with less information and workability of linguistic terms, can absorb human knowledge without having to translate it into a complex mathematical model. In this research, the advantages and the challenges of evaluating building performance by using fuzzy logic is discussed. The method is proposed for quick-response performance assessment in the preliminary design phase, with an intelligible model for each project member. In the following parts of the study, the definition of fuzzy logic with fuzzy expert systems and hybrid fuzzy systems which combine other methodologies with fuzzy logic are explained.

A. Fuzzy Logic

Fuzzy logic is developed by by Zadeh (1965), on the idea that all things admit of degrees. The classical (Boolean) logic was expanded to consider the partial truth and all values between “completely true (1)” and “completely false (0)” (Zimmermann). In general, the design of fuzzy controllers consists of defining three parameters, the domain for the input and output of linguistic variables, the set and the type of membership function for each linguistic value. A linguistic variable differs from numerical variable since its values are not numbers but words or sentences in a natural or artificial language [2]. In the fuzzy logic system, the linguistic variables describe the vague concept of decision-making (e.g. good performance), while the membership functions define the shape of the fuzzy set. Several input parameters with corresponding subdivisions are combined with expert opinion to give an output value [10].

Fuzzy systems used in many areas such as data classification, imperfections detection and to support decision making. Fuzzy systems have advantages to evaluate performances by representing uncertainties. However, the extension of the system is done through the addition of new rules, which may be the disadvantage since the rules depend on the existence of experts. Therefore, for more complicated models, the fuzzy systems combined with other systems such as fuzzy expert systems, fuzzy neural network, fuzzy reasoning and fuzzy clustering to improve the decision-making capacities.

B. Hybrid Fuzzy Systems

In construction management research, it is observed that hybrid fuzzy techniques are widely adopted since they can better solve problems that fuzzy logic alone may not solve [2]. In order to integrate the uncountable, undefined, and uncertain information in decision-making process, fuzzy expert systems are used. Expert systems use domain specific knowledge to simulate the reasoning of an expert in the field in order to perform intelligent tasks [11]. Based on experts’ dependency on common sense when solving problems by using vague and ambiguous terms, the expert system is developed with five main steps [12]:

- specify the problem and define linguistic variables,
- determine fuzzy sets,
- construct fuzzy rules,
- encode the fuzzy sets and fuzzy rules to perform fuzzy inference,
- evaluate and tune the system.

![Fuzzy expert system model (Nilashi et al., 2011)](image)

In the fuzzification interface, the input variables are structured and fuzzified through membership functions, and the degree of belonging of input variables is determined. In fuzzy rule base module, if-then rules are set by experts by using linguistic values. Fuzzy if-then rules and fuzzy reasoning are the basis of fuzzy expert systems to structure the decision-making system. On the other hand, the consequence of each rule is computed by inference engine. Finally, in defuzzification phase, fuzzy output is converted to crisp output and the performance result is calculated by using membership degree of the output value [13].

On the other hand, for more complicated systems and decision processes fuzzy sets are combined with neural networks with learning and generalization capacity. Neural networks are strong in pattern recognition and automatic learning while fuzzy logic are strong in modeling of uncertainties.

III. APPLICATIONS OF FUZZY LOGIC IN BUILDING PERFORMANCE EVALUATION

Performance requirements for building systems such as serviceability, safety, security, comfort and functionality are often affected by various uncertainties. The definition of these uncertainties can be hardly described by traditional probabilistic methods. Moreover, translation of human needs, especially those concerning occupancy comfort to provide performance requirements often results in a vague and imprecise definition of the technical requirements. Thus, in addition to the natural randomness of basic variables, performance requirements may be considerably affected by fuzziness [14]. Fuzzy techniques have been increasingly applied to the research area of construction management discipline over the last decade [4]. Fuzzy logic and hybrid fuzzy techniques are
used applications of decision making, performance, evaluation, and modeling of building systems. In this study, fuzzy system application areas used for building systems are explained, as a decision support methodology to detect defects of projects in early stages. As one of the key building objectives, passive fire safety decision making fuzzification modules with input parameters are expressed.

A. Performance Evaluation of Building Systems

When compared to other industries, the construction industry subject to more risks due to the unique features of construction activities, such as long period projects including complicated processes together with dynamic organizational models [15]. Within the complicated process, in order to function more efficiently, the building performance systems must be integrated together. Systems must be compatible and share common information to eliminate multiple data entry. Based on this concept, the fuzzy expert system aims to control the building design input variables within the acceptable limits.

Fuzzy logic can be adopted for building systems to develop models and to make decisions and to evaluate the performance in a wide range of areas which are often viewed as complicated, uncertain, and ill defined. Moreover, fuzzy systems define the relationship between risk sources (input) and the consequences (output) by using knowledge base (fuzzy rules) [16].

The studies using fuzzy systems to evaluate building objectives have wide range of applications to support the decision making in construction field. When conducting the performance assessments, the severity factor should be taken as close as possible to objectives at the time of assessment [16]. Most of the fuzzy applications focused on time, cost, quality, and safety performance measures. Some of them are predicting potential cost overruns on engineering design projects [17], time cost trade off model [18], time-cost optimization [9], project scheduling [19], safety management [21]. Other researches considering planning and sustainability are dealing with acceptable building levels of environmental impact and socioeconomic characteristics of residential building [22], site layout and planning [21], sustainable housing decision support tool [23], performance of green buildings [24].

There are fuzzy systems based on building technology and information technology disciplines related with building thermal dynamic response [25], user acceptance and adaptation [26], car-parking guidance [27], thermal conductivity [28], heating control [29], however, these applications are limited. Furthermore, building design objectives are not interrelated to assess the comprehensive fuzzy performance assessment, although most the building performance objectives including fire safety, sustainability, cost effectiveness, security, maintainability, accessibility / circulation, structural stability / constructability and occupant activity include uncertainty with multi-criteria (Fig. 2). Thus, the definition of membership functions, linguistic variables and interdependency rule of input variables can be fuzzified to support acceptable building performance levels.

B. Performance Evaluation of Building Construction Parameters in Fire Safety

Fire safety, as one of the key objectives, is an important need, although it has a lower priority than other design objectives since not generating explicit benefit such as comfort or convenience [30]. In addition, it has low level of risk perceived from fire, however, the consequences of fire make it one of the most life threatening hazards that needs importance in performance evaluation. Fire safety evaluation systems are regarded as subjective and uncertain methods even if experienced experts conduct them [31].

Designing of fire prevention starts with the building design process. Therefore, important safety measures can be involved in the preliminary design phase by confining fire by construction parameters. In this process, architects lead both the architectural and fire safety concerns at the same time. The evaluation process including building parameters depends on designing a building in such a way that it is difficult for a fire to start and spread within. The construction parameters and their interrelationships are described in the Figure 3.

Accordingly, the measures to prevent fire spread through boundaries and through external fire spread comprise fire reaction of interior linings, structure separation and load bearing and door protection and closing. These common
parameters for both architectural and fire safety design can be expanded according to performance objectives and the detail level of assessment. The evaluation factors and the input variables for each parameter defines the database set for evaluation. The input variables of the building objectives that are generated in categorical functions with crisp numbers, and fuzzy membership functions with triangular membership functions form the database. The membership functions are need to be generated for each sub-parameter under the input parameter, such as resistance, integrity, insulation of structural members and providing fire stop joints in concealed and intersection spaces express structure separation performance assessment. The output membership function for each sub-parameter, parameter and building objective is required to have same number of severity levels to interrelate final linguistic value. The example of five scale risk assessment levels from the least severe level “low”, to the most severe level to “high”, and the intermediate levels “low-to-medium”, “medium”, and “medium to high” are represented in Figure 4.

![Membership functions for risk assessment](image)

Fig. 4. Membership functions for risk assessment (Tah & Carr, 2000)

The fuzzy system to assess building performance is rule-based model, so that the domain knowledge contains the rules. Rules are generated in the If-Then form to represent the expert’s reasoning process. For example, If “the interior lining are A1”; Then “the fire risk severity is Low”. The literature reviews are conducted to develop sub-parameter evaluation tables and the structured interviews are needed to include expert opinion. The success of the system relies on the ability to formalize and represent the knowledge within the applied field. The collected knowledge is subjective, incomplete, and ill-defined, based on expert experience, judgement and intuition.

IV. CONCLUSIONS

Fuzzy performance evaluation of building objectives provides an alternative method to regulation-based deterministic evaluation methodologies. In this paper, the limitation of studies for comprehensive fuzzy evaluation in construction field is criticized and uncertain characteristics of building objectives are emphasized. As an example, fuzzy methodology is described in relation to fire safety objective, by means of confining fire by construction. The performance evaluation model enables the project team members such as designers and engineers, entering the project data in terms of numerical and linguistic values and to detect imperfections in the form of severity levels to take necessary precautions. For the multi-objective building performance evaluation model, using hybrid fuzzy systems provides advantages with learning and generalization capacity, in order to define interdependency of parameters. Moreover, further research is required to test the applicability of method in terms of quick response assessment analyses.

REFERENCES

Abstract—The mining industry is a sector that hosts on site many of occupational health and safety risks from the search phase to the production and shipping. In case of failure to prevent these risks it is encountered high occupational accidents and diseases. In mining, the main thing is to produce according to constantly changing environmental conditions that’s why it differs from other business branches. In this situation in mining sector in determination of risks and obtaining projective measures correctly, the statisticall evaluation of the previous accidents is very important. For this purpose there can be found many learning systems that learn from the past and make estimations for the future. Therefore in this paper a classification model is constructed that makes estimation of the sum of injured employees in the mines according to some attributes. In this estimation model the amount of production, amount of production yield, total number of employees, amount of dynamite in kilos, amount of capsules, mast consumption and total number of injured are used as the attributes. Thus with this model estimation of injured employees is performed according to these attributions using MATLAB platform. For this study the database is used obtained from Turkish Hard Coal Enterprise that belongs to the years between 2010-2014. As the classification algorithms Linear Regression and Artificial Neural Networks (ANN) are used and the comparative results are evaluated.

Keywords—Learning System, Classification Model, Mine Industry, Machine Learning Algorithms

I. INTRODUCTION

As occupational safety is a concept of engineering, all steps for prevention of occupational accidents carry within itself the stages that require engineering solutions. However although there is a rapid development of science, technology, development and industrialization it can not be said these developments are exactly reflected to the process of working life, occupational health and safety. Within industrial sectors mining industry is a sector that hosts on site many of occupational health and safety risks from the search phase to the production and shipping. According to the data obtained from Social Security Administration of Turkish Republic in 2012, 11.79% of work accidents occurred in coal mining in Turkey [1]. In mining sector due to the occupational accidents each year many people come to a state that can not work and many deaths occur. It can be seen from the accident statistics in mining across the country, especially in underground coal mine methane gas explosion and uncontrolled caving are the major accidents [2].

Source of hazards in mines can be given as methane content in coal seam, uncontrolled caving due to lack of support, spontaneous combustion in coal seam, gas poisoning or gas suffocation, coal or metal dust explosion, haulage, drilling and blasting, and sub-contract system [3]. In this situation in mining sector it is very important to be aware of the possible risks and to take precaution because these can save lifes. In determination of risks and obtaining projective measures correctly, the statisticall evaluation of the previous accidents is foremost. For this purpose there can be found many learning systems that learn from the past and make estimations for the future ([2],[4]-[6]).

In this paper a classification model is constructed that makes estimation of the sum of injured employees in the mines according to some attributes. In this estimation model the amount of production, amount of production yield, total number of employees, amount of dynamite in kilos, amount of capsules, mast consumption and total number of injured are used as the attributions. For this study the database is used obtained from Turkish Hard Coal Enterprise that belongs to the years between 2010-2014. The rest of the paper is organized as follows: In the second section hard coal mining in Turkey is considered. In the third section material and methods are given, in the fourth section experimental results are given and in the final part conclusion is given.

II. HARD COAL MINING IN TURKEY

Hard Coal is a fossil fuel and it is used as a source of energy for hundreds of years. As an energy source coal has many advantages and is being used for electricity production. It is one of the most abundant sources of energy, more so than oil and natural gas. According to the 2010 BP Statistical Energy Survey, Turkey had end 2009 coal reserves of 1814 million tonnes, 0.21% of the world total. The most important
coal reserves of our country are located in Zonguldak Basin [7]. Hard coal reserves in Turkey are as given in Table 1. Zonguldak Basin where deep in underground coal mining has been made has a complex geological structure. That’s why instead of full mechanization coal production is mainly carried out on the basis of the labor-intensive manpower.

### III. Material and Methods

In this paper a classification model is constructed that makes estimation of the sum of injured employees in the mines according to some attributes. The database is used obtained from Turkish Hard Coal Enterprise that belongs to the years between 2010-2014. Linear Regression (LR) and Artificial Neural Networks (ANN) are used as the classification algorithms.

**A. Material**

A database is used obtained from Turkish Hard Coal Enterprise that belongs to the years between 2010-2014. It includes the data from Turkey Hard Coal Enterprises. The data includes eight attributes such that amount of production, amount of production yield, total number of employees, amount of dynamite in kilos, amount of capsules, mast consumption and total number of injured. The database includes five years data that belongs to Turkish Hard Coal Enterprise. A sample of the database for 2010 is given in Table 2.

**B. Methods**

In this paper to make estimations for the future from the data in hand a classification model is developed by using two different algorithms. These algorithms are Linear Regression and Artificial Neural Networks (ANN). Classification is a supervised machine learning algorithm. In a supervised algorithm the database is split into two sets such as a training set and a test set. The model is constructed according to the training set which class values are available. The test set values are used to test the performance of the constructed model.

#### 1) Linear Regression:

Linear regression is a predictive analysis and it is used to obtain the relationship between one dependent (class) and one or more independent variables (attributes). The objective of this analysis is fitting a single line through a set of data points and finding the equation representing the line [8]. Then according to the line equation obtaining the unknown dependent variable value by putting the known independent variable values. In the simplest form of the linear regression there are only one dependent and only one independent variable. The form of the model can be given as in Eq.1

\[ y = ax + b \]  

(1)

where y is the dependent variable (estimated), a is the regression coefficient, b is the constant and x is the independent variable. In multivariate Linear Regression there are more than one independent variables as can be seen from Eq. 2.

\[ y = \hat{b} = \sum_{i=1}^{k} c_i x_i \]  

(2)

where y is the dependent variable (estimated), a is the regression coefficient, b is the constant and \(x_i\) \(i = 1,...,k\) are the independent variables.

#### 2) Artificial Neural Networks (ANN):

Artificial Neural Network is a learning system that can learn from data samples known as training examples and then develop a system which can learn from these training examples. Working of this process is similar to a simple simulation of the working of the human brain. Neuron is the basic part of ANN and its working principal can be seen in Fig.1. The sum of the weighted inputs to a neuron is applied to an activation function then an output is produces according to that activation function [9].

IV. EXPERIMENTAL RESULTS

In this study three different experimental studies are performed. Two of them are regression analysis and one of them is ANN application. Two different regression analyses are performed. One of them is simple one variable regression analysis and the other one is multivariate regression analysis.

A. Linear Regression

Two different regression analyses are performed such as simple one variable regression analysis and multivariate regression analysis. In one variable regression analysis each attribute in the database given in Table II is related with the class information that is the total number of injured. With this analysis it is aimed to show the relationships between each attribute with the total number of injured. Thus it can be seen that which attribute most affects the estimation accuracy. The MATLAB simulation of this regression analysis can be seen in Fig. 2 and the results are given in Table III.

In multivariate regression model the six attributes such that the amount of production, amount of production yield, total number of employees, amount of dynamite in kilos, amount of capsules and mast consumption are used. Then using these attribute values as the variables multivariate regression analysis is performed and according to the obtained regression model the linear line is given in Eq. 3

\[ y = 1.859526 + 1.2429 \times x_1 - 0.039297 \times x_2 + 0.00306 \times x_3 + 0.3781 \times x_4 + 0.09853 \times x_5 - 4.3550 \times x_6 \]  

(3)

number of injured employees are estimated. The \( R^2 \) for this analysis is determined as 0.733. With respect to the regression equation given in Eq. 3 when there is an increase in the amount of production, total number of employees, amount of dynamite, amount of capsules an increase is also observed in the number of injured. In contrast when an increase is observed in the amount of production yield and the mast consumption it is observed a decrease in the number of injured.

Residual plots help to discover errors, outliers, or correlations in the model [10]. Among the several residual plots the histogram plot in Fig. 3 that is the simplest one and the probability plot in Fig. 4 are preferred.

![Fig. 1 Working process of a simple neuron](image)

**TABLE III**

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Production amount</th>
<th>Production yield</th>
<th>Total employee</th>
<th>Explosive (kilos)</th>
<th>Number of capsules</th>
<th>Mast costs</th>
</tr>
</thead>
<tbody>
<tr>
<td>( R^2 ) Value</td>
<td>0.6936</td>
<td>0.0858</td>
<td>0.0106</td>
<td>0.0106</td>
<td>0.0106</td>
<td>0.6192</td>
</tr>
</tbody>
</table>

![Fig. 2 MATLAB simulation of the one variable regression analysis](image)

According to the results given in Table III the amount of production is the most effective factor in determining the total number of the injured and then the mast consumption are the second important factor. The other attributes that are amount of production yield, total number of employees amount of dynamite and amount of capsules are not effective in determining the total number of injured.

![Fig. 3 The histogram plot of residuals for the multivariate linear regression model](image)

According to this histogram it can be seen that production levels, total number of employee, explosive used in kilos and number of capsules used have peaks. Thus it can be
understood that these attributes are the most effective ones in the model.

Fig. 4 The probability plot of residuals for the multivariate linear regression model

The placement of the data dots as shown in the graph in Fig. 4 is not a linear line but it can be approached in such a linear line shows that the model is significant and the data has a positive and high correlation on the total number of injured.

B. Artificial Neural Networks (ANN)

In this classification model MATLAB ANN Toolbox (Fig. 5) is used. The six attributes given in Table I are all used as the inputs and the class is used as the output of the ANN configuration given in Fig. 6.

This configuration has three layers basically such that input layer, hidden layer and output layer. Input layer has six neurons, hidden layer has ten neurons and the output has one neuron.

Fig. 6 The ANN configuration of the classification.

According to the results best performance is obtained during the 26th epoch (Fig. 7).

Fig. 7 Mean squared error versus epochs.

The evaluation of the constructed network is as given in Fig. 8. The plot of regression is given in Fig. 9.
V. CONCLUSIONS

In this study using the data obtained from Turkish Hard Coal Enterprise that belongs to the years between 2010-2014 three different classification models are constructed. The two of them are linear regression models and the other one is the AAN model. In each model amount of production, amount of production yield, total number of employees, amount of dynamite in kilos, amount of capsules, mast consumption are used as the attributes and the total number of injured is used as the class information (the estimated parameter).

According to the simple linear regression model results given in Table III the amount of production is the most effective factor in determining the total number of the injured and then the mast consumption are the second important factor. The other attributes that are amount of production yield, total number of employee, amount of dynamite and amount of capsules are not effective in determining the total number of injured.

According to the multivariate linear regression model results when there is an increase in the amount of production, total number of employees, amount of dynamite, amount of capsules an increase is also observed in the number of injured. In contrast when an increase is observed in the amount of production yield and the mast consumption it is observed a decrease in the number of injured. According to this histogram it can be seen that production levels, total number of employee, explosive used in kilos and number of capsules used have peaks. Thus it can be understood that these attributes are the most effective ones in the model. And also the probability plot in Fig.4 shows that the model is significant and the data has a positive and high correlation on the total number of injured. The ANN classification model results are also significant.

Abstract— In this study, a solution to the Monk’s problem (Monk’s 2- M2) employing a single neuron dependent on rules which use either modified translated multiplicative (πm) neuron or McCulloch-Pitts neuron model, is proposed. Since M2 problem is similar to N-bit parity problem, first N-bit parity problem is examined with translated multiplicative (πt) neuron. Then this architecture is modified for M2 problem. Also, McCulloch-Pitts neuron model is used to increase classification performance. When the result of proposed only one πm neuron model that is not required in any training stage and hidden layer is compared with the other approaches, it shows satisfactory performance.

Keywords— Machine learning; Translated multiplicative neuron model; Modified translated multiplicative neuron model; N-bit parity problem; Monk’s problems

I. INTRODUCTION

Translated multiplicative neuron (πt-neuron) is primarily used to the N-bit parity problem. N-bit parity problem is an approach to test neural network architectures and learning algorithms. The N-bit parity problem is considered as a very hard problem to be solved by neural networks, because a single ‘flip’ of a bit in the input string requires a complementary classification. The N-bit parity problem is a generalization of the ‘exclusive-OR’ (XOR) problem. N-bit parity problem can be explained as follows. Let x = [x₁, …, xₙ]T is N-bit binary vector and xᵢ ∈ {0,1} (i = 1, …, N). The parity generator function which is stated as shown in Eq.1, can be determined the parity as follows:

\[ p(x) = \begin{cases} 0, & \text{if } \sum_{i=1}^{N} x_i \text{ is even} \\ 1, & \text{otherwise.} \end{cases} \] (1)

There are many neural network architectures applied in N-bit parity problem [1-8]. Kim et al. proposed a method of improving the learning time and convergence rate to exploit the advantages of ANN and fuzzy theory to neuron structure. Their method is applied to the XOR and N-bit parity problems [6]. But, Iyoda et al. make a comparison between neural architectures for the N-bit parity problem [1]. The comparison result shows that πt neuron model is not required any hidden neurons and learning algorithm. πt neuron model is called translated multiplicative neuron model. It uses threshold activation function. Since πt neuron model stems from multiplicative neuron model, then several multiplicative neurons which have been proposed [9, 10, 11] can be examined to comprehend πt neuron model. The model is defined as follows:

\[ v = b \prod_{i=1}^{N} (x_i - t_i) \quad y = f_{th}(v) \] (2)

where, b ∈ R and tᵢ ∈ R (i = 1, …, N) which are the neuron’s adjustable parameters, are bias and weights, respectively. The neuron’s output is y.

The threshold activation function \( f_{th} : \mathbb{R} \rightarrow \{0, 1\} \) is defined as follows:

\[ f_{th} = \begin{cases} 1, & v \geq 0 \\ 0, & v < 0 \end{cases} \] (3)

In fact, πt-neuron model which is shown in Figure 1 is inspired from McCulloch-Pitts. McCulloch-Pitts neuron model is given by the following equation:

\[ v_m = w_0 + \sum_{i=1}^{N} x_i w_i, \quad y = f_{th}(v_m) \] (4)

where, \( w_0 \) is bias and \( w_i \) are the weights.

Comparing Eq. 4 with Eq. 2, \( w_0 \) is equivalent to b and \( w_i \) are equivalent to \( t_i \) parameters. The parameters of multiplicative \( \pi_t \) neuron, which uses to threshold activation function, are defined as:

\[ 0 < t_i < 1 \quad (i = 1, \ldots, N), \text{ If } N \text{ is even then } b < 0, \text{ If } N \text{ is odd then } b > 0. \]

If the same activation function is used in the Eq.2 and Eq.4, the mathematical procedure’s complexity is equivalent of these two models. Table 1 and Table 2 show the solutions of 2-bit XOR parity problem and 10x10-bit parity problem’s. b and all \( t_i \) parameters ([t₁, ..., tᴺ]) are selected as constants: -24 and 0.8, respectively. Iyoda et al. proved that the
translated multiplicative πt neuron model can solve the N-bit parity problem for ∀ N ≥ 1 [1].

![Figure 1. πt- Multiplicative neuron model](image)

An N-bit Parity problem can easily be solved by only one πt neuron using threshold activation function and parameters defined in certain intervals. This approach has the lowest process complexity, which is presented between neural network solutions so far [1]. Therefore, modified translated multiplicative (πm) neuron or McCulloch-Pitts neuron model, is proposed for solution of Monk’s M2 problem which has a nonlinear relationship similar to XOR problem. In Eq. 2 and Eq. 4, all biases and weights are chosen as constants with their optimum values. Since, they are chosen as constants; there is no need any learning stage for the both networks. The main contribution of the study that it presents modified translated multiplicative neuron model to solve Monk’s M2 problem by expressing it as an N-bit parity problem.

In the following section, Monk’s problem is presented. Previous studies in Monk’s problem are given in Section 3. The πm neuron model and results obtained from the application of either one πm neuron model or one McCulloch-Pitts neuron model to Monk’s M2 problem are given in Section 4.

II. DESCRIPTION OF MONK’S PROBLEM

An artificial robot named as Monk’s problem has six attributes that is defined by [12]:

- Problem M1: If head shape and body shape have same value or jacket color is red, this problem belongs to M1 (head shape = body shape or jacket color = red).
- Problem M2: If exactly two of six attributes of robot have their first value, this problem belongs to M2.
- Problem M3: If jacket_color is green and holding is sword or jacket_color isn’t blue and body_shape isn’t octagon, it belongs to M3 ((jacket_color = green and holding = sword) or (jacket_color ≠ blue and body_shape ≠ octagon)).

Data which are taken from 6 different places of the artificial robot must be rearranged to simulate to the parity rule. The arrangement is done by the following statements:

- Problem M1: has_tie \( \in \{0000, 0001\} \)
- Problem M2: holding \( \in \{0000, 0001, 0010, 0011\} \)
- Problem M3: has_tie \( \in \{0000, 0001\} \)

As it is seen above, decimal values are given to attributes for each point of the robot. These decimal values are converted to 4 bit binary number system. To adjust the data according to N-bit parity rule, each decimal value is decreased for one, and then the decreased decimal number is converted to its binary value.

III. OTHER STUDIES RELATED WITH MONK’S PROBLEM

Thurn et al., summarize the comparison of different learning techniques in a report which was performed at the 2nd European Summer School on Machine Learning, held in Belgium during summer 1991 [12]. A variety of symbolic and non-symbolic learning techniques are compared on Monk’s problems. In Table 4, only the comparison results of Monk’s
M2 problem with this study are given. One significant characteristic of this comparison is that it was performed by a collection of researchers, each of whom was an advocate of the technique they tested. Here some algorithms that have recognition rate more than this study are explained in this section. Since Thrun et al. give brief description about their studies [12], special properties of the algorithms e.g. rules that are used in their algorithms or other things which are based on neural networks will reemphasize in the following:

**AQ17 Algorithms.** AQ17-DCI algorithm is based on AQ learning programs. Here is a brief description of the AQ algorithm:
1. Select a seed example from the set of training examples for a given decision class.
2. Using the extend against operator, generate a set of alternative most general rules (a star) that cover the seed example, but do not cover any negative examples of the class.
3. Select the “best” rule from the star according to a multi-criteria rule quality function (called LEF – the Lexicographical Evaluation Function), and remove the examples covered by this rule from the set of positive examples yet to be covered.
4. If this set is not empty, select a new seed from it and go to step 2. Otherwise, if another decision class still requires rules to be learned, return to step 1, and perform it for the other decision class.

AQ17-DCI uses 2 rules for Class 0 and 1 rule for Class 1.

**Backpropagation and Backpropagation with weight decay.** There were 17 input units, all having either value 0 or 1 corresponding to which attribute-value was set. All input units had a connection to 2 hidden units, which itself were fully connected to the output unit. An input was classified as class member if the output, which is naturally restricted to (0; 1), was ≥ 0.5. Training took between ten and thirty seconds on a SUN Sparc Station. On a parallel computer, namely the Connection Machine CM-2, training time was further reduced to less than 5 seconds for each problem. The following results are obtained by the plain, unmodified backpropagation algorithm. After 90 training epochs, the system performance was reached to 100% accuracy. Weight decay widely used technique often prevents backpropagation nets from overfitting the training data and thus improves the generalization. With weight decay α=0.01 Thrun improved the overfitting the training data and thus improves the technique often prevents backpropagation nets from overfitting the training data.

The system performance is 88.166%.
The following rules and threshold activation function given in Eq.3 are used for both πm and McCulloch-Pitts neuron models:

- Rule 1: IF (x1=3 or x2=3 or x4=3 or x5=3) THEN b=2 use Eq.2 ELSE b=2 use Eq.4
t Only Rule 1 is used, the 125 of 169 data are correctly classified.
The system performance is 73.964%.
- Rule 2: IF x5=4 THEN b=2 use Eq.2
If Rule 1 and Rule 2 are used together, 143 of 169 data are correctly classified.
The system performance is 84.615%.
- Rule 3: IF x5=4 and ((x1 = x2 = x3 = 1 and x4 ≠ 1) or (x1=3 and x2 ≠1 and x3 ≠ 1 and x4 ≠ 1 and x6 ≠ 1) or (x1=2, 3 and x2 = 2, 3 and x3 ≠ 2, 3 and x4 = 2, 3 and x6=2)) THEN b=2 use Eq.2 ELSE b=2 use Eq.2
If Rule 1, Rule 2 and Rule 3 are used together, 149 of 169 data are correctly classified. The system performance is 88.166%.

- Rule 4: IF (x1=3 or x2=3 or x4=3 or x5=3) and ((x1= x2= x3 = x6=1) or (x1=3 and x2 = 2, 3 and x3 = 2, 3 and x4 = 2, 3 and x5 = 2, 3 and x6=2) or (x1 = 2, 3 and x2 ≠ 2 and x3 ≠ 2 and x4 ≠ 5 and x6 = 1) or (x1 = 2 and x2 = 3 and x3 = 2 and x4 ≠ 1 and x6 ≠ 1) or (x1 ≠ 3 and x2 ≠ 2 and x3 = 1 and x4 = 1 and x6 ≠ 2) or (x1 =

**IV. MODIFIED TRANSLATED MULTIPLICATIVE (Tm) NEURON MODEL.**

Only M2 problem is similar to parity problem among these three Monk’s problems. So, πm neuron model that is formed by the algorithm of π is applied to M2 problem. When πm neuron model is used stand alone, no good classification performance is obtained. Therefore, πm or McCulloch-Pitts neuron models alternatively are used according to the rules.

Data matrix that has size of 169x7 is obtained from ftp server of University of California, Irvine [13]. According to robot’s attributes, 64 of the data produced the output 1 while the rest produced output 0. The first experiment is done for examining the πm neuron model using 169 data matrix. The b and ti parameters of πm neuron model are chosen -1 and 0.5, respectively (b=-1, 1,...,n = 0.5, where N=24). Since the robot has 6 attributes and each of them is represented by 4-bit binary number, the model has 24 inputs. For the first classification, 105 of the data have been correctly classified with 62.130% success. While 115 out of 169 data are already 0, the 62.130% system performance is not satisfying for the classification given above. If all the outputs of the model are assumed to be 0, anyway 68.047% performance is obtained. The input data are examined to get a better solution than above. When any of x1, x2, x4, and x5 has the value “3” in decimal number system, it is observed that πm neuron model is not good in classifying according to N-bit parity rule. So, some changes in algorithm are made by adding rules to multiplicative πm neuron model. This neuron model is named as modified translated multiplicative (Tm) neuron model. Here, b parameter in πm neuron model is chosen different from π that is used for N-bit parity problem.

The following rules and threshold activation function given in Eq.3 are used for both πm and McCulloch-Pitts neuron models:

- Rule 1: IF (x1=3 or x2=3 or x4=3 or x5=3) THEN b=2 use Eq.2 ELSE b=2 use Eq.4
- Rule 2: IF x5=4 THEN b=2 use Eq.2
- Rule 3: IF x5=4 and ((x1 = x2 = x3 = 1 and x4 ≠ 1) or (x1=3 and x2 ≠1 and x3 ≠ 1 and x4 ≠ 1 and x6 ≠ 1) or (x1=2, 3 and x2 = 2, 3 and x3 ≠ 2, 3 and x4 = 2, 3 and x6=2)) THEN b=2 use Eq.2 ELSE b=2 use Eq.2
- Rule 4: IF (x1=3 or x2=3 or x4=3 or x5=3) and ((x1= x2= x3 = x6=1) or (x1=3 and x2 = 2, 3 and x3 = 2, 3 and x4 = 2, 3 and x5 = 2, 3 and x6=2) or (x1 = 2, 3 and x2 ≠ 2 and x3 ≠ 2 and x4 ≠ 5 and x6 = 1) or (x1 = 2 and x2 = 3 and x3 = 2 and x4 ≠ 1 and x6 ≠ 1) or (x1 ≠ 3 and x2 ≠ 2 and x3 = 1 and x4 = 1 and x6 ≠ 2) or (x1 =
3 and \( x_2 = x_5 = x_6 = 1 \)) THEN \( b = -2 \) use Eq.2 ELSE \( b = 2 \) use Eq.2.

If Rule 1, Rule 2, Rule 3 and Rule 4 are used together, 154 of 169 data are correctly classified. The system performance is 91.124%.

- Rule 5: IF \((x_1 \neq 3 \text{ or } x_2 \neq 3 \text{ or } x_4 \neq 3 \text{ or } x_5 \neq 3)\) THEN \( b = -2 \) use Eq.4

If Rule 1, Rule 2, Rule 3, Rule 4 and Rule 5 are used together, 163 of 169 data are correctly classified. The system performance is 96.45%. In the all rules, weights of the neuron models are chosen as 0.5.

A study is carried out to examine the performance of \( \pi_m \) neuron model parameters \( b \) and \( t_i \) as shown in Table 3. To get the best performance, the parameters \( b \) and \( t_i \) are to be chosen in M2 problem as follows:

- \( b: \pm 1 \text{ and } t_i: 0.3 \)
- \( b: \pm 2 \text{ and } t_i: [0.5-0.6] \)
- \( b: \pm 3 \text{ and } t_i: [0.8-0.9] \)

In addition to performance sequence of previous studies on Monk’s problem, \( \pi_m \) and McCulloch-Pitts neuron models proposed in this study are given in Table 4. The results obtained in this paper have higher performance when compared to the some of the studies given in Table 4. Studies supplying 100% performance for M2 problem are already known. This paper proposes a new approach which is called \( \pi_m \) neuron model. Moreover, 6 individual rules can be defined for the remaining 6 data, which are not correctly classified to make system performance 100%.

V. CONCLUSIONS

Modified translated multiplicative neuron which is inspired by the architecture of translated multiplicative neuron that is an effective ANN model in solving N-bit parity problem and McCulloch-Pitts neuron models are applied to Monk’s M2 problem. The 100% classification performances of studies given in Table 4 utilize hidden layer in ANN architecture such as the Backpropagation and Cascade Correlation models. The
proposed model consists of only one neuron. While AQ17-DCI algorithm uses 3 rules for obtaining 100% system performance, unfortunately the proposed model uses 5 rules with 96.45% performance. Six additional rules can be individually defined for the remaining 6 data, which are not correctly classified for accomplishing 100% performance. Since the weights and bias are optimally selected, the proposed model does not require learning stage.

Abstract— Facility layout which increases productivity and provides the most effective way to run the organization, is used both determine the location of departments, assistant services, facilities and edit this sections. There are numerous studies in the literature for the solution of facility layout’s problems. We have observed that the heuristics are preferred in some of these solutions. We used data mining in this study. Data mining continues to offer new horizons, perspectives and new methods in a new area every day. The basic objective of this study is to develop a model of the layout for the purpose of improving the emergency department’s functionality, the quality of patient care, the satisfaction of patient and employee. Firstly in this study data warehouse was created by using data of the past year in the hospital information system. Data warehousing is the entry of the association analysis model. Then a system will be develop to solve the problem using association analysis with Apriori association analysis which is one of the methods of data mining. The application of the study is carried out in Kirikkale University Faculty of Medicine Hospital. The goal of this study to develop a model proposal through utilizing the method of Facility layout techniques for emergency department which will be designed according to way of intervention on patients.

Keywords— Apriori Algorithm, Association Analysis, Data Mining, Emergency Department, Facility Layout Problem

I. INTRODUCTION

Data mining is process that various advance data analysis based on statistics and artificial intelligence are used by way of visual programming interface in order to find out hidden patterns and relations in huge data stacks. Data mining algorithms include statistical algorithms, mathematical algorithms and artificial intelligence algorithms (such as neural networks, decision trees, association rules) together.

Emergency department where data mining technique was applied is the first line in hospitals to face emergency patients. As a major function of emergency department, when a patient comes to the emergency department, the emergency department personnel perform a triage procedure and then transfer the patient to associated departments for treatment [1]. For patients waiting in the emergency services, delay in the medical examinations decrease the quality of service and customer satisfaction. At the emergency services these factors are of much more importance since patients who have risky healthy come emergency department. While taking care of patients, hospital staff, materials and flow of information between emergency service departments must be quick. In this regard layout is important.

In this study after receiving the necessary data from the information systems department of the Emergency Department in Kirikkale University Faculty of Medicine Hospital, data correction and data categorization work was done. Then the data table was converted into text file format that accepted by the apriori software format. After the data preparation stage, apriori algorithm was applied on the data which was categorical structure according to the predetermined support and confidence value and association rules was obtained by using SPSS Clementine software. Then the desired rules were generated from large item sets and then these association rules were used as a reference during the decision-making process for developed algorithm. This algorithm was applied on apriori algorithm’s results. Finally alternative facility layout planning was created.

Data mining algorithms have been used in various Facility Layout Problem in literature review. K-means clustering algorithm is applied to evaluate supermarket’s layout Larson et al.[2]. Ay and Çil [3], in their study, used apriori algorithm and multidimensional scaling to acquire relational database. Kundu and Dan [4] used genetic algorithm so as to cope up with facility layout problems. The aim of Altuntas and Selim’s study [5] is to propose new weighted association rule-based data mining approaches for facility layout problem. In Cil[6]’s study, different weighted association rule-based data mining approaches was applied to facility layout problem. Lee [7] offers an integrated model that forecasts the total walking time of a passenger by simulation and searches for a near-optimal layout by ant colony optimization. Aiello et al. [8] offers in their study a new multi objective genetic algorithm for dealing with unequal area facility layout problems. In Ozcan and Esnaf’s study[9], a mathematical model is propose based on association rule mining for store layout problem which involves the identification of the position of products and product categories which are shown in-store shelves. Yener [10] aims to find an interior design of a warehouse that is minimizing the costs occurs while orders gathering within the main distribution warehouse which is performing in retailer
sector. Performances of different warehouse designs obtained via different methods are examined with the aid of simulation techniques. In the workshop, data mining techniques which have association rules are also benefited from. Gonçalves and Resende [11], in their study propose a biased random key genetic algorithm for the unequal are a facility layout problem where a set of rectangular facilities with given area necessities has to be placed, without aliasing, on a rectangular floor space. Arulkumar and Saravanan used to solve the layout problem Artificial Bee Colony algorithm and Particle Swarm Optimization algorithms in their paper [12]. In Aktepe et al.’s study [13], association analysis which is one of the data mining technique and VIP-Plant Optimization was used to develop a new proposal of facility layout for a shopping center. In paper of Lin and Guan [14] a hybrid algorithm based on variable neighborhood search and ant colony optimization is pro-posed to solve the single row facility layout problem.

Studies implemented FLP and Data mining in hospital are very little in literature review. The contribution of paper of Yeh [15] is a new framework which is named annealed neural network. Aim of framework is to find vying solutions for the FLP efficiently. This framework take place the integration of Hopfield neural networks and simulated annealing. A Hopfield neural network is a representation model of the layout problem and simulated annealing is a search algorithm for finding the optimum or near optimum solutions. In Cakar’s PhD thesis [16] genetic algorithm is used to optimize the emergency department’s layout.

In the second section, methodology which is used in this study was mentioned. Studies which were done, developed algorithm, new facility layout which was generated were explained under application title that was explained in the third section. In the fourth section, summary of study was explained and improvement acquired was expressed numerically.

II. METODOLOGY

A. Data Mining

Data mining is the process of finding of information which is unseen from a big data. Data mining, analyzing the data from different source and transform it meaningful information [17]. Data mining is also named as knowledge discovery process, knowledge extraction, data analysis or knowledge mining from data.

Several techniques and algorithms such as Classification, Clustering, Regression, Artificial Intelligence, Neural Networks, Association Rules and Decision Trees are used for information exploration from databases [19]. One of the techniques is clustering which is used to describe the object of similar classes. The clustering technique defines the classes and assigns each object to a particular class. Classification widely used data mining technique, to develop a class and learning. Most frequent item in the large data set is found by association analysis. The main aim is to release interesting correlation and association between a big data set [17]. Regression analysis can be used to model the relationship between one or more independent variables and dependent variables. In data mining independent variables are attributes which is known and response variables are what we want to forecast. Neural network implies a set of connected input or output units and each connection has a weight present with it. Neural networks have the significant ability to derive meaning from complicated or indefinite data and can be used to acquire patterns and find trends that are too complicated to be noticed by either humans or other computer techniques [18]. Decision tree is one of the most important classification methods. Decision tree is a method used to divide data sets including more registries into smaller data sets via an array of decision rules. Artificial intelligence is capability that a computer or a robot controlled by computer carries out various activities like intelligence living creature.

B. Association Analysis in Data Mining

Association analysis, one of the most important and well researched techniques of data mining, was first introduced in study of Agrawal et al. [19]. The association rule algorithm is commonly used to identify relationships between items or features that occur synchronously in a database. The Apriori algorithm [20] is widely used to mine frequent item sets and learning association rules in a datamining field. It seeks to generate the desired rules from large item sets and then uses these association rules as a reference during the decision-making process. The Apriori algorithm is usually divided into two separate steps. First, minimum support is applied to find all of the frequent item sets in a database. Second, these frequent item sets and the minimum confidence constraint are used to form rules [21]. Association rules are rules presenting association or correlation between item sets.

C. Apriori Algorithm used for Association Analysis

Apriori algorithm the most popular algorithm which is used for the association rules discovery. The algorithm's name comes from the word "before (prior)".Because this algorithm receives information from a previous step. Apriori algorithm’s steps are given below:

- Determination of the number of minimum support and the value of minimum confidence.
- Finding the value of support of the each element in the element sets.
Disabling elements having a lower value than the minimum support value.

Creation of binary association with considering the created single associations.

Removal of cluster elements that have low value than the minimum support value.

Elements are divided into groups of threes/fours etc. and the same procedure is repeated.

Derivation of association rules after identifying the product group according to support measures.

D. Facility Layout Planning

Aim of facility planning is to determine best plant design by defining related work areas and material locations in facility. It also includes supporting organization task in order to conduct material handling, material controlling and workshop, effective use personnel, material, area and energy, minimizing capital investment, facilitating maintenance to provide flexibility, ensuring work satisfaction and labor safety.

Fig. 2 Facility Layout Planning Hierarchy

Facility layout problem is NP-Hard problem as it has complexity in terms of modelling and calculating [22]. It is related to how facility locates in bounded area. Layout decision problems are called as plant layout problem or facility layout problem in literature. Facility Layout Planning is divided into four groups as p-median, p-center, unbounded capacitated facility layout and quadratic assignment problem [23].

Facility design is coordination with stations’ activities such as handling, storage, quality control etc. with regard to their physical locations. Main target of facility design is to minimize movement of entities related to production activities. The reasons why facility design is necessary are changing in manufacture design and volume of demand, adding a new equipment or good, enlarging or reducing areas, replacing an area, new plan for facility, increasing working accidents, worsening working conditions, minimizing production costs.

III. APPLICATION

In application, Apriori Algorithm was applied to emergency departments’ data by SPSS Clementine with respect to SPSS model which is shown in Fig 3 and confidence coefficient between departments was found.

Fig. 3 SPSS Clementine Model for Apriori Algorithm

Utilizing present facility plan (Fig. 4), rectilinear distance between departments was calculated via Equation 1.

\[ d_{AB} = |X_A - X_B| + |Y_A - Y_B| \]  

(1)

Fig 4: Present Facility Plan

Flow distance values with coefficient were acquired by multiplying flow between departments, distance and coefficients obtained through developed algorithm. Alternative facility layout in Fig. 5 was generated by way of minimizing flow distance values and considering emergency service doctor’s advices such as:

- Patients coming emergency service on foot and by ambulance should enter emergency service from different entrances,
- Patients coming emergency service on foot should not pass red area to head for green district,
- Department of Radiology should be located near red and yellow area,
- A new emergency entrance should be opened for patients coming emergency service on foot.
Compared present and alternative facility layout, we noticed that alternative facility layout is better than other. But this is not optimal solution. It can be improved.

Developed Algorithm Steps;

1. A list is created from relations whose coefficient of reliability was determined by Apriori Algorithm. If there is a single relation whose reliability rate is over %60 or a mutual single relation whose reliability rate is over %50, 7 points are given.

2. Single relations which have 7 points are removed from the list. For the rest, if there is a relation which is single for one side and dual for other side and over %50 coefficient of reliability, 6 points are given.

3. Single relations which have 6 points are removed from the list. For the rest, if there is a relation which is just single for one side and over %50 coefficient of reliability, 5 points are given.

4. Single relations which have 5 points are removed from the list. For the rest, if there is a mutual single relation which is over %40 coefficient of reliability, 4 points are given.

5. Single relations which have 4 points are removed from the list. For the rest, if there is a relation which is single for one side and mutual for reverse side and over %40 coefficient of reliability, 3 points are given.

6. Single relations which have 3 points are removed from the list. For the rest, if there is a relation which is just single for one side and over %40 coefficient of reliability, 2 points are given.

7. If relations are under %40 or there is no any relation, 1 point is given.

IV. CONCLUSIONS

Speed of service is one of the most important indicators for patient coming emergency service. Any delay can be ended with death.

In this study applied in emergency service, flows between the emergency departments (emergency entrance, pediatric emergency department, pediatric emergency observation, radiology, isolation room, minor surgery, resuscitation room, red area, yellow area, green area, plaster room) of patients which come to the emergency departments are examined via SPSS Clementine and confidence rates were found in the relationships between departments. Considering these rates, coefficients were appointed to interdepartmental relationships with the help of algorithm developed. Flow distance values with coefficient were acquired by multiplying flow and distance between departments and coefficient. Alternative facility layout was generated considering emergency service doctor’s advices for minimizing flow distance values taking in consideration patients flow between departments in emergency service; a new facility layout was created.

Multiplying distance and flow was tried to reduce by only decreasing distance. Departments which have the most flow were tried to zoom one another. Multiplying of distance and flow decreased from 83131, 15 to 53385, 7. So, improvement acquired is %36.

ANT COLONY BASED DYNAMIC NAVIGATION FOR TRABZON CITY

Volkan Gangal*, Gökçe Hacıoğlu*

Department of Electrical Electronics Engineering
Karadeniz Technical University
61080 Trabzon, TURKEY

{volkan.gangal, gokcehacioglu}@ktu.edu.tr

Abstract—This study contains a simulation of dynamic road navigation system for intelligent transport system. The proposed system uses wireless sensor networks in roadsides. Through a vector map of Trabzon and ant colony algorithm, the optimum route is calculated in vehicles. Wireless sensor networks provide some coefficients such as traffic jams, road length, and average delay time for ant colony algorithm. A small area in Trabzon is considered for the proposed dynamic road navigation. In literature search, it has not found any realistic study that contains intelligent transportation system for Trabzon city.

Keywords—Ant Colony Algorithm, Wireless Sensor Networks, Dynamic Road Navigation, Intelligent Transport System

I. INTRODUCTION

In recent years, there is a growing interest to navigation works. However, many of these works don’t contain actual information about the road or roadside. The proposed method uses Ant Colony Algorithm and coefficients which come from WSN to determine the reliable and short route to the target.

A. WIRELESS SENSOR NETWORKS

Wireless sensor networks (WSN), consist of multiple sensor elements and these networks collect information from the environment in a particular purpose. These sensors usually work autonomously and can adapt to changing environmental conditions. [1]. WSNs are composed of elements called nodes, and the joint work of several units. A sensor node generally contains four main components. These units are: power unit, sensor unit, processing unit and communication unit.

Many studies have been made on routing for WSNs using Ant Colony Algorithm (ACO) [2,3,4]. The majority of these algorithms aim to extend the network lifetime [2]. In this study, it is assumed that there were WSN nodes on the roadsides. And these WSN nodes provide some coefficients such as traffic jams, road length, and average delay time for ant colony algorithm. In this way, the proposed approach can easily find optimum route between two points based on current data in Trabzon city.

B. ANT COLONY ALGORITHM

Ants live in colonies and they make division of labor between them to overcome the difficulties. When an ant finds the food source, the other ants can reach the food source easily by using the most convenient way. The chemical which causes that phenomenon known as pheromone. Ants leave pheromone chemical on the roads which they pass. In addition, they prefer the ways that have much pheromone. Also the pheromone substance has evaporation property. Therefore the amount of pheromone is much more where they frequently pass. Assume that the ants have same speed and they drop pheromone with same rate. Therefore, there will be much pheromone on the shortest path and the ants will prefer that route to go to food source [5,6].

There are two main parameters in the Ant Colony Algorithm. The first one is selection possibility of the route and the second one is evaporation rate of pheromone.
The selection possibility of an ant from r point to s point expressed as follows. [2].

\[ p_k(r,s) = \frac{|T(r,s)|^\alpha C^\beta}{\sum_{u \in M^k} |T(r,s)|^\alpha C^\beta} \]  

(1)

Where \( \alpha > 0, \beta > 0 \) are the effect parameters and take the value as \( \alpha \approx \beta \approx 2 \) typically [7]. \( T(r,s) \) is pheromone matrix and indicates pheromone value related row and column. \( C \) is the cost function and it is thought as multiplication of \( w \) weights come from WSN and path length \( d \).

\[ C = \sum d \ast w \]  

(2)

The pheromone matrix is updated as follows [2].

\[ T_k(r,s) = (1-\rho)T_k(r,s) + \Delta T_k \]  

(3)

In the above equation \( \rho \) indicates that the evaporation rate. In this study, \( \rho \) value was obtained as 0.5.

II. SYSTEM IMPLEMENTATION

A. Using Vector Map of Trabzon for Routing

Firstly the vector map of Trabzon was read in Matlab program and it was selected a particular region for navigation. The satellite image of the selected region shown in Figure 2 below.

Fig. 2 Selected region for navigation work

Random coefficients are assigned to the way parts in this region initially. These weights represent feedbacks that come from Wireless Sensor Networks. Starting point and endpoint coordinates are described to make navigation work.

It is necessary to obtain all possible routes between these points. To make this, it was investigated that how the roads connected to each other.

“extractfield” command was used to extract road coordinates from vector data, so that related x and y coordinates were obtained.

For this purpose the same coordinates were found to find the intersection of two roads. Then the next point was obtained similarly. If there were two or more points which have same coordinates, roulette wheel was used to determine next point.

The coordinates of the path are the sequence shown as figure 3 below. The first row refers x coordinates and the second one refers y coordinates. Column number indicates the index number. As can be seen from the figure, every part of the road separated by "NaN" statement. So the "NaN" statement refers a part of the road.

Fig. 3 The appearance of the extracted coordinates

Different routes to the target were found and then their costs were calculated. Vector map of the selected area with lengths and weights of the paths are given in figure 4.

Fig. 4 Paths lengths and their weights

B. WSN Supported ACA Based Dynamic Navigation

The amount of pheromone will be effective to determine optimum route. Therefore the variations at the pheromone levels are important too. Thus if there are WSN feedbacks such as congestion, rain or slippery surfaces on the road, this will affect the cost function of related path. And some parts of the path will not be preferred in generated route. In this way the dynamic and shorter route that based on actual data will be selected.

The weights are between 0 and 1. The number 1 represents the worst road condition. If the coefficient closer to 0, it indicates that the road condition is fine.
III. CONCLUSIONS

In this study, ACA-based dynamic navigation work was discussed. It is assumed that there were WSN nodes on the roadsides. It is also assumed that these nodes provide some coefficients as feedback. Using these coefficients the cost function was calculated and optimum route was obtained.

Four routes which have minimum costs are shown in figure 5 below. High cost routes aren't shown in figure.

![Fig. 5 Four routes which have minimum costs](image)

Table 1: Routes and their costs

<table>
<thead>
<tr>
<th>Route</th>
<th>Cost</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>207.82</td>
</tr>
<tr>
<td>2</td>
<td>286.09</td>
</tr>
<tr>
<td>3</td>
<td>161.56</td>
</tr>
<tr>
<td>4</td>
<td>188.80</td>
</tr>
</tbody>
</table>

Route 3 has the lowest cost as can be seen Table 1. Thus Route 3 will be selected as optimum route. In this study all the roads are assumed to be bidirectional. This topic can be handled in future studies.

A Robust Hand Pose Correction Method for Palmprint Recognition

Özkan Bingöl*, Murat Ekinci+

*Department of Software Engineering, Gümüşhane University
Gümüşhane, Turkey
bingolo@gumushane.edu.tr

+Department of Computer Engineering, Karadeniz Technical University
Trabzon, Turkey
ekinci@ktu.edu.tr

Abstract— The selection of the appropriate pattern for palmprint recognition systems depends on the success of the segmentation techniques used. Segmentation can be difficult due to free movement of the hand in unrestricted environment. Also holding the hand at different angles causes perspective distortions. In order to correct these distortions, active scanning systems have been proposed to find the 3D position of the hand. However, as the cost of these systems is high, it seems that they are not possible to spread.

In this study, a stereo camera system which is more cost effective, have been used. With the help of this system, 3D coordinates of the landmarks falling on hand are calculated. A new transformation is defined based on the main axis of the distribution of these points. Thus perspective distortions are substantially corrected. The success of the proposed approach has been tested on our dataset consisting of hand images taken from 138 people. As a result of the experiments, recognition rate even in the cases reached over 90%.

Keywords— Palmprint Recognition, Stereo Camera, Pose Correction

I. INTRODUCTION

In the first devices developed for palmprint validation [1, 2] cameras which have own lighting system are used. At the time of taking image, a flat surface is used to keep the hand at the same distance. The movement hand is significantly restricted by the pegs in the device. Despite the successful results obtained in these studies, it is mentioned that the pegs cause distress for some users (especially those with physical problems in their fingers) [3-6]. Then unrestricted systems without pegs are proposed. [7-10] However, they are contact systems and cause hygiene problems especially in a multiuser environments [11].

Recent studies about hand biometric systems has focused on unrestricted and contactless techniques that do not need user cooperation. In the unrestricted and contactless systems, in order to overcome alignment problems, hand’s pose and the distance to the camera should be known. It is very difficult to obtain these informations in 2D image. For this reason, some researchers have proposed 3D hand acquisition systems with different characteristics (digital laser scanner [12], structured ligh [13], the depth camera [4], ultrasound [14] etc.). 3D information offered by these systems raise recognition rates as well as presenting some security advantages. However, extra cost of these methods makes difficult to apply them on the palmprint recognition system.

In this study in order to eliminate alignment problems, a stereo camera device which has two webcam is used. Stereo camera systems are more advantageous in terms of cost compared to other 3D techniques. However, the computational complexity of these systems makes it difficult to precise 3D scanning. In the proposed method rather than precise 3D scanning, it has been tried to dermine number of landmarks that may help finding the orientation and location of the hand. Thus, factors affecting the recognition in a negative way emerged in contactless systems (rotation, translation and scaling like) are eliminated to a great extent. After determining hand’s pose in 3D space, perspective correction is performed using geometric transformations. In order to evaluate the performance of the proposed approach, a dataset that contains the stereo images of 138 different people is used. Pose corrections on the images in the dataset are made and necessary patterns for recognition are produced. Hand segmentation on the corrected images and the detection of the palm area (ROI) are made using Active Appearance Method (AAM). Feature vector is produced by Gabor based Kernel Fisher Discriminant Analysis method (Gabor-based KFA). Cosine Mahalanobis (cosmah) distance is used for similarity measure between the vectors.

II. MATERIAL AND METHODS

A. Hand Acquisition Device

An open access dataset of stereo-based palm images was not found in the literature. Therefore, in order to test the proposed approach in this study, a new dataset was created consisting of stereo image pairs. In the device prepared to generate this dataset, two CMOS cameras having the same physical properties were used (Fig. 1). The cameras were placed vertically in the system (up and down cameras). The camera system has its own light source to avoid exposure of ambient light sources. 12 V led strips are used for lighting. The height of the protective box was 25 cm. The distance from the central focus of the two cameras was approximately 3 cm. In the stereo camera system, the internal values and the detection of relative positions of the camera used are required to be gathered the 3D information. Thereby, pre-treatment (camera calibration) is
available in the system. For calibration, 32 chess images consisting of 7x5 squares with edge length of 25 mm are used.

![Fig. 1 Hand Acquisition System](image1)

**B. Dataset**

In the dataset, there were a total of 2760 images (640 x 480 pixels) taken from 138 (47 female and 91 male) individuals based on 10 different scenarios (S1, S2, ..., S10). Images were taken according to previously identified scenarios by giving instructions to the users, but no intervention was made during the making of the images. In six of the specified scenarios (S1, S2, S3, S4, S5 and S10), it has been asked from user to keep their hands parallel to cameras. In the others, it has been asked from users to keep their hands in different directions with an angle of about 30 degrees (S6, S7, S8 and S9).

![Fig. 2 Sample images of a user from the dataset](image2)

**C. Pose Correction**

Perspective distortions arise when the hand is not parallel to the camera plane. Kanganhad et al. [3] apply Iterative Reweighted Least Squares approaches on the point cloud obtained from digital 3D scanner to make pose corrections and have determined the normal vector of the hand plane. 3x3 transformation matrix is defined with the help of this vector. Another approach can be seen in [15]. In this study, the relative coordinates of 7x5 pieces light points directed from light source to the hand is calculated. Projective matrix is created with the help of the normal vector of the plane formed by points. Geometric correction was performed with this transformation matrix. On the correction step of these experiments, rather than finger positions and the distance between hand and the camera, midpoint of the hand is taken as reference and the correction process is made in that position. As the background is monochrome, segmentation is performed without problem.

In our study, first landmarks on each stereo cameras are detected by SURF[16] method. Depth information of these points is obtained with the help of epipolar geometry techniques by matching. Assuming that the hand is the nearest object to the camera plane, all points over a certain distance from the plane have been eliminated. Thus, only point clouds falling on hand was detected.

The pose correction process was conducted according to the distribution of the 3D point cloud detected on the hand. As shown in Fig. 3a, these points are approximately in the form of an ellipse. This ellipse \( \langle \mathbf{e}_1, \mathbf{e}_2, \mathbf{e}_3 \rangle \) and its main axis, which are perpendicular to each other, can be found using Principal Component Analysis (PCA). The eigenvector \( \langle \mathbf{e}_1 \rangle \) corresponding to the maximum value detected by PCA is the primary main axis. This axis is in line with the fingers and usually falls on the middle finger. If it is assumed that \( P'_{3D} \) and \( P_{3D} \) are new and current 3D points respectively, then the transformation is represented as:

\[
P'_{3D} = RP_{3D}
\]

where \( R \) is the \( 3 \times 3 \) transformation matrix and is defined as follows:

\[
R = \begin{bmatrix}
\mathbf{e}_1 \\
\mathbf{e}_2 \\
\mathbf{e}_3
\end{bmatrix}
\]

The 3D points detected on the hand and the transformation results of their centralized coordinate values are shown in Fig 3b. It can be seen from the figure that the center of the transformed points is O(0,0,0) and the main axis is along the X, Y and Z axes.

![Fig. 3 (a) The ellipse form of 3D points; (b) original points (black) and transformed points (green)](image3)

In order to apply the proposed transformation to the image, the \( P_{2D} \) constant matrix was created:

\[
P_{2D} = \begin{bmatrix}
y_1 - y_c & y_2 - y_c & \ldots & y_n - y_c \\
x_1 - x_c & x_2 - x_c & \ldots & x_n - x_c \\
0 & 0 & \ldots & 0
\end{bmatrix}
\]

where \( x_i \) and \( y_i \) are image coordinates, \( x_c \) and \( y_c \) are the image’s center points and \( n \) is the number of pixels in the image. In this representation, the image coordinates are assumed as a point cloud along the axis of \( Z = 0 \) in 3D space. The new pose corrected coordinates can be found with the following formula:

\[
P'_{2D} = R P_{2D}
\]

\( P'_{2D} \) represents a transformed new surface in the 3D space and the \( Z \) values are different from 0. \( P_{2D} \) points are transformed to the homogeneous coordinates, and as in equation 5, the perspective projection of the axis \( Z = d \) is obtained.
where \( d \) is the average distance of the points on the hand to the camera plane. The new image coordinates were determined by adding \( x_c \) and \( y_c \) values to \( x_{f_i} \) and \( y_{f_i} \) in the matrix \( P_{2D_r}' \):

\[
x'_{f_i} = x_{f_i} + x_c \quad \text{and} \quad y'_{f_i} = y_{f_i} + y_c
\]

Intensity values corresponding to each coordinate were found by making an interpolation of the values in the original image. With the help of the transformation, the middle finger was arranged along the Y axis in the new image. Thus, the pose of the hand in 3D space was corrected and the fingers in the new image were aligned to face upward (Fig. 4).

**D. Hand Segmentation**

The AAM [17] is based on the philosophy of finding the model parameters that minimize the difference between the target image and the learned average image. Training images previously annotated by an expert are used to create an average image model. Points marked on each image are aligned with Procrustes Analysis and the shape model of the AAM is created. Variations of the shape model are determined by PCA. According to the average shape image, each image in the training set is subjected to a warp process. The texture model is obtained by transforming textures within the delaunay triangulation established between points of the warped image to a vector [18, 19].

\[
s = s_0 - \phi_s p \quad \quad p = \phi_s^T (s - s_0) \tag{7}
\]

\[
g = g_0 - \phi_t q \quad \quad q = \phi_t^T (g - g_0) \tag{8}
\]

where \( s \) and \( g \) are the shape vector and synthesized shape-free texture vector; \( s_0 \) and \( g_0 \) are mean shape and mean texture; \( \phi_s \) and \( \phi_t \) are the eigenvectors of shape and texture; \( p \) and \( q \) are shape and texture parameter vectors, respectively.

It has been recommended that the inverse compositional image alignment approach be the adapted AAM [20]. This algorithm tries to minimize equation 9.

\[
\sum_i [I(W(x; p) - A_0(W(x; \Delta p))]^2
\]

where \( A_0 \) is an average image, \( W(\cdot) \) represents the warping process, \( p \) is the necessary parameter for the warp operations, and \( \Delta p \) shows the parameter change in the next iteration.

In this study, 51 points on 70 randomly selected images in the stereo database are marked for the training of AAM model (Fig. 5). Shape and appearance models of annotated images have been created by training with AAM. AAM points on other images has been tried to be determined using this model. 3 level image pyramid has been created to perform the search process faster.

![Fig. 5 AAM points and ROI](image8)

**E. ROI Extraction**

Detection of the ROI is one of the most important stages of palmprint recognition and affects recognition performance significantly. As AAM-based hand segmentation uses texture information, it provides a significant advantage in the detection of the valley points. In this study, the ROI extraction method used is similar to that proposed by Zhang et al. [1], with an approach allowing a wide area to be selected (Fig. 6c). The valley points required by this method are selected from the control points determined by the AAM. Here, the distance \( d \) between the two valley points was via a proportional relationship. The selected valley points were P15 and P37 (Fig. 5). The ROI was determined to be a square with each side 1.4 d and 0.2 d from the mid-point of the valleys. The obtained ROIs were scaled to 128 \( \times \) 128 pixels.

![Fig. 6 Various RIO extraction methods: (a) Zhang et al. [1]; (b) Connie et al. [11]; (c) proposed method. Skin color segmentation is used in (a) and (b); AAM segmentation is used in (c).](image9)

ROI extraction approach is applied on the image before the pose correction actually the importance of correction emerges clearly. Related results of the same images are shown in Fig. 7.
The Gabor-based KFDA used in the study of Ekinici and Aykut [46] was applied for palmprint feature extraction. In this method, first the frequency and orientation characteristics of the palm pattern are extracted by Gabor wavelets [21]. Then, KFDA is used for transforming low-dimensional feature space in order to distinguish these properties efficiently.

Gabor wavelets inspired by orientation and frequency characteristic of tapered optic nerves of developed live [22] and a filtering technique extensively used in many recognition and representation algorithms. A Gabor function is formulated as (18):

$$g(x,y;\lambda,\theta,\psi,\sigma,y) = \exp\left(-\frac{x'^2 + y'^2}{2\sigma^2}\right)\exp\left(i2\pi \frac{x'}{\lambda} + \psi\right)$$

Where x and y represent coordinates of two dimensional generated matrix. \(\theta\) is Gabor core’s orientation angle, \(\psi\) is the phase angle of the core matrix to be formed, \(\lambda\) is wave length, \(\gamma\) used to calculate standart deviation of y. \(x'\) and \(y'\) is calculated as (19).

$$\begin{bmatrix} x' \\ y' \end{bmatrix} = \begin{bmatrix} \cos(\theta) & \sin(\theta) \\ -\sin(\theta) & \cos(\theta) \end{bmatrix} \begin{bmatrix} x \\ y \end{bmatrix}$$

Kernel Fisher Discriminant (KFD) uses FDA in order to determine non-linear features to distinguish classes in non-linear space. Let us \(\phi\) is a non-linear transformation in \(\mathcal{F}\) feature space. In this case, the objective function of KFA can be written as similar to normal FDA[23]:

$$J(w) = \frac{w^T S_{\mathcal{F}} w}{w^T S_{\mathcal{F}} w}$$

$$S_{\mathcal{F}} = \frac{1}{n_1 + n_2} \sum_{i=1}^{n_1} \sum_{j=1}^{n_2} (\phi(x_i) - m_{\mathcal{F}i})(\phi(x_j) - m_{\mathcal{F}i})^T$$

$$m_{\mathcal{F}i} = \frac{1}{n_{\mathcal{F}i}} \sum_{j=1}^{n_{\mathcal{F}i}} \phi(x_i)$$

In order to formulate the problem in non-linear feature space, it needs to be expressed in the from of inner products of the use of training samples. After implementation of several calculations, the objective function of KFA can be written as follows:

$$J(\alpha) = \frac{\alpha^T K_{\mathcal{F}} \alpha}{\alpha^T K_{\mathcal{F}} \alpha}$$

The solution to this problem is provided by obtaining eigenvalues of \(K_{\mathcal{F}}^{-1} K_{\mathcal{F}}\). The projection of a point \(\mathbf{x}\) to \(\mathbf{w}\) in \(\mathcal{F}\) is given in (31).

$$\mathbf{w}, \mathbf{\phi}(\mathbf{x}) = \sum_{i=1}^{n} \alpha_i k(x_i, \mathbf{x})$$

k is inner product kernel function

$$k(x,y) = \langle \phi(x), \phi(y) \rangle$$

In this study, Gaussian kernel function \((k(x,y) = \exp(-\frac{||x-y||^2}{2\sigma^2}))\) was preferred. To represent the number of class \(\mathcal{C}\), a multi-class structure \(K_{\mathcal{C}}\) and \(K_{\mathcal{B}}\) can be calculated as follows [49].

$$K_{\mathcal{B}} = \frac{1}{C(C-1)} \sum_{i=1}^{c} \sum_{j=1}^{c} (m_i - m_j)(m_i - m_j)^T$$

$$m_i = \frac{1}{n_i} \sum_{j=1}^{n_i} k(x_j, x_j), \ldots, \frac{1}{n_i} \sum_{j=1}^{n_i} k(x_n, x_j)$$

$$K_{\mathcal{C}} = \frac{1}{c} \sum_{j=1}^{c} \sum_{i=1}^{n} (\zeta_i - m_i)(\zeta_i - m_i)^T$$

$$\zeta_i = (k(x_1, x_j), k(x_2, x_j), \ldots, k(x_n, x_j))^T$$

G. Similarity Measurement

The cosine Mahalanobis (cosmah) distance metric [24] was used for the similarity measurement between the feature vectors. To be able to use this metric, first a conversion between feature space and Mahalanobis space is needed. Let us assume that \(\hat{u}\) and \(\hat{u}\) are two vectors to measure the similarity of features in the feature space, and \(\hat{m}\) and \(\hat{n}\) are their conversions in the Mahalanobis space. In this case, \(\hat{m}\) and \(\hat{n}\) are represented as in equations 23-24.

$$\hat{m} = \begin{bmatrix} \hat{u}_1 \\ \vdots \\ \hat{u}_p \end{bmatrix}$$

$$\hat{n} = \begin{bmatrix} \hat{v}_1 \\ \vdots \\ \hat{v}_p \end{bmatrix}$$

where \(\sigma_i\) is standard deviation of the vectors in ith dimension; cosmah is the cosine angle between the vectors after having been projected to the recognition space.

$$D = \cos(\theta_{mn}) = -\frac{\hat{m}^T \hat{n}}{||\hat{m}|| ||\hat{n}||}$$

III. EXPERIMENTAL RESULTS

On the performance evaluations, all comparisons were made by the leave-one-out strategy, and the minimum distance between two feature vectors was regarded as the best match. First, all experiments were performed with the features taken from uncorrected perspective images. Then, the same process was repeated with the features taken from the corrected images, and finally, comparisons of the two were made.

In the evaluation stage of the study, first, the performance of the scenarios parallel to the camera plane (S1, S2 and S3) was measured. The evaluation was made for each camera separately. During the classification process, it was noted that the images
used for training did not match with itself. The cumulative match curves (CMCs) of the first comparisons are shown in Fig. 8, and the verification rates are given in Table 2.

![Fig. 8 CMCs for the unangled scenarios: (a) Up camera; (b) Down camera](image)

</tbody>
</table>

According to the Rank one recognition rate values success of the system on uncorrected images is sufficiently high. However some improvements are achieved on the corrected images.

According to the data in Table 2, the success of the system on the image without corrected perspective was considered satisfactory. Therefore, the rest of the study focused on the performance of the proposed approach on images taken according to the scenario with an angle. In all other evaluations, S1, S2 and S3 images were used for training and the other images were used for testing. The results are given in Table 3 and Fig. 9. All images except the training set were used as the test set (Training set = S1+S2+S3 and Test Set = S4+S5+S6+S7+S8+S9+S10).

![Fig. 9 ROC curve for the angled scenarios before and after transformation](image)

As seen in Table 3 and Fig. 9, the recognition rate on pose corrected images was improved by around 25%, while the EER values decreased significantly. Another important advantage was that the system was also capable of simultaneously producing two patterns of a hand. Two simple fusion models were applied using these two patterns. In these models, images taken from two cameras were used together as a training set. In the first fusion model, if one of the test patterns obtained from the two cameras was more similar to one of the patterns in the training set, it was classified by its label. In the second model a single pattern was obtained by taking the average of the test images taken from the two cameras. Here, in order to evaluate the performance correctly, fusion models were applied on the untransformed and transformed images, and the comparative results are given in Table 5 and Fig. 10. The fusion approaches produced better results than the data in Table 3 in both the transformed and untransformed images. In particular, the Fusion 2 approach applied to the transformed images increased the recognition rate by 3.25% according to the down camera, which had the best value in Table 3. In addition, the EER values decreased from 3.42% to 2.28%.

IV. CONCLUSIONS

In this study, the pose information for the palm was obtained from stereo-based hand images in a 3D environment and the images were converted with the help of the proposed geometric transformations. Thus, a pre-processing operation was produced for the powerful 2D recognition techniques. It is evident that the existing 3D systems are more advantageous for feature extraction than 2D. However, the extra cost of these systems and their nonportable devices reduce their applicability.

In this study, 3D information was used only to make geometric corrections with a different perspective because the web cameras, which were used to keep the recognition system’s cost low, were incapable of producing very detailed 3D point information. Detection of depth in high-resolution stereo images does not seem advantageous for real time applications. The most important advantage of this study is that very detailed 3D information is not needed. Also miscalculations of some points because of noise in the images can be tolerated at determination of hand plane equation.

One of the major advantages of the study was that two palm patterns could be produced from two different cameras at the same time used by the proposed simple fusion models to improve the chances of success.

In this study, in order to make the evaluations needed, a stereo-based dataset was compiled using images taken from 138 different people. As a result, the recognition rate ratios of about 62% obtained by each camera evaluated individually were increased to 93.17% by employing a simple stereo fusion approach.

This study revealed the need for perspective correction on the images taken parallel to the camera plane in contactless and unconstrained systems. Although after the evaluations, significant improvements were observed for all scenarios, the obtained results could be further improved upon. In particular, on the high-angle images, pattern distortions can arise, depending on the 3D structure of the hand. Furthermore, some users are unable to completely extend their fingers, in which case, the inner surface of the hand resembles a curved structure. This is one of the factors that negatively affected the success of the system. In the future, studies must further examine the problem of correcting the curves of the palm, and develop techniques to improve the quality of the images.

Abstract—Computer and technological developments are positive influences every aspect of life. Parallel to the developments in technology, artificial intelligence applications, mathematical and statistical models, are widely used in many other fields of the industry. Fire chemical is a dynamic event and does spread very quickly if there is no barrier. Today, fire doors are being used as required in all kinds of buildings. Therefore, it’s vital to determine the fire resistance of different doors for different buildings. This determination should be monitored by the experimental studies. In single and multiple regression equations there is a dependent variable which affects a single or multiple independent variables. Artificial Neural Networks (ANN) are intelligent computer software which mimics human brain's neural networks, mainly connected through networks and has the ability to discover, creating and deriving new information by way of learning by making generalizations from samples. In this study experiments were conducted to determine the resistance of the fire door. After the experiments a regression analysis (RA) and an artificial neural network model have been developed by using data obtained from experiments. With this regression model (RM) the internal temperature of the fired room which plays an important role in the resistance of fire, doors have been evaluated. In the proposed system, the temperature values of the thermocouples above the door, Top Left, Top Right, Middle Left, Middle Right, Bottom Left, Bottom Right Temperature (°C) and Time (minute) have been taken as input and In-Room Temperature (°C) as output parameters. The results improved by these two approaches were evaluated in comparison with each other. Regression analysis and the results obtained by the artificial neural network have been compared with experimental data. Accuracy was determined as a percentage. Correlation and determination coefficients were calculated and the fire doors resistance determination ability of models have been compared. It has been observed that the developed model of this kind can be safely used in the determination of the fire door resistance.

Keywords—Regression model, Artificial neural network, Fire doors, In-Room temperature

I. INTRODUCTION

In buildings, fire doors are utilized commonly. These doors entail specific fire resistance and they act as delimiters or fire enclosures. Nevertheless, the thermal and mechanical properties of materials generally change with high temperatures so sufficient knowledge needs to be known about fire behaviors of construction materials of doors to utilize these doors ideally [1]. Structural steel members can be used for the vertical and lateral support in multi-story buildings. These members may be included inside fire-resistant enclosures enabling house elevators, stairs and other services [2].

With the aim of preventing fires spreading, structural failure and enabling evacuation of occupants and intervention by firemen, necessities for fire resistance are given. These are generally expressed for standard fires. This approach that requires classifying products as their fire behaviors is still used in many countries. As compared to the natural fire, thermal actions from conventional fires are symbolic. However, from conventional fires, more severe thermal actions are needed under some conditions [3, 6].

Fire chemical is a dynamic event and does spread very quickly if there is no barrier. Today, fire doors are being used as required in all kinds of buildings. Therefore, it’s vital to determine the fire resistance of different doors for different buildings. This determination should be monitored by the experimental studies. The precautions to be taken to the fire are proportional to recognizing the fire. If the burning and not yet burned but likely possible to be burn materials, fire loads and other conditions are well-defined then the measures to be taken in fire case will be very effective [4, 5].

With the entrance and widely use of computers actively in human life, the usage of biological structure of the artificial intelligence model for the solution of complex problems and increased the use of statistical methods. Referring specifically to engineering research in recent years, there are lots of
different methods like regression models, artificial intelligence-based (ANN, fuzzy logic, support vector machines, etc.) used in different estimates based operations. In this study the ANN and RM which are the most widely used methods have been used.

In this study, at first an experimental study has been carried out to determine the fire resistance of fire doors. Thermocouples were placed at the surface of door and were connected to data logger to record the data. System was modeled by an artificial neural network with 7 inputs and 1 output which is an artificial intelligence techniques and RM using non-linear experimental data and fire room interior temperature values were estimated. These two models were compared with each other and the model that give the closest result to experiments have been identified.

II. EXPERIMENTAL SETUP

In the study, a test mechanism was prepared for one fire and smoke control doors used as fire doors according to the rules of TS EN 1634-1 and an experimental study was carried out. At the same time, digital thermometers (thermocouples), thermal camera, fire door, gas concrete wall and inflammable wooden materials are used materials [7].

The experimental study was carried out at the laboratory of Construction Department of Selcuk University Higher School of Vocational and Technical Sciences. The experiment images from fire door and mechanism and is given in Fig. 1.

After the experimental mechanism was prepared, all the indicators and devices were tested in terms of working and first fire was lit. Since the beginning of the fire, all data records were beginning to be recorded. Experiment time continued for 136 minutes and during this experiment all data were recorded. For each one minute, data were recorded to data logger from 6 thermocouples and at the end of the experiment these data were transferred to computer [8].

III. ANN MODELING

Artificial Neural Network can be defined as a mathematical model that tries to mimic the human brain cells.

There are many advantageous aspects of ANN such as being able to do parallel processing, ability to learn, making generalizations and ease of analysis and design. One of the most important features is that different information can be derived without requiring help from the new knowledge acquired through learning.

In this study, for the predict the in-room temperature (°C), an ANN structure with 7 inputs and 1 output was designed and application was performed using the designed structure (Fig. 2). As input parameters, Top Left, Top Right, Middle Left, Middle Right, Bottom Left, Bottom Right Temperature (°C) and Time (minute), as output parameter In-room Temperature (°C) were taken. The performance of the ANN was presented by examining the consistency between the values obtained through the ANN approach and the experimental data [10].

![Fig. 2 Structure of ANN model for this study](image)

Feed-forward back-propagation algorithm was used in feed forward single hidden layers. It was aimed to find the most appropriate network model by changing certain parameters such as the number of hidden layers, the number of neurons used in hidden layers, epoch number, training functions and transfer functions. The data sets selected for training and testing were trained using Levenberg-Marquardt (trainlm) algorithm respectively and the results were obtained. Training algorithm and activation functions were tested using the software developed and results were obtained in the matlab program.

IV. REGRESSION ANALYSIS

One of the most widely used area of utilization of the statistical studies is regression analysis. In case there are more than one factor affecting a case, researching of cause-effect relation becomes possible with regression analysis. A regression model consists of dependent and independent variables. Independent variable is the variable which is not coincidental and used to express dependent variable.
Generally, multiple regression analysis is used to find mean output values relating to dependent variable \( y_9, 11 \).

Functional form of simple linear regression model can be written in the form of equation (1) for a mass \([9]\).

\[ Y = \beta_0 + \beta_1 X + \varepsilon \]  
(1)

In this model;
- \( Y \): Value of dependent variable,
- \( X \): Value of independent variable,
- \( \beta_0 \): Sectional of \( Y \) for mass (constant term),
- \( \beta_1 \): Slope of mass regression line,
- \( \varepsilon \): Error term

In this study, modelling approach is developed with ANN by utilizing the data obtained experimentally \([10]\). Using statistical analysis of the same data, the system of single and multiple regression equations was created with the SPSS program. Temperature values were found with the estimation of in-room temperatures (°C), by using the mathematical expressions obtained with RM. RM results were compared separately with the values obtained by both the experiments and ANN model.

The descriptive statistics 136 values for the in-room temperature can be seen in Table I.

RM models and temperature (°C) determines dependent variable In-Room Temperature (°C) and independent’s variables affecting this situation, Top Left, Top, Right, Middle Left, Middle Right, Bottom Left, Bottom Right Temperatures (°C) and Time (minute) based on regression equations were generated using seven parameters. The regression equations generated by the SPSS software, the status of each variable were calculated correlation coefficients obtained and determination.

The highest correlation (R=0.986) is obtained by linear multiple regression equation by using these seven variables. And, the closest results to the experiment are obtained in this way. In addition, when in-room temperature (°C) is predicted with multiple regression equation, determination coefficient is found as \( R^2=0.973 \) (Table II-model summary). The best result in the regression models is seen in Table III. It suggests that the values are meaning and compatible statistically. According to correlation values found, it is seen in the \( r \) column in Table II that there is a general strong relation in the same direction between in-room temperature (°C)’s calculated with RM and in-room temperature (°C) measured in the experiment (Table III).

V. RESULTS AND DISCUSSIONS

This study is the determination and testing process of the fire resistance of the fire door which would be used in a fire that may be encountered in all living spaces. A model has been established that can determine the fire resistance value of the fire door in line with the regulations. The study emerges as the application of two different methods. First method is the ANN model using data generated in experimental studies. The second study is the formation of RM phase by using the same data again. The results obtained by these two methods were compared with the experimental data and attempts to determine the best model has been made.

As a result of ANN modelling:
In the single hidden layer network structure, number of neurons in the hidden layer values respectively and epoch number were used for all training and testing algorithms and the results were observed. What is more, considering the smallest values in Mean Square Errors (MSE) and the biggest values in $R^2$, their averages were calculated. Then, the best models were found according to this. Among all the circumstances, the trainlm training algorithm and logsis transfer function gave the best result. Also the (7-14-1 (50 epochs)) model was used, which had the lowest MSE error values and the highest $R^2$ values. The graphs that show the comparative results are presented below. The developed ANN system (training) results and the real measured values were evaluated. The graph shown in Fig. 3 indicates that the correlation coefficient was 0.99992 which indicates a perfect match between ANN estimation values and real data [9].

![Fig. 3. The relationship between experimental and ANN prediction values](image)

When temperature is estimated with RM approach which is used as the second resolution method, it has been shown that the effective results can be obtained. In the estimation process with RM, when values obtained at the end of the studies using linear regression analysis (Equation 2) compared with the experimental data, it was observed to be considerably proximate. Correlation analysis between the RM experiment values (Figure 4) yielded $R$ as 0.986. Correlation results of the two groups of data from the experiment and the model, shows that the results are interrelated and the consistency between data can be seen.

Linear multiple regression equation obtained in this way is expressed and the system is guessed (equation 2).

$$y=24.168+(b_1*9.699)+(b_2*12.620)+(b_3*(-2.687))+(b_4*(-3.057))+(b_5*2.664)+(b_6*(-8.839))+(b_7*(-1.652))$$

(2)
In this study, regression analysis which is a statistical approach and artificial neural network approach has been performed separately using data from experimental work and two different methods have been established to predict in-room temperature (°C). The data obtained from the developed model with experimental data has been compared statistically, it is seen that the designed model gives successful outcome. When the analysis was assessed, the in-room temperature obtained from the ANN was very close to the experimental results. It has been observed that the developed models of this kind can be safely used in the determination of the fire door resistance. In the subsequent studies, the workspace can be expanded by adding more number of parameters and using different models.

Abstract—Traffic accidents are one of the most important and serious problems, our country encounters. As the percentage of injured and casualties in traffic accidents are huge in numbers, it causes thousands of people injured or dead in a year. In the situation of coming by a traffic accident that we face commonly in daily life, generally people directly use their mobile phones and call the related units. However, as the required, right and adequate information is not given to these related units, the cases may sometimes end with casualties. One of the most important reasons of casualties in car accidents is the wrong, senseless first aids performed to the victims of injuries by surrenders. In this study, the aim is to determine the exact location of the accident with its latitude and longitude that is determined automatically via the application present in the responsive citizen who tries to help the victims of the accident.

With this system named as “Mobile Accident Notification” the users are aimed to send accident notification in online or via sending message when there is no internet access with the help of mobile applications that process in Android Operating System. These accident data kept in remote server are monitored on web pages or Android mobile phones. In this thesis, a web-based, open-source accident filtration system was developed and the accidents were provided to be monitored by the authorized people in related units.

Keywords—Mobile accident, Accident notification, Mobile accident tracking, Android mobile accident statement

Preventing traffic accidents is a shared concern of the whole world. Since the ratio of deaths and injuries significantly high, thousands of people die and hundreds of thousands of people get injured in considerably high number of accidents in each year. When an accident occurs in daily life, the common practice is to call relevant units and institutions. However, since sometimes correct information is not given to relevant units, many lives are lost. Minutes after the accident occurs (the time from the injury until the hospital care) are crucial for resuscitating accident victims and reducing physical effects of the accident. Improving first aid services is anticipated to reduce casualties up to 20% [1]. Among the reasons of injuries in traffic accidents resulting in casualties and permanent disabilities are late arriving ambulances and series of unapprised interventions of bystanders to accident victims. When reasons of late arrivals of ambulances are examined, various causes listed below are observed [2].

- Distance of the accident scene to the location of ambulances
- Ambulances receiving wrong directions
- Ambulance drivers not being able to locate accidents due to lack of knowledge of exact latitudes and longitudes of accidents.
- Directing ambulances to false locations (pranks etc.)
- Deploying un-operational ambulances from faraway centers to the accident scene, rather than nearest ones, due to lack of communication
- Inadequate number of ambulances when the accident occurred
- Traffic jams
- Ambulances not being able to pull up close to accident scenes due to irregularly parked cars on streets and avenues.

The objective of this thesis is to avail responsive citizens to notify accidents with an application downloaded into their personal mobile phones and to directly locate the scene of the accident on the map by automatically retrieving latitude and longitude values of the informant. Additionally, by filling a form included with the application, appropriate number of ambulances and police will be diverted to the accident scene since the exact number of people injured will be learned or possibly life saving information will be given to healthcare professionals since the nature of the injuries will be identified. Further objectives of this thesis are grouped under general headlines below.

ACCIDENT NOTIFICATION AND DETECTION SYSTEMS

Accident notification systems are usually the process of calling the phone numbers of related units and informing about an accident. With this notification method generally people either call the police and request other units to be dispatched or call the emergency services to request an ambulance to be sent to the scene of the accident.

In case of accident detection systems, usually the detection is realized by reading the data from sensors attached to
vehicles. Another method is a study conducted by Amin et al.[3] where data from GPSs of smart phones are read in 0.1 second intervals and the location of the vehicle is located by map matching algorithms and then the previous speed values collected in 0.1 second intervals are subtracted from the subsequent speed values where the difference is then compared to the threshold values to determine if an accident occurred or not. Additionally there are other solutions such as detecting accidents without interaction with Electronic Control Units, false positive preventions and WreckWatch client-server architecture. One final distinctive study is done by placing noise and image recording cameras on junctions and start recording exactly when the accident occurs by recognizing the noises from the cars involved in an accident and by not recording continuously but only when the accident took place [4].

User prefers this method if there is internet connection and when he/she does not want to enter too much information. When the user clicks on fast notification (GPS must be active), a record of the accident is created in the database immediately. The other information on the form is updated with the data entered by the user. Since the location of the accident and the location where the user filled the form may significantly differ, a record is immediately created when fast notification is clicked. For that reason the record is created immediately after the user clicked on the fast notification; other information can be updated at a later time.

- Detailed Notification

The user prefers this method if there is internet connection and if he/she is willing to give detailed information such as a photograph of the accident scene, license plates of vehicles, number of vehicles involved, estimated distance of the accident, etc. When the user clicks to the detailed notification (GPS must be active), a record of the accident is created on the system database. Other information is updated by the user entering appropriate data. When detailed notification is clicked, the notification is generated. The reason for creating an immediate record is explained in Fast Notification section.

FILTERING NOTIFICATIONS

When an accident occurs, many notifications are sent by users. However since these notifications are for the same accident, they have to be filtered and recorded under one singular accident. For that purpose several constraints should be defined. These constraints can be listed as follows;

- Diameter

Indicates the required diameter for notifications sent by different users to be perceived as belonging to the same accident. It is a parameter used to add all informants under the same category.

- Estimated distance

This is a criteria put forth to receive data from the nearest point to the accident among many
different notifications by taking the estimated distance of the informant to the accident scene.

SENDING RELATED ACCIDENT MESSAGE TO RELEVANT UNIT WORKERS

This is the process of sending messages according to the notifications of various informants to the closest Police Headquarters, Health Institutions and Fire Department workers.

M- ACCIDENT NOTIFICATION APPLICATION

With this application; it is targeted to create awareness among end-users by involving latest technologies to intervene accidents in a timely manner. This study came forth with the idea of ensuring fast and productive interference to accidents and with minimizing the response period during when accidents occur until first aid services reached to victims, is developed by using many integrated web and mobile technologies altogether.

In the thesis, two of them mobile, one of them web based, three different applications are developed. A single database is used for every each application. The application is consisted of three modules. These are; SMS Filtering module, Notification Sending module and administrator follow-up module. Detailed explanations and screen shots from these modules will be given in the upcoming sections.

CONCLUSION

One of the major concerns of our country as well as the world is traffic accidents. In the name of preventing these accidents which result in hundreds of thousands of casualties each year and cause many of them left with permanent disabilities, science people and researches have conducted many widespread studies. In the light of these studies, they have proposed several accident detection and accident tracking systems underlying how these accidents can be prevented. In one of those studies, a three-step protection method has been offered by Kraus et al[5]. The first of these protection methods is the detection of causes of accidents and taking necessary protections against them; the second method is things that need to be done when an accident occurs and measures that need to be taken to reduce severe effects of accidents; and the final method is what needs to be done after accidents occur and necessary precautions to minimize effects of injuries[5].

Taking inspiration from what needs to be done when an accident occurs, as pointed out in the second method of the study by Kraus et al above, and many other similar studies, actions to be taken in order to minimize the time from the moment the accident occurs until the first intervention to the accident victim (the golden hour) and to treat accident victims in the shortest possible time with the help of the support of a mobile application has been tried to be conveyed in this thesis. With this study, automatically obtaining latitudes and longitudes of exact locations of user/users who have witnessed the accident through GPS, either via the internet connection or when there are no internet connections, via SMS text messaging method has been achieved. With numbers of people injured as well as other pertinent data entered in the form, dispatching both adequate number of ambulances and diverting relevant police units to the accident scene have been targeted. Depending on the nature of injuries, determining and transferring probably life saving information to healthcare professionals has been proposed. At the present time when an accident occurs, among reasons of late arrivals of relevant units to the accident scene are; receiving wrong directions or not being able to find the correct address. With this application, actions such as; direct determination of the exact location of the accident on the map by taking the information of the closets users was targeted. In summary, with this thesis actions such as; contacting emergency services of nearest hospitals, contacting nearest Police Headquarters, totally eliminating the risk of giving wrong directions to ambulances, dispatching ambulances to the correct location by extracting exact latitudes and longitudes of accident scenes on the map, by collecting data from the informant such as his/her exact latitude and longitude, number of vehicles involved, number of injured, and the nature of injuries, dispatching adequate number of ambulances with appropriate equipment, when tens, sometimes hundreds of people inform an accident, giving only the notification of the relevant accident will be taken. When this mobile application is used, it is our belief that the time passed from the moment the accident occurs until the first intervention to accident victims will be minimized, adequate number of equipment and vehicles will be dispatched to the accident scene, assistance will arrive on the shortest time possible by utilizing maps, closest relevant units will be dispatched to the location and many similar advantages will be provided. No such study has been conducted ever before. Therefore a study like this is believed to immensely contribute to the literature as well.

Real Time Blood Type Determination by Gel Test Method on an Embedded System

Enes Ayan*, Erdem Kamil Yıldırım*
*Department of Computer Engineering, University of Kırıkkale, Turkey
{enesayan, erdemkamilyildirim}@.kku.edu.tr

Abstract— Determination of a blood type has a crucial importance for blood transfusion. Therefore it is mandatory doing tests to determine blood type before the transfusion. In order to prevent the errors in determining blood type and to save time these tests are carried out by the automatic devices. However these devices are very expensive and it is necessary to develop cheaper alternative systems. In this study, we designed a basic device which will be a first step for a cheap and fast prototype. It utilizes the image processing techniques and gel test method for real time blood type determination on embedded system. During the tests, fifty gel test cards data were used and, it is found that the proposed system can process each gel test card in 2 seconds with 99% accuracy on average.

Keywords— Image Processing, Blood Types, Embedded Systems, OpenCv, Gel Test Method

I. INTRODUCTION

Determination of blood type is a vital process before the blood transfusion. Otherwise fatal consequences may occur.

It must mandatory doing blood type determination tests to avoid this situation. International Society of Blood Transfusion (ISBT) had recognized a total number of 30 human blood group systems, with ABO and Rh as the two most common groups [1]. The most important blood group is the ABO group. The ABO group system has A, B, AB and O blood types. Type A, B and AB have A, B and AB antigens respectively on the surface of the red blood cells (RBCs), whereas type O has none of these antigens [2]. The second most significant blood-group system is the Rh system. The Rh system determines blood type from the presence or absence of a “Rhesus factor” surface on red blood cells. If Rh factor is present on surface of the RBC it is positive otherwise it is called negative. According to the ABO and Rh grouping systems there are 8 blood groups. These are A Rh+, A Rh-, B Rh+, B Rh-, AB Rh+, AB Rh-, O Rh+, O Rh-. A, B, D (Rh) antigens tests are carried out for determination of blood type [3].

Until recently different methods have been developed to determine the blood group types. Most of the techniques applied today are based on the principle of interaction between antigen and antibody. As a result of this interaction, results are interpreted as positive if agglutination of RBCs occurs and negative if otherwise. The first method used for determination of blood type is called Slide method in which three blood drops are dripped on separate lams then A, B, D antigens are dripped respectively on lams and blood type is determined by angulation [3].

In this study gel test method is used for determination of blood type which is widely used in Tukey. The gel card used in this method is shown in Fig 1. Gel card has a special gel and blood cells which don’t agglutinate passes through this gel and accumulate at the bottom of the tuple [4].

Looking at literature there are several studies for determination of blood type. Zarifi and co-workers used plate method for detection of blood type on FPGA [5]. Feraz developed a prototype system for emergency situations and used slide method in this system [6]. Fatima determined blood type using slide method microscope images by using image processing techniques [7]. Dolmashk and colleagues using laser light radiation and image processing techniques together have shown that the detection of blood group is possible [8]. Swarp and colleagues compared conventional tube method and gel test method [9]. Toz and colleagues developed a software for reading gel test cards by using image processing techniques [10]. Also there are several devices for blood type determination. Some of them are Technicon Auto Analyzer [11-13], Auto-Grouper [12], Technicon Auto Analyzer II [14,15].

Gel test method needs three devices. These are gel test centrifuge, gel test incubator and gel test reader. These devices are very expensive. In general, technicians in hospitals are detecting blood type visually instead of gel test reader. Therefore errors in reading or interpreting cause hundreds of fatal blood transfusions over a year. Furthermore, analysing a large number of samples consumes a lot of time and requires special care for the sampler. In this study, our aim is to develop a cheap, fast and efficient system for gel test reader device. For this purpose a system is designed on Beagle Bone Black (BBB) which is a mini computer card which can run Linux operating systems. It is useful, stronger and cheaper alternative for image processing applications. Using an USB web cam gel card images were taken and image processing techniques are applied on BBB for detection of blood type.
II. MATERIALS AND METHODS

Designed system is consist of BBB and an USB camera connected to it, a fix background and a moving belt.

A. Gel card test method

Gel card used for gel testing method is manufactured by company DiaPro. Fig 1 shows an example of gel card. The size of gel card is 5x35 cm and it has 8 tubes in total but first 5 tuples are necessary for detection. Fig 5 shows the required area for detection. Every tube has a special gel which allows the passage to the bottom of the tube for non-agglutinated blood cells. If blood cells don’t agglutinate they move to bottom of the tube. This situation reveals a negative result (Fig 2). 25 ul of blood was added drop wise into each tube and centrifugation was performed for the detection of blood group. After this process gel card image is taken. Fig 4 shows a B Rh + gel card, ready for determination of blood type.

B. Image processing techniques and Embedded System

OpenCv library and python programming language is used for image processing techniques. On the hardware side BBB minicomputer card and an USB web cam is used. USB can take 640x480 resolution image. BBB has Angstrom Linux operating system. The system has been tested in closed environment and constant intensity of light used to stop the effects of external factors. In this way, the problems of intensity of light and light angle have been removed.

III. RESULTS

Fig 3 shows image processing algorithms used in this study.

1) Detection of motion in System: Static background motion detection algorithm is used for detection of motion in the system. This algorithm is based on substruction of static background image taken at the (t-1) time from the image taken at (t) time principle. A threshold value is set and after subtraction every pixel is compared with this threshold (Th) value. If pixel value is bigger than threshold value it is counted by counter. When the counter value reached to a predetermined value (Th2) motion is detected. The formulization of this process is given below.

\[ |I_t(x) - I_{t-1}(x)| > Th \Rightarrow c = c+1 \text{ and if } c > Th2 \text{ motion is detected.} \]

2) Conversion of grey level image: Fig 4 shows an example of a gel card image taken after motion detection. RGB (Red, Green, Blue) image was converted grey image by using
formula given below. Fig 5 shows grey level gel card image example.

\[ Y = 0.299R + 0.587G + 0.114B \]

![Figure 4. BRH + gel card example](image)

**Figure 4. BRH + gel card example**

**Figure 5. Grey level gel card**

3) Detection of ROI (Region of Interests) and conversion binary image: In this process ROI area was cropped from the grey level image for detection of blood type. In this system since each gel card has a static location in front of the camera, ROI was obtained by cropping the gel card image from specified points. In order to obtain binary image, the adaptive threshold algorithm was applied on ROI

![Figure 6. Cropping ROI area](image)

**Figure 6. Cropping ROI area**

4) Edge detection and Dilation: After the binary conversion the Canny algorithm was applied for edge detection. Furthermore to enhance the image dilation operation was performed. Fig 8 and Fig 9 shows results respectively.

![Figure 7. Binary image](image)

**Figure 7. Binary image**

![Figure 8. Edge detection](image)

**Figure 8. Edge detection**

![Figure 9. Dilation](image)

**Figure 9. Dilation**

5) Cropping ROI areas for detection: A, B, AB, RH1, RH2 ROI areas was cropped from the image for determination of blood type. First white areas was detected and then this areas was cropped from the image. FindCounters function in OpenCv library was utilized for this purpose. Fig 10 shows results respectively.

After cropping operation y coordinates of white areas was detected and compared with each other. According to this comparison blood type is determined and saved in a txt file in BBB. After saving blood type, the system is ready for another gel card. All process explained above is taken 2
second. This time is very efficient value for a real time system [5].

![Figure 10. Cropped gel card tubes](image)

IV. CONCLUSIONS AND DISCUSSIONS

The Blood type determination test is one of the most important test performed in hospitals, blood banks, and other health organizations. Gel test method is one of the blood type determination methods which is widely used in Turkey. In this study our aim is to develop a cheaper and efficient alternative system for blood type determination. During the tests, fifty gel test cards data were used and, it is found that the proposed system can process each gel test card in 2 seconds with 99% accuracy on average.

Abstract— Timber is used widely in construction industry lately due to its some advantages such as neutrality, lightness, environmentally-friendly, resistant against earthquakes, manufacturing flexibility, and having a good compatibility with other construction materials like steel, concrete, and adobe-like materials. Fire retardant materials are used in order to protect wood from the fire. The main task of the fire retardant material is to protect timber against fire, besides it is very important to know whether the retardant material has any effect on the compressive strength of the material or not and it would help the designer to make a choice based on material sections. Today computer technology is widely used in the construction industry as well as in all sectors. Various mathematical and statistical methods are used for computer-aided models. In this study samples with different dimensions and different fire-retardant materials has been prepared from most commonly used wood materials in the construction sector. The compressive strength test has been applied on the samples after certain operations. The data obtained from experiments have been used to apply regression analysis (RA) which is a statistical approach and regression models (RM) have been established to predict compressive strength (CS). Data like wood sample weight, cross-section, volume and breaking load were used to create regression equations for estimating the tension. The data obtained from the regression model developed by experimental data were statistically compared, it is seen that the outcome of the designed model is successful. When the correlation coefficient between predicted compressive strength values and generated models was calculated, it has been seen that the methods applied can be used safely. The data obtained from regression models is close to experimental data and such models can be used to estimate the compressive strength wood.

Keywords— Regression analysis, Species of wood, Resistance of wood against pressure

I. INTRODUCTION

Since ancient times, trees and timber have been used as construction materials. In that sense, the importance and preservation of the forests is crucial. The fact that wood can be used in different fields of life, is closely related to strength of timber-type materials in the field where it is used. Therefore, it is important to determine the applicability of timber, namely mechanical properties of it should be determined. In design stage, it is very crucial to determine the physical and mechanical properties of the materials used in structures. In addition, the safety of element composed from timber are determined by whether it is strong enough to withstand against internal stresses which occurs as a result of external forces [1-2].

Because of the many advantages of timber such as strength and versatile ease of use, it has been widely used as a construction material for many years from the past till today [3]. Timber is a natural material which is used in today’s construction sector and it has been widely used in the past and will continue to be used. Moreover, timber can be renewed in terms of planting new one and can be accepted as a non-consumable resource [4]. The properties like naturalness & temperature, lightness, being an eco-friendly and, earthquake resistant material, providing manufacturing flexibility, compliance with other construction materials such as steel, concrete and adobe, aesthetical and acoustic properties have a huge role in the preference of timber, in spite of increasing acceleration in technological developments in the construction sector in recent years [5]. Historical structures where wooden material usage providing good examples in many fields, can be encountered in both our country and many other countries. Because necessary measures weren’t/aren’t taken in the past/future when wooden material is used, lots of wooden structures catch on fire they are completely destroyed or substantially damaged [6].

With the aim of protecting wooden materials from fire, fire retardant polishes, boron-based impregnated materials, fire retardant paints, etc. are used. An experimental study was performed about whether coating materials which are fire retardant at specific rates, decrease the strength of wooden material or not. 3 different dimensions used with different aims in construction affairs, 3 different types of wood which is easily supplied in our country and 2 different coating materials which are widely used and a raw material which is coated as proof bar are used in experimental study [7-8].

In engineering studies, statistical approaches, regression analysis, mathematical modelling, fuzzy-set-based technical, artificial neural nets and artificial intelligence approaches etc. can be widely used to estimate one or more than one parameter and for different modellings. Regression analysis is a linear or
non-linear statistical field, where it is used with the aim of being able to determine the cause-effect relation between two or more variables that can be used to estimate or approximate about that subject. Therefore, one of the most suitable methods of the process of determining wooden compressive strength is to use regression model. In this process, the fact that parameters can be included in statistical model positively affects the accuracy of result [9].

In this study, samples are prepared at different dimensions and with different fire retardant from different types of wooden materials which are widely used in the sector of construction. Tension stress tests are applied to these samples after specific processes. Regression analyses (RA), which are a statistical approach by using data in these experimental studies, are made and regression models (REM), which can estimate compressive strength (CS), are composed. Results are compared considering coherence between REM and experimental results.

II. EXPERIMENTAL STUDY

For the experimental studies, primarily, the types of fire retardant materials which are most frequently available in the markets were analysed. For wood, an imported fire retardant which are in conformity with UNI EN ISO 14001: 2004 (ISO 14001: 2004) [10] standards and boron impregnated material in conformity with (ISO 14001, 2004) standards were preferred.

Three types of wood were chosen to use in the experimental studies. One of them is Scotch Pine (Pinus silvestris L.) with the density of 620-780 kg/m³ frequently preferred in the buildings, the other is fir tree (Abies sp.) which has the density of 430-520 kg/m³ and poplar tree (Populus sp.) with the density of 310-400 kg/m³ were preferred.

For pressure tests, a computerized full automatic testing device with the capacity of 200 tons (2000 kN) which was produced by Ankara originated Yüksel Kaya Machinery in accordance with the standards of ISO9001(2000) Quality Management System and Press 5.4 version prepared by the company and the experiments were conducted. The pressing machine and computer program which the experiments were conducted are seen in Fig. 1.

The prepared wooden samples were located cantering the pressing machine a gradually increasing pressure stress (0.3 - N/s) was applied from bottom and top surfaces until the samples were broken. The pressure values applied to the wooden samples were automatically given by the computer program. In the experiment, the averages of each 3 samples were taken and the 27 results were obtained [8].

III. REGRESSION ANALYSIS

One of the most widely used area of utilization of the statistical studies is regression analysis. In case there are more than one factor affecting a case, researching of cause-effect relation becomes possible with regression analysis. A regression model model consists of dependent and independent variables. Independent variable is the variable which is not coincidental and used to express dependent variable. Generally, multiple regression analysis is used to find mean output values relating to dependent variable [9].

Functional form of simple linear regression model can be written in the form of equation (1) for a mass [11].

\[
Y = \beta_0 + \beta_1X + \varepsilon
\]

In this model;
- \(Y\): Value of dependent variable,
- \(X\): Value of independent variable,
- \(\beta_0\): Sectional of \(Y\) for mass (constant term),
- \(\beta_1\): Slope of mass regression line,
- \(\varepsilon\): Error term

For it, the specifications of wood materials are created with single and multiple regression equations of the system with SPSS program by statistical analysis method by taking advantage of data obtained experimentally [8]. The values of compressive strength (CS) are found and compared to experimental results by estimation Tension (kgf/cm2) with mathematical notation obtained with RM. The descriptive statistics 27 values for compressive strength can be seen in Table I.

In this study, regression equations are composed using these four parameters by getting dependent variable Tension (Tn-kgf/cm²) which determines compressive strength and independent variables, Test Material Weight (TMW-gr), Material Cross-Section (MCS-mm²), Material Volume (MV-mm³) and Breaking Load (BL-kgf) which affect this situation. With the regression equations composed in the software SPSS, the situation of each of the variables is calculated with correlation and determination coefficients obtained.

The best result in the regression models is seen in Table II. The highest correlation (R=0.926) is obtained by linear multiple regression equation by using these four variables. And, the closest results to the experiment are obtained in this way. In addition, when Tn is guessed with multiple regression equation, determination coefficient is found as (R²=0.858). It suggests that the values are meaning and compatible statistically. According to correlation values found, it is seen in the r column in Table II that there is a general strong relation in the same direction between Tn’s calculated with RM and Tn measured in the experiment.

Linear multiple regression equation obtained in this way is expressed and the system is guessed (equation 2).

\[
Tn = 401.929 + (0.017 \times TMW) + (0 \times MCS) + (-0.0000936983624273154 \times MV) + (0.006 \times BL) \tag{2}
\]

Mathematical formula can be created without a need for MCS variable in RM developed like Table II.
IV. RESULTS AND CONCLUSION

It is seen that Tn is estimated with the RM approach and effective results can be acquired in this study. When the values, which are obtained in the end of the study by using linear multiple regression model equation (2) in the estimation process with RM, are compared to experimental data, it is seen in Figure 2 that two groups of data are very close to each other.

R is calculated as 0.926 with correlation analysis made between RM-experiment data (Figure 3). Results of the correlation suggest that two groups of data among the results obtained by models with experiment are correlated and prove that there are no differences among data in terms of meaning.

In this study, regression analyses, which are statistical approach by using data in experimental studies, are made and regression equations, which can estimate compressive strength, are composed. When experimental data and data which is obtained from developed regression models are statistically compared, it is seen that designed models give successful results. As a result, RM shows its usability in determining Tn values with this study. RM models can transform disadvantages in experimental studies into advantages. Furthermore, it has such significant advantages as interpolation which is not done in this experiment. By increasing the number of parameters in...
future studies and developing different regression models, the field of study can be expanded.

Abstract— Although wind energy at certain intervals and random in nature, today it is one of the commonly utilized alternative energy source in the world. Because of sustainability and environmentally-friendly energy source, countries increasingly benefit from wind energy. Several estimation methods are applied in the determination of a region’s wind energy potential. Today, one of the most commonly used prediction methods is artificial neural network (ANN) method. In this study, Estimation of wind power in Osmaniye district was investigated in method with artificial neural network (ANN) using data from meteorological measurement stations from the meteorological measurement device at the campus of Osmaniye Korkut ATa University. In order to give the best values of prediction results, several methods increasing the impact on output of different models for the input variables were investigated.

Keywords— Wind Power, Prediction, Artificial Neuron Network

I. INTRODUCTION

In recent years, the importance of the renewable energy sources grows worldwide. The reasons of this growth are that the sources named as fossil fuel are exhaustible, and they have negative effects on environment. Especially as a result of the gradual increase in greenhouse gases like Carbon dioxide and Methane which have direct impact on global warming, our environment is affected negatively [1]. Although there are some saving studies worldwide considering the issue of fossil fuels in energy usage, these are not enough. Because the energy need of people and corporations increase gradually. To avoid from this deficiency, renewable energy sources are used in recent years. Renewable sources are becoming one of the leading actors all around the world in the production of electric energy. In a short time, they are foreseen to become alternatives for power plants running fossil fuels, and they will become more widespread.

When the renewable energy types are considered, the first ones to remember are wind and sun. They are also the energy sources on which the highest number of research and scientific studied are conducted. The popular method to use to produce electric energy by using solar energy is to make use of radiation. While producing energy from the wind; first, the energy turns into kinetic energy, then into electric energy. The velocity of the wind is one of the most important parameters in the production of energy from the wind. For this reason, it is a must to measure both the velocity and potential of the wind in a certain area before launching a wind power plant [2]. For this reason, the researchers developed methods to predict the wind potential in recent years. These prediction methods aim at measuring the wind power of a certain area or predicting it by using certain inputs. As it is shown in (1) the power of the wind is stated as a mathematical function in which it equals the cube of the wind velocity [3].

\[
P = \frac{1}{2} \rho Av^3
\]

Equation (1) according to the formula, it is seen that the calculated or predicted value of the wind velocity grows exponentially. Hence, the wind velocity acts as a defining factor in power calculation more than other variables in the formula. This velocity variant is taken into account in the detection of establishing wind power plant into a certain place and of the identification of their performance [3]. When we have a look at the recent studies, it can be seen that the methods used to predict the velocity and power of the wind are artificial intelligent based (ANN, Fuzzy Logic, Support Vector Machine) methods. The commonly used one is the ANN method. The studied conducted by using this method are indigenous to a definite area. A model can create using the data chosen such as the latitude, longitude, elevation, and average of wind velocity (yearly, monthly, daily, hourly), their minimum and maximum velocity values, distance to the sea level, air pressure, density and temperature. These chosen data are defined as input variants in the model. These input variants are chosen by trying as many different methods as possible to do the best predictions. There are many layers in these models. The input and output are the main layers. There are one or more hidden layers between them. There are a few neurons in each layer. When a model has been created, some of the data is used for education (learning) while some of it is used for test (prediction). The aim is to predict the wind velocity and power belonging to a certain
area as output. Besides, by making use of Box-Jenkins statistical model (ARIMA-Autoregressive Integrated Moving Average) which is used to predict seasonal or non-seasonal time periods, fuzzy logic methods (ANFIS-Adaptive Network-Based Fuzzy Inference System), Genetic Algorithm based models; and by creating a hybrid or a different model with ANN, it can be used both while predicting the wind potential and while comparing the predictions. [3-11].

In our study, the short term wind power prediction with ANN is aimed using the data taken from the meteorological station which was mounted at the Campus of University of Osmaniye Korkut Ata. The data from the first half of 2013 is used (between January and June). With the aim of evaluating the prediction performances of a model created with ANN, three different statistical indicators are used such as coefficient of determination ($R^2$), Mean Absolute Percentage Error (MAPE) and Root Mean Square Error (RMSE). The power plant potential of Osmaniye province for the first six months has been estimated using these indicators.

II. MATERIALS AND METHODS

A. The Structure of Artificial Neural Network

The artificial nerve nets were discovered in the second quarter of the 20. Century and they started to be used. It is an informatics technology developed by inspiring the data processing capacity of human brain. Generally it was emerged out of the inspiration of human brain and operation of central neural system. The principle of biological neural system is imitated with ANN. These nerve cells include neurons, and they create neural networks by binding themselves in different kinds. The created nets carry the potential of learning, remembering and finding relationship between data. In other words, they can find a solution to those problems requiring human beings’ thinking and natural observation abilities. The created nets were successfully used in different disciplines such as mathematics, engineering, medicine, meteorology, economics, computer and electronic fields [9-12].

![Fig. 1 Biological nerve cell structure of human.](image)

With the entrance and proliferation of computer systems into human life, the model in Fig. 1 is used for the problems seeking for attention. A mathematical model trying to imitate human brain cell’s operation can be defined among artificial neural networks. It has many advantageous aspects as it can be paralleled, generalized, and as it is easy to analyze and design. One of the most important features of it is its capacity to derive as much information as possible without the need to any assistance. A mathematical model of an artificial neural network and its working principle are given in Fig. 2. This structure is the process of imitating the human brain and the process of transferring learning to the computer based systems [12].

![Fig. 2 ANN Mathematical Model.](image)

B. Wind Data

The data used in our study has been provided from active meteorological stations at Osmaniye Korkut Ata University. The coordination of the station is 37.05 north and 36.14 east. It is 120 meters above the sea level. The distance from the sea is 20 kilometers. The experimental date used in the study was measured by using Vantage Pro2 meteorological measuring device. This device has been planted in the elevation of 20 m. [13].

With the aim of predicting short term wind power, Wind Velocity, Temperature And Humidity data of 2013’s first half (January-June) has been taken. The hourly averages of the data have been measured as the station measures the data every 5 minutes. The wind power of each input variables have been measured by using the strength formula in (1) as a part of emerging results. At the same time the normalization formula given in (2) has been used to capture more accurate results in models formed with ANN.

$$X_n = \frac{X - X_{min}}{X_{max} - X_{min}}$$ (2)

It is a fact that the using ANN models in measure values without doing anything gives worse performance results then using it after normalization. This situation is quite apparent in whether forecast. Min-Max normalization method is a way which provides linear normalization for data between 0 and 1. It is used commonly. It defines minimum value while describing the maximum related data’s possible peak value [14].

C. The Generated Model and Validation Methods

The best models have been tried to be created in order to estimate the wind power with MATLAB, using input
variables (Wind Velocity, Temperature, and Humidity). Multilayer Feed-Forward (FFMLP) Backprop Network has been used because of the best performance in the developed model. TRAINLM is chosen as the education function, and TRAINGDM is chosen as the learning function in this network. As an activation function, LOGSIG is used in the first layer, and TANSIG is used in the second one. Neurons are recommended to use twice as much as for the input variables at the generated hidden layer of ANN model [15]. Hence, 6, 9, 12, 15, 18, 21, 24, 27, 30, 60, and 90 neurons in the hidden layer are formed, as a result of 11, 20, 16, 19, 8, 54, 101, and 236 epoch trying, smallest MSE (Mean Square Error) test error for network capable of generalization is tried to get. Both the best performance and 30 neurons model with high velocity are formed after 16 epoch model and is shown in Fig. 3.

![Fig. 3 3 Input 1 Output ANN model.](image)

The achievement status for the developed model is necessary to compare statistically. When we look at the literature, the most widely used statistical error methods are Mean Absolute Percentage Error (MAPE) and Root Mean Square Error (RMSE). There are also some other methods to use. Among the statistical error methods, MAPE is the most effective one in terms of making sense without other factors when it is compared with other methods [1, 3, 7-13]. MAPE and RMSE which are the statistical error methods are used in this paper. At the same time, the models have been compared by measuring the coefficient of determination (R²). MAPE, RMSE and R² formulas are given respectively in Equation (3), (4) and Fig. 4.

\[
\text{MAPE} = \frac{1}{n} \sum_{i=1}^{n} \left| \frac{P_i - O_i}{P_i} \right| \times 100 \tag{3}
\]

\[
\text{RMSE} = \sqrt{\frac{\sum_{i=1}^{n} (P_i - O_i)^2}{n}} \tag{4}
\]

Pᵢ and Oᵢ represent the calculated actual values in the equation of (3) and (4) respectively.

At the end of the conducted studies, R² values are seen to be at 0.99 level when examining the results of Table I. Examining MAPE, results that are above 10% are accepted to be well in success rate. Assessing the MAPE results for a prediction model or models, the values under 10% are very good, values between 10% and 20% are good, values between 20% and 50% are acceptable level. If the result of MAPE is over 50%, model should be considered as a wrong or failure [16]. If the RMSE value is 0.0015, it will show us that performance success of the model is a good level.

Regression graphic of concerned model in MATLAB program at 16 epoch result, it is seen as in Fig. 5.

![Fig. 4 Coefficient of Determination (R²) formula, y, y' and & values respectively of supplied Real, Estimate and Mean Values.](image)

### III. MODELS RESULTS

In this study, 4344 data has been used between January and June considering the hourly value. The data obtained between January and June has been put into the system as education (training), and it is aimed to predict the wind power data of June. For this reason, 3624 (83.4%) rating between January and May has been used as education, and 720 (16.6%) rating within June has been used for testing purposes. R², RMSE and MAPE results of ANN model have been given below in Table I.

<table>
<thead>
<tr>
<th>R²</th>
<th>RMSE</th>
<th>MAPE</th>
</tr>
</thead>
<tbody>
<tr>
<td>0.999159</td>
<td>0.001467</td>
<td>13.79</td>
</tr>
</tbody>
</table>

At the end of the conducted studies, R² values are seen to be at 0.99 level when examining the results of Table I. Examining MAPE, results that are above 10% are accepted to be well in success rate. Assessing the MAPE results for a prediction model or models, the values under 10% are very good, values between 10% and 20% are good, values between 20% and 50% are acceptable level. If the result of MAPE is over 50%, model should be considered as a wrong or failure [16]. If the RMSE value is 0.0015, it will show us that performance success of the model is a good level.

Regression graphic of concerned model in MATLAB program at 16 epoch result, it is seen as in Fig. 5.
In these regression graphics, test, training and verification graphics of related model is seen. Performance graphic of developed model according to Mean Square Error (MSE) is given in Fig. 6.

```
Fig. 5 Regression Graphics of ANN Model
```

Generally speaking when compared statistically, obtained MATLAB results are approximately same. Comparison between actual calculation of 24-hour power estimation measurements of an arbitrary day (11th) in June and power rating with estimation of ANN model is given in Fig. 7.

```
Fig. 6 MSE Performance Graph
```

```
Fig. 7 Comparison of 11th of June between actual and estimated ratings
```

As it is well understood from the Fig. 7, success rate between estimated and actual value can be seen, it is very close to each other and this figure also shows us that the prediction method gives quite good results according to the actual value.

**IV. CONCLUSION**

In this conducted research to estimate potential wind power of Osmaniye city, feedback forward neural network is utilized by using MATLAB program. Wind power estimation of June is calculated by educated models by means of changing a series of parameters of model as hidden layer, learning and education function and neuron number in order to optimize the estimated results of created model. When estimated values compare with the actual values statistically, $R^2$ values of estimated model are quite good result and it is very close to 1 shown in Table 1, and this value determines the success rate of the estimated model substantially. Furthermore, the results of the MAPE and RMSE shows us the power of prediction of estimated model and the it is shown clearly in Fig. 7. By this means, short term wind power estimation with high success rate is made in Osmaniye.

Abstract— In many texture recognition problems, Local Binary Patterns (LBP) method is used for feature extraction. This method is based on comparison of each centre pixel and its neighbours’ intensity value in image. Due to its simplicity of calculation, LBP has become one of the most popular feature extraction techniques. In literature, different neighbourhood topologies of LBP structure are given such as circle, square, ellipse, parabola, hyperbola, and Archimedean spiral. This paper focuses on the use of uniform and basic LBP that have spiral topology in texture classification. We first derive basic and uniform LBP features based on spiral topology. Then the performances of several classification methods such as linear discriminant analysis (LDA), linear regression classifier (LRC), support vector machines (SVM), Chi-square test, and G-test are compared using these features in UIUC texture database.

Keywords— Local binary patterns, texture recognition, feature extraction, classification methods, spiral topology.

I. INTRODUCTION

Texture can be defined as a repeating pattern of local variations in image intensity. Texture contains information about the spatial arrangement of the colours or intensities in an image. Texture classification basically means that assignment of unknown image to one of known classes. Texture classification process consists of two main operations. The first operation is extracting features of the image and the second one is classification phase.

The best description of image is a very important step for classification phase of texture classification. There are a lot of feature extraction methods in literature for the best description of image. In [1], Raju and Durai presents texture classification techniques based on feature extraction in two categories according the local and global features.

Local Binary Pattern (LBP) is one of the methods which used local features. It is gray-scale invariant local descriptor which was proposed by Ojala [2] and is a powerful descriptor for texture recognition. The descriptor is used various fields of image processing problems such as shape localization [3], interest region description [4], gender classification [5], palmprint recognition [6], digital image stabilization [7] and especially face recognition problems [8]. There are a lot of improved versions of original LBP. In [9], authors present rotation invariant and uniform LBP which include fundamental information about texture. In [10], multi-dimensional LBP was proposed to using multi-dimensional histograms for different radii. Several versions of LBP were studied in [8].

The basic LBP calculates histograms with circular neighbourhood topology. Using this topology is advantage for rotation invariant problem in the texture classification application but anisotropic structural information may important features for some problems. An elliptical neighbourhood topology was used to exploit this anisotropic structural information for a face recognition system in [11].

Other variants of LBP are proposed by [12]. Different shapes such as ellipse, circle, parabola, hyperbola and Archimedean spiral for the neighbourhood calculation are tested. Different encodings to create LBP code are described for the evaluation of the local grayscale difference. According to this work, proposed quinary encoding and using elliptic neighbourhood performs the best with the medical image databases.

In the classification phase, performance of subspace based classification method is better than the statistical tests based on similarity measures [13]. We employed Chi-square test, G-test, support vector machines (SVM), linear discriminant analysis (LDA) and linear regression classifier (LRC) for the classification. LRC is one of the subspace methods [14] that is generally used for face recognition problems [15-17]. The experimental results of our study show that using LRC with SLBP features gives better results in texture recognition.

The remainder of the paper is organized as follows. Section 2 introduces the LBP operator. Our approach for computing the LBP codes is explained in Section 3 and classification methods are presented in Section 4. The experimental study performed in this paper is given in Section 5 and finally conclusions are presented in Section 6.

II. LBP

LBP proposed by Ojala et al. is one of the most famous texture descriptor. LBP operator is the grayscale invariant
texture measure. This operator works with the gray value of image pixels.

For the each pixels of an image which is defined as centre pixel, binary code is generated by comparing it and its neighbours. If the difference between compared neighbouring pixel value and centre pixel value is higher or equal to 0, compared neighbouring pixel value is coded as a binary 1, in the other case it is coded 0. Fig. 1 shows an example of LBP method.

![Fig. 1 Basic LBP Operator](image-url)

The limitation of the basic LBP operator is using 3x3 square neighbourhoods for the description of local binary pattern. To eliminate the disadvantage, the operator was extended to use different size of neighbourhood and Fig. 2 illustrates two circularly symmetric neighbour sets for different radii.

![Fig. 2 (8,1) and (16,2) LBP Operator](image-url)

Let \( LBP_{p,R} \) denote the LBP code of a pixel’s circularly neighbouring neighbourhoods, where \( P \) is the number of sample points on the circle of radius \( R \), \( g_c \) represents intensity value of centre pixel and \( g_p \) is the gray value of its \( p \)th neighbour. Then the \( LBP_{p,R} \) can be calculated as follows:

\[
LBP_{p,R} = \sum_{p=0}^{P-1} s(g_p - g_c)2^p, \quad s(x) = \begin{cases} 1, & x \geq 0 \\ 0, & x < 0 \end{cases}
\]

As a result of calculation of LBP operator, decimal number is assigned to each pixel of image. After this process, a histogram is built to represent the image and used for pattern recognition as feature.

The concept of uniform patterns is to extract fewer feature of image texture. Any LBP pattern is called as uniform (ULBP) if the binary pattern consists of at most two bitwise transitions from 0 to 1 or vice versa. For example, binary code of the pattern that given in Fig. 1 is 00101101. This pattern is not a uniform pattern because of having higher than two bitwise transitions. It has three 0-1 transitions and two 1-0 transitions. A pattern having 00011000 binary codes is uniform pattern. If each pixel in image has 8 neighbours, there are totally 58 uniform patterns. In histogram, only one bin is allocated for the all non uniform patterns so histogram consists of 59 bins.

### III. CLASSIFIERS

#### A. G-test

G-test is defined as the following equation:

\[
G(S, M) = 2 \sum_{b=1}^{B} S_b \log \frac{S_b}{M_b}
\]

where \( B \) is the bins number of the histogram, \( S_b \) and \( M_b \) represents probabilities of sample and model distributions at bin \( b \) respectively. \( S_b \log S_b \) is the same for each model during classification and there is no effect of constant scaling factor 2 on classification result so G-test can be simplified as:

\[
L(S, M) = \sum_{b=1}^{B} S_b \log M_b
\]

As a result, test sample \( S \) is assigned to \( M \) model which maximizes the \( L \) statistic.

#### B. Chi-square \((\chi^2)\) Test

Assume that we have two histograms \( S \) and \( M \) for comparison. \( \chi^2 \) test is computed as:

\[
d_{\chi^2}(S, M) = \sum_{i=1}^{B} \frac{(s_i - m_i)^2}{s_i + m_i}
\]

where \( B \) is the number of bins, \( s_i \) and \( m_i \) represents value of \( S \) and \( M \) distributions at bin \( i \), respectively. A simple nearest-neighbour rule is used for classification.

#### C. Support Vector Machine (SVM)

The purpose of SVM is to select a hyperline or a hyperplane which separates the features of two classes. If features can be separated linearly, this procedure can be applied otherwise, features are mapped onto higher dimensional space that can separate the features linearly.

#### D. Linear Discriminant Analysis (LDA)

LDA is the most commonly used as dimensionality reduction technique and maximizes the linear separability of the groups belonging to different classes in data.

The aim of LDA is to maximize the distance between distributions of classes and to minimize variation in each class. Thus it can reduce dimensionality and save the information that is used in classification process at the same time. Objective function that is maximized in LDA defined as:

\[
f(w) = \frac{S_B}{S_W} = \frac{w^T S_B w}{w^T S_W w}
\]

where \( S_B \) is between the classes scatter matrix, \( S_W \) is within the class scatter matrix.

#### E. Linear Regression Classification (LRC)

Assume that we have \( C \) classes with \( N \) training images. The matrix \( W_i \) contains all feature vectors from \( i \)th class. Thus

\[
W_i = [x_i^1; \ldots; x_i^1; \ldots; x_i^N]
\]
where $\chi^j_i$ represents the $j$th feature vector of the $i$th class. If $y$ belongs to the $i$th class, it should be represented as a linear combination of the training images from the same class and can be defined as

$$y = W_i \beta_i + \epsilon$$  \hspace{1cm} (7)

where $\beta_i$ is the vector of parameters that is estimated using least squares estimation. Hence the estimation of $\beta_i$ is

$$\hat{\beta}_i = (W_i^T W_i)^{-1} W_i^T y$$  \hspace{1cm} (8)

The estimation of the vector $y$ is calculated as follow:

$$\hat{y}_i = W_i (W_i^T W_i)^{-1} W_i^T y$$  \hspace{1cm} (9)

The minimum distance between the original vector and the projected vector is calculated according to the Euclidean distance measure, i.e.,

$$\text{argmin}_i \{||y - \hat{y}_i||\}, \hspace{1cm} i = 1, 2, ..., C.$$  \hspace{1cm} (10)

IV. SPIRAL LOCAL BINARY PATTERN (SLBP)

We introduced basic encoding LBP operator with spiral topology for texture recognition in this section. The basic LBP calculates histograms with circular neighbourhood topology. Using this topology provides rotation invariant but cannot exploit the anisotropic structural information. This information may an important source in some problems. An elliptical neighbourhood topology has been used to exploit this anisotropic structural information for a face recognition system in [11].

Other variants of LBP are proposed by [12]. Different shapes such as ellipse, circle, parabola, hyperbola and Archimedean spiral for the neighbourhood calculation have been tested and different encodings have been used for the evaluation of the local grayscale difference. According to this work, proposed quinary encoding and using elliptic neighbourhood gives the best accuracy with the medical image databases.

The equation of the Archimedean spiral is expressed in terms of polar coordinates such as ($r, \theta$). The equation of Archimedean spiral can be described as follows

$$r = a + b \theta$$  \hspace{1cm} (11)

where $a$ and $b$ can be any real numbers. Changing the parameter $a$ turns the spiral, while $b$ controls the distance between the turnings. Fig. 3 illustrates an example of spiral neighbourhood which we used to extract features.

Each pixel in the image is selected as the centre point respectively. Black circle is the centre pixel and its eight neighbours are represented as blue stars in Fig. 3.

The neighbour points are identified by choosing theta intervals of $\pi/4$. If a point doesn’t overlap to the centre of the pixel, the intensity value of the point is interpolated by bilinear interpolation.

Calculation of LBP code is the same as basic LBP for SLBP. Firstly the nearest neighbour of centre pixel is compared and then comparison continues towards the farthest one. Consequently binary code is generated depending on whether the central pixel is higher than or equal to neighbours. Obtained binary code is converted to decimal value and this value is labelled to centre pixel. Finally, histogram of decimal values is created.

Uniform spiral LBP (USLBP) is determined like uniform LBP and non uniform ones correspond to only one bin in histogram.

V. EXPERIMENTAL RESULTS

This section describes experiments that show the efficiency of the proposed spiral neighborhood topology for texture classification.

UIUC texture database which involves 40 textures from each of 25 textures is used for evaluation. Fig. 4 shows example images from each class (the resolution of the samples is 640×480 pixels). Samples of each class have different viewpoint and scale differences. Furthermore, the dataset includes non-rigid deformations, illumination changes and viewpoint-dependent appearance variations.

To get statistically significant experimental results, 30 training images are randomly selected from each class of UIUC database while the remaining images per class are used as the validation set.

The Archimedean spiral starts in a centre pixel and makes a curve with one round ($2\pi$). So 8 sampling points on a spiral are computed intervals of $\pi/4$. Sampling points which do not overlap to centre of a pixel are computed by bilinear interpolation. In (11), $b$ parameter is set as 0.3 for the best performance of spiral neighbourhood topology.

All texture images of UIUC database are represented by LBP, ULBP, SLBP and SULBP histograms. The LBP codes are computed using 8 sampling points on a circle of 1 radius for comparison with SLBP.

The extracted features are classified with Linear SVM, LDA, LRC, Chi-square test and G-test for measure of dissimilarity between features.

The classification algorithms are implemented ten times independently. The average classification accuracies obtained with different texture databases are shown in Table I. The best recognition result achieved is 85.64% with LRC where the SLBP features of UIUC database is selected as shown in Table I as bold and underlined style.
Performance of proposed SLBP is higher than the other feature extraction methods for all classification methods. The statistical tests based on similarity measures perform worse from subspace based methods. LRC is the best classification method in UIUC texture database as a result of experiments.

### VI. CONCLUSIONS

In this paper, we have presented uniform and basic Local Binary Pattern (LBP) with Archimedean spiral neighbourhood topology to texture recognition. Firstly, we derived basic and uniform LBP features based on spiral topology. Then the performances of several classification methods such as linear discriminant analysis (LDA), linear regression classifier (LRC), support vector machines (SVM), Chi-square test, and G-test are compared using these features. Experimental results obtained from UIUC texture database clearly demonstrate that the best recognition rate is obtained with using SLBP features and LRC method. In the future, we plan to focus on improving spiral topology to obtain more meaningful information.

WAREHOUSE DESIGN APPLICATION WITH VIP PLANOPT IN A MANUFACTURING COMPANY

Süleyman ERSÖZ*, Adnan AKTEPE†, Ahmet DALGIÇ†

Kirikkale Üniversitesi Müh. Fak. End. Böl. 71451 Yahşihan/Kirikkale
aaktepe@gmail.com

ABSTRACT

If storage systems are well analyzed and if method of storage is well-known, we can save time, energy and money. Therefore, a successful warehouse management is significant for companies. Efficient warehouse management is possible with effective warehouse design applications. In this study, a warehouse design model is developed. In this model, a hybrid heuristic algorithm is used for solution of design problem. We use VIP-Planopt for application. It is a flexible software program that enables us to enter specific constraints. VIP-Planopt is optimization software that produces optimal or near-optimal layouts. In the application, we study with eight different structured big shelves in a manufacturing company warehouse. As a result of application, we found a new and better warehouse design minimizing total material flows. We discuss application results with algorithm outputs in detail in the study.

Keywords: Plant layout, Warehouse management, VIP-Plant Optimization.

I. INTRODUCTION AND LITERATURE

Warehouses are temporary storage points used during the distribution of the products. Warehouses make significant contribution to the effective implementation of the logistic activities and the operation of the supply chains in accordance with the target goals. Warehouses can be located in or near the manufacturing plants and also can be built separate and special complexes. Stores/products are stored in the shelves in various items, the entry and exit of the products are carried out by means of loading ramps and loading and unloading processes are made by using forklift trucks.

In order to understand to what extent the storage takes place in the supply chain, it is necessary to comprehend the basic stores/products distribution strategies firstly. The three basic strategies used in the distribution of the stores/products are the following: [1]

- **Traditional Distribution:** In this type of distribution, which is made through warehouses, warehouses are temporary storage points for products. In this strategy, functions like goods acceptance, arranging on shelves, storage, consummation, order collection, packing and shipment/delivery are carried out.

- **Direct shipment:** It is direct transmission of the products from supplier to the customer.

- **Cross-docking:** The products received from the supplier are sent to the customer by keeping them temporarily (less than 24 hours) without storing in the warehouses called cross-docking plants.

In order to carry out the production and service systems effectively, not only the implementation of optimum plans and operational policies, but also a good projection is required. The optimum design of the physical layout is a crucial topic that should be considered in the early stages of the projection. [2]. The studies on the design of the plant layout are generally required as a result of the changes in the ground requirements, people or equipments [3]. An efficient plant projection decreases the time of delivery, increases the outputs and as a result, increases the efficiency of the plants. [4]

The plant layout design is one of the most important issues that affect the efficiency of a production system. The plant layout is crucial for companies and an inseparable part of planning process. Plan Layout Problem (PLP) is interested in arranging the physical sectors in a plant for the efficient operation of a plant. PLP has been subject to many researches because of its interdisciplinary importance. According to Jajodia vd., a good solution to the PLP contributes to all activities. A bad layout causes the stocks to pile up, the
product transport systems to be overloaded, the time for preparation to increase and product queues to be longer [5]. Therefore, the solution to PLP is a strategical stage for all enterprises.

Generally, two different approaches are being used to solve PLP. One of them is the qualitative approach which tries to maximize the total amount of the proximity scores among the sectors. Systematic Layout Planning procedure developed by Muther [6] is one of the most important studies on this issue. The second one is the quantitative approach which tries to minimize the total amount of the product transport costs among sectors. The study made by Armour and Buffa [7] can be shown as a good example for his approach.

Many studies in the literature have used the qualitative and the quantitative approaches separately so as to solve the PLP. However, many researchers questioned whether it is logical to consider only one criterion to solve the PLP. Both of the approaches have some advantages and disadvantages [8]. However, those models which are based on only one criterion is not explanatory, because there are too many factors to affect the plant layout. In fact, PLP should include both the qualitative and the quantitative criteria. For this reason, it is in the category of multi-functional plant planning projection problem. [9].

According to Malakootii, the aim of the multi-functional plant layout planning is to produce efficient layout plan choices to be given to the decision maker. Thus, the decision maker can prefer the best layout plan option by considering the conflicting aims. There are three different methods to solve this problem. One of the is to find out the proactive cluster of the layout plan options and to submit them to the decision maker. The second one is that the preferences of the decision maker are found out first and then the optimum layout plan option is indicated according to these preferences. The third one is to use an interactive way to find out the optimum layout plan option. [10].

In order to solve the multi-functional plant layout planning problem, many studies have been carried out. In many of these studies, predetermined loads has been given to each goal and combined and only one goal has been acquired in order to indicate the optimum layout plan option. The quadratic assignment problem formulation has been used to model the multi-functional plant layout planning problem.

In this study, an optimal solution has been targeted by using VIP-Plant Optimization program for plant layout problem. Different from the methods mentioned in the literature, the convenient plant layout has been found out by using a package program. In addition, some information about the abovementioned program has been given in this study and it has been aimed to shed light on many problems’ solutions.

II. PLANT LAYOUT WITH VIP-PLAN OPTIMIZATION PROGRAM

VIP-PLANOPT is an important solution instrument for plant designing problems in engineering, industrial planning and plant designing. VIP-PLANOPT (Visually Interfaced Package of PLANOPT) is a package software program developed to produce optimum layouts for blocked or modular problems that have small, medium or large scaled unequal rectangular dimensions. The term “optimum layouts” means locating the certain number of modules in the Euclidean space in the best way without any extensions out.

A. Optimization Algorithm

The PlanOPT optimization algorithm is a research product. It is a robust, registered and hybrid algorithm. The Algorithm occurred as a result of the development of a technic that was producing better results and developed by two university professors to solve the KAP in unequal sizes in 1995.

VIP PlanOPT 2006 has reinforced its superiority over the other algorithms by making the following additions to this algorithm.

In order to bring the variability of the algorithm observed in some circumstances, double-precision arithmetic has been added.

- In order to decrease the dependence on the starting point determined by the user, new technics has been added.
- In order to provide the optimal layout within boundaries with complicated and mixed shapes and simple rectangular shapes determined by the user, punishment functions has been added.

The user interface screen of the program is shown in Attach-1.

B. Terms Used in the Program

Modul: The term “modul” used fort he rectangular blocks stands for the functional units like sectors, machines, rooms and areas. The size of a module along with the x line stands for its length and the size along with the y line stands for its width, and they are shown with the symbols L, and W.

The Modul width-length rate: This rate is described as the rate of the width of a module to its length. If the width-length rate for a i modul is shown as R, it can be shown as the followig equality:
\[ R_i = \frac{W_i}{L_i} \]

**The Modul area:** For an i modul, the area of the modul is calculated in the multiplication of the width and length of \( A_i \), and ve it can be shown as in the following equality.

\[ A_i = W_i \times L_i \]

**The Modul Type:** There are two basic modul types in the PLANOPT software. They are described as solid and flexible. The size of the solid modules is determined by the user and these sizes cannot be changed during the optimization. The user can determine the modul type himself/herself. The areas of a flexible modul are stable but its sizes can be changed during the optimization. The part related to the model is shown in the Attach-2. The required features of each modul can be entered in this part.

**Surrounded area:** This term is being used for the rectangular layouts involving all modules. The user can indicate the width and length of the area in which he/she will locate the modules by means of the program. This part is shown in the Attach-3. The layout can be determined by entering the coordinates or manually.

**Flow Matrix:** This matrix provides the product, hardware and staff flow in all pairs of modules. One component of this matrix shows the flow among \( f_{ij}, i \) and \( j \) modules. This flow can be explained as the unit load carried in a unit of time between two modules.

**Unit cost matrix:** This matrix shows the cost of transport of a unit load to a unit distance among all pairs of modules. One component of this matrix shows the cost of transport of a unit load to a unit distance among \( u_{ij}, i \) and \( j \) modules.

**C. Cost Functions**

PLANOPT finds out the optimal layout by minimizing the the aim function. The program uses four different aim (cost) functions. The cost functions are shown in the Attach-4.

**Cost function F1:** This function is used when the cost matrix is symmetrical. The formulation of the function is:

\[ F1 = \sum_{i=1}^{n-1} \sum_{j=i+1}^{n} f_{ij} \times u_{ij} \times d_{ij} \]

**Cost function F2:** This function is used for layout problems in which function cost matrix is both symmetrical and dissymmetrical. The formulation of the function is:

\[ F2 = \sum_{i=1}^{n} \sum_{j=1}^{n} f_{ij} \times u_{ij} \times d_{ij} \]

**Cost function F3:** This function is used when the cost matrix is symmetrical. This is a composit function. The formulation of the function is:

\[ F3 = \sum_{i=1}^{n-1} \sum_{j=i+1}^{n} f_{ij} \times u_{ij} \times d_{ij} + \omega \times A_B \]

\( AB \) in the formulation expresses the area of rectangular layout; \( \omega \) expresses the weight determined by the user on this area.

**Cost function F4:** This function is used for office planning problems in which the cost matrix is not symmetrical. This is a composit function. The formulation of the function is:

\[ F4 = \sum_{i=1}^{n} \sum_{j=1}^{n} f_{ij} \times u_{ij} \times d_{ij} + \omega \times A_B \]

**III. IMPLEMENTATION**

For implementation, the optimum layout of a warehouse with 8 shelves has been chosen. The optimum layout plan has been calculated by entering the different physical features of the shelves. Data is shown in the Attach-5. The flows among the shelves should be indicated for the optimal arrangement of the shelves in the plant layout. The cost will be calculated after these flows. The flow matrix is shown in the Figure 1.

![Flow Matrix](Attach-6)

**Figure 1. Flow Matrix**

After the entry of probe data, the optimum layout plan has been generated by a solution with 6 iterations. According to the "F1" cost function, a cost has been calculated. The optimal layout plan is shown in the Attach-6.

The cost results about the solution has been shown in the Attach-7.
IV. CONCLUSION AND EVALUATION

It has been seen in the literature research and implementation that the optimum layout for the factory has been found with the method used, but the important points are that the solution should be convenient for the operation of the factory and the real life. In other words, it should be feasible. In this study, studies about the plant layout planning problem which is one of the most important and basic issues in production systems has been reviewed and then an optimum layout plan has been acquired through real data taken from a real production system by using VIP-PLANOPT software. In the implementation stage, 8 shelves with different features and the relations with each other has been indicated and the convenient layout plan has been emerged.

dakgun@sakarya.edu.tr

Abstract—One of the widespread image processing applications is image filtering with two dimensional convolution. Determining the weights of image filters are of importance for the success of filtering operation. Heuristic algorithms such as genetic algorithms provide an efficient way of training these types of filters. Due to the high computational cost of repetitive image filtering operations, this process may take hours to implement using single core computing. OpenMP (Open Multi Processing) provides an efficient library for utilizing the computing power of multicore processors. In this study, OpenMP accelerated training of separable filters that are a subclass of convolution filters has been implemented based on genetic algorithms. Comparative speed-up results for various sizes of images using various sizes of filtering kernels were presented. Also the effect of population size of genetic algorithm and the number of working cores have been investigated.

Keywords—OpenMP, separable filters, image processing, genetic algorithms

I. INTRODUCTION

Image filters are widespread operators in image processing applications such as image enhancement, image smoothing, edge detection and noise elimination [1]. Linear filtering using two dimensional convolution or correlation is one of the main filtering operations. This is realized by applying the filtering kernel to each pixel of input image where the kernel is a matrix of weights. The size of the matrix can be 3×3 or 5×5 larger such as 21×21. If the kernel has symmetric properties, it can be expressed as the multiplication of a row and column vectors. This form is called as separable filter and it reduces the number of multiplication/addition operations.

The values of the filter weights are determined according to the desired behaviour of the filter. Weights can readily be obtained using different analytical techniques [2], [3]. In another approach, the kernel weights can be trained using the original and noisy image samples [4]–[7]. Heuristic algorithms provide an efficient way for the computation of the filter kernel weights [8]–[10]. One of the well-known heuristic algorithms is Genetic algorithm which provided its efficiency in various researches. Genetic algorithm is selected to train the weights of the separable filter. In the application of genetic algorithms, a fitness function is used to define the problem. In the present case, fitness functions is formed according to mean squared value of original and noisy images. For the computation of fitness function, intense multiplication and addition operations are carried out to obtain fitness value. Furthermore, computation time depends on the number of weights as well as the image size. During computations, fitness function is called at each iteration of the genetic algorithm. This significantly slow down the process and make the applications impractical. A method for the acceleration of the process is to utilize the computational power of multicore processor. For this purpose, OpenMP provides a useful tool for efficient use of the cores of a multicore processor. OpenMP helps distribute the computational load to defined number of threads.

In the present study, OpenMP is utilized to accelerate the computation of fitness function. Fitness function is computed for all individuals in the population and these operation can be realized independently on processor cores. In the experiments, an eight core computer is used and the results are obtained against the number of cores to see the effect of the number of cores. Also various filter kernel sizes, image sizes and the population sizes used in the experiments to show the efficiency of the OpenMP based acceleration.

II. SEPARABLE IMAGE FILTERS

Separable image filters are used in a slightly different way from the non-separable filters. An example of non-separable image filter is shown by Fig. 1 which has size 3×3. The filter kernel has a total of 9 weights. This means that the image filtering process train weights number of genetic algorithms is 9. When the size of the filter kernel grows, it is increasing training time of genetic algorithms. For instance, 25 weights for the filter kernel with 5×5, 49 weights for the filter kernel with 7×7, 81 weights for the filter kernel with 9×9, etc. The growth of genetic algorithms filter kernel increases the training time. The 3×3 filter kernel used in separable image filter is shown in Fig 1. This filter kernel which horizontal and vertical vectors as shown in Fig. 2 in the separable image filter is used.
The product of this vector also gives the filter kernel shown in Fig. 1.

\[
\begin{bmatrix}
1 & 2 & 1 \\
2 & 4 & 2 \\
1 & 2 & 1 \\
\end{bmatrix} \times \begin{bmatrix}
1 \\
2 \\
1 \\
\end{bmatrix} = \begin{bmatrix}
1 \\
2 \\
1 \\
\end{bmatrix}
\]

Fig. 2 Separable image filter is used filter kernel

Separable image filtering process can be divided into two stages. The first stage is to filter noisy image using one of the vectors. The second stage is to filter the resulting image from the first stage using the other vector. Therefore, image filtering process is completed in two stages. Separable image filter has the advantage of reduced number of weights over non-separable filter. For example, the number of filter weights to be trained in separable image filter for $5 \times 5$ is 10, while it is 25 for non-separable image filter.

### III. GENETIC ALGORITHMS

Genetic algorithm is a search and optimization method which is based on natural selection [7], [12], [13]. Genetic algorithms randomly generate multiple solutions. Bad solutions are eliminated in the next generation. Therefore, best solutions appear as the best solutions transferred to next generations.

- **Initial population**
- **Fitness**
- **While (termination criteria is not met)**
  - **Selection**
  - **Crossover**
  - **Mutation**
  - **Fitness**
- **End while**

Fig. 3 Genetic algorithm steps

Genetic algorithm involves applying selection, crossover, mutation and Fitness calculations on candidate population which are initially formed randomly. A pseudo code illustrating the operation of genetic algorithms is shown in Fig. 3. In the present case, computationally most intensive part is calculating the value of the fitness function due to the image filtering operations.

### IV. OPENMP (OPEN MULTI PROCESSING)

OpenMP is an application programming interface (API) which provide opportunity parallel computing on multicore processors. The calculations are done on multi-core processor architectures OpenMP thanks to coequally distribute all core [14].

OpenMP Architecture is shown figure 4. OpenMP, compiler directives, runtime library and environment variables are comprised from. Programmers write the code to run concurrently by putting special comments in that codes. For instance “#pragma omp parallel”. This study was parallelization of the fitness value calculating for “for” block.

OpenMP’s operation diagram is shown in Fig 5. OpenMP is identified one of the threads as main thread. Tasks are distributed in equal amounts other threads by the main thread. Due to the fact that this study was developed with C programming language, to use the OpenMP function “#include <omp.h>” as is included in the project.

Fig. 6 shows the area of the genetic algorithms parallelization process on the flow chart. This block is calculated fitness function value. This block contains computationally intensive mathematical operations. Therefore parallelization process is performed here.
V. EXPERIMENTAL RESULTS AND DISCUSSION

Experimental studies on Windows Server 2012 Essentials™ 64-bit operating system, Quad-Core AMD Opteron™ 2378 2.40GHz dual processor, 18GB Ram, have been working on computer servers. The algorithm is written in C programming language. In the experiments, 256×256, 512×512 and 1024×1024 with a pixel size images are used [15]. 3×3, 5×5 and 7×7 sizes filter masks are used for images filtering process. The developed algorithm was running 10 times for each image and at the end of working, these 10 average MSE (Mean Squared Error) value and average times for each image and at the end of working, these 10 average MSE (Mean Squared Error) value and average training time are taken. The number of population for analysing the impact of population on training time while 100 and 200 were obtained results determined separately. The number of iterations has been fixed at 400 for all calculations. Mutation rate 0.005 and crossover rate 0.3 is defined as the constant. Termination criteria of genetic algorithms are defined as the number of iterations. Noisy image used were obtained by adding Gaussian noise on the original image.

VI. CONCLUSIONS

In this study, OpenMP with accelerated training of separable image filter were analysed. In the experimental results, various sizes of kernels, and images and population sizes were tested. According to the results, doubling the population size has an increasing effect when the speed-up values on the average. Increasing the kernel size doesn’t change the results much. In general, the results show significant accelerations over single core running durations. For future studies the results will be obtained on a machine to see the efficiency limit of the number of cores.

Abstract—The number of devices connected to the Internet is increasing, data centers are growing continuously and computer networks are getting more complex. Traditional network management approach is becoming more difficult and insufficient. Software-Defined Networks (SDN) is a new generation networking approach which is expected to take place of the traditional computer networks. SDN architecture provides effective management of the large and complex networks. Although SDN have benefits from the network security perspective, it also brings new attack vectors. We believe that the network security problems in SDN architecture need more advanced solutions. In this work, a survey on the SDN security problems is presented, challenges are discussed. In this context, security threats and attack surfaces in SDN are described, the significant SDN security solution examples in the literature are given.

Keywords—Software-Defined Networks, SDN, SDN Security

I. INTRODUCTION

There are many network devices in computer networks such as router, switch, firewall, Intrusion Detection System (IDS) and Intrusion Prevention System (IPS). Complex and different protocols are running on these devices. Every day, new technologies such as Internet of Things (IoT), smart cities and smart management are emerging, data centers are growing and the number of devices in computer networks is increasing. Computer networks are getting more complex and heterogeneous and management of the network is becoming more difficult. Traditional network management approach is insufficient in large-scale computer networks. There is a need for a better network management approach and new methods. Software-Defined Networks (SDN) is an emerging concept that bring a new generation network management approach which is expected to take place of the traditional computer networks. SDN promise administrative convenience, hardware-independent, dynamic, scalable and flexible networking architecture. SDN provide a centralized network management and a global perspective on the network. So, this enables effective management of the large and complex networks.

With the rising of popularity of the IoT concept recently, the number of devices connected to the Internet increases every day. IoT offers an environment that interact the objects we use in daily life with the other objects. All of devices that support networking technology such as computers, smart phones, tablets, air conditioners, refrigerators, cars etc. continuously produce data and this data is growing each day. As a result, big data concept emerges that represents high-volume, complex and irregular data. Big data can not be processed, stored and managed by traditional methods. Big data which becomes more valuable requires meaningful results. So, big data should be processed. Big data needs more bandwidth for processing. Nowadays, smart cities and smart management concepts come to the fore more and SDN management, security and optimization topics will need more advanced mechanisms.

In the second section of this study, the basic concepts of SDN, the benefits of SDN architecture are explained. In the third section, security threats and attack surfaces in SDN are described. In the fourth section, significant SDN security solution examples in the literature are given. In the last section, this study is summarized and future works are presented.

II. SDN & BENEFITS

There are three planes/layers including application, control and data and two interfaces including application-control and control-data. Control plane decides where frames/packets will be forwarded/routed. The data plane forwards the traffic to the destination. Routers and switches that we used in today, includes control plane and data plane are integrated on the same hardware. SDN concept is based on the idea of the separation of these planes. Control plane in other words network intelligence is moved to a high performance server and network management is performed with centralized controller software. The data plane is left on OpenFlow-enabled router or switch and is responsible for forwarding of packets only. SDN architecture is shown in Figure 1. This architecture provides ability to directly programming the network and enables underlying infrastructure layer to be abstracted for network services and applications [1]. So this provides more dynamic, flexible, scalable platform and easy
management of the network compared to traditional network infrastructures.

SDN architecture brings some benefits from the security perspective. SDN provides programmability and centralized controller has a global view on the network. These characteristics of SDN have an advantage against security threats. For example, when an anomaly is detected on the network, related traffic can be sent to the controller for analyzing. After the analysis process, existing rules can be updated or new rules can be created for prevent attacks.

SDN benefits are obvious. It is expected that SDN will replace the traditional computer networks in the near future. SDN also have some security threats which will be discussed in the next section.

III. SDN SECURITY THREATS & ATTACKS

SDN architecture has network programmability and centralized control advantages but these advantages can lead to new security threats and increase of the attack surfaces. There are variety of security threats targeted to the plane and interface of the SDN. Security threats and attack surfaces in SDN are shown in Figure 2.

Security threats in SDN can be classified as seven different threat vectors, three of which are SDN-specific [3]. The security threats such as Denial of Service (DoS), unauthorized access, data leakage, data modification, malicious applications which are seen in all other network architectures is also seen in SDN [4]. The SDN specific ones are the attacks which target the controller software, communication between the control plane and the data plane (control-data interface) and the communication between the control plane and the application plane (controller-application interface). All those threat vectors have a potential effect on the operation of the entire network. Attacks against SDN planes and interfaces and the targeted security services are given in Table I.

DoS and Distributed Denial of Service (DDoS) attacks against the controller and flow table flooding attacks against the switches in the data plane target the availability principle or service of the security. One of the main features of the SDN is the logically centralized controller. Although this feature provides a global perspective on the network, it emerges as one of the major weaknesses in terms of security of the SDN architecture. In [3], it is shown that the faked traffic flows can be used to make DoS attacks to OpenFlow switches and controller sources. The attacker may expose DoS attacks to the controller by sending too many packets to the controller. Similarly, more than one attacker or botnets may send large amount of packets to the switches in a systematic way. As not all of the rules are included in the flow tables of switches, this will cause a large number of queries to be sent to the controller. In this case, the controller will be exposed to DDoS attack and will become unable to respond to legitimate requests. DoS and DDoS attacks on the controller have a potential affect the functioning of the entire network in a negative way. Similarly, DoS attack may be possible also for the switches in the data plane. The flow tables of the switches which have limited cache will be vulnerable to flooding attacks when the attackers send large packets which belong to different flows. As previously stated, some of the flow rules are not available in the flow table so the queries are sent to the controller. While waiting the answer to these queries, the cache of the switches will fill up quickly. This type of attack is also called as DoS Switch [5].
Controller hijacking or unauthorized controller access attacks target the confidentiality principle of the security. Vulnerabilities in the controller may have consequences which can put the entire network at danger [3]. The attacker can take over the management of misconfigured, vulnerable controller and also the management of the network. Then, the attacker can programme switches in the data plane to drop the traffic coming to the controller can use to launch attacks on other targets [5].

In the absence of mechanisms to ensure security in the communication between the control plane and the application plane, malicious applications can insert fraudulent rules into the flow table of switches. This will cause the conflict rules in the network. Therefore, reliable connection must be established by creating authorization and authentication mechanisms between controllers and applications [4].

Man-in-the-middle (MITM) attack, which occurs between control plane and the data plane communication targets confidentiality and integrity principle of security. Both the control plane and data plane will be affected by this attack type. The data modification between the control plane and the data plane is one of the most important problems in SDN. SDN architecture brings discrete planes and using unencrypted protocols in the communication between these discrete planes can cause serious consequences. MITM attack, which performs in the second layer of the OSI reference model, allows eavesdropping or modifying the traffic flow between network resources such as server, router or switch and endpoint on the network. In this case, the attacker may modify flows on the switches or be able to add new flow rules [4]. Communication channel can be made more secure by the use of TLS which is a cryptographic protocol [6]. OpenFlow protocol supports TLS connection by default. Mutual authentication can be done by exchanging certificates between controllers and switches which are responsible for the transmission of network packets. The attacker cannot view or modify the contents of messages when encrypted protocols are used. However, TLS/SSL and Public Key Infrastructure (PKI) has some weaknesses and these vulnerabilities could be exploited [7]. If an attacker can access control plane by benefiting the protocol vulnerabilities in communication, switches under its control can be used to launch DDoS attacks [3].

Unauthorized and unauthenticated applications target confidentiality and integrity principle of the security. There are many third-party applications which run at the application layer. Controller provides abstraction for the SDN applications and this enables the applications to read and write network state [4]. This situation poses a problem for the control of the network. The attacker can use the applications that cause unauthorized access to hide himself and access network resources and manipulate the operation of the network [4].

Administrative computers that are directly connected to the controller can cause an entry point into the network. If these computers have some vulnerability the attacker can use these vulnerabilities to get control of the computers to access the controller easily.

Additionally, not quickly detecting an error or a problem in the network and a failure to obtain a reliable recovery point of the network is considered as a threat vector [3].

IV. SDN SECURITY SOLUTIONS

There are some comprehensive surveys [4], [8]-[11] on SDN and SDN security. In these papers, concept, architecture, core components, advantages, current challenges of SDN and SDN specific security threats and solutions are discussed in detail.

Despite the advantages provided by SDN architecture, it is necessary to review network security issues. In this context, there have been some studies carried out in literature. In these studies, prevention and mitigation of DoS and DDoS attacks are mainly considered. Furthermore there are also the studies on authentication and authorization mechanisms, development of network security applications such as IDS/IPS and firewall. In this section, some of these studies on SDN security are described.

Some security measures are offered in [3] where also SDN-specific threat vectors are discussed. In case if only one controller is used and the controller is collapsed, there will not be a fault tolerance of the network and whole network may have collapsed which is called Single Point of Failure (SPOF). To avoid this situation creation of replication of controllers and applications is proposed. Against software bugs usage of diversity of controllers is recommended. Furthermore, it is stated that the switches in data plane must be able to keep in touch with another controller in case the controller is collapsed. In such a case, dynamic device association mechanism which provides the connection of switches with multiple controllers dynamically would tolerate the faults in the network.

Use of OpenFlow protocol leads to some security issues with it. For example, an attacker may send too many OpenFlow request and expose the control plane to DoS attack. This case will cause a bottleneck between control plane and data plane. So, the network will be unmanageable. Therefore, the central controller must be protected from DoS and DDoS attacks which can affect the entire network. A framework which is called AVANT-GUARD [12] has been developed for the purpose of enhancing security in OpenFlow networks. This framework is located in the data plane and consists of two modules named Connection Migration and Actuating Trigger. Intelligence is added to the data plane in Connection Migration and control plane is being more resistant against DoS attacks such as TCP SYN. This is carried out by analyzing the TCP sessions opened in the data plane. Connection Migration module decreases the interaction between control plane and data plane. The Actuating Trigger module provides the installation of the necessary flow rules. It is stated that this plug-in is also effective against network scanning attacks but does not provide any protection against DoS attacks in application-level and UDP or ICMP protocols-based attacks. It is expressed that after the attack is detected, control plane should be able to respond quickly. Therefore, quick access to the statistics belonging network traffic from data plane is of great importance. Within the scope of study, the statistics are collected from data plane and sent to the control plane. Accordingly, the behaviors detected as attack are prevented.

IDS and Anomaly Detection System (ADS) are used for the purpose of providing protection against threats in traditional network infrastructures. These security systems are generally located in Internet Service Providers (ISP) or backbone devices. This approach changes in SDN. These systems can be brought to the endpoints with SDN. In a study [13], ADS is proposed for home and Small Office/Home Office (SOHO) networks using OpenFlow. Accordingly, an application which runs in NOX [14] controller is developed and implementation of four anomaly detection algorithms are showed. This solution offers more efficient anomaly detection in home and SOHO networks than the ISP.

In another study [15], usage of central controller is proposed for the detection of DDoS attacks. Random distribution of incoming packets to the network is calculated in this method that runs on POX [16] controller. Entropy is used in order to calculate this probability. There are two components in DDoS detection. One of them is windows size and the other one is threshold. The window size is depended on time period and number of packets. Entropy calculates random distribution of incoming packet depending on window size. If the entropy value exceeds the predefined threshold value, traffic is determined as an attack. The proposed method can detect the attack within the first 250 packets of harmful traffic by using destination IP addresses. It is stated that attack detection rate for the predefined threshold value is %96. Furthermore, such parameters as destination IP addresses, window size and threshold value can be set to the desired values in real time according to the requirements of the controller. In this respect, it offers a flexible solution. Also, tests are performed and same results are obtained for TCP and UDP packets. It is stated that detecting DDoS in its early stages is depended on tolerance of the server used as a controller and traffic properties.

In a recent work [17], a simple DoS prevention system is performed in SDN. A solution is offered against DNS DoS attacks using flow information obtained from each network device. Therefore, anomaly detection can be performed on each switch in the local area network. Also, the advantage of central management which is brought by SDN architecture is discussed.
Controller acts like a firewall in OpenFlow-based networks. The traffic is passed on the controller and analyzed. According to its result, passing of packets is allowed or rejected. In [18], it is discussed that a design acts like a firewall of each switch in data plane and sending of packets to the controller is not necessary. A flow-based distributed firewall prototype is developed in this work for developing a simple packet filtering firewall in SDN. The rule set is installed on each network device as flow entries. This firewall prototype creates a firewall object for each network device connected to the controller. Firewall object is connected to the related device without any delay. Each firewall object has an index number and stored in a list in order. The functions of each firewall object can be accessed through command line by index number in the list. Firewall can control the traffic by modifying flow tables of switches in data plane.

In [19], more than one controller usage is suggested for the purpose of protecting control plane from unauthorized access in SDN. Each switch in data plane can be managed by more than one controller using byzantine fault tolerance algorithm.

A security application kernel which is called FortNOX [20] is proposed for preventing fraudulent rule insertion that may be caused by malicious applications. FortNOX provides prioritizing the flow rules by performing role-based authorization. Furthermore, it detects a new flow rule which conflicts with an existing flow rule.

Security Enhanced Floodlight (SE-Floodlight) which is an extension of OpenFlow controller Floodlight is introduced in [21]. SE-Floodlight which is an improvement of FortNOX offers a Security Enforcement Kernel (SEK). It provides role-based authorization between control plane and OpenFlow applications in application plane. SE-Floodlight has a digital signature validation for each rule insertion. OpenFlow application is digitally verified by the SEK at runtime. After the application is signed and validity is verified, it is permitted for the purpose of making query, modification on the network or creating traffic flow rule.

In [22], assignments of full privileges for each OpenFlow application which cause unauthorized access problems are discussed. In this context, an isolation mechanism is proposed. The system which is called PermOF provides permissions with minimum privileges for applications. PermOF enforces to perform these permissions in Application Programming Interface (API) entry of the controller. It is stated that this solution protects the network from unauthorized controller attacks.

In [23], a solution which is called Virtual Address Validation Edge (VAVE) is proposed for IP spoofing in OpenFlow/NOX architecture. VAVE is an application that runs on the controller. It performs source address validation against IP spoofing attacks. If any incoming packet does not match a rule in the flow table of OpenFlow switch then first packet is sent to the NOX controller for source address validation. If an IP spoofing is detected then controller adds a rule to the switch in order to stop incoming traffic from this source address. VAVE provides protection against data plane DoS attacks such as flow table flooding.

OpenFlow and sFlow is combined for anomaly detection and mitigation in [24]. This solution consists of collector, anomaly detection and anomaly mitigation modules. Flow statistics are gathered by using OpenFlow and sFlow protocols in the collector module. The statistics are analyzed and anomalies are identified in anomaly detection module. Flow-entries are inserted in the flow table of switches in order to neutralize malicious traffic in anomaly mitigation module. Flow-entries which are inserted have higher priority than any existing flow-entry in the flow table. These modules act as a feedback control loop. This architecture supports various algorithms such as statistical anomaly detection, machine learning-based anomaly detection and data mining-based anomaly detection according to preferred design. In this study, entropy-based algorithm is used. DDoS attacks, worm propagation and port scan attacks are detected successfully.

SDN, Network Functions Virtualization (NFV) and cloud computing technologies will play important role to meet the requirements of future mobile networks. In [25], multi-tier security architecture is presented to solve the security problems in the future of Software-Defined Mobile Networks (SDMN). This architecture consists of four components. Security is provided between the control and data plane communication by using Host Identity Protocol (HIP) and IPSec tunneling techniques. Rule-based approach is used to protect the network to unwanted access, source address spoofing and DoS attacks. Software-Defined Monitoring (SDM) is used to detect and prevent security threats on the network. SDM uses Deep Packet Inspection (DPI) and traffic monitoring techniques. Synchronizing network security with the network traffic provides real-time information and necessary flow rules are installed to the flow tables of switches in the data plane.

V. CONCLUSION AND FUTURE WORK

SDN bring a new generation networking approach. Traditional and cumbersome network architectures transform into the dynamic network architecture with SDN. Although SDN provides an open and programmable platform there are many problems to be solved in topics such as network security, routing algorithms, virtualization and load balancing. SDN must be designed in a good manner from the security perspective.

At this stage, we believe it is too early that we can say SDN provide a secure network infrastructure. There is much work needs to be done and more effort should be spent on SDN security for SDN potential.
Cognitive Networks (CN) which exhibit intelligent behaviours will probably come out in the near future, we believe AI-based solutions in SDN security would be much more useful. Studies on integration of AI techniques with SDN, 4G/5G networks, Heterogeneous Networks (HetNets) and mobile networks can play an important role in the creation of CN. Processing big data with using AI techniques such as machine learning will allow the development of CN. CN will depend on information and be learning-based, exhibiting intelligent behaviors. With CN, it may be possible to develop networks which can learn from past data and decide automatically about encountered in future events. It will be possible to give specific services to the users with this intelligent network architecture. As a future work, we plan to represent these issues and propose new solutions in the following publications.

Parlak Bölgeleri

Önerilen Algoritmalar (Eşleştirilmiş filtre)

Optimum Parametrelerin Bulunması ve Uygulanması

Morfologikal yöntemleri kullanarak

Damarlar bölüldendi

Şekil 1. Önerilen yöntemin akış diyagramı

Aşağıda eşleşme yöntemi uygulayarak sonuçlar elde edilmiştir. Sonuçlar göre threshold (eşleşme yöntemi) çok iyi bir sonuç vermemiştir. Mesela aşağıdaki sonuç 130 ve 150 için elde edilmiştir. Bazı bölgeler damar olarak yanlış bulunuyor ve bazı damarlar yanlış olarak damar bulunmamıştır.

Bu çalışmada bulunamayan ve yanlış bulunan bölgeleri iyileştirmeye çalışılmıştır.

Bu bölgeler aşağıdaki şekilde gösterilmiştir.

Şekil 2. Eşleşme yöntemi kullanarak elde edilen sonuçlar, sağdaki sonuç 130 için ve soldaki sonuç 150 için.

Bu çalışmadan bulunamayan ve yanlış bulununun bölgeleri iyileştirmeye çalışılmıştır.

Bu bölgeler aşağıdaki şekilde gösterilmiştir.

Algoritma değerlendirme parametreleri

TP (Doğru Pozitif): Algoritmanın damarlara ait olduğunu tespit ettiği piksel sayısını gösterir. Bu pikseller damarlara bulunmaktadır.

FP (Yanlış Pozitif): Algoritmanın damarlara ait olduğu tespit ettiği piksel sayısını gösterir fakat aslında damarlarda mevcut değildir.

TN (Doğru Negatif): Algoritmanın damarlarda bulunmadığını tespit ettiği piksel sayısını gösterir; gerçekte de bu pikseller damarın bir parçası değildir.

FN (Yanlış Negatif): Algoritmanın arka plana ait olduğunu tespit ettiği piksel sayısını gösterir fakat bu pikseller damarlara aittır.

Şekil 4'te, söz konusu parametreler kısaca gösterilmiştir.

Şekil 4. TPR ve FPR örneklemeleri; TP, doğru biçimde pozitif olarak etiketlenen pozitif pikselleri gösterir; FP, pozitif olarak etiketlenen negatif pikselleri gösterir; FN, yanlışlıkla negatif olarak etiketlenen pozitif pikselleri gösterir ve TN, doğrulan biçimde negatif olarak etiketlenen negatif pikselleri gösterir.

TPR ve FNR, sırasıyla, damarla ait olan toplam piksel sayısına göre doğru pozitif oran kriterini ve yanlış negatif oran kriterini verir. FPR ve TNR, sırasıyla, damarlara ait olmayan toplam piksel sayısına göre yanlış pozitif kriter ve doğru negatif kriter oranını verir. Bölgesel tanımlarla ilgili olarak, algoritma doğruluğu denklem (3)'deki gibi açıklanır.

\[
Acc = \frac{TP+TN}{TP+FN+TN+FP}
\]

(3)
Bahsedilen kriterlere ek olarak, “Hassaslık” olarak adlandırılan diğer bir görüntü sınıflandırma kriteri vardır ve denklemi şu şekildedir;

\[
Sensitivity = \frac{TP}{TP+FN}
\]

Abstract— Gastric cancer is one of the most common and the most common fatal cancers in the world. In this study, our aims to detect the cancerous regions semi-automatically according to the endoscopy images obtained. In this process, semi-automatic diagnosis of cancer is done according to the endoscopic images received from the patients using image processing techniques and the results are compared with the cancerous region determined from the endoscopic images by specialized doctors. The Gastric cancerous region obtained semi automatically using image processing techniques and determined by the specialized doctors are compared. 96.1641% accuracy rate is determined from the comparison results. Considering the results obtained, it can be seen that the suspected region can be determined via software by the specialized doctors.

Keywords— Gastric Cancer, Image Processing, Endoscopic Image

I. INTRODUCTION
Gastric cancer is the fourth most commonly diagnosed cancer and the second leading cause of cancer-related deaths worldwide [1]. Symptoms associated with gastric cancer often seen in advanced stage tumors. Therefore, it is not easy to diagnose the tumors at an early stage of the cancer. Endoscopic examination and biopsy is the most important tool in the diagnosis of the gastric cancer. In the examination, all parts of the gastric can be seen and the cardia and fundus evaluation can be provided. The accuracy rate of diagnosis by biopsy is around 80% - 85% [2]. The detection of cancerous regions using image processing techniques is aimed by benefitting from endoscopy images obtained from the patients in the Selcuk University Medical Faculty Hospital Gastroenterology Unit. Endoscopic images generally contain elements that are unsuited or irrelevant for our analysis. For example, specular reflections and intestinal juices cover the surface tissue with color and texture patterns, rendering these image parts unsuited for cancer detection based on color and texture analysis. The black image border and the lumen do not show any tissue, which makes them irrelevant for our detection system. Since we aim to use color and texture information for the detection of early cancer, we define a region of interest for two reasons: (1) decreasing the number of false positives that are caused by other texture-rich or color-deviating parts of the image and (2) reducing the computation time by only analyzing the relevant image area[3].

II. MATERIAL VE METOTLAR
In this study, image processing techniques and Image Processing Toolbox of Matlab R2016a has been used for this study.

2.1. Digital Image Processing:
Image processing is a rapidly growing area of computer science. Its growth has been fueled by technological advances in digital imaging, computer processors and mass storage devices. Fields which traditionally used analog imaging are now switching to digital systems, for their flexibility and affordability. Important examples are medicine, film and video production, photography, remote sensing, and security monitoring. These and other sources produce huge volumes of digital image data every day, more than could ever be examined manually [4].

The comparison between semi-automatically detected cancerous region and the detected region by specialized doctors is done in this article.

In computer vision, image segmentation is the process of partitioning a digital image into multiple segments (sets of pixels, also known as super-pixels). The goal of segmentation is to simplify and/or change the representation of an image into
something that is more meaningful and easier to analyze.[5][6] Image segmentation is typically used to locate objects and boundaries (lines, curves, etc.) in images. More precisely, image segmentation is the process of assigning a label to every pixel in an image such that pixels with the same label share certain characteristics.

In one kind of segmentation, the user outlines the region of interest with the mouse clicks and algorithms are applied so that the path that best fits the edge of the image is shown.

Techniques like SIOX, Livewire, Intelligent Scissors or IT-SNAPS are used in this kind of segmentation. In an alternative kind of semi-automatic segmentation, the algorithms return a spatial-taxon (i.e. foreground, object-group, object or object-part) selected by the user or designated via prior probabilities[7][8].

2.2. Implementation of Semi-Automatic Image Processing Techniques to the Image Captured From Endoscopy

In this section, the image processing software is implemented to the endoscopy image captured in Selcuk University Faculty of Medicine, Gastroenterology Unit.

The endoscopy image taken from the patient is shown in Fig.1.

Fig1

In this application, it is required for the doctor to click on the image to determine the predicted cancerous region due to the application being semi-automatic. Afterwards, the software calculates the accuracy rate by comparing the regions determined by the specialized doctor and determined by using image processing techniques.

III. RESULT AND DISCUSSION

When the software is executed, it starts the segmentation process on the endoscopy image. Fig.2 below shows the field scanning system applied on the image. This system is created based on the method which combines the discrete areas.

Fig2

The representation of images, which is the combination of discrete areas, applied on the endoscopy image is shown in Fig.3.
At this stage, after the segmentation process, the specialized doctor activates the software by clicking on the suspected cancerous regions. During the execution of the software, the region determined after the segmentation process and the region determined by the specialized doctor is compared and the accuracy rate is calculated.

The cancerous region determined by the software is shown in Fig. 4.

On the other hand, the region determined as cancerous by the specialized doctor is shown in Fig. 5.

IV. CONCLUSIONS

In this study, success is obtained in the semi-automatic detection of gastric cancer with image processing techniques. In our study, values such as accuracy rate of 96.1641% and 0.8160 Area Under Curve (AUC) value indicates our success rate. Roc Analysis chart belonging to AUC is shown in Fig.6.

Department of Computer Technology & Information System

Abstract—Data mining is used for the extraction of secret, valuable and usable data from the big data and to provide strategic decision support. It created a new perspective for the use of the data in healthcare in addition to finding the answers of unexplored questions. It has gained wider usage as a method. The aim of this study is to develop a decision tree and a list of rules by data mining for the early diagnosis of renal calculi. A data set including blind and retrospective data for 150 people can diagnose with 6 attributes. A decision support system analysis was developed for the diagnosis of the patients with suspected renal calculi. Based on the results obtained and the analysis developed, a decision tree and list of rules were created to determine the factors that affect renal calculi. Weka program and J48 algorithm were used to create the decision tree and the list of rules and it was found to be 74.63% successful.

Keywords—Data Mining, Decision Tree, Renal Calculi Diagnosis, J48

I. INTRODUCTION

The aim of medical informatics is to use computer and communication technologies that are interacting with other sciences in order to utilize, analyze and reconstruct medical information in an effective way. Medical informatics helps to obtain valid, detailed and reliable results on a global scale as it exponentially improves the data collection, process and evaluation capacities in medical centers [1].

A renal calculus is among the most common diseases in Turkey. About 15% of women and 5% of men in Turkey have been diagnosed with nephrolithiasis. It generally occurs in thirties for the first time. Kidneys are like filters in the human body and they help the disposal of waste through the urinary tract. Sometimes some of this waste might cumulate in the kidneys. Renal calculi are the solid pieces that are formed with the crystallization of calcium, phosphate and other minerals in the urine.

Drinking inadequate amount of water, obesity, consuming too much sugar and salt might cause nephrolithiasis as well as genetic factors. Most of the renal calculi are calcium stones resulting from the accumulation of the calcium in the kidneys.

In addition to the environmental factors in the formation of renal calculi, genetic factors may be the primary cause. Not having enough water is one of the biggest risk factors for renal calculi. It is often recommended to drink about 2 liters of water daily. Besides, it is good for our well-being in general not to consume too much sugar and salt, to follow a balanced diet, to stay away from convenience food and not to be overweight. Renal calculi may also stay in the kidneys without showing any symptoms or doing any harm to the kidneys. Following the general information given for renal calculi, we are going to talk about data mining.

Data mining is the extraction of secret, valuable and usable information from a big amount of data. Data mining which is used to provide strategical decision support aims to construct decision making models based on analysis methods.

It creates directive models for decision making techniques for medical institutions where the data is collected for analyses [2]. It is important to emphasize the difference between flaws and misappropriations in health services, to minimize the risks and to take necessary precautions based on
this distinction for patients’ security and well-being [3] [4]. A large amount of information can be retrieved from the various data sets used in daily life [5, 6]. Data mining has made life easier by enabling us to access to more data in a shorter time span [7]. In the simplest term, data mining is the extraction of imprecise, valid and applicable data from data stacks with a dynamic process [8, 9]. It is possible to obtain valuable information from the big data stacks using data mining and statistical analysis techniques. This information helps doctors during the decision process with computer-aided diagnosis work and contributes to the improvement of health care applications [10].

Although potent devices have been produced by expert systems, they have not gained common use because of the field-related data changing rapidly and the diversity of views among experts [11]. Data warehouse is a large store of data accumulated from a wide range of sources under the same roof [12]. The steps in data mining include the definition of the problem to be solved, the obtaining of previous data about the problem, the selection of usable data, housekeeping of the data, the evaluation of analysis results, and the utilization of these results [13, 14]. The time saving and accelerating effect of the data selection will be obvious in the later stages [15].

A decision tree is an approach commonly used in data mining for categorization and estimations. Decision trees benefit the decision makers as they are easy to interpret and understand [16, 17].

C5.0 Algorithm

It is one of the most common decision tree algorithms, especially used for big data sets. C5.0 helps us to get more proper decision trees in terms of form [18]. WEKA is an open coded data mining program with a functional graphics interface which keeps machine learning algorithms together [19, 20].

II. RECENT STUDIES

İlkuçar examined the chronic kidney disease with the help of artificial neural networks in his study. He emphasized what is to be done and which tests to be run for early diagnosis of chronic kidney disease [21]. Danacı et al. focused on the diagnosis of breast cancer cells using data mining methods [22]. In the study conducted by Yurtay et al. they did a data mining research for anaemia diagnosis. In a study on iron deficiency anaemia, the system is run with decision trees [23]. Özkan et al. tried to improve the diagnosis accuracy of the laboratory tests used for the diagnosis of fibromyalgia syndrome which are supported by sympathetic dermal response parameters. SSR parameters and laboratory tests which were calculated by Matlab were analyzed with artificial neural networks and the percentages of accuracy were found [24]. Kökver et al. probed the factors affecting hypertension with data mining methods. They developed a diagnosis system that will estimate whether the patients have hypertension or not [25].

Kusia et al. work through a decision support system which will determine whether the lung tumor is benign or malignant [26]. In their research, Topaloğlu & Sur created a decision support system to diagnose hepatitis and to minimize the number of wrong diagnoses. It will help the doctors with the diagnosis of hepatitis [27].

III. MATERIALS AND METHODS

The Aim of the Study

The aim of the study is to make the diagnosis of renal calculi easier and help doctors with the process. A decision tree and list of rules were created based on the full urinary tests for the diagnosis of the disease. It is possible to avoid misdiagnoses with the decision tree and the list of rules based on facts. Patients can benefit from early diagnosis of a disease they have.

Weka program was utilized for the design of the list of rules and the decision tree. The values of the patients were categorized and the roots and the branches of the decision tree were determined.
The Importance of the Study

Urinary analysis is one of the most common methods used for the diagnosis of renal calculi. Especially substances like uric acid and calcium present in normal urine become crystallized and form the structures called renal calculi. These formations can have great negative effects on a patient’s daily life. The diagnosis of the disease of which treatment process is quite hard is also of utmost importance.

Data Set

For this study, a data set including retrospective and blind data from 150 people. Six attributes were used for the diagnosis of the disease. The seventh attribute is the comments “yes” and “no” for the diagnosis. The six attributes used are as follows;
- Leucocyte
- Urine color
- PH
- Bilirubin
- Appearance
- Erythrocyte.

The Decision Tree Model and Algorithm to Be Applied to the Data Set

A decision tree and a list of rules were formed with the Weka program used in the study. Before that, the data set was processed in csv format and the data was converted to arff format and transferred to Weka Program. J48 algorithm was used to determine the factors contributing to the formation of renal calculi and for the diagnosis. RISK was selected as the root node. The results were transferred with the decision tree and the list of rules.

IV. FINDINGS

Full urine analysis can provide us with very important information of the presence of kidney problems and activities. After the full urine analyses that make up the data set were categorized, they were transferred to Excel program. The file was saved in csv format for WEKA program.

The Formation of the Decision Tree with Weka

J48, which is a decision tree algorithm, was used in the program. The last one of the training set with seven attributes is the “RISK” attribute where the diagnosis is made. The others are as follows; Leucocyte (LOW, MILD, HIGH), Urine Color (COLORLESS, STRAW-COLORED, YELLOW), PH (LOW, NORMAL, HIGH), Bilirubin (NEGATIVE, POZITIVE), Appearance (CLEAR, BLURRED, SLIGHTLYBLURRED, HEAVILYBLURRE), Erythrocyte (TRACE AMOUNT, RARE, NORMAL). 55% of the data obtained were used for training while the rest was used for testing. Classification model provides information about the structure and the size of the tree. This model belongs to the learning set.

Full Urine Analysis and Value Ranges

If Leucocyte value is between; 0 and 3 \(\rightarrow\) Low, 3 and 5 \(\rightarrow\) Mild, 5 and above \(\rightarrow\) High
If PH value is between; 4,5 and 5,5 \(\rightarrow\) Low, 5,5 and 6,5 \(\rightarrow\) Normal, 6,5 and 7,5 \(\rightarrow\) High.
If Erythrocyte value is between; 0 and 4 \(\rightarrow\) Rare, 4 and 9 \(\rightarrow\) Normal, 10 and above \(\rightarrow\) Trace Amount

The relation and attribute expressions of the arff file is shown below;
@relation kidney disease
@attribute LEUCOCYTE string
@attribute COLOR string
@attribute PH string
@attribute BILIRUBIN string
@attribute APPEARANCE string
@attribute ERYTHROCYTE string
@attribute DISEASE string
@Data

The number of the leaves is 7 while the size of the tree is 10.
Evaluation module gives the classification error and the Kappa (=0.482) statistic both. The mean absolute error and the root mean squared error of the category probability estimations assigned by the tree are found 0.3049 and 0.4345, respectively. Classification performance was calculated as 74.63%. This value shows that the decision tree is 74.63% successful.

The algorithm excludes meaningless variables automatically and it makes the selection of the variables itself during the new learning process [28]. Here, the gender was considered to be a meaningless variable and it was excluded from the decision tree variable order. Activity was chosen as the root node. The decision tree created based on J48 algorithm is presented in Figure-1.

The list of rules based on the decision tree created by J48 algorithm is as follows:

1. If ERYTHROCYTE = Trace amount, then Risk = Yes
2. If ERYTHROCYTE = Rare, then Risk = No
3. If ERYTHROCYTE = Normal and Color = Colorless, then Risk = Yes
4. If ERYTHROCYTE = Normal and Color = Yellow, then Risk = No
5. If ERITROSIT = Normal and Color = Straw-colored and LEUCOCYTE = Low, then Risk = No
6. If ERITROSIT = Normal and Color = Straw-colored and LEUCOCYTE = High, then Risk = Yes
7. If ERITROSIT = Normal and Color = Straw-colored and LEUCOCYTE = Medium, then Risk = Yes

V. CONCLUSIONS

Full urine analysis values were examined with the method used in this study. It is possible to diagnose renal calculi without a surgical examination of the patient. Thus, it helps to take the necessary precautions for nephrolithiasis.

According to the design of the decision tree, the most important attribute to take into account is the amount of Erythrocyte. If the amount of the Erythrocyte is above 10, then a pathological test needs to be done with ultrasonography. Again, if the amount of the Erythrocyte is between 4 and 9, then the color of the urine, which is among the attributes, should be examined. If the color is “Yellow”, it means that you do not have any renal calculi. If the color is “Straw-yellow”, then the amount of the Leucocyte should be examined. If the amount of Leucocyte is more than 3, then you are very likely to have renal calculi. If it is below 3, then you do not have it. If the color of the urine is “Colorless”, then you need to have and pathological test. If the amount of the Erythrocyte is below 4, it means that you are less likely to have kidney problems.

The application we designed using data mining methods would help the diagnosis and treatment processes in medicine. It would be very beneficial for biological/medical fields, both clinically and executively, to get help from data mining. It is important to use the results in a safe way in every stage of diagnosis and treatment processes. The aim is to use the decision tree results through the data mining application based on the results obtained. Besides, the first step towards the formation of decision support system was taken with the list of rules created.

Abstract— In this study, the banknote authentication data set in the UCI machine learning repository was used as classification data set. Four features obtained from banknote images that were taken from genuine and counterfeit banknotes were used for classifying them as genuine or counterfeit. 906 of 1372 data in the dataset were assigned for training and rest of them were assigned for testing. Weka (Waikato Environment for Knowledge Analysis) software was used as classification environment. The classification success rates were calculated by using data mining algorithms like Multilayer Perceptron, RBFNetwork, RBFClassifier, kNN, J48, RandomForest, RandomTree, NaiveBayes, BayesNet, OneR, DecisionTable and Kstar. The best classification success rate was achieved by using Multilayer Perceptron model. The classification success rates for various number of neurons in the hidden layer were obtained in Multilayer Perceptron model. The best success rate was obtained as 100% when the model has 4 neuron in the hidden layer.

Keywords— Data mining, Weka, MLP, kNN

I. INTRODUCTION

By the improvement in banking services the Asynchronous Transfer Mode (ATM) machines have been grown up worldwide. Due to this fact the classification of banknotes as genuine or counterfeit become an important issue. Image processing occupies an important role during feature extraction. After the feature extraction operation data mining algorithms have to be used for classification.

Shan et al. (2013) used quaternion wavelet transform for feature extraction. In their study, Artificial Neural Network (ANN) has been used as classifier. The lowest classification error rate is determined as 0.58%. Ali et al. (2004) have proposed a method that rejects counterfeit banknotes. The improvement of reliability in banknote neuro-classifier is investigated and a reject option is proposed based on the probability density function of the input data. In their study, for modelling the non-linear correlation among the data variables and extracting the features, a local principal components analysis (PCA) is applied. The method is tested with a learning vector quantization (LVQ) classifier. The results show that by taking a suitable reject threshold value and also a proper number of regions for the local PCA, the reliability of system can be improved significantly. Esra et al. (2015) has performed clustering process using ANN approach on the pictures belonging to our dataset to determine if the banknotes are genuine or counterfeit. Four input parameters, one hidden layer with 10 neurons and one output has been used for the ANN. Wavelet Transform tool are used to extract features from images. It is determined that the training regression is 0.99914, testing regression is 0.99786 and the validation regression is 0.9953, respectively. Mariana et al. (2013) have used Raman spectroscopy and Partial least squares discriminant analysis (PLS-DA) for determining the authentic and counterfeit banknotes. The classification method PLS-DA is employed to discriminate authentic and counterfeit banknotes, as well as the counterfeit type. In the proposed method all fake and not fake banknotes used to validate the analysis are correctly classified. Hinwood et al. (2006) have designed a system that helps the blind Australians to recognition of banknotes. Each note has the same feel, with no Braille markings, irregular edges or other tangible features in Australia. Their portable system called MoneyTalker scans and speaks about the banknote. The accuracy, weighted by the percentage breakdown of total notes in issue is determined as 98.9%.

In this study the banknotes have been classified as genuine or counterfeit by using 4 attributes created from their images that obtained from banknote authentication dataset. In classification process 12 machine learning algorithm have been used. The classification success rates and error values obtained from each classification algorithm have been compared.

II. MATERIAL AND METHODS

Dataset

In this study, images that were taken from genuine and counterfeit banknote-like specimens have been used to extract four attributes. For digitization, an industrial camera usually used for print inspection, was used. The final images have 400x400 pixels. Due to the object lens and distance to the investigated object gray-scale pictures with a resolution of about 660 dpi were gained. Wavelet Transform tool were used to extract features from images. The attributes that have were
variance of Wavelet Transformed image, skewness of Wavelet Transformed image, curtosis of Wavelet Transformed image and entropy of image. The data set was obtained from UCI machine learning repository [6].

Software-WEKA

Developed by Waikato University in New Zealand, WEKA is an open-source data mining software with a functional graphical interface which incorporates machine learning algorithms [7]. WEKA includes various data pre-processing, classification, regression, clustering, association rules, and visualization tools. The algorithms can be applied on the data cluster either directly or by calling via Java code [8][9]. They are also suitable for developing new machine learning algorithms.

Machine Learning Algorithms

It is a feed forward type artificial neural network model which maps input sets onto appropriate output sets. A multilayer perceptron (MLP) is composed of multiple layers of nodes where each layer is connected to the next. Each node is a processing element or a neuron that has a nonlinear activation function except the input nodes. It uses a supervised learning technique named back propagation and it is used for training the network. The alteration of the standard linear perceptron, MLP is capable of distinguishing data which are not linearly separable [9]

For classification of banknotes as genuine or counterfeit MLP model have been executed by using 4 attributes that obtained from those pictures. By using same data set RBFNetwork, RBFClassifier, kNN, J48, RandomForest, RandomTree, NaiveBayes, Bayesnet, OneR, DecisionTable and Kstar machine learning algorithms have been proposed for classification. The block diagram of the classification process is seen in Figure 1.

III. RESULTS AND DISCUSSION

During classification process the WEKA software have been used for application of algorithms. Classification success rates and error values like MAE and RMSE have been determined by changing the neuron numbers in the hidden layers in the classification by using same dataset on MLP model. The success rates, MAE and RMSE values have been presented on Table 1. The highest success rate have been obtained when the number of neuron in the hidden layer is 4 for MLP model. The MLP model for best situation has been presented in Figure 2.

<table>
<thead>

IV. CONCLUSION

In this study the banknote authentication dataset that obtained from UCI Machine Learning Repository have been used for classification of banknotes as genuine or counterfeit. This data set consists of 4 attributes created from banknote images. For classification 12 machine learning algorithm (Multilayer Perceptron, kNN, J48, Naïve Bayes, Bayes Net, KStar) have been used. The success rates and error values have been obtained for the mentioned machine learning algorithms. The best classification success rate have been obtained by using MLP model when there are 4 neurons in the hidden layer. In this situation the obtained success rate, MAE and RMSE error values are 100%, 0.0036 and 0.0115 respectively.

SPEED CONTROL OF DC MOTOR USING TYPE-2 FUZZY CONTROLLER

Ilker Ali OZKAN*

'Selcuk University, Faculty of Technology, Konya, Turkey
ilkerozan@selcuk.edu.tr

Abstract—In this study, a type-2 fuzzy controller is designed for the speed control of a DC motor. The type-2 fuzzy controller can handle the rules of which membership functions cannot be fully determined or the rules which involve many uncertainties because the type-2 fuzzy controller contains type-2 fuzzy sets for its antecedent and consequent membership functions. The designed type-2 fuzzy controller serves the change in control signal as output according to the input values which are the error values and the error change values. The developed type-2 fuzzy logic controller has been simulated in MATLAB/SIMULINK. The simulation results show that the proposed type-2 fuzzy controller has a high performance for the speed control of a DC Motor.

Keywords—DC Motor, fuzzy control, type-2 fuzzy, PI type fuzzy

I. INTRODUCTION

Direct Current (DA) motors are frequently utilized in open and closed circuit applications in the industry. Majority of these applications require control to ensure high performance [1]. Acquisition of high performance in industrial applications is crucial. In the present study, chopper direct current drivers which display high efficiency, flexible control capability and small and light-weight physical characteristics in number of applications were employed [2-3]. Speed and load fluctuations on DC motors are undesired circumstances. Difficult hardware infrastructure of control methods and their dependency to mathematical modeling allow formation of control methods through various artificial intelligence-based control systems.

Type-1 fuzzy logic systems are not capable of directly tolerating some uncertainties because they use Type-1 fuzzy. Type-2 fuzzy set concept was entered by Zadeh as an extension of traditional fuzzy set concept known as Type-1 fuzzy sets [4]. On the other hand, Type-2 fuzzy logic systems are useful especially when it is difficult to determine certain membership function for a fuzzy set. Thus, Type-2 fuzzy logic systems could be utilized to eliminate uncertainties related with rules and even with measurements [5,6].

In the present study, a driver circuit application controlled by the armature current GTO (Gate Turn Off) thyristor was taken into consideration through the MATLAB/Simulink and electro-mechanical system was controlled by the control system. Regarding the speed control of the DC motor, results were acquired by harnessing the Type-2 fuzzy logic within the Matlab/Simulink environment.

II. DC MOTOR

Direct current (dc) choppers give direct potential applied its entrance by transforming it into a different potential value at its exit by means of the switching element. Direct current choppers encountered in numerous direct potential application cases use choppers rather extensively [7].

DC motor constitutes an open foundation for advanced control algorithms of electric appliances. DC motor is perceived as a SISO system in terms of control systems [8].

Dynamics of a DC motor is described by the following equation:

\[ K_{po}(t) = -R(t) - L \frac{di(t)}{dt} + V(t) \]  \hspace{1cm} (1)

\[ K_{i}(t) = J \frac{d\omega(t)}{dt} + D\omega(t) + T_{f}(t) - T_{L} \]  \hspace{1cm} (2)

where the parameters [8] of the DC motor are shown in Table 1.

III. TYPE-2 FUZZY LOGIC

Fuzzy logic (BM) and Fuzzy Set (BK) Theories were first introduced by Ph.D. Lotfi A. Zadeh in 1965 [9]; and embraced quite extensive practice area. Fuzzy logic is applied in numerous research areas such as Fuzzy Math, Fuzzy Systems, Fuzzy Decision Making and Artificial Intelligence. In the meantime, the Type-2 Fuzzy Set Concept was also introduced by Zadeh [10]. Then, Mendel and his students [11,12] and Turksen [13,14] have improved the Type-2 Fuzzy System Theory on the basis of the Fuzzy Set Concept. Similar to the Type-1 Systems, the Type-2 Fuzzy Systems are comprised of “If-Then” rules as well. However, entry and exit membership sets are the Type-2 Sets in these. When certain membership function is difficult to find for Fuzzy Sets, utilization from the...
Type-2 Fuzzy Sets is extremely beneficent to cope with uncertainties. The Block Diagram indicating the structure of a Type-2 Fuzzy System was exhibited in Figure 1 [5,6].

![Figure 1. Structure of a Type-2 Fuzzy Logic System](image)

**IV. TYPE-2 FUZZY CONTROL OF A DC MOTOR**

In Figure 2, the block diagram of the Type-2 fuzzy control system was exhibited for chopper-fed DC motor. A PI-type controller was designed in this system. Entry variables of the Type-2 fuzzy controller error (e) and change of error (de); exit variable is “ref Δu”. In order to create the controller structure of Type-2 Fuzzy, IT2-FLS Matlab/Simulink Toolbox was harnessed [15].

![Figure 2. The Type-2 fuzzy logic controller used in controlling of a DC motor](image)

**Rule structure in the Type-2 Fuzzy System:***

\[ R^k : \text{IF } e \text{ is } P^{k}_{e} \text{ and } de \text{ is } P^{k}_{de} \text{ THEN } Δu = w^{k}_{1} + w^{k}_{2} \]

\[ k = 1, \ldots, M \]

Type-2 fuzzy sets with \( P^{k}_{e} \) and \( P^{k}_{de} \) interval; where \( w^{k}_{1}, w^{k}_{2} \) are left and right limits of the singleton exit membership functions. Whereas Figure 3 and Figure 4 exhibit the membership functions of entries and exits of the Type-2 fuzzy control system; Table 2 exhibits rule table of the system.

**V. THE MATLAB SIMULINK MODEL**

Figure 5 exhibits chopper-fed DA motor driver in the SimPowerSystem [16].

![Figure 5. The MATLAB/Simulink Model](image)

DA motor is fed by the chopper circuit comprised by the GTO (Gate Turn Off) thyristor connected to the DC resource and a free D1 diode connected to this. Where J refers moment of inertia of the mechanical load driven by the motor; B refers frictional moment; and TL refers the torque loading. Non-hysteresis current controller compares the received signal with the reference signal; and sends trigger signal to the GTO thyristor so that motor current could follow the reference value. The speed control cycle generates reference for the Type 2 Fuzzy controller current cycle. Scope was utilized in order to monitor current and potential signals. As an initial condition, \( \omega=120 \text{ rad/s} \) and \( TL=5 \text{ Nm} \) were taken as reference values [16].
VI. RESULTS

Figure 6 exhibits the plotted graph displaying the change in speed measured at the exit of the system in which Type-2 fuzzy controller was used. It is possible to observe with the MATLAB SimPowerSystem that suggested system was able to reach the reference value of 120 rad/s without exceeding.

![Figure 6. Output of the Type-2 Fuzzy Controller](image1)

Figure 7 exhibits the change in error observed in the Type-2 fuzzy controller system over the time. According to the plotted graph, it was observed that error reduced zero.

![Figure 7. Change in Error in the Control System Over the Time](image2)

As a result of monitoring of the Type-2 Fuzzy Controller in the MATLAB/Simulink environment, change in signs of Va, Ia and motor over the time was exhibited in Figure 8. Where, Va refers chopper exit potential; Ia refers armature current; and these were the graphs plotting the change in Speed w.r.t motor speed over the time.

![Figure 8. Change in Va, Ia and Motor Speed in a Control System over the time](image3)

According to the results obtained by means of the Type-2 fuzzy controller, it was observed that controller acquired the reference speed shortly without exceeding the determined value.

Abstract— Flyback converter circuit is a type of DC-DC converter circuits widely-used in industry. This paper presents analysis and modelling of flyback converter circuit using state-space technique. Switching elements in the converter are modelled with ideal switch concept. The model of flyback transformer and system equations concerning every topology are given. The circuit is realized. Experimental waveforms are compared with the analysis to show the correctness of the modelling and analysis.

Keywords— Flyback DC-DC converter, state-space model, analysis

I. INTRODUCTION

Flyback converter is a type of DC-DC converter circuits. It is widely used in industry because of some advantages: (i) it provides an complete isolation between input and output, (ii) One can get multiple and high voltage outputs, (iii) it is the simplest one if compared with other isolated DC/DC converter types, (iv) it is cheap and practical to implement. Besides these advantages, it requires a protection for leakage inductance and because of the B-H curve limitations it is designed for maximum 150W power applications. Depending on the applications, the flyback DC-DC converter can be operated in two different modes. These modes are continuous conduction mode (CCM) and discontinuous conduction mode (DCM). The proposed model in this study is suitable for both continuous conduction mode (CCM) and discontinuous conduction mode (DCM).

Electronic circuits which use integrated-circuits need a standard DC voltage of fixed magnitude. In some electronic equipment, one may need multiple output power supplies. These DC power supplies are generally provided from the standard power source i.e. AC voltage. For low power applications, the most preferred converter is flyback. The circuit topology of flyback converter is the simplest if we compare it with other isolated DC-DC converters used in the switch mode power supplies (SMPS) [1]. The input given to the converter is generally unregulated DC voltage which is obtained by rectifying the AC voltage followed by a capacitor filter. Flyback converter uses a transformer so that they can give single or multiple isolated output voltages. We talk about energy efficiency, the flyback converter is not good as compared with other SMPS circuits though its topology is very simple [2]. It is presented a simple methodology to design flyback converter with parasitic components in [3]. The authors realize the small-signal analysis of flyback converter. Ref.[4] gives analysis of different flyback converter topologies: Active clamp converter, converter with RCD snubber, interleaved converter, two switch converter, Dual AC and DC output converter. Functionalities of these converters are simulated and their results are compared. Active clamp flyback converters, the one of the most popular flyback converters, are analysed, designed and implemented in [5-9]. The resonant flyback converters [10] were proposed to increase the system efficiency and reduce the switching losses. In Ref.[11], based on the mechanism that the primary and secondary currents of flyback converter do not appear at the same time, two different equivalent models of flyback transformer are brought forward correspondingly. In Ref. [12, 13], the authors analysed the influence of transformer parasitic to low power high voltage output flyback converter by utilizing the simplified transformer model.

The objective of this paper proposes an effective modelling and analysis method for Flyback Converter. The structure of the paper is as follows. Section 2 explains fundamental properties and working stages of flyback converter. In Section 3, first, the flyback transformer is modelled with an ideal transformer and a magnetizing inductor, then, system equations concerning every topology are obtained. Experimental and simulation results are given and compared in Section 4. The paper closes with conclusions in Section 5.

II. BASIC FLYBACK CONVERTER CIRCUIT

The basic flyback converter circuit is shown in Fig.1. It has a transformer, a main switch, (Q), a diode (D), a filter capacitor, a load (R), an input (E). In the circuit, Ip and Is state primer current and secondary current of the transformer, respectively. The converter operates in two stages according to the states of the main switch (Q). Mode 1: when the main switch (Q) is on-state and the diode is off-state, and Mode 2: when the main switch (Q) is off-state and the diode is on-state.

Stage 1: In this mode, the main switch (Q) is turned on-state, the primary winding of flyback transformer is connected to the supply. The current and magnetic flux in the primary side are increased and energy is stored in it. While the potential induced in the secondary winding has opposite polarity than the primary winding, it causes the diode (D) to
get reverse biased and as a result the diode doesn’t allow current through it. The output filter capacitor (C) supplies energy to the load.

Stage 2: It starts when the main switch is turned off-state after conducting. Since the main switch (Q) is open, the current and magnetic flux in the primary side are decreased. According to laws of magnetic induction, the voltage polarities across the windings get reversed. So now, the positive voltage is induced in secondary side and the diode is forward biased. Energy stored in the transformer is delivered to output capacitor and the load.

![Fig. 1 Basic flyback converter circuit](image1)

The major advantage of flyback converter is its filtered output, which eliminates inductive filter, saving cost and volume. High voltage freewheeling diode is also eliminated. Because of this, flyback converters are suitable for high load voltages compared with forward converters. Moreover, in flyback converter, it is possible to get multiple outputs through multiple secondary windings.

III. MODELLING OF CONVERTER CIRCUIT AND SYSTEM EQUATIONS

The flyback transformer is the most complicated as well as the most important component in a flyback DC-DC converter. Before giving the detailed converter model, the flyback transformer must be modelled. Different purposes and different requirements often lead to different equivalent models. In this paper, the transformer is modelled by magnetizing inductor \( L_m \) and ideal transformer, which includes two controlled sources, as shown in Fig. 2. Here, \( U_1 = -nU_2 \), \( J_2 = nI_1 \) (\( n \): turn ratio). Transformer leakage inductances and resistances are ignored to simplify the analysis of the converter.

![Fig. 2 Model of flyback transformer](image2)

After adding the equivalent circuit concerning flyback transformer into the converter, the exact equivalent circuit relating to the flyback converter is obtained as in Fig. 3. Although primary and secondary currents of flyback converter do not appear at the same time, only one equivalent circuit model for transformer is used during a period. The model is valid for both continuous conduction mode (CCM) and discontinuous conduction mode (DCM).

![Fig. 3 Exact equivalent circuit of flyback converter](image3)

In system analysis, state-space analysis technique is used because it has min. variables [14]. The converter circuit has two topologies according to the states of the main switch (Q). Every topology and the relevant space equations are given as follows. The unknowns of system equations are state variables: The current through the magnetizing inductor, \( I_{LM} \), and voltage across the capacitor, accordingly output voltage, \( U_C \).

Switching elements in the converter are modelled with ideal switch concept [15]. This model has zero resistance in the on-state (short-circuit element) and infinite resistance in the off-state (open-circuit element). It provides the most insight in the behaviour of circuits and the fastest simulation.

A. The Topology 1: The main switch is on-state, the diode is off-state

In this topology, the main switch turns on-state by control signal and the diode turns off-state because of the negative induced voltage in secondary winding. During this part of period, the magnetizing inductance (Lm) stores energy and the output capacitor supplies the load. The equivalent circuit is given in Fig. 4.

![Fig. 4 Topology 1: Main switch is on-state, Diode is off-state](image4)
\( i_c = C \frac{du_c}{dt} = -i_R \) \hspace{1cm} (1)

\( u_{LM} = L_m \frac{di_{LM}}{dt} = E \) \hspace{1cm} (2)

\[
\frac{d}{dt}\begin{bmatrix} u_c \\ i_{LM} \end{bmatrix} = \begin{bmatrix} -1/RC & 0 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} u_c \\ i_{LM} \end{bmatrix} + \begin{bmatrix} 0 \\ 1/L_m \end{bmatrix} E
\] \hspace{1cm} (3)

B. The topology 2: The main switch is off-state, the diode is on-state

In this topology, the main switch turns off-state after conducting (by cutting off control signal) and voltages polarities across the windings gets reversed. The energy stored in magnetizing inductor supplies the capacitor and the load. The equivalent circuit is given in Fig.5.

![Fig. 5 Topology 2: Main switch is off-state, Diode is on-state](image)

The state-space equations concerning the equivalent circuit in Fig 5 are obtained in Eq.(6).

\[
u_{LM} = L_m \frac{di_{LM}}{dt} = U_1 = -nU_2 = -nu_c
\] \hspace{1cm} (4)

\[
i_c = C \frac{du_c}{dt} = -i_R - i_2 = -\frac{u_c}{R} - ni_1 = -\frac{u_c}{R} + ni_{LM}
\] \hspace{1cm} (5)

\[
\frac{d}{dt}\begin{bmatrix} u_c \\ i_{LM} \end{bmatrix} = \begin{bmatrix} -1/RC & n/C \\ -n/L_m & 0 \end{bmatrix} \begin{bmatrix} u_c \\ i_{LM} \end{bmatrix} + \begin{bmatrix} 0 \\ 0 \end{bmatrix} E
\] \hspace{1cm} (6)

IV. EXPERIMENTAL AND SIMULATION RESULTS

The converter has been designed to have 34V DC output from 220V, 50Hz AC supply. The first step is to convert AC voltage to DC voltage, a rectifier circuit is used. Then, unregulated DC voltage is filtered using a capacitor (called as link capacitor) and this output is given to a DC to DC converter, single ended isolated flyback converter. The power MOSFET is used for the switching of the converter. The specification of MOSFET are N-Channel, 650V, 5.4A, 400mΩ. The value of switching frequency is chosen so that the circuit can be worked at high frequency and obtain a minimized circuit dimension. Specification of the converter is given in Table 1.

![Fig. 7 Experimental waveform of output current](image)

As shown from Fig.8, during the on-state of MOSFET, the primer current of transformer is increased linearly, this result is compatible with Topology 1 in Fig.4. Similarly, as shown from Fig.9, during the off-state of MOSFET, the seconder current of transformer is decreased linearly, this result is compatible with Topology 2 in Fig.5.
The flyback converter circuit with the design parameters in Table I are simulated with MATLAB using state-space equations (3) and (6). The result is illustrated in Figure 10. Since the input of converter has a ripple voltage, the output voltage in Fig.10 has a wide range oscillation. As shown from Fig. 10, the min. and max. simulation values of output voltage are: 30V-49V.

The simulation and the experimental results concerning the output voltage are compared. These experimental results can verify the modeling and analysis in this paper very well.

**V. CONCLUSION**

Flyback Converter is used in various applications due its less complexity, cost effectiveness, multiple output and isolation. In this paper, the flyback transformer, the most important component of the converter, is modeled with an ideal transformer and a magnetizing inductor. Although the primary and secondary currents in the transformer do not appear at the same time, only one equivalent model for the flyback transformer is brought forward. By using this equivalent model, the working process of the flyback DC-DC converter under DCM mode is analyzed. The flyback converter topologies are analyzed by state-space technique. Experimental results of a real converter are presented to show that the working process can be well explained through the models presented in this paper.

Abstract — The correction of power factor in electric power systems is called reactive power compensation. A synchronous motor is used as a capacitive reactive power generator in compensation systems. It is less costly for an enterprise to use a synchronous motor as both mechanical power generator and power factor corrector, which increases their efficiency. There are various studies on increasing the efficiency, capacity and stability of a power system using power factor correction under different operating conditions. This study focuses on the power factor correction of the system by controlling the excitation current of the synchronous motor via fuzzy logic thanks to the asynchronous motor connected to the system.

Keywords — Power factor, Fuzzy Logic, Synchronous Motor

I. INTRODUCTION

As a result of technological improvements, energy consumption has increased in recent years due to the increasing use of inductive loads in industrial applications. Besides active power, inductive loads also absorb reactive power from the grid [1]. Although reactive power absorbed from the transmission line feeds, it cannot be converted to the energy [2]. Therefore, reactive power absorbed from the grid causes losses in electric power systems, and these losses must be minimized. The minimization of energy losses will reduce cable and other measurement and protection costs, thus creating a more cost-effective electric power system. This can only be achieved when reactive power needed by the inductive loads, which the transmission line feeds, is supplied to the load as closely as possible. Reactive power needed by the loads is supplied statically by a capacitor or reactor and dynamically by a synchronous motor [3-5]. Reactive power compensation via a synchronous motor can be achieved by changing the excitation current of the motor if the motor operates in a capacitive or inductive character [6]. In addition, the amount of reactive power that a synchronous motor absorbs from the grid can be adjusted thanks to the excitation current. An efficiently compensated system will improve the power factor, minimize losses and become efficient [7-9].

This study focuses on the power factor correction of an electric power system using a fuzzy logic based and excitation current controlled synchronous motor. Because it is difficult to determine control parameters via methods requiring mathematical models when a synchronous motor is used for power factor correction, a fuzzy logic based compensation control system was used in this study.

II. POWER FACTOR

Reactive power compensation plays an important role in the improvement of efficiency and capacity of electric power systems. The current of inductive power consumers is supplied by two components of the current. The former is active current converted to work while the latter is reactive current which creates the necessary magnetic field for electric machinery and devices.

Types of power corresponding to these currents are:

\[ S = \text{Apparent Power (VA)}, \]

\[ P = \text{Active Power (W)}, \]

\[ Q = \text{Reactive Power (On)}, \] then

\[ S = \sqrt{P^2 + Q^2} \]  \hspace{1cm} (1)

the equation above can be obtained, which can be geometrically defined as a power triangle as shown in Fig.1.

![Power triangle](image)

Here, \( \phi \) is defined as the phase angle. \( \cos \phi \) is the power factor, which is defined as follows [12].

\[ \cos \phi = \frac{P}{S} \]  \hspace{1cm} (2)

III. SYNCHRONOUS MOTOR

Synchronous motor is an alternative current motor in which rotor rotational speed is equal to the rotational speed of the stator rotating field and the rotation speed does not vary in
loading. When excitation current of the synchronous motor changes, it absorbs ohmic, inductive and capacitive current [13]. In a synchronous motor operating at a constant load and voltage, the characteristic which yields the relationship between excitation current and stator current is called V-current. The point at which excitation current forming the lowest load current at a constant load exists is called ohmic operating point of the motor. The synchronous motor operates inductively under an excitation current lower than that of the ohmic operating point while it operates capacitively under an excitation current higher than that of the ohmic operating point. V-curves which account for the relationship between load current and excitation current for different loads of the synchronous motor are shown in Fig. 2.

As shown in Fig. 2, V-curve of the synchronous motor varies based on different loads. V-curves are at the outermost part when the motor operates at an unloaded state, and they come closer to the ohmic operation curve as the motor is loaded. In case of ohmic operation, the necessary excitation current in the unloaded state increases in a directly proportional way to the load, which is because armature reaction varies depending on the various loads and the saturation increases.

IV. FUZZY LOGIC CONTROL

Fuzzy logic is defined as a mathematical order created in order to explain fuzzy situations and work under fuzzy conditions. Fuzzy logic can control systems when knowledge and predictions about the system are placed within it. In other words, a mathematical model of the system to be controlled is not needed. Fuzzy logic control system consists of four basic units: general fuzzification, inference, defuzzification and rule base [15]. A block diagram of a general fuzzy logic controller is shown in Fig. 3.

Fuzzification is the process of converting inputs obtained from the system to linguistic qualifiers as symbolic values. The fuzzy clusters and membership degrees to which inputs belong are identified thanks to the membership function, and linguistic values such as big or small are assigned to the numerical values.

Fuzzy inference unit creates fuzzy results by applying fuzzy values obtained from the fuzzification unit to the rules in the rule base. The connection between inputs and outputs is created using rules in the rule base. The value obtained in this unit is converted to a linguistic expression based on the rule table and transferred to the defuzzification unit. This study benefits from Mamdani method, which is the most widely used method among fuzzy inference methods.

Defuzzification unit helps distinguish between the non-fuzzy real value to be applied and fuzzy knowledge transferred from the decision unit. Defuzzification is the process of converting fuzzy knowledge to precise results. Various methods are used in defuzzification process. Among these methods, center of gravity method is the most widely used defuzzification method. The equation for this method is given in equation 3.

\[ y = \frac{\sum_{i=1}^{n} y_i \mu_A(y_i)}{\sum_{i=1}^{n} \mu_A(y_i)} \]  

Knowledge base is a data table consisting of knowledge related to the system to be controlled. The connections between inputs and outputs are created using rules in the rule base. If a rule base is to be developed for a system, input values that may influence system output must be identified [16-17].

V. FUZZY LOGIC CONTROLLER DESIGN

V-curves of the synchronous motor and reactive power that it absorbs from the grid were used to design fuzzy logic controller in this study. Fig. 4 and 5 were drawn based on the data obtained from the performance of synchronous motor under nominal conditions. Based on these graphs, the reactive power that the synchronous motor absorbs from the grid and changes in the excitation current of the synchronous motor eliminated the need for a mathematical model, and thus a power factor correction was performed via the synchronous motor based on fuzzy logic.
Input variables of the fuzzy logic control unit designed for this study were determined as error (e), Q (reactive power) and output variable (I_E). Error (e) is found when power factor value is subtracted from input reference power factor value as given in equation 4.

\[ e = \cos \phi_{\text{ref}} - \cos \phi_{\text{inst}}. \]  

(4)

Q (reactive power) as an input variable is applied to the controller input, and its unit is ‘Var’. Output variable (I_E) denotes the current flowing through excitation windings of the synchronous motor, and its unit is ampere. Five different linguistic variables, NB (Negative Big), NS (Negative Small), Z (Zero), PS (Positive Small) and PB (Positive Big), are defined for error (e), Q (reactive power) and excitation current (I_E), which are the variables of the fuzzy logic controller unit. Membership functions in the form of triangles and trapezoids were designed for error, reactive power and excitation current. These membership functions are shown in Fig. 7, 8 and 9.
Five membership functions that are widely used in the designed fuzzy logic controller unit were assigned, and they proved to be suitable for this study. The sum of control rules are twenty-five. Fuzzy rules are given in table I.

<table>

</tr>
<tr>
<td>PB</td>
<td>Z</td>
</tr>
</tbody>
</table>

As far as the performance of fuzzy controller is concerned, rule base uses existing knowledge about the behavior of a system to be controlled instead of a mathematical model of the system. Such knowledge is used during design process, which helps placing long standing experiences in the system following a process of interpretation [19].

VI. SIMULATION STUDIES

Power factor is a parameter that measures the efficiency of electricity energy. The efficiency of electric power system is directly proportional to its power factor. Asynchronous motors possess feedback power factor. The power factor of synchronous motor can feed back or forward when the excitation current is adjusted. The values of the asynchronous motor and synchronous motor used in the simulation study are given in table II and III.

When voltage is applied to the stator windings of the synchronous motors, they cannot move forward due to their inertia. Therefore, several methods exist to start the synchronous motor. In the present study, the synchronous motor was started as if it were an asynchronous motor.

As shown in Fig.10, the synchronous motor reached a synchronous speed after it moved for 0.9 seconds. Afterwards, an excitation current of 5 percent is applied to the synchronous motor via fuzzy controller, which supplied reactive power in a capacitive character to the power system of the synchronous motor. Thus, the synchronous motor compensated itself and fixed the power factor of the system at 0.98, which was 0.8 at the beginning.

VII. CONCLUSION

In the present study, a fuzzy logic control method was used in order to create a more sensitive power system performance and increase system efficiency instead of a conventional control system requiring mathematical models for the calculation of controller parameters. During the operation of control system, the excitation current of the synchronous motor, the reactive power that it absorbs from the grid and its power factor were constantly observed. These values were evaluated in the rule table, and it was aimed to more effectively apply the change in the excitation current of synchronous motor to the system. Contrary to previous studies, this new fuzzy logic control
method increases the power factor to a more favorable level by effectively adjusting the excitation current based on the reactive power that the synchronous motor absorbs from the grid.

Chaotic encryption based data transmission using Delta and Delta-Sigma modulators

Günyaz Ablay
Abdullah Gül University
38080 Kayseri, Turkey
gunyaz.ablay@agu.edu.tr

Abstract—Delta and Sigma-Delta modulation methods have been getting a great interest recently due to the great progress in analog-digital very large scale integration technology. Since the outputs of these methods are digital, the data can be securely encrypted using very simple standard hardware. In this work, a chaotic random bit generator based approach for encrypting digital data of the delta and delta-sigma modulators is studied. The chaotic bit generation can easily be implemented in the digital hardware of the modulators due to simplicity of the chaotic dynamics. The randomness of the generated chaotic bits are proved with visual and statistical tests. The security of the proposed approach is evaluated via key space estimation based attacks. The efficiency of the methods is validated with simulations.

Keywords—Chaos, delta modulation, delta-sigma modulation, random bits, cryptography, communication

I. INTRODUCTION

The delta (Δ) and delta-sigma (ΔΣ) modulators offer simple, efficient methods for telecommunication and signal processing applications. The Δ modulation systems have gained significance in recent years due to their very simple hardware structure, digital transmission and easy to add adaptive features. In addition ΔΣ modulators have noise shaping feature that makes them well-suited for low-frequency, high-accuracy measurements. There are many applications of Δ modulators including reliable voice communications, analog-to-digital signal conversion, performing audio delay lines, telemetry systems and feedback power control in code-division multiple-access radio communication systems [1]–[5]. The Δ modulation systems, a type of variable structure control, are also getting a special interest in the control community [6]–[10]. Other recent studies on Δ modulators have been focused on multibit modulation, chaotic modulation, chaoticification and tone suppression in communications [11]–[17].

The digital output of the Δ modulation systems can be encrypted by using chaotic systems. Since chaotic dynamics have strong similarities with the cryptography, e.g., aperiodicity, deterministic dynamics, ergodicity and sensitivity to initial conditions, they have recently been utilized in cryptosystems [18]–[23]. To encrypt the Δ modulation systems, while the required random bits can be generated from a hardware-based generator (e.g., using thermal noise [24] and radioactive decay [25]) or from software-based generators (e.g., linear congruential generators [26]), chaotic systems are very simple to realize and offer a hybrid structure with the features of hardware and software based approaches [27]–[30]. The number of the chaotic systems have been increased over time in the literature, which allows us to benefit from chaotic dynamics for generating efficient chaotic random bits for use in cryptographic applications [31]–[35].

In this work, a chaotic random bit generator is developed and integrated into the Δ and ΔΣ modulators for data encryption. The goal is to provide security in such systems during data transmissions. The Δ modulation systems offer low cost solutions with a strong immunity against crosstalk and noise in the transmission line, and integration of the chaos into these systems will enhance reliability and security.

In the following sections, the Δ modulation methods are overviewed and a chaotic map based encryption scheme is applied to digital outputs of the Δ and ΔΣ encoders.

II. CHAOTIC DATA ENCRYPTION FOR Δ AND ΔΣ MODULATION

Chaotic systems are able to provide diffusion and confusion, i.e., hiding and spreading plaintext over the ciphertext, and for this reason have potential applications in some functional blocks of communication systems including encryption, modulation and compression. By considering a delta modulation scheme, the chaotic random bits can easily be used for encrypting digital plaintext for secure communications. Figure 1 shows a chaos based digital data encryption and decryption approach for Δ modulators.

Fig. 1 Chaos based encryption for delta modulation system

Similarly, the chaotic bits can also be incorporated into digital output of the ΔΣ modulator and demodulator systems for securing the data as illustrated in Fig. 2. In data encryption the exclusive-or (XOR) logical function is used. The Δ modulated signals are easily demodulated at the receiver by
using a low pass filter, but now with the chaotic encryption, it is not possible to extract message without correct chaotic decrypter with correct initial conditions and parameter values.

\[ \dot{x} = x(t) - \delta \text{sign}(x(t)) \]  

(1)

where \( u(t) \) is the input signal, \( n(t) \) is the integrator output, \( x(t) \) is the error signal and the quantization level is given by \( \pm \delta \). The \( \text{sign}(.) \) function is defined by \( \text{sign}(x) = 1 \) if \( x \geq 0 \), and \( \text{sign}(x) = -1 \) if \( x < 0 \). In order to make the \( \Delta \) modulator function correctly, the error must be forced to zero in finite time by the feedback signal. To find stability conditions of the \( \Delta \) modulator, if we define a positive definite Lyapunov function as

\[ L = x^2 / 2 \]  

(2)

Then, the time-derivative of (2) can be written as

\[ \dot{L} = x \dot{x} = x(\dot{u} - \delta \text{sign}(x)) \leq -\delta |x| \]  

(3)

Thus, the modulator is stable if the following condition holds

\[ \delta > \max |\dot{u}(t)| \]  

(4)

The equivalent condition for the discrete-time (sampling) implementations is given by

\[ \delta f_s > \max |u(t)| \]  

(5)

where \( f_s \) is the sampling frequency. Equation (5) shows that the \( \Delta \) modulator produces a binary coded output from the time-derivative of the analog input signal.

For \( \Delta \Sigma \) modulators seen in Fig. 2, since the input signal first passes through an integrator, then the governing equation can be written as

\[ \dot{x}(t) = u(t) - \delta \text{sign}(x(t)) \]  

(6)

Similar to (2), if the Lyapunov stability is applied, one can easily obtain the following stability condition

\[ \delta f_s > \max |u(t)| \]  

(7)

Therefore, the \( \Delta \Sigma \) modulators have noise suppression advantage compared to \( \Delta \) modulators because the quantization level is proportional to the amplitude of the input signal (while \( \delta \) is proportional to the derivative of the input signal in \( \Delta \) modulators). This noise-shaping feature of the \( \Delta \Sigma \) modulators is well suited to signal processing applications, e.g. communication and digital audio.

![Fig. 2 Chaos based encryption for delta-sigma modulation system](image)

![Fig. 3 Delta modulation technique](image)
satisfied for the related modulator type. There exist adaptive algorithms for adjusting quantization step size to eliminate quantization errors of the Δ modulator systems. On the other hand, the performance of these modulators is dependent on the quantization and channel noise. The quantization noise averages to zero and can be defined by its root mean square (rms) value for a dynamic input signal by considering its limits ±δ/2. Thus, the quantization error 𝑥(𝑡) is given by

\[ x_{rms} = \sqrt{\frac{1}{\delta} \int_{-\delta/2}^{\delta/2} x^2(t) dt} = \frac{\delta}{\sqrt{12}} \]  

(8)

The noise level is equal to quantization noise of an analog-to-digital converter. For rms value of the input signal \( u(t) \), the signal-to-noise ratio (dB) can be given by

\[ \text{SNR}(dB) = 20 \log \left( \frac{u_{rms}}{x_{rms}} \right) = 20 \log \left( \sqrt{12} \frac{u_{rms}}{\delta} \right) \]  

(9)

In these calculations, These results are valid only for uniformly distributed quantization noise and the effect of the slope overload distortion is ignored. The quantization noise remains the same at the demodulator.

B. Chaotic Random Bit Generation

Many chaotic systems are available in the literature to serve as a source for chaotic random bit generations for use in encryption/decryption algorithms. For such applications both continuous-time and discrete-time chaotic systems can be utilized, but the discrete maps are preferred because of their convenience for digital realizations and superior performances. To acquire random bits in a fast, simple way, the robust chaotic maps can be used since they do not have any periodic windows in a large parameter range of the chaotic behaviour. Robust chaotic maps are defined with piecewise linear and discontinuous maps whose Lyapunov exponents are positive throughout the chaotic parameter range [36]. In addition these maps are able to provide statistically uniformly distributed random numbers, which is critical to generated random bits without performing and de-skewing method. Consider a symmetric tent map described by

\[ \theta_{i+1} = 1 - \eta |\theta_i| \]  

(10)

where \( \eta = 1.9999 \). To show the existence of chaos in the system for \( 1 < \theta \leq 2 \), the Lyapunov exponent and bifurcation diagram of the system are given in Fig. 4 for \( \eta \) versus \( \theta_i \). The map has a positive Lyapunov exponent (LE) when \( \eta > 1 \) with a maximum value 0.672. The bifurcation diagram shows that the map has chaos without any periodic windows for a wide range of parameter variations. The map exhibits a robust chaos since the Lyapunov exponent is always positive in the chaotic region.

Even though, statistical tests are not enough to determine the quality of the randomness, they are needed to get an idea. The randomness features of (10) can be evaluated with the visual and test statistics based methods. Visualization is a quick way to get rough information about the chaotic random sequences. The bifurcation diagram and the histogram plot are used for visual evaluations. Figure 5 displays a histogram plot of the chaotic map for 100 categories. The histogram plot shows a uniform distribution over the ±1 range. This means that the chaotic map with the selected parameter value generates a uniformly distributed random sequence.

Fig. 4 Bifurcation diagram and Lyapunov exponent.

![Fig. 4 Bifurcation diagram and Lyapunov exponent.](image)

Fig. 5 Histogram plot.

Now, since we verify that the chaotic map provides uniformly distributed random numbers, we can generate bits (or binary sequences) from this chaotic map by using a simple comparator defined by

\[ h_i = \begin{cases} 1, & \theta_i \geq 0 \\ 0, & \theta_i < 0 \end{cases} \]  

(11)

The usage of a comparator is a simple, efficient and convenient way to generate binary values from the chaotic source [37]. The chaotic random bits should also be evaluated with some qualitative statistical tests to confirm that the generated random bits are unbiased, uncorrelated random bits. To assess the randomness of the generated random bits, many statistical tests are available in the literature including monobit, serial, overlapping template matching, cumulative sum, poker, autocorrelation, runs, discrete Fourier transform (spectral) and
frequency within a block (or block frequency) tests [38]–[40]. These tests are used to determine whether the chaotic random bits are unbiased and uncorrelated. That is to say, the chaotic random bits \( h_i \) with security bound \( S \) bits should include unbiased bits (probability of 0 and 1 must be equal) and indistinguishable bits without performing at least \( 2^S \) operations [41]. Even though the statistical tests alone are not enough for such evaluations, it is nice to see that the chaotic bits pass all these statistical tests. Note that for practical applications, application-specific tests are usually carried out for randomness analysis. The statistical test results are given in Table I. It is clear that all tests are successfully passed, and for this reason, the robust chaotic map (10) with the binary converter algorithm (11) produces a highly-satisfactory random bits for use in cryptosystems.

### III. SIMULATION RESULTS

The Matlab/Simulink based numerical simulation results are given in Figs. 6-7. Figure 6 shows the chaotic data encryption in \( \Delta \) modulator based data transmission results. The message signal which includes ASCII codes of “chaos” is seen in Fig. 6a. The digital output of the \( \Delta \) modulator is displayed in Fig. 6b, where there are some windows in the modulated signal. This digital signal can easily be demodulated with an integrator and low-pass filter. To encrypt the modulator output bits, the XOR logic function is used for the chaotic bit sequence and the modulator bits, namely,

\[
    w_j = v_j \otimes h_j
\]

Figure 6c shows the encrypted modulator output bits, which does not have any visual pattern. The same chaotic bit generator is used in the demodulator to decrypt the original modulator output bits and then a demodulator is employed to extract the original message signal. The recovered message signal is seen in Fig. 6d, which shows a perfect recovery. The security of the scheme is tested with the use of \( \Delta \) demodulator, low-pass filtering and estimated key sequence-based tests. In Fig. 6e, the test result for a wrong chaotic key sequence is illustrated. In this test, the same chaotic map and binary converter algorithm is used. The initial condition of this eavesdropping system is assumed to be estimated with a very small initial condition error, e.g., \( \gamma = \theta_0 - \theta'_0 = 1x10^{-7} \), and it is seen in Fig. 6e that the message cannot be recovered. The chaotic maps in the transmitter and receiver must be exactly the same with the same parameters and initial conditions to generate the correct key sequence and to decrypt the correct message.

Similarly, the numerical simulation results for the \( \Delta \Sigma \) modulator based data transmission are given in Fig. 7. The waveform of the first-order \( \Delta \Sigma \) modulator is illustrated in Fig. 7a when the input signal is a sinusoid as given in Fig. 7a. It is should be noted that the modulator performs both the sampling and the quantization operation in this example, which is typical in practical circuit implementations. The \( \Delta \Sigma \) modulator output shows that the output is either plus or minus full scale and when the sinusoidal input to the modulator is close to the full scale, the output is either positive or negative during the cycle. It is seen that the local average of the modulator output follows the input signal. When the input signal is around zero, the modulator output changes fast between ±\( \theta \) with nearly zero mean. Therefore, the input signal can easily be recovered by using a low pass filter as...
From security developments in mixed signal integrated circuits, a scheme is designed for very small estimation error. The modified map and binary converter algorithm is used for improving the security of the approach, taking into account the patterns. On the other hand, the chaotic bits based on a chaotic key sequence are used for modulating the message. In this work, we have proven the effectiveness of the chaotic modulation technique in communication systems, where the randomness of the robust chaotic map based random bits are evaluated with qualitative statistical tests. The robustness of the delta modulation systems under chaotic encryption is tested with low pass filtering and key space estimation based attacks, and it is shown that the methods are highly secure and reliable. The use of chaos in securing delta modulation approaches provides a good option to be considered as a framework for the next generation communication and data transmission systems.

**IV. CONCLUSIONS**

A chaotic random bit generator based data encryption scheme is designed for digital transmission through delta and delta-sigma modulators. The practically proven technology of the delta modulation systems are used in many signal processing and communication applications with the developments in mixed signal integrated circuits. The implementation of the chaotic encryption is able to provide security for such systems. The approach allows us to benefit from the advantages of the delta modulation techniques and chaos theory. The randomness of the robust chaotic map based random bits are evaluated with qualitative statistical tests. The security of the delta modulation systems under chaotic encryption is tested with low pass filtering and key space estimation based attacks, and it is shown that the methods are highly secure and reliable. The use of chaos in securing delta modulation approaches provides a good option to be considered as a framework for the next generation communication and data transmission systems.

#Pamukkale University, Engineering Faculty, Denizli, Turkey, esraerdem90@hotmail.com

Abstract—This work presents a performance comparison of phase shifted full bridge (PSFB) converter and inductor-inductor-capacitor (LLC) resonant converter for on-board electrical vehicle (EV) battery charge applications. In the comparison, lithium-ion battery cells are taken into consideration to evaluate the performance of converters because of their high power density. In the performance evaluation, for both converter, soft switching operation of the primary semiconductors is discussed to provide output requirements of the battery. The performance of both converter are also validated experimentally by two prototypes, operating with 810 W maximum output power. Experimental results are obtained in good match with theoretical results. According to obtained results, PSFB converter works with soft switching from 50 V to 54 V output voltage, with constant output current, at 200 kHz switching frequency. LLC resonant converter works with soft switching from 42 V to 54 V but with changing switching frequency between 150 kHz and 200 kHz.

Keywords—On-board battery charge, PSFB converter, LLC resonant converter, li-ion battery charge.

I. INTRODUCTION

The use of electrical vehicle (EV) increases greatly every day since the fossil fuels run out, rapidly. Therefore, EV provides benefits in the area of the economy for the most country in the world. The battery charge of vehicles can be possible from a battery charge station or directly a power outlet with on-board chargers. On-board battery chargers can encourage the user to use EV giving flexibility to charge vehicle’s battery from any power point [1]. However, the volume, weight and the cost of the EV increase with on-board chargers [2]-[6].

The lithium-ion battery cells have high voltage and current rate so their power density is higher compared to the other battery cells [7], [8]. However, larger voltage range of the battery cell brings the need of wide range output voltage regulation for the converter. An on-board battery charger is composed of two stages which are AC –DC conversion stage and DC-DC conversion stage. This work focuses on the second stage of a battery charger. The second stage usually uses soft switching converters to provide high efficiency and high power density. The phase shifted full bridge (PSFB), pulse width modulated (PWM) converter and resonant converters are good candidates, and they are mostly used for the second stage of the battery charger [1], [9]-[11].

The PSFB-PWM converter can operate with SS providing phase delay for the control signals of the cross-conducted primary switches of the converter. However, this soft switching process is affected by load conditions and dead time [12], [13]. The resonant converters operates naturally with soft switching and their soft switching operation doesn’t depend on load condition. However, the resonant converter can regulate the output voltage with the change of switching frequency. Moreover, they have also high conduction loss due to increased rms currents. The LLC resonant converter topology provides the narrow switching frequency compared to series, parallel and series-parallel resonant converter topologies [14]. Therefore, it is usually preferred for battery charge applications [9]-[11], [15] and [16]. It seems both PSFB PWM converter and LLC resonant converter have some advantages and disadvantages. Therefore, the performance of PSFB converter and LLC resonant converter needs to be discussed for battery charge applications.

The lithium-ion battery charge process has wide range load and output voltage condition. Therefore, this work discusses the performance of PSFB PWM converter and LLC resonant converter based on their soft switching operation according to lithium-ion battery charge characteristic. For this purpose, two experimental setup are built to validate presented theoretical evaluations. The built setups were tested for 42-54 V output voltage range with 810 W maximum output power.

II. THE PRINCIPLES OF LLC RESONANT AND PSFB PWM DC-DC CONVERTERS

A. LLC Resonant Converter

A circuit diagram of LLC resonant converter is shown in Fig. 1. In the diagram, resonant tank consisted of L1, Lm and C1, S1, S4 are the primary MOSFETS, D1 and D2 are the rectifier diodes producing dc output voltage. The output voltage is \( v_o \), the output capacitor filter is \( C_o \), the load resistor is \( R_o \). The input voltage is \( v_{in} \) and TR represents the transformer with \( N \) turns ratio.

The voltage gain characteristic of the converter based on normalized frequency, \( f/f_o \), and quality factor, \( Q \), variation is given in Fig. 2 [17].
MOSFETs and works below resonance too, but with capacitive operation. The Region 1 always works with inductive mode. Region 3 is used when the switching frequency is higher than the resonance frequency. The Region 1 works with inductive mode and Region 3 works below resonance too, but with capacitive operation. The converter is usually operated at \( f_1 \) for constant voltage applications to reach maximum efficiency [18]-[21]. However, battery charge application should provide wide range output voltage regulation and this operation can be possible with the varying switching frequency [9], [14].

The Region 1 and 2 provide ZVS operation for the primary switches with the operation in inductive mode. Region 3 presents the capacitive mode and this is not suitable for ZVS operation of primary MOSFETs. Therefore, converter can be operated in Region 1 and 2 according to desired output voltage range.

**B. PSFB PWM DC-DC Converter**

The circuit diagram of PSFB converter is given in Fig. 3. \( S_1 \)– \( S_4 \) represent the primary MOSFETs. \( L_s \) is the snubber inductance. \( L_m \) is the magnetizing inductance. \( D_{S1} \) and \( D_{S2} \) are rectifier diodes. \( L_o \) and \( C_o \) are the output filter components. \( V_m \) is the input voltage source. \( V_o \) is the battery voltage. \( N \) is the turns ratio of the transformer. \( S_1 \)– \( S_4 \) represents the leading leg MOSFETs and \( S_2 \)– \( S_3 \) represent the lagging leg MOSFETs.

In the power stages, two diagonal MOSFETs of each leg are turned on, and in the freewheeling stage, the upper or lower side MOSFET \( (S_f \) or \( S_l) \) and an antiparallel diode of the opposite MOSFET \( (S_f \) or \( S_l) \) are switched on. During the output current commutation, both rectifier diode stays on condition and the secondary side of the transformer is short circuited.

In this converter, SS operation of the primary MOSFETs depends on the load condition and dead time. The SS operation of leading leg switch can be achieved easily with the reflected output current. However, lagging leg operated with hard switching after certain load condition. The critical load boundary of lagging leg MOSFETs can be determined by

\[
\frac{1}{2} L_s I_{p-c}^2 \leq \frac{1}{2} \left( C_{S2} + C_{S3} \right) N^2.
\]

Where \( I_{p-c} \) is the critical current to be discharged the parasitic capacitors, \( C_{S2} \) and \( C_{S3} \) are the parasitic capacitors of lagging leg MOSFETs, \( S_2 \) and \( S_3 \). Above equation, it is shown that \( L_s \) is the main parameter to determine the critical load condition.

The dead time of leading and lagging leg should be enough to allow charge/discharge the parasitic capacitors and the dead time for each leg can be defined as follows:

\[
t_{\text{dead–lead}} \geq t_{d(\text{off})} + t_{r_s}.
\]

\[
t_{\text{dead–lag}} \geq t_{d(\text{off})} + t_{r_s}.
\]

Where \( t_{d(\text{off})} \) represents the turn-off delay time and \( t_{r_s} \) is the voltage rising time. For the lagging leg, the dead time should be completed before the primary current falls to zero. Otherwise, reverse resonance starts and so discharged parasitic capacitors charge again [12], [13]. Thus, ZVS turn-on of lagging leg MOSFETs is lost. Therefore, dead time optimization is also important parameter to achieve ZVS turn-on of lagging leg MOSFETs. It can be optimized according to time interval required to charge/discharge the parasitic capacitors, \( t_{\text{ZVS}} \), and the time interval allowing the primary current to fall zero, \( t_{p0} \) defined as follows:

\[
t_{\text{ZVS–lag}} \leq t_{\text{dead–lag}} \leq t_{p0}.
\]
III. PERFORMANCE COMPARISON

For the comparison study, design of each converter is evaluated based on wide range output voltage regulation and soft switching operation for the second stage of a battery charger. At the output, series connection of 14 lithium-ion battery cell is assumed for both converter. Thus, the output of the battery package has 43.4-53.9 V / 15 A with that assumption. The input of converters are fed with 385 V dc voltage obtained from a dc voltage source. The battery charge control has two modes which are constant current mode and constant voltage mode. In this work, performance of each converter is evaluated based on constant current mode with changing battery voltage. The operation analysis of the converters are performed by Matlab and obtained results are summarized in Table I.

According to obtained results, LLC resonant converter has higher transformer turns ratio compared to PSFB converter because LLC resonant converter has no lost duty ratio like it happens in PSFB converter. The increased transformer turns ratio of LLC resonant converter can help to reduce the conduction and turn-off switching loss. However, increased rms current value negatively affects the conduction loss and cost of the converter. The output voltage regulation of LLC resonant converter is provided with the switching frequency changing from 150 kHz to 200 kHz while PSFB converter provides with duty change at constant 200 kHz switching frequency.

The soft switching operation of PSFB converter depends on load condition and dead time condition. For the output voltage regulation the duty ratio is changed in constant current mode control. This results HS operation at low values of the output voltage due to extended dead time.

IV. EXPERIMENTAL RESULTS

In order to test the performance of the compared converters, two prototype are built and separately operated for 1 kW output power and 42-54 V output voltage. 385 V dc voltage is applied to the input of the converters. The component specifications and values used in built converters are given in Table II.

Fig. 4 (a) shows the measured waveforms of LLC resonant converter when output voltage is 54 V and output current is 15 A at 153 kHz. Fig. 4 (b) provides the waveforms obtained when the output is 42 V / 15 A at 200 kHz. ZVS turn-on of primary switch is achieved over wide output voltage.

The PSFB PWM converter was operated at 200 kHz switching frequency to test its performance. The SS operation of leading leg MOSFETs is usually achieved with the reflected load current to the primary side. The lagging leg MOSFETs usually have problem due to their dependence on load and dead time condition. Therefore, the measured results are given in Fig. 5 for lagging leg MOSFET’s switching. Fig. 5 (a) shows the SS operation of S2 MOSFET with 54 V / 15 A output. The converter can operate with SS until 48 V with full load due to no optimized dead time then primary switches work with HS as shown in Fig. 5 (b).

Fig. 4 The measured results of LLC resonant converter. (a) With 54 V / 15 A at 153 kHz and (b) with 42 V / 15 A at 200 kHz.
The efficiency values as a function of battery voltage were measured and obtained results are shown in Fig. 6. The obtained results show that the efficiency of PSFB PWM converter is higher than the LLC resonant converter although the soft switching feature of PSFB PWM converter is not maintained below 50 V battery voltage. Because the conduction loss of LLC resonant converter is higher due to its increased rms currents. The maximum efficiency of PSFB converter and LLC resonant converter is 94.4% and 93.6%, respectively.

V. CONCLUSIONS

In this work, soft switching operation of PSFB PWM converter and LLC resonant converter was discussed based on lithium-ion battery charge profile for on board EV battery charge applications. The operation of the converters is evaluated constant current mode and constant voltage mode of battery charger. The soft switching boundary of the primary switches are extracted theoretically and obtained results were validated experimentally. The prototype of each converter was built and tested separately for 42-54 V / 15 A output. The obtained results show that the efficiency of PSFB PWM converter is higher than the LLC resonant converter due to increased rms currents of LLC resonant converter. The maximum efficiency of PSFB converter and LLC resonant converter is 94.4% and 93.6% at full load condition, respectively.

Current-Mode Rail-to Rail Instrumentation Amplifier for General Purpose Instrumentation Applications

Ugur Cini
Trakya University, Faculty of Engineering, Edirne, Turkey
ugurcini@trakya.edu.tr

Abstract
Instrumentation amplifiers are used extensively in bio-potential reading, industrial sensor applications, Wheatstone bridge amplifiers etc. In this work, a high input common-mode range instrumentation amplifier is presented. The amplifier is composed of two second generation current conveyors (CCII+) with common-mode input range close to supply swings and a differential difference current conveyor (DDCC) at the second stage with high voltage swing at the output. Also an optional DC servo loop is employed as a feedback to second stage for the removal of any possible DC offset voltage at the output which can be used for AC coupled applications. The simple design strategy with high input common-mode range and nearly rail-to-rail output stage together with increased bandwidth advantage of current-mode approach makes the proposed implementation desirable for many of the general purpose instrumentation applications. The design is made using 0.35μm AMS technology with 3V supply voltage. The operation is verified by HSPICE simulations.

Keywords— current-mode circuits, biomedical instrumentation, current-conveyors, amplifier design, current-mode instrumentation amplifier.

I. INTRODUCTION
Instrumentation amplifiers are extensively used for engineering applications to amplify small differential signals. The key property of these amplifiers is the ability to reject undesired common mode voltages [1]. Therefore, Common-Mode Rejection Ratio (CMRR) is the key parameter to measure the quality of an instrumentation amplifier. Generally, voltage-mode instrument amplifiers are employed in many of the engineering applications.

Especially three op-amp instrumentation amplifier is the most popular structure among instrument amplifier topologies. [1-2]. CMRR is directly dependent on resistor matching in three op-amp configuration. Moreover, voltage-mode amplifiers are limited by gain band-width product, i.e., as the gain increases, frequency band-width decreases. An alternative is to use current-mode circuits where CMRR is not directly dependent on resistor matching. Moreover, bandwidth is not directly limited by gain in current-mode instrumentation amplifiers [3, 10-11]. The first proposed configuration of Current-Mode Instrumentation Amplifier (CMIA) implementation [4] is depicted in Fig. 1. Idealized CCII+ equations are:

\[ I_Y = 0 \]  
\[ V_X = V_Y \]  
\[ I_Z = I_X \]  

The design is made using two of the second generation current conveyors of plus type (CCII+). In the circuit, node Y is high impedance node where the input voltage is copied to low impedance node X. In the circuit of Fig. 1, differential input voltages at node Y of both conveyors are replicated at nodes X. The voltage difference of the two of the X nodes results as current at nodes of X. Then, the current flowing through X nodes is copied to node Z. Therefore the voltage at Z node is amplified by the ratio of the gain resistors of the circuit. Basic gain formula (using idealized components) of the CMIA shown in Fig. 1 is:

\[ V_{out} = \frac{R_z}{R_x} (V_{in+} - V_{in-}) \]  

International Conference on Advanced Technology & Sciences (ICAT’16) September 01-03, 2016 Konya-Turkey

512
The advantage of the circuit in Fig. 1 is its simplicity, high CMRR without resistor matching and wide bandwidth. Although CMIA in Fig. 1 gives good performance without resistor matching requirements, improved configurations are proposed utilizing both outputs of the current conveyors [2, 5-7].

In this paper, two of the CCII+ elements with high input common-mode range with high output swing close to rail-to-rail swing is employed at the input stage. Then, another current conveyor, i.e. Differential Difference Current Conveyor (DDCC) is used at the second stage. So that higher CMRR performance and gain is possible. DDCC element is a rather new current conveyor element providing a variety of algebraic operations over the input ports [8]. By employing DDCC element at the second stage, variety of algebraic equations is handled easily. Moreover, an optional DC servo loop is designed for the removal of potential offset at the output which is desirable for the AC coupled instrumentation requirements. In the next section, the structure of the design together with internal structure will be explained.

II. CMIA STRUCTURE

The structure of the instrumentation amplifier is shown in Fig. 2. Two-stage amplification scheme is suitable for higher gain for the instrumentation implementation. The first stage of the amplifier is implemented using rail-to-rail CCII+ elements. The first stage implementation is critical for high CMRR which will be explained in next section. At the second stage, the difference operation of the dual outputs of the first stage is handled using DDCC element. Moreover, integration of the output is feedback from the output to the third terminal of the DDCC. The gain formulation of the system is given as:

\[
V_{X(DDCC)} = V_{Y1} - V_{Y2} + V_{Y3}, \quad (3.a)
\]

By employing DDCC element at the second stage, variety of algebraic equations is handled easily. Moreover, an optional DC servo loop is designed for the removal of potential offset at the output which is desirable for the AC coupled instrumentation requirements. In the next section, the structure of the design together with internal structure will be explained.
\[ f_{HP} = \frac{1}{2\pi \tau} = \frac{1}{2\pi R_1 C_1}. \] (5)

If the offset cancellation loop is not employed, i.e. node Y3 of the DDCC is connected to GND, the gain formulation is equal to:

\[ V_{OUT} = \frac{R_4}{R_3} \left[ \frac{2R_1}{R_2} (V_{in+} - V_{in-}) \right]. \] (6)

### III. INTERNAL BUILDING BLOCKS

The CMIA is built using CCII+ and DDCC elements. CCII+ elements are redesigned for rail-to-rail operation using a novel output biasing structure. DDCC element is also designed for rail-to-rail output swing together with precision output current mirrors to make the component operate close to idealized voltage and current equations. Basic operation principle of the CCII+ element is shown in Fig. 3. The circuit is composed of two differential blocks composed of PMOS input stage and NMOS input stage. Therefore the circuit is functional up to rail-to-rail swing. Differential blocks works as unity gain buffer cells to copy the input voltage at Y node to X node. The output transistors are biased using an output biasing circuit. Whenever any of the differential blocks is inactive, output biasing circuit still provides sufficient current drive for the output transistors M_{op} and M_{on}. Then, current at node X copied to the Z node by class AB current mirrors. The output biasing scheme for the X node output is simple so that, supply voltage is divided between the gate-to-source voltages of the four transistors as:

\[ V_{SG,OP} + V_{SG,D1} + V_{GS,D2} + V_{GS,ON} = V_{DD} \cdot V_{SS} \] (7)

Since \( V_{DD} - V_{SS} \) is 3V, there is sufficient voltage headroom for each of the transistor to operate properly. If the bias circuit does not exist in the structure, whenever

---

Fig. 3. CCII+ working principle

\[ I_{X(DDCC)} = I_{Z(DDCC)} = \frac{1}{R_1} (V_{Y1} - V_{Y2} + V_{Y3}), \] (3.b)

\[ V_{OUT} = \frac{R_4}{R_3} (V_{Y1} - V_{Y2} + V_{Y3}), \] (3.c)

\[ V_{Y1} = \frac{R_1}{R_2} (V_{in+} - V_{in-}), \] (3.d)

\[ V_{Y2} = -\frac{R_1}{R_2} (V_{in+} - V_{in-}), \] (3.e)

\[ V_{Y3} = -\frac{1}{R_1 C_1} \int V_{OUT} dt. \] (3.f)

Then output of the CMIA is,

\[ V_{OUT} = \frac{R_4}{R_3} \left[ \frac{2R_1}{R_2} (V_{in+} - V_{in-}) + \left( -\frac{1}{R_1 C_1} \int V_{OUT} dt \right) \right]. \] (4)

The integrator loop in the structure removes DC offset available at the output of the system. If the integrator loop is active, high pass cutoff frequency is:

\[ f_{HP} = \frac{1}{2\pi \tau} = \frac{1}{2\pi R_1 C_1}. \] (5)

If the offset cancellation loop is not employed, i.e. node Y3 of the DDCC is connected to GND, the gain formulation is equal to:

\[ V_{OUT} = \frac{R_4}{R_3} \left[ \frac{2R_1}{R_2} (V_{in+} - V_{in-}) \right]. \] (6)

---

Fig. 4. Circuit diagram of the CCII+
one of the driving operational trans-conductance amplifiers (OTA) are in the off state, related output transistor \( M_{O1} \) or \( M_{O2} \) gate input floats and there exists extreme current consumption at the output stage. Using the proposed scheme, both of the output transistors are active for the full swing and provide class AB operation properly. Adjustment of the output biasing can be done by sizing of the diode connected transistors \( M_{D1} \) and \( M_{D2} \). Selecting larger length \( (L) \) for the diode connected transistors limits the output biasing current which is important for low-power operation. Self-biasing scheme for driving of OTAs and output stages provides stable operation over large temperature range. Whenever bias currents of OTAs increase by temperature, bias currents \( I_{b,\text{out}} \) also increase, then quiescent drain currents \( (I_{Dr}) \) of \( M_{ON} \) and \( M_{OD} \) is limited. So that low power operation is provided over a large temperature range. Full circuit diagram with self-biasing scheme is shown in Fig. 4. Miller compensation is also employed between node X to drain of \( M_{D8} \) and node X to drain of \( M_{I} \) is also employed.

As explained before, the proposed instrumentation amplifier is composed of two amplifier stages. First stage of the CMIA is based on the basic structure shown in Fig. 1. Second stage is also a differential amplifier constructed using DDCC element. DDCC element is a rather new current conveyor, providing wide variety of algebraic operations. However, DDCC element has lower common-mode range. Since common-mode voltage is mostly removed at the first stage, only residual common-mode voltage appears at the second stage. So that, DDCC element can be effectively employed at the second stage. Moreover, various input algebraic operations provide also an optional DC removal input at node Y3 as shown in Fig. 2. DC removal procedure is important especially for biopotential recordings since a low-offset voltage at the input saturates the instrumentation amplifier and prevents proper operation. So that after pre-amplification at first stage, remaining DC offset is removed using an integrator feedback loop, i.e. DC servo loop. The current-mode integrator provides grounded capacitor implementation for the integrator, which is advantageous for various implementations such as capacitance multiplication for large capacitance values, etc. The integrator is employed using a CCI\( ^{+} \) with a capacitor shown as \( C_{f} \) in Fig. 2. Filter high-pass cut-off frequency can be calculated using (5).

The internal structure of the DDCC element is shown in Fig. 5. The DDCC element is based on two equivalent differential input stage, one output stage with feedback for the output X and current copying circuit from X to Z to generate Z output. The circuit is the improved version of the DDCC proposed in [8]. The aspect ratios of the circuit are given in Table 2. In the second stage of the CMIA, i.e. DDCC circuit, a rail-to-rail input is not required since large common-mode voltage component is removed at the first stage. Here, low-voltage cascode output is employed at Z node, so that rail-to-rail output is possible with high precision the output of the proposed CMIA. Current source \( I_{b} \) is set to 2\( \mu \text{A} \) with cascode current sources in the circuit. Moreover, the circuit is operational under wide variety of current values. Bias voltages \( V_{bias1} \) and \( V_{bias2} \) are set to \( V_{DG1-1V} \) and \( V_{SS+1V} \), respectively. In the proposed scenario, desired gain is possible by adjusting the \( R_{f} \) and \( R_{t} \) resistances if \( R_{t} \) and \( R_{f} \) are internally adjusted to a constant value in Fig. 2 and using (6). DC servo loop can also be de-activated by connecting Y3 input to GND. Since X node of the DDCC is constructed using voltage followers and Z node is implemented using cascade stages, output gain can be precisely adjusted.

For DC coupled implementations, Y3 node can also be used for offset removal by removing the integrator and applying a voltage divider network at node Y3. So that a simple rail-to-rail input and output operation with precision gain and various configurations is possible using the proposed CMIA structure. Output can also be supplied by a unity gain amplifier.
IV. SIMULATION RESULTS AND DISCUSSIONS

The proposed CMIA is configured for 40 dB gain. The first stage gain is selected to be 20, the second stage gain is set to 5. Using (6), \( R_1 \) and \( R_2 \) are selected to be 5kΩ and 500kΩ, respectively. However, \( X \) nodes of the CCIIIs have non-zero resistive input impedance. Due to input resistance of \( X \) nodes, using simulations, \( R_2 \) is replaced by 485Ω. As a result the \( X \) node resistance of each CCII+ is estimated as \( (500-485) \Omega / 2 = 7.5 \Omega \). Second stage X and Z nodes of the DDCC element are close to ideal, since better output stage is designed for the DDCC element. For the second stage, \( R_3 \) and \( R_4 \) are selected as 100kΩ and 500kΩ, respectively. Capacitor \( C_f \) is selected as 1μF. Using (5) high-pass frequency for DC removal is 1.5 Hz, which is suitable for electro-cardiography (ECG) signals. The frequency response of the amplifier is shown in Fig. 6. The gain of 100 with cutoff frequency of 1.5 Hz is achieved using the given component values.

The CMRR performance of the proposed differential amplifier is dependent on two main design issues. One is dependent on device sizing; the other is related to device mismatch effects. CMRR related to device sizing do not have main impact when differential design strategy is selected [10]. Sizing effects mostly cancels out in the proposed structure, since differential design strategy cancels out common-mode effects two of the differential inputs applied to \( Y_1 \) and \( Y_2 \) nodes of the DDCC input at the second stage as the outputs from the CCII+ elements are subtracted using the second stage amplifier. If mismatch effect is not included the CMRR of the proposed structure is as high as 150 dB which is not possible in reality. By applying geometry mismatch to the differential stages of the CCII+ elements in the simulations, the CMRR is recorded as 105 dB. Therefore, matching is very critical for the pairs of \( M_1-M_2 \), \( M_3-M_4 \), \( M_5-M_6 \); and, \( M_7-M_8 \) of Fig. 4. CMRR calculation in [13, 14] also shows that if two of the differential inputs have same gain error, the common-mode effect is minimized.

Larger \( L \) values are employed for the transistors at the first stage of the CCII+ in Fig. 4, NMOS transistor lengths especially kept larger to reduce flicker noise at the first stage. As a result, 850 nV/√Hz input referred noise at 1 Hz is recorded. Noise level is reduced at higher frequencies, as expected. The results are summarized in Table 1. The CMRR recording of the proposed CMIA is comparable with the implementations in [14-16].

V. CONCLUSION

In this paper, a rail-to-rail CMIA circuit is designed. The circuit is designed for general purpose needs and suitable for bio-potential amplification, industrial sensor conditioning etc. The CMIA is based on two amplifier stages and DC off-set removal is possible for AC coupled implementations. The design has high CMRR, and low input referred noise compared to amplifiers without
chopper stabilization. Simplicity of the design procedure with rail-to-rail operation, easy implementation of DC offset removal are the advantages of the proposed CMIA.

Abstract—Signal levels of GSM900, GSM1800 and UMTS bands were measured as mobile on the main streets in the city center of Diyarbakır at the same time and route during a week. The measurements were performed by using high precision and portable spectrum analyzer with an isotropic electric field antenna and a laptop. The high precision spectrum analyzer is a device that measures the high frequency electromagnetic fields. The isotropic electric field antenna allows a three axis measurements. The laptop was used to record and analyze the measurement samples. Electric field strengths were measured as signal levels in this study. Some statistical parameters such as standard deviation and variance were calculated with 95% confidence interval for measurement samples. The highest signal levels were measured as 3.8580 V/m for GSM 900 band, 2.9440 V/m for GSM1800 band and 6.0900 V/m for UMTS band during a week. Similarly, mean electric field strength values as average signal levels were calculated as 0.4985 V/m for GSM 900 band, 0.2350 V/m for GSM1800 band and 0.6281 V/m for UMTS band. According to the mean electric field strength values, the average signal levels of three bands were ranked as UMTS, GSM900 and GSM1800 from the largest to the smallest, respectively. The highest variation in standard deviation and variance was observed on Wednesday for GSM900 and UMTS bands and Thursday for GSM1800 band.

I. INTRODUCTION

Advanced technological developments in mobile communication systems have influenced people's lives in many ways. Electromagnetic field (EMF) signal levels of mobile communication systems such as Global System for Mobile Communications (GSM) and Universal Mobile Telecommunications System (UMTS) are very important for epidemiological studies [1-3]. The effects of EMF signal levels on human health were examined by many scientific studies [4, 5]. Basic restrictions for EMF signal levels were recommended by the International Commission on Non-Ionizing Radiation Protection (ICNIRP) [6]. Turkey has adopted the ICNIRP's reference levels for EMF exposure.

Mobile communication systems such as GSM and UMTS use different technologies. For this reason, signal levels of them may be different in the environment. GSM uses time division multiple access technology (TDMA) and frequency division multiple access technology (FDMA). The maximum output power of a radio transmitter used in GSM is 10-40 watt and frequency of power control is about 2 Hz [7]. UMTS uses code division multiple access technology (CDMA). The maximum output power of a radio transmitter used in UMTS is 20-60 watt and frequency of power control is 1500 Hz [7]. Power control and discontinuous transmission are two smart techniques [8] which are used in GSM and UMTS networks to reduce the EMF signal levels in the environment. Thus, these smart techniques enable to save the power of mobile phone and base station.

The aim of this study was to measure signal levels of GSM900, GSM1800 and UMTS bands as mobile in the city center of Diyarbakır in Turkey at the same time and route during a week. Then, signal levels of them were compared with each other and statistically analyzed. Some statistical values such as standard deviation and variance were calculated with 95% confidence interval. The average signal levels of three bands were evaluated.

II. MATERIAL AND METHOD

The measurements were performed between 10 November 2014 and 16 November 2014 as mobile on the main streets where people spend time and have fun. Communication way from base station to mobile phone is called downlink. Likewise, communication way from mobile phone to base station is called uplink. Output power of the base station is much higher than output power of the mobile phone. Therefore, downlink band was only taken into account during the measurements. Downlink frequency bands of GSM900, GSM1800 and UMTS as shown in Table 1 were measured during the whole week between 17:00 and 18:20 hours at the same route.

DL: Downlink
The measurement set consisted of selective radiation meter SRM-3006 (Narda Safety Test Solutions, USA) connected to isotropic antenna by a radiofrequency cable and a laptop for data collection. SRM-3006 is a high precision and portable spectrum analyzer which measures the high frequency electromagnetic fields. The isotropic antenna is the three axis electric field antenna frequency range from 27 MHz to 3 GHz, dynamic range 0.2 mV/m - 200 V/m and maximum extended measurement uncertainty +2.6/-3.8 dB for 85-2200 MHz. Cable contains ferrite to reduce the effects of the external electromagnetic fields. The isotropic antenna by a radiofrequency cable and a laptop for SRM is portable. Channel bandwidth for GSM900 [10] and GSM1800 [10] is 200 kHz, and for UMTS [11] is 5 MHz. Resolution bandwidth of SRM-3006 for GSM900 and GSM1800 was set to 50 kHz and for UMTS was set to 1000 kHz for better measurement. SRM-3006 equipped with three axis electric field antenna which was placed at 1.70 meter height above ground was mounted on the top of the car. Average speed of the car in the measurement route was about 40 km/h.

In this study, electric field strength values of three bands were chosen as measurement samples at an interval of 10 second during the mobile measurements. Then, the number of measurement samples for each EMF band was become equal to 472 samples per a day and 3304 samples per a week. The program written by us got information (e.g., latitude, longitude, the maximum instantaneous electric field strength values) from the SRM-3006 and recorded measurement samples for statistical analysis. Descriptive statistics such as standard deviation and variance were calculated with 95% confidence interval. Measurement samples were analyzed using IBM SPSS Statistics software, version 21 [12].

### III. RESULTS AND DISCUSSION

Currently, there are three mobile network operators in Turkey. GSM frequency band of two mobile network operators is 900 MHz but the other is 1800 MHz. UMTS frequency band of three mobile network operators is 2100 MHz. As seen in Table 2, Table 3 and Table 4, _10, _11, _12, _13, _14, _15, _16 denote measurement days (Monday, Tuesday, Wednesday, Thursday, Friday, Saturday and Sunday).

N: number of samples  Std: Standard
The highest variation in standard deviation and variance was observed on Thursday for GSM1800 band. The standard deviation is 0.2713217 and the variance is 0.074 as seen in Table 3.

IV. CONCLUSIONS

Signal levels of GSM900, GSM1800 and UMTS bands were measured as mobile on the main streets in the city center of Diyarbakır during a week.

In terms of the mean electric field value, it was determined that the average signal level of the UMTS band during a week was greater than the GSM900 band and the average signal level of GSM900 band was greater than GSM1800 band. The average signal levels of three bands can be listed as UMTS, GSM900 and GSM1800 from the largest to the smallest, respectively.

The highest variation in standard deviation and variance during a week was observed on Wednesday for GSM900 and UMTS bands. Furthermore, the highest variation in standard deviation and variance was determined on Thursday for GSM1800 band.

Abstract—Microwave imaging technology has attracted many interests nowadays. This imaging system has been used in a variety of applications such as: non-destructive testing and evaluation, through-the-wall imaging, concealed weapon detection at security check points, structural health monitoring and medical imaging. Microwave imaging techniques have in recent decades experienced strong growth as a research topic in biomedical diagnostics. The basic idea of using microwave imaging system is to transmit electromagnetic waves from a transmitting antenna to the target material and receive the scattered waves at a receiving antenna. Thus, antenna choice plays an important role for the system. There is a need for compact sized, low cost and high efficiency antennas which can radiate ultra-wideband signal to transmit short pulses. Especially, ‘large bandwidth’ is vital to attain good time domain characteristics which is important for microwave imaging systems. In this study; we selected the circular patch antenna with a slot, due to their ease of fabrication, properties, small size and other advantages of microstrip technology. The schematic of the proposed antenna is presented and the dimensions are summarized in the paper. Ansoft HFSS software is used to design the proposed structure and optimize the radiation pattern and return loss. Simulation results such as directivity and return loss are given and discussed in the result part.

Keywords—Microstrip Antenna, Ultra-Wide Band Antenna, Return Loss, Microwave Imaging

I. INTRODUCTION

Microwave imaging techniques have shown excellent capabilities in various fields such as civil engineering, nondestructive testing, industrial applications, and have in recent decades experienced strong growth as a research topic in biomedical diagnostics. Many research groups throughout the world work on prototype systems for producing images of human tissues in different biomedical applications, particularly breast tumor detection [1]. The basic idea of using microwave imaging system is to transmit electromagnetic waves from a transmitting antenna to the target material and receive the scattered waves at a receiving antenna. Thus, antenna choice plays an important role.

Microwave imaging systems require certain preprocessing steps, which accept only a single polarization of the incident field as input. Also, the designed antenna must have higher gain levels together with a higher front-to-back ratio level. Furthermore, there is a need for compact sized, low cost and high efficiency antennas. Consequently, microwave imaging systems require wide-band, linearly polarized, high gain and compact antennas as their scattered field sensors [2].

For microwave imaging, researchers are interested in the 1-11 GHz frequency range because it appears to balance the conflicting demands of better spatial resolution (higher frequencies) and better penetration depth (lower frequencies) [3].

In this study; the microstrip antenna which has circular shaped patch with slot is selected due to their ease of fabrication, properties, small size and other advantages of microstrip technology. Ansoft HFSS software is used to design the proposed structure and optimize the radiation pattern and return loss.

The paper is organized as follows. In Section II, the schematic of the proposed antenna is presented and the dimensions are summarized. In Section III, simulation results are demonstrated and discussed.

II. ANTENNA DESIGN

Ultra-wideband (UWB) technology has its frequency defined in the range of 3.1 GHz to 10.6 GHz by the Federal Communication Commission (FCC) for UWB radio applications [4]. This technology has become very popular in recent years and has found widespread applications in communications landmine detection and biomedical applications. Another important application is the UWB technology in early breast cancer detection by using microwave imaging system. For this system, there is a need for compact sized, low cost and high efficiency antennas which can radiate ultra-wideband signal to transmit short pulses. Large bandwidth is vital to attain good time domain characteristics which is important for microwave imaging systems [5]. Recent research is on UWB antenna is planar technology as they are more practical in term of manufacturing and integration with the entire system.

There are several compact UWB antennas are proposed in planar technology but they exhibit omnidirectional radiation property. However, in microwave imaging system, antenna's HPBW is one of the main parameters determining the resolution; finer details can be resolved by using a narrower beam.
In this study, first omni directional planar UWB antenna is designed, then we try to improve it to directional planar UWB. The proposed antenna is a modification of the antennas given in [6], which didn’t use slot on patch.

Microstrip antennas produced with printed circuit technology includes a thin layer of low loss nonconductive material with a radiating conductive layer on one side and conductive ground layer that completely covers the non-conductive. Microstrip antennas are basically fed by the microstrip or a coaxial line. Along with technological advances, researchers have focused on different feeding structures and developed three different feeding techniques [7,8,9]. In this study a microstrip line feeding technique that is easy to design and produce is presented.

The purpose of our study is to propose an antenna which has the impedance bandwidth between 5 and 10.5 GHz for use in near field near surface imaging applications. According to this span, center frequency will be 7.5 GHz and wavelength (λ) is equal to 40 mm. For the optimum results, radius of the circular disk should be λ/4 =10 mm [10]. Also we added a slot to circular patch which has 4 mm radius and return loss graphic has been improved by using this slot. To achieve directivity in designed circular monopole antenna, generally L– shaped reflector is used. In our study, ground parameters were changed manually to obtain better results. Due to this modification, front-to-back ratio is higher than the antenna which presented in [11].

Figure 1 shows the layout view of designed circular disc monopole antenna. Dimension of ground plane is shown in figure. Width and length of microstrip line feed is 3mm and 17.2 mm respectively to match with 50Ω impedance line. Center point of slot is same with center of circular patch and diameter of circular disc is 20 mm.

As nonconductor material “FR4_epoxy” was selected for the constructed antenna, dielectric constant (εr) was taken as 4.4 and dielectric height (h) was 1.6 mm.

When simulation results are analyzed based on 10 dB return loss criterion, it was observed that the impedance bandwidth is between 5 and 10.5 GHz. At maximum operating frequency of the proposed antenna Return Loss value was obtained as -33.98 dB. RL characteristic (S11) of the antenna is presented in Figure 3.

One of the important parameters that demonstrate the antenna performance for microwave imaging is the directivity. Radiation pattern of the antenna at 7 GHz is given in Figure 4. According to pattern, front-to-back ratio is calculated 14 dB which is the good value for directivity feature. Unfortunately, it seems that there are unwanted side loop which cause to fall quality of antenna. We will try to improve this negativity and hope to obtain better radiation pattern before the operation of printing antenna on board.
Figure 4. Radiation pattern of proposed antenna at 7 GHz

IV. CONCLUSIONS

Size, directivity and a good reflection coefficient are the most important characteristics of the antenna design requirements for use in near field near surface measurement applications such as the microwave breast cancer imaging system. In this study, compact and small size of the antenna is presented. Simulation results confirm that reflection coefficient is under -10dB throughout 5-10.5 GHz. The properties of compact and UWB antennas have been ensured. Radiation pattern shows that, front-to-back ratio is 14 dB which is the good value for directivity feature. Unfortunately, it seems that there are unwanted side loop. This problem can be resolved by making some modification on ground plane.

From simulation we can conclude that circular monopole antenna is favorable for microwave imaging systems.

Abstract— An annular ring patch antenna (ARPA) constructed by loading a circular slot in the center of the circular patch antenna is a popular microstrip antenna due to its favorable properties. In this paper, an application of artificial neural network (ANN) using bayesian regularization (BR) learning algorithm based on multilayer perceptron (MLP) model is presented for computing the operating frequency of annular ring ARPAs in UHF band. Firstly, the operating frequencies of 80 ARPAs having varied dimensions and electrical parameters were simulated with IE3D™ packaged software based on method of moment (MoM) in order to generate the data set for training and testing processes of the ANN model. Then ANN model was built with data set and while 70 simulated ARPAs and remaining 10 simulated ARPAs were employed for ANN model training and testing respectively. The proposed ANN model were confirmed by comparing with the suggestions reported elsewhere via measurement data published earlier in the literature. These results show that ANN model with BR learning algorithm can be successfully used to compute the operating frequency of ARPAs.

Keywords— Annular ring patch antenna, operating frequency, artificial neural network, bayesian regularization learning algorithm

I. INTRODUCTION

The wireless communication systems are also moving towards the miniaturization very rapidly [1-2]. All these requirements of today’s age wireless communication systems have led the antenna researchers to work on the various aspects of antenna designing with distinctive ideas of manufacturing and synthesis. Present portable communication and handheld devices inherently need miniaturized patch antennas (PAs). By using the substrate materials with high dielectric constant, the smaller antennas can be achieved but this gives rise to decrease the bandwidth and efficiency performances [1-2]. Thus, it is not an easy task to design a small PA managing the requirements of mobile communication devices. To cope such shortcomings of the traditional PAs, compact patch antennas (CPAs) which are formed by applying some modification such as shorting-pin/wall and slot-loading on the antenna structure, have been introduced in recent years [1]. Several slot loaded CPA configurations such as C [3], E [4-5], H [3, 6], L [7], rectangular ring [3] and annular ring [8] shapes have been presented in the literature as an alternative and effectively method to reduce the size of antenna.

Annular ring patch antennas (ARPAs) are miniaturized antenna constructed by loading a circular slot in the center of the circular patch. The size of the ARPA is substantially smaller than circular patch antenna (CPA) at the same operating frequency [8]. It can be appreciated that the average path length travelled by the current in the annular-ring patch is much longer than the corresponding circular patch for the lowest order mode [8]. Also, by choosing the inner and outer radius of the ring properly, both bandwidth broadening [8] and controlling the separation of resonant modes can be managed [9]. Due to these useful properties, it is the one of the most studied PAs. In the literature, the ARPA was theoretically investigated its resonator model in [10-13]. The mathematical tools such as vector Hankel transform, Galerkin’s method and Green functions were greatly utilized in the analysis of the ARPAs [14-19]. Methods based on cavity model and transmission line model was presented to investigate some parameters such as the operating frequency, input impedance and bandwidth [20-26]. The experimental studies concerning the ARPA were also performed to confirm the theoretical calculations in [9-10, 15-16, 26-30]. It can be seen from the literature that these methods include rigorous calculation of Hankel and Fourier transforms and Bessel functions.

Analytical methods seems to be easier but they result in accurate solutions only for regular shapes of the patch, whereas the numerical electromagnetic computation methods are suitable for all shapes of the PA. However, the numerical methods require much more time in solving Maxwell’s equations including integral and/or differential computations. So, it becomes time consuming since it repeats the same mathematical procedure even if a minor change in geometry is
carried out. On the other hand, antenna designers prefer the easier approaches without requiring much rigorous computations and consuming time.

Over a last decade artificial neural network (ANN) adopts remarkable importance in field of wireless communication due to its fast and accurate modelling, simulation, and optimization. In ANN model, we can use measured, simulated, and calculated data for training. Trained ANN model predicts accurate operating frequency for every small variation in the geometry both for thin and thick substrates. The purpose behind the training of ANN model is to minimize the error between actual output and reference output. The use of ANN in computing resonant frequency of CPAs have been proposed in [5-6].

In this study, a method of feed forward back propagation ANN (FFBP-ANN) with bayesian regularization (BR) learning algorithm [31] based on multilayered perceptron (MLP) model has been applied to compute the resonant frequencies of ARPAs. The operating frequency values of 80 ARPAs corresponding most of UHF band covering GSM, LTE, WLAN and WiMAX applications were determined by the electromagnetic simulator IE3D™ using method of moment (MoM) [32]. The simulation parameters of 70 ARPAs representing the overall problem space were used to training and the remaining 10 were then employed to test the accuracy. The results of the ANN model obtained in this study was confirmed by comparing with the measurement results published earlier in the literature [9, 10, 15, 16, 26-30].

II. ANNULAR RING PATCH ANTENNA AND SIMULATION PHASE

As shown in Fig. 1, ARPA has an annular ring patch formed by loading a circular slot with radius ai on a circular patch of radius ao on the substrate having relative dielectric constant εr overall on the ground plane.

![Fig. 1 Geometry of ARPA](image)

In order to determine the operating frequency values, the simulations were performed by means of the IE3D™ packaged software for 80 ARPAs having various parameters of antenna dimensions and dielectric constants listed in Table I. The antennas operate among 0.66 – 3.71 GHz corresponding to the UHF band.

In the simulations, the antennas were supposed to a probe feed with 50 Ω. For meshing process, cell/wavelength rate values were assumed as 40 in limit of 4 GHz. The built in optimization module of the IE3D™ was utilized to determine the feed point which gives the best return loss value with the objective function S11(dB) < -10 for the operating frequencies at TM11 mode.

III. MODELING OF THE ANN FOR THE COMPUTATION THE OPERATING FREQUENCY OF ARPAS

ANN is one of the popular intelligence technique in solving engineering and mathematical problems. An ANN consists of neurons which are organized into different layers. These neurons contain non-linear type of functional, they are mutually connected by very much similar synaptic weights. During the learning process, these synaptic weights could be weakened or strengthened and therefore helping the data to be kept in the ANN. Different learning algorithms (LAs) are used for ANN networks. Some famous type of different backpropagation LAs are Levenberg Marquardt (LM), Bayesian regularization (BR), cyclical order incremental update (COIU), Powel-Beale conjugate gradient (PBCG), Fletcher-Powell conjugate gradient (FPCG), Polak-Ribiere conjugate gradient (PRCG), one step secant (OSS) and scaled conjugate gradient (SCG) [31].

In this study, the BR algorithm was used in ANN model as learning algorithm. BR learning algorithm updates the weight and bias values according to the LM optimization and minimizes a linear combination of squared errors and weights [33]. It also modifies the linear combination so that at the end of training the resulting network has good generalization qualities.
A. Training Stage of the ANN Model

The physical dimensions \((a_o, a_i, h)\) and dielectric constant values \((\varepsilon_r)\) of the simulated ARPAs were given as inputs and their respective operating frequency values of IE3D™ were given as output to the ANN model. While 70 of 80 ARPAs were employed for training phase, others 10 were used for test the models. After several trials, a hidden layer with four neurons, which yields satisfactorily results was employed. Thus, MLP ANN model having one input layer with four neurons, one hidden layer with four neurons and one output layer with one neuron was constructed, as shown in Fig. 2, where \(f_{IE3D}\) and \(f_{ANN}\) are the operating frequencies computed by IE3D™ and ANN model, respectively.

Fig. 2 The block diagram of ANN model

In the ANN model trained with BR learning algorithm, “tangent sigmoid” function was used for both input and hidden layers, whereas “purelin” function was utilized for output layer. The parameters of the ANN model used in this work are listed in Table II. The topology of the training process and calculation of average percentage error (APE) are illustrated for ANN model in Fig. 3. According to Fig. 3, the value of APE for the operating frequencies computed by the ANN model was obtained as 0.437% for the 70 ARPAs’ training data. The training results of the ANN model together with the results of IE3D™ were given in Fig. 4.

Fig. 3 The calculating of APE for ANN model

B. Testing Stage of the ANN Model

To test the performances of the ANN model constructed here, 10 simulated ARPAs whose electrical and psychical parameters listed in Table III are employed. The predicted operating frequency results and APE value of the ANN model with BR learning algorithm are tabulated in Table IV. For further comparison, the numerical results of several methods previously published in the literature [12-13, 25-26] are also listed in Table IV. It is apparent from Table IV that, the ANN model give the remarkable results in comparison with those calculated by the methods presented in the literature [12-13, 25-26].

10 ARPAs were utilized for the test. It was seen that computed electrical parameters of 70 ARPAs were utilized training data, simulation software based on MoM prediction of accurate operating frequency of ARPAs. IE3D™ nonlinear. The training process is once completed in a few unknown parameters in any problem including highly transformations nor rigorous expertness to determine the unknown parameters in any problem including highly nonlinearity. The training process is once completed in a few minutes by properly choosing the network parameters and the learning method, one can easily compute any parameters of interest in microseconds.

IV. CONCLUSIONS

In this paper, an application of ANN model which have been used BR learning algorithm is successfully implemented for the prediction of accurate operating frequency of ARPAs. IE3D™ simulation software based on MoM was used to define operating frequency of 80 ARPAs. ANN model, physically and electrical parameters of 70 ARPAs were utilized training data, 10 ARPAs were utilized for the test. It was seen that computed model learning with BR has been compared with those of the methods reported elsewhere [12-13, 25-26] over several measurement data of ARPAs published earlier in literature [9-10, 15-16, 26-30]. Table V gives the operating frequency values predicted with the ANN model with BR and calculated with the methods given in [12-13, 25-26], and also the their respective APE values according to the measurement parameters [9-10, 15-16, 26-30]. It should be noted that these measurement parameters were not employed for training the ANN model. As can be seen from the Table V, the methods proposed for operating frequency of the ARPA yield the comparable results, however, some calculations are in good agreement with some measured data, and others are far off. But, the operating frequency results of the ANN providing the least APE value within 1% are closer to the measurement ones for the most cases. The results achieved here show that the ANN can effectively be employed to estimate the operating frequency of ARPAs.

In order to verify the accuracy and validity for the crosscheck, the operating frequency results obtained by means of the ANN

As an important matter of the fact that, although the method of ANN seems more complicated as compared to the other ones, it provides the more accurate and relatively simple way since it requires neither sophisticated functions of mathematical transformations nor rigorous expertness to determine the unknown parameters in any problem including highly nonlinearity. The training process is once completed in a few minutes by properly choosing the network parameters and the learning method, one can easily compute any parameters of interest in microseconds.

Abstract— There are two regions in the orbital path of the satellite such as dark and bright region. The energy is provided by solar panels in the bright region and by flywheel energy storage system (FESS) in the dark region. Brushless dc motor (BLDC) are extensively used in satellite power system as motor and generator. Also, these motors are preferred in the FESS due to the low weight, high power density, high efficiency and high speed. The voltage is obtained by BLDC motor in the generator mode and generated voltage is must be constant a value. The FESS speed and the BLDC motor phase voltage are reduced in the dark region. Therefore the voltage regulation is provided by using the boost converter in the generator mode. Boost converter is designed by using the three phase inverter which used as BLDC motor driver in the bright region. Information of the hall-effect sensors are used to the voltage regulation of BLDC generator. In this paper, sensorless control method was proposed in order to regulate the voltage of the satellite power system. The performance of the proposed method has been demonstrated by using the Matlab/SimPowerSystem blocks.

Keywords— BLDC generator, Flywheel, Energy storage, Three-phase boost rectifier

I. INTRODUCTION

FESS has been used power regulated in grid power system, electrical vehicle, satellite power system and uninterrupted power supplies in the last two decades. The FESS is preferred according to electrochemical battery in satellite power system [1]–[9]. Because, the FESS is advantages such as longer life time, bigger depth of discharge and be integrated at moment control gyroscope. The energy is provided by the FESS in the dark region. The mechanical energy is stored by the solar panels in the bright region and the stored energy is used to provide the satellite's power needs in the dark region. Another task of the solar panels is provide the energy of the satellite in the bright region.

The FESS is occurred from some mechanical parts such as flywheel, vacuumed environment, electric machinery and high speed mechanic or magnetic bearing. The magnitude of energy stored in the flywheel is proportional to the speed of flywheel. The BLDC motors are extensively used in the FESS besides industrial application such as automotive industry, medical, automation system and aircraft applications. BLDC motors are used due to high power density, low weight, high efficiency and high speed in the satellite power system [10]. The high speed BLDC motors are used as motor in charge mode and generator in discharge mode.

Three phase converters is widely used in motor drive, energy systems and other power electronic applications. Many works related to the three phase direct AC-DC boost rectifier are presented such as resistive input behavior of converter, low voltage and low power applications, boost rectifier for high-speed permanent magnet generator, energy regenerative damping [11]–[14] and optimal energy harvesting [15]. Three-phase boost rectifier topology is extensively used in low power applications.

In generator mode, the flywheel speed with the BLDC motor back-emf is decreased during the dark region time. Therefore, voltage regulation cannot achieved in power system of satellite in dark region. In this applications, voltage regulation is presented by using three-phase boost rectifier in discharge mode of the FESS.

Phase back-emf of BLDC motor is corresponded position of hall-effect sensors which used boost converter switching [16]. Phase back-emf of BLDC motor is measured to determine phase conduction order in proposed method. Therefore, sensor placement errors are eliminated with sensorless control algorithm. Lower switches of the inverter are made ON by using the BLDC motor of the phase back-emf, respectively. Upper switches of the inverter are continually made OFF and their parallel diode used as boost converter diode.

Current reference is obtained by using the DC bus voltage which measured by voltage sensor. Generator current can be controlled by using current reference. Flywheel speed and DC bus voltage is presented by using MATLAB/SimPowerSystem blocks in generator mode with conventional method and proposed method.
II. FLYWHEEL ENERGY STORAGE

Control diagram of a FESS is shown in Fig. 1 and herein motor and generator mode are determined by using voltage measurement of the solar panels. Motor current and speed is controlled by using the motor controller block in the bright region. Generator current and DC link voltage controlled by using the generator controller block in the dark region.

![Control diagram of a FESS](image)

A BLDC motor has three-phase stator windings and permanent magnet on the rotor. Switching technique of the BLDC motor is preferred as two phase conduction mode (six-step mode) due to simple switching in charge region. In this situation, the BLDC motor of voltage and moment is defined in Eq. (1) and Eq. (2), respectively.

\[ V = i_s R_s + L_s \frac{di_s}{dt} + E_z \]  
\[ T_m = T_L + J \frac{d\omega_m}{dt} + B\omega_m \]

where \( V \) is the armature voltage, \( i_s \) is the armature current, \( R_s \) is the armature resistance, \( L_s \) is the armature inductance, \( E_z \) is the back EMF voltage, \( K_s \) is the back EMF constant, \( K_s \) is the torque constant, \( T_m \) is the torque developed by the motor, \( T_L \) is the load torque, \( \omega_m \) is the angular speed, \( J \) is the moment inertia of motor and flywheel load, \( B \) is the frictional constant of motor and load.

The high speed BLDC motor has low inductance and resistance. Therefore the current ripple is too high which must be reduced. High switching frequency is required because of the high fundamental frequency are taken 500 Hz / 1 kHz. \( dv/dt \) stresses are seen on the motor winding because of high switching frequency. These voltage stresses and current ripples must be reduced by using an LC filter which transfer function is given in Eq. (3) [17].

\[ \frac{V_a}{V_i} = \frac{sC_f R_d + 1}{s^2 C_f L_f + s(C_f R_f + C_d R_d) + 1} \]  

Resonance frequency of the LC filter must be three times lower that the power converter switching frequency which taken 50 kHz. Corner frequency of the LC filter 15.93 kHz which is given in Eq. (4).

\[ f_c = \frac{1}{2\pi \sqrt{L_f C_f}} \]  

The power of satellite is provided by the flywheel energy storage while the dark region in the orbital path of the satellite. In this region, mechanical energy is transformed to the electrical energy by using the power converter. The amount of stored energy must be sufficient to provide the mechanical losses, electrical losses and mission of the satellite. The wind losses have been neglected due to space environment.

In generator mode, power of BLDC generator is given Eq. (5), where \( T_c \omega_m \) is defined as consumed power by satellite. If the Eq. (5) arranged according to the FESS, the Eq. (6) is obtained containing bearing the losses. Stored energy is obtained as shown in Eq. (7) when integral of Eq. (6) is calculated. Thus generated total energy by flywheel can be calculated by using bearing losses and needed power of satellite.

\[ J \frac{d\omega_m}{dt} \omega_m = T_c \omega_m + B\omega_m^2 \]  
\[ J \frac{d\omega_m}{dt} \omega_m = T_c \omega_m + P_b \]  
\[ E = \frac{1}{2} J(\omega_{min}^2 - \omega_{max}^2) = \int_{\omega_{min}}^{\omega_{max}} T_c \omega_m + \int_{0}^{t} P_b \]  

where \( \omega_{min} \) and \( \omega_{max} \) have been defined when FESS is designed. Calculation of the friction losses of bearing are given from Eq. (17) to Eq. (22).

\[ P_b = (M_0 + M_1)\omega_m \]  
\[ M_0 = f_0 \times (v \times n)^2 \times d_m^3 \times 10^{-10} \]  
\[ M_1 = f_1 \times P_i \times d_m \]  
\[ P_i = \omega_m (F_r + F_b) \]  
\[ F_r = m \times g \]  
\[ F_b = m_r \times e \times \omega_m^2 \]  

where \( f_0 \) and \( f_1 \) are coefficient of bearing, \( n \) is the bearing speed, \( v \) is the kinematic viscos friction of bearing grease, \( m \) is the weight of flywheel, \( m_r \) is the residual mass, \( e \) is the eccentricity between the rotational axis of the flywheel and
the mass center and \( d_a \) is the average diameter of bearing. Viscous friction of bearing grease have been not calculated due to use lean full-ceramic bearing.

### III. THREE-PHASE BOOST CONVERTER

Speed of the flywheel is reduced according to demand energy of the satellite during dark region. Therefore voltage of BLDC generator is decrease but the voltage of satellite power system must be constant a value. In generator mode, three-phase inverter and LC filter inductance are used as three-phase boost converter and boost inductor, respectively.

Figure 2 shows the general control technique of a three-phase boost rectifier. Generator current and the DC link voltage are controlled by the PI controller as shown in Fig.2. Current of BLDC generator is calculated as given in Eq. (14).

\[
I_s = \frac{I_a + I_b + I_c}{2}
\]

where \( I_a, I_b \) and \( I_c \) are current of BLDC generator phase, \( I_s \) is current of generator.

DC link voltage is measured to compare by reference voltage. Voltage controller output is obtained as reference to current controller. Upper legs of the three-phase inverter have been continually made OFF and their diodes have been used as boost converter diode. PWM has been respectively applied in lower legs by using the BLDC generator phase voltage. Conduction switch is determined by using the phase voltage in generator mode.

![Image](image.png)

**Fig. 2** The general control technique of a three-phase boost rectifier

The three-phase boost converter which used in the generator mode has been simulated by using the hall-effect sensors and the sensorless method as shown in Fig. (3). Q2, Q4 and Q6 are switched in the three-phase boost converter. Q1, Q3 and Q5 are made continually OFF.

The energy flow is performed as follow when Q2, Q4 and Q6 are made ON/OFF:

- When Q4 is turned to the ON, circuit of boost converter consist of two and two series inductors. Current flow is realized through phase-a and phase-b by following the path D1-C-D4. In this situation, the inductor energy is transferred to the DC bus capacitor and load.

![Image](image.png)

**Fig. 4** The hall-effect sensors signals and the phase voltage waveform

### IV. SIMULATION RESULTS

Phase voltage waveform of the BLDC generator was obtained by using the hall-effect sensors in conventional method.
Simulation parameters are given as follow,

\[ f_0 : 1.3; \]
\[ f_i : 0.00037; \]
\[ d_m : 18 \text{ mm}; \]
\[ m : 0.670 \text{ kg}; \]
\[ g : 9.8 \text{ m/s}^2; \]
\[ m_r^e : 10 \text{ gmm}; \]
\[ J : 0.008 \text{ kgm}^2; \]

Maxon EC-25 high-speed BLDC motor is used in simulation. Phase voltage waveform obtained by using the hall-effect sensors and phase voltage are shown in Figure (4) and Figure (5), respectively.

Q2, Q4 and Q6 are done respectively ON at the positive region of this voltage as shown in Fig. (6). Thus hall-effect sensors have been synchronized by the phase voltage of BLDC generator.

The phase voltage of BLDC generator was measured by using the star point of the LC filter capacitors in the proposed method. Positive region of the phase voltage is obtained by Eq. (15).

\[ V_{pa,ph,pc} = \frac{1}{2} \left( V_{a,b,c} + V_{a,b,c} \right) \]  \quad (15)

Peak region of the positive phase voltage was used in order to do ON lower switches. And it was obtained as shown in figure (7).

In proposed method, state of boost converter switches and phase voltages of BLDC generator are the similar to conventional method as shown in Fig. 8. Phase voltage, positive region of the phase voltage and switching sequence is shown in Fig 8, respectively.

Full ceramic bearing has been used in simulation of the FESS. The bearing losses has been calculated to obtain load.
moment of the BLDC generator. RL load resistance has been selected as the electrical load.

DC bus voltage obtained by conventional and proposed method is respectively shown in Fig (9a) and Fig (9b).

DC bus voltage remained stable in both methods despite decrease of speed of the BLDC generator.

DC bus voltage is decreased when the energy demand by satellite is bigger from the stored mechanical energy. Phase currents of BLDC generator are shown in Fig. 11 for both conventional and proposed method.

By using sensorless method, constant DC bus voltage was obtained and voltage ripple was reduced. Flywheel speed is shown in Fig (10a) and (10b) during discharge time.

DC bus voltage remained stable in both methods despite decrease of speed of the BLDC generator.

Fig. 9 DC bus voltage a) by using hall-effect sensor b) sensorless method

Fig. 10 Flywheel speed a) by using hall-effect sensor b) sensorless method

Fig. 11 Phase currents of BLDC generator. Top: Sensorless method, Bottom: By using hall-effect sensor

V. CONCLUSION

The BLDC motor is used as motor and generator in FESS which used in satellite power system. In this paper, the three-phase inverter has been used as the three-phase boost rectifier in dark region of satellite orbit.

Sensorless control method has been proposed to obtain as stable output voltage of three-phase boost rectifier. In the generator mode, generator current and DC bus voltage were controlled by using PI controller. Bearing losses and resistive load were used as generator load during discharge time of FESS. Wind losses was neglected due to vacuum environment.

Three-phase boost rectifier was performed by using Matlab/SimPowerSystem blocks for both conventional and proposed method. DC bus voltage was obtained as a constant value in both method.

Thus, hall-effect placement errors have been eliminated and DC bus voltage ripple has been reduced by using proposed method.

Abstract—this paper presents low noise, high voltage gain($\text{Av}$), and wide bandwidth($\text{GW}$) CMOS folded cascade Op-Amp. The strategy used for improving the input referred noise of the proposed CMOS operation amplifier based on maximizing the value of the small-signal transconductance ($g_{m}$) of MOSFET transistors. This strategy can be achieved using a large DC bias current. For test the operation of the proposed CMOS op-amps, Electrocardiogram (ECG) signal used as input signal with 2mV peak to peak value and 200Hz frequency. PSPICE (version 16.6) used for simulation the proposed CMOS OP-AMP with 0.18$\mu$m channel length. The simulation results with 10$\mu$A DC biasing current showed that, the value of DC power consumption is 0.296mW, the input referred noise is 67.003nV/$\sqrt{\text{Hz}}$, THE $\text{Av}$=13.6dB, 203KHz. The simulation results of the proposed CMOS op-amp with 100$\mu$A DC biasing current consumes DC power around 1.002mW and exhibits a lower input referred noise of 16.119nV/$\sqrt{\text{Hz}}$, the voltage gain is 51.4dB and $\text{GW}$ is 10MHz. The simulation results confirmed the theoretical calculations and verified very good noise performance of the proposed CMOS OP-AMP.

I. INTRODUCTION

An instrumentation amplifier is normally and essentially employed in both portable and battery powered devices. CMOS transistor uses little power and does not produce as much heat as the traditional Bipolar Junction Transistor (BJT) [1]. The noise performance of the CMOS differential amplifier can also be due to both thermal noise and $1/f$ noise. At low frequencies, $1/f$ noise is so important whereas at high frequencies/low current thermal noise is important [2]. Several publications used to improve noise performance of CMOS OP-AMP are literature in [3, 4, 5, 6], P.K. Chan, et al, in 2000 [3] presented The strategy for minimizing the flicker noise in the folded-cascade amplifier topology and the inter-relationship of design parameters for optimum design. The proposed solution offers good tradeoff on the conflicting performance parameters such as noise, silicon area, bandwidth and power consumption. Yamu Hu, M. Sawan, in 2000 [4] described a low-noise, low-power and low voltage amplifier dedicated to very low amplitude signal acquisition from implantable electronic devices. Low noise and low DC offset are realized by means of Chopper Stabilization (CHS) technique. Reid R. Harrison, Cameron Charles, in 2003 [5] designed and tested a novel bio amplifier that uses a MOS-bipolar pseudo resistor element to amplify low-frequency signals down to the milli hertz range while rejecting large dc offsets, and they derived the theoretical inversion Pedram Mohseni, and Khalil Najafi, in 2004 [6] addressed low noise, low power fully integrated operational amplifier for a variety of biomedical neural recording applications. They demonstrated full functionality of this amplifier through in vitro measurements in saline using a polyimide sieve electrode and a micro-machined penetrating silicon probe. 4

This paper present novel strategy for improvement noise performance of folded cascode CMOS OP-AMP based on maximizing small signal transconductance ($g_{m}$) using different values of biasing current. This approach showed efficient input referred noise with acceptable range of power consumption. ECG signal as input of front end data acquisition circuit used to test the operation of the proposed folded cascode CMOS OP-AMP. Simulation results showed the excellent agreement with theoretical calculations.
II. METHODOLOGY

Our objective is the simulation and the design analysis of a high voltage gain, low noise, and low power folded cascode CMOS OP-AMP using 0.18\(\mu\)m CMOS technology so as to use it in many applications such as in Bio-potential signal acquisition systems [7].

Folded cascode CMOS operation amplifier with biasing current circuit and active stage current mirrors shown in Fig. 1. The steps that are followed in designing the folded cascode CMOS op-amp are given in [8].

The noise sources in MOSFETs include: (a) thermal noise introduced by the channel; (b) flicker noise from the channel. When a MOSFET is biased in the active region, this noise source can be represented by a current noise generator connected from the drain to source, the power spectral density PSD of this current noise generator is \(\frac{I_{\text{thermal}}^2}{2}\) which is described in the following equation [9]:

\[
I_{\text{thermal}}^2 = 4kT \frac{2}{g_m}. \tag{1}
\]

The current noise source introduced by the channel is referred back to the gate by dividing the PSD of the current noise generator by the square of the MOSFET transconductance \(g_m\). This results in an input-referred voltage noise source which is connected in series with the gate. Its approximate PSD is given as [9]

\[
V_{d,\text{thermal}}^2 = 4kT \frac{2}{g_m^2}. \tag{2}
\]

Minimizing the channel thermal noise of a MOSFET is straightforward from the above formula: the small-signal transconductance must be maximized. This can be achieved by using a large DC bias current and having a large width to length (W/L) ratio for the device [9]. Two different values of the biasing current are used to improve noise performance of the proposed folded cascode CMOS OP-AMP. Table (1) summarized the gate dimensions for MOSFETs of the proposed folded cascode CMOS OP-AMP.

III. SIMULATION RESULTS FOR THE PROPOSED CMOS OP-AMP

Figure (2) and figure (3) shows the frequency response (magnitude and phase) of the proposed folded cascode CMOS op-amp using biasing current equal to 10\(\mu\)A. It can be seen the value of open loop voltage gain is 13.603dB, unity gain bandwidth is 203.392KHz, and phase margin around 77.765º.
Simulation results of the input referred noise, and noise spectral density of the proposed folded cascode CMOS OP-AMP with 10µA basing current are shown in Figure (4) (a) and Figure (4)(b) respectively. We note that, the value of input referred noise is $67.003nV/\sqrt{Hz}$ and the value of spectral density is $319.62\mu V$.

Noise performance of the proposed folded cascode CMOS OP-AMP using 100µA basing current are shown in Figure 5(a) and Figure 5(b) respectively. It can be note that, when the value of basing current increased from $10\mu A$ to $100\mu A$, the value of input referred noise decreased to $16.119nV/\sqrt{Hz}$. This improvement due to maximize the value of small signal transconductance ($g_m$) of MOSFETs that inversely proportional with thermal noise of the CMOS OP-AMP.

The performance parameters for folded cascode CMOS op-amp using 100µA biasing current are obtained and compared with the performance parameters of proposed folded cascode CMOS op-amp using 10µA biasing current. This comparison is illustrated in table (2):

### IV. BIOMEDICAL APPLICATION (ECG SIGNAL) BASED ON THE DESIGNED CMOS OP-AMP

The ECG signal that acquired is in the range of 5µV to 8 mV. Due to the weak voltage level, the signal is fed into an amplifier circuit to be amplified to a desirable voltage level. Output from the amplifier is then fed into a bandpass filter circuit and a High Q notch filter. The purpose of this filter is to filter out the very low and high frequency noise components of the signals and the 60-Hz power line interference. The desirable analog output from the filter is then sent to S/H and ADC to become a digital signal. After that, these digital data will process in PCs or microprocessors. Figure 1 shows the proposed ECG data acquisition system [10].

Meanwhile, the recording electrodes might pick up much other unneeded interference. However, the biomedical electronics might be unable to detect small biomedical signals. Therefore, we need a high gain, accurate, and high CMRR amplifier to reduce the common mode noise and to amplify the biomedical signal only [11, 7].

For testing the designed folded cascode CMOS OP-AMP, a closed loop voltage gain of figure 7, with feedback resistor and input resistor are 500kΩ, 1kΩ are used.

![Fig. 7. Closed loop voltage gain of proposed CMOS OP-AMP with ECG as input signal](image)

A low noise and low power consumption amplifier is one of the key circuits for detecting the small level signals in the biomedical applications.

![Fig.8. ECG signal as input of the proposed CMOS OP-AMP](image)

![Fig. 9. ECG signal as output of the proposed folded cascode CMOS OP-AMP](image)
As we seen in figure (8) and Figure (9) the ECG signal with 2mV magnitude is amplified to 42mV using closed loop amplifier with the proposed folded cascode CMOS OP-AMP of figure (7). These results verified the low noise, high voltage gain operation of the designed OP-AMP.

V. CONCLUSION

CMOS op-amp with low input-referred voltage noise, low Power Spectral Density (PSD), high voltage gain, and wide gain bandwidth product GW(>1MHz) is still challenge the researchers, because of the factors like noise-aliasing and charge injection. This goal is achieved using biasing current technique (variation the bias current from 10μA to 100μA). A proposed folded cascode CMOS op-amp with PMOS input differential pair and four NMOS active load is redesigned using 0.18μm TSMC technology. The simulation results showed that, when increasing the value of biasing current of proposed CMOS OP-AMP design leads to increasing the values of small signal transconductance \( g_m \) of MOSFETs as a result the value of input referred noise is improved. Moreover, the performance parameters of the proposed OP-AMP are optimized except of power consumption is increased with acceptable range. The proposed design of CMOS operational amplifier is tested using biomedical application (ECG signal) with 2mV and 200Hz frequency as input signal. As we seen in simulation results of PSPICE program the ECG signal is amplified successfully to 42mV without distortion. Simulation results showed excellent agreement with that of theoretical calculations.

Residual Lsf Vector Quantization Using Arma Prediction

Selma Ozaydin

selmaozaydin@cankaya.edu.tr

Cankaya University,
Department of Electronics & Communication,
Etimesgut-Ankara/TURKEY

Abstract—The residual LSF vector quantization yields bit rate reduction in the vocoders. In this work, a residual LSF vector quantization obtained from Auto Regressive Moving Average (ARMA) prediction is proposed for designing codebooks at very low bit rates. This residual quantization method is applied to multi stage vector quantization method and codebooks are designed. For each codebook, the effectiveness and quality are investigated by calculating the spectral distortion and outliers. The proposed quantization method reduced the distortion without any additional complexity.

Index Terms—very low bit rate, speech processing, residual vector quantization, formant tracking, arma prediction

1. INTRODUCTION

Speech coding refers to process of reducing the bit rate of digital speech representations for transmission or storage, while maintaining a speech quality that is acceptable for the application. Most of the speech coders reported in the literature are based on linear prediction (LP) analysis [1]. For the LP based vocoders, the bit rate reduction is strongly tied to efficient quantization of the LPC filter coefficients \(\{a_i\}\). The Line Spectral Frequencies (LSF)—an equivalent representation of \(\{a_i\}\), more suitable for quantization and interpolation—can alternatively be used. In this sense, the Multi-Stage Vector Quantization (MSVQ) of LSF parameters presented in [2] has an efficient quantization performance at 22-24 bits per 20 ms frames. Furthermore, the multi stage structure has more flexibility than a single stage VQ in terms of search complexity, codebook storage and channel error protection. Very low rate speech communication systems require efficient fixed-rate and low delay coding methods which operate at lower bit rates.

Generalized vocal tract model consists of the oral tract and nasal tract. On the other hand, the linear predictive coding, which has been widely used in the speech analysis and synthesis, uses all pole type digital filters. Speech signals are assumed to be produced by filtering glottal excitation with these filters. This all pole type filter model approximates the true physical configuration of the human vocal tract, but with the nasal tract left out. The most crucial and well known shortcoming in this assumption that during any voiced pronunciation the velum is always closed and the sound wave proceeds only through the oral tract. So the influence of the nasal tract is ignored in this assumption. There is no big problem when non-nasal sounds are processed but in case of nasal sounds the mismatch of the LP model becomes severe. The zeros during nasal sounds supress the peaks in mid-frequency by flattening the spectrum there but this effect cannot easily fitted by all pole modelling. In order to include the effect of both oral and nasal tracts, it is necessary to modify all pole modelling into a pole zero modelling [3]. In order to obtain more efficient speech coding algorithms especially for transmission over noisy channels, differential quantization or predictive quantization of spectrum parameters are used. There are some pole zero modelling approaches in the literature [5-11] but they usually uses nonlinear equations or approximations. While all pole modelling is simple, pole-zero modelling requires complex nonlinear calculations. Although a pole-zero algorithm based on adaptive kalman filtering presented in [11] linearize the nonlinear components by dividing the frequency range of each formant into four bands, this nonlinear approximation method also requires too many calculations causing a complexity in the pole zero modelling.

In this work, we propose an ARMA prediction model for predictive quantization of spectrum parameters. This ARMA prediction method combines the good features of AR and MA prediction methods while eliminating their some drawbacks.

In section 2, basic formulas of MSVQ are given and then in section 2.2, residual vector quantization method using ARMA prediction is described. In section 3, designed codebook results using proposed method are presented.

2. RESIDUAL LSF QUANTIZATION

In this section, a brief description of the MSVQ method presented in [2] is outlined. The definitions presented in this section are introductory information for the residual MSVQ.

The training technique we used in designing the codebooks is the joint design technique [2]. Representative results of the residual LSF scheme with the joint design technique are presented in section 3.
2.1. Notation and Definition

The MSVQ codebooks are designed using the Generalized Lloyd Algorithm (GLA) to minimize average Weighted Mean Square Error (WMSE) based on a sufficiently rich training sequence. The training sequence is first partitioned into decision regions or cells for a given set of centroids (or codevectors). Then, for the given partitioning, the codebooks are re-optimized to minimize the distortion over the particular decision regions.

In the MSVQ system [2], the parameter vector \( x \) consisting of \( p \) LSF parameters is approximated as a quantized parameter vector \( \hat{x} \) using the minimum distortion rule

\[
\hat{x} = y_0^{(h)} + y_1^{(h)} + \ldots + y_{K-1}^{(h)}
\]

where the superscript \( n \) identifies the \( n \)th vector from the training sequence and the subscript \( r \) represents the iteration number during the training of a codebook. For details of designing a codebook in MSVQ, the reader is referred to [2].

2.2. Residual LSF vector Quantization with ARMA prediction

In the R MSVQ method, the residual LSF parameters of current frame are predicted from the quantized LSF parameters of the previous frames using interference correlation feature of spectrum parameters [5-8] and then residual LSF vectors are coded with a MSVQ codebook. Firstly, the LSF parameter vector is obtained by transforming the 10th order LPC parameter vector. Next, the average LSF vector of the training set \( x_{DC} \) is subtracted from the LSF vector \( x^{(i)} \) belonging to the \( i \)th frame. By defining mean removed LSF vectors \( \left( z^{(i)} = x^{(i)} - x_{DC} \right) \) and its quantized version \( \left( \hat{z}^{(i)} = x^{(i)} - x_{DC} \right) \), the residual LSF vector \( e^{(i)} \) is calculated using

\[
e^{(i)} = \hat{z}^{(i)} - r^{(i)}
\]

where \( i = 1, 2, \ldots \text{and} \ r^{(0)} = 0 \). The quantized residual vector \( \hat{e}^{(i)} \) is found by quantizing \( e^{(i)} \) with a VQ codebook. Depending on how \( r^{(i)} \) is computed, various prediction schemes can be proposed. If \( r^{(i)} = \alpha \left( \hat{e}^{(i-1)} + r^{(i-1)} \right) \), a first order Auto Regressive (AR(1)) predictor is obtained [5]. When \( r^{(i)} = \alpha \hat{e}^{(i-1)} \) we have a first order Moving Average (MA(1)) predictor [5]. The research in the literature have focused on these two schemes [6-8] which show that codebooks designed with using AR predictors produce lower distortion than codebooks with MA predictors, however the use of an alternative ARMA model in residual LSF prediction, which is untouched in the literature, can be more advantageous. The ARMA(1,1) predictor is

\[
r^{(i)} = \alpha_1 \hat{e}^{(i-1)} + \alpha_2 r^{(i-1)}
\]

Here, we optimize two parameters instead of one in AR(1) and MA(1) predictors. It has been observed that residual LSF codebooks designed by an ARMA(1,1) predictor have lower distortion than AR(1) and MA(1) predictor codebooks. The lowest distortion using an AR(1) model is obtained by using \( \alpha = 0.5 \). In an ARMA(1,1) predictor the lowest distortion is obtained when \( \alpha_1 = 0.3 \) and \( \alpha_2 = 0.6 \). To see the advantage of the ARMA(1,1) predictor, consider the reconstructed quantized LSF vector \( \hat{z}^{(i)} \) in the decoder

\[
\hat{z}^{(i)} = \hat{z}^{(i)} + r^{(i)}
\]

\[
= \hat{e}^{(i)} + \alpha_1 \hat{e}^{(i-1)} + \alpha_1 \alpha_2 \hat{e}^{(i-2)} + \ldots
\]

To see the advantage of the ARMA(1,1) predictor, consider the reconstructed quantized LSF vector \( \hat{z}^{(i)} \) in the decoder

\[
\hat{z}^{(i)} = \hat{z}^{(i)} + r^{(i)}
\]

\[
= \hat{e}^{(i)} + \alpha_1 \hat{e}^{(i-1)} + \alpha_1 \alpha_2 \hat{e}^{(i-2)} + \ldots
\]

\[
\alpha_1 \alpha_2 \hat{e}^{(i-3)} + \alpha_1 \alpha_2 \alpha_3 \hat{e}^{(i-4)} + \ldots
\]
which is compared to the reconstructed quantized LSF vector of the AR(1) predictor

\[ z^{(i)} = \hat{e}^{(i)} + \alpha_2 \hat{e}^{(i-1)} + \alpha_1^2 \hat{e}^{(i-2)} + \alpha_1^3 \hat{e}^{(i-3)} + \alpha_1^4 \hat{e}^{(i-4)} + \ldots \]  

(9)

It is well-known that [5] AR prediction schemes are susceptible to channel errors due to infinite memory as seen in (9). For example, for \( \alpha = 0.5 \) in AR(1), the weighting of previous quantized residuals decay like \( \{0.5, 0.25, 0.125, 0.0625, 0.0312, \ldots\} \). However, in ARMA(1,1) with \( \alpha_1 = 0.3 \) and \( \alpha_2 = 0.6 \) the weighting is \( \{0.3, 0.18, 0.108, 0.0648, 0.0388, \ldots\} \). As can be seen, the decay in ARMA(1,1) is faster which means that the susceptibility to channel errors compared to AR(1) is decreased. Hence by using an ARMA predictor not only do we reduce the distortion but also we decrease the effect of channel errors when compared to AR predictors.

![Fig. 1. Block diagram of proposed ARMA prediction](image)

Marca [7] suggested an AR predictive scheme in which prediction is performed only on every other frame which limits error propagation at most one adjacent frame. The same approach can be applied to ARMA(1,1) predictors. In practice, AR and ARMA predictive models correspond to higher order MA models as the weighting of previous quantized residuals decay to zero after a sufficiently large previous frame index, say \( p \), which means that the same spectral distortion and outlier results can be obtained by optimizing \( p \) coefficients of a MA(\( p \)) predictor. However, undue codebook design complexity would be introduced as the search is now over a \( p \) dimensional space instead of two in ARMA(1,1).

A weighted Euclidean distance measure is used for training the codebooks and during the search for the best codevector during quantization. The weighted Euclidean distance measure \( d(e, \hat{e}) \) between the input residual LSF vector \( e \) and the quantized residual LSF vector \( \hat{e} \) is given by

\[ d(e, \hat{e}) = \sum_{j=1}^{n} w_j (e_j - \hat{e}_j)^2 \]  

(10)

where \( p \) (\( p=10 \) in our case) is the number of elements in the residual LSF vector and \( w_j \) is the weight coefficients assigned to the \( j^{th} \) residual LSF vector \( (e) \).

III. PERFORMANCE EVALUATION

LPC/LSF quantization performance can be assessed using subjective tests and/or objective distortion measures. The performance of the codebooks is measured by using spectral distortion method. Hence,

\[ A(z) = 1 + \sum_{j=1}^{p} a_j z^{-j}, \quad \hat{A}(z) = 1 + \sum_{j=1}^{p} \hat{a}_j z^{-j} \]

\[ d_{SD}(A(z), \hat{A}(z)) \approx \frac{1}{n_1 - n_0} \sum_{n=n_0}^{n_1} 10 \log_{10} \frac{(\hat{A}(e^{2\pi i n/N})^2)}{(A(e^{2\pi i n/N})^2)} \]  

\[ SD = \sqrt{\frac{1}{T} \sum_{j=1}^{T} d_{SD}^2 (e^{j2\pi j/N})} \]  

(16)

where \( n_0 \) and \( n_1 \) correspond to 100 Hz and 3800 Hz respectively. \( A(z) \) is the optimal \( p^{th} \) order linear predictor and \( \hat{A}(z) \) is the predictor with quantized coefficients. \( N = 256 \) point FFT is used.

The training database (65,685 vectors) is extracted from TIMIT databases, which consists of 630 speakers of 8 major dialects of American English, each reading 10 phonetically rich sentences. The extracted database is lowpass filtered and down sampled to 8 kHz. M-L tree search procedure are used for training and testing [2] and \( M=8 \) is taken as the search depth of codevectors.

To further test the efficiency of the R_MSVQ codebook, a novel very low bit rate speech coding-decoding algorithm is designed which is described in detail in [4]. MSVQ codebooks and new residual codebooks with the same bit rate are used respectively. For each designed codebooks, the effectiveness and the limitations of codebooks are investigated by calculating the SD and percentage of outliers. For comparison purposes spectral distortion and outlier results for the codebooks designed with MSVQ and R_MSVQ algorithms are given in Table 1. For lower bit rates, there is approximately 10% bit rate reduction in the R_MSVQ scheme for identical spectral distortion values.

Listening tests and spectral distortion results for test speech data show that a three stage 22 bit/frame R_MSVQ codebook gives the same quality as the four stage 24 bit/frame MSVQ codebook in the new vocoder. We have tried to keep the bit rate of the residual LSF vector quantization as low as
possible at an acceptable level as the major contribution to the bit rate of the vocoder comes from the LSF vector quantization.

REFERENCES

IV. CONCLUSIONS

This article has presented an ARMA prediction modelling approach which has been shown to produce lower distortion results. The proposed prediction algorithm improves the performance for all investigated bit rates. Furthermore, the new method has the good features of both AR and MA model. The new residual quantization method reduce the bit rate using residual LSF vectors obtained from ARMA prediction with little calculations in the algorithm. With this method error propagation is limited to a few frames for noisy channels.

It is expected that additional improvement will come with analysing of how adaptive coefficients can be found to model cepstral coefficients. Antiformant tracking here remains challenging although it has been found better results with the modelling here. On the other hand, the effectiveness of this approach is its ability to model both poles and zeros with a simple algorithm without giving nonlinear complex calculations. Further research is planning to evaluate the effectiveness of this method according to different speech databases and to find an adaptive method to adjust alfa coefficients adaptively.
A Low Cost Smartphone-Controlled Wireless Data Logger System for Monitoring of Safety-Critical Areas

Osman Karapür*, Görkem Mert Keskin†, Yaser Dalveren†, Ali Kara*

†Department of Electrical and Electronics Engineering, Atılım University
Ankara, Turkey
†KORTEK Engineering & Consultancy Co. Ltd.
Ankara, Turkey

Abstract—Environment monitoring systems have gained a great attraction to maintain human health and safety in human working areas. To assure appropriate working conditions especially in safety-critical areas, wireless communication systems are mainly preferred. As a main component of such monitoring systems, wireless data loggers are required to collect, store and display sensor data at high speed, lower cost and high efficiency. This paper presents the results of a design process regarding a wireless data logger. The system is designed to detect released toxic gases along with conventional video monitoring of safety-critical areas. The system provides measurement time and date stamped sensor data onto video signal for real-time monitoring of the environment. The system also offers instant access to stored data using a mobile application through Android devices. This provides cost effective solution from end-user perspective.1

Index Terms—data logger, android, wireless communication, remote control, microcontroller

I. INTRODUCTION

Data logger is an electronic device that records several types of measurements over the time. It stores all data into memory storage and informs user at any time required. Data loggers, which use digital technologies, are commonly equipped with sensor, microcontroller, external memory, real time clock, and wireless communication module. However, structure of the data logger may be varied. Typically, data loggers work together with sensors to take input data. This data is converted to binary data and then analyzed by full-featured software to store for further processes. With emerging technologies, functionality of the data loggers has been enhanced by generic programming techniques.

Using data logger has been considered in many applications for different purposes. A survey on data logger system is presented in [1]. In [1], several studies in data logger field are reviewed. More recently, developed systems are proposed to monitor sensed data in various environment types. The works in [2-4] propose wireless data logger systems for monitoring temperature using ZigBee communication protocol. For building a wireless data logger for thermal validation systems for pharmaceutical industry is given in [5]. Another data logger system is developed for industrial cooling applications [6]. The work in [7] aims to propose a data logging system that store large numbers of data from analog signal over an extended long time. In [8], a wireless sensor network that uses data logger for a real-time air quality monitoring system is presented. The study in [9] introduces a wireless data logger system for real-time monitoring with remote control capability via PC and tablet. Although it has been successfully developed, today’s industrial market demands more cost-effective systems.

In this work, wireless data logger system is designed to monitor real-time measurements, which is the combination of sensed and video recorded data, in a specified area. Furthermore, this system enables end-users to control the stored data with all Android smartphones. Hence, it provides cost effective solution for environment monitoring system. Proposed wireless data logger system may be beneficial in detecting unsafe or hazardous conditions for human health in the working or common areas. This forms the foundation for a security system with a view to protecting human health. Besides, sensor modules that used for gas detecting are protected from external effects now that these modules are not depended on external resources. Therefore, data transmission could not be interrupted from external effects which is the another advantage of the developed data logger system.

This work is developed as an industry sponsored undergraduate project. In fact, it reports the results of the system developed by undergraduate students. All development stages of the system, such as PCB layout, software, hardware and prototyping, were completed at Atılım University laboratories.

The paper starts with describing the concept of the developed system with a block diagram as given in the next section. In section III, hardware development of data logger, software architecture, development of end-user application,
II. CONCEPT OF THE SYSTEM

The system that presented in this article comprises of three main modules which are measurement, data management and On Screen Display (OSD). The block diagram of the proposed data logger system is shown in Fig. 1.

![Block diagram of the system.](Image)

In measurement module, the amount of gases released in a specified area is measured by means of gas sensors. Measured data is gathered and stored in data management module, which is the core part of the data logger system. Since used sensors are analog sensor, an Analog-to-Digital Converter (ADC) is required to read measured data. For this purpose, the data management module first converts analog data to digital one. Then, it stamps sensed data with date and time. Data storing is the last phase of the data management module. The module is able to send data to Bluetooth module, as well. This enhances the data logger to transmit the data directly to end user. The last part of the system is OSD module which retrieves time and date stamped data in order to put them on the video signals of an area that inclined to observe. It should be noted that a wireless surveillance camera is used for the purpose of observing an area. The details of the system are given in the next section.

III. SYSTEM DEVELOPMENT

This section describes the details of proposed data logger system. First, hardware of the data logger system is discussed and then, software architecture of developed system is explained. In the third part, design process of android application for end-users is described. In the last part, system implementation is presented.

A. Data Logger Structure

As discussed in Section II, the system has three main parts. In the first part, measurement module, two types of gas sensors, MQ-4 and MQ-7, are chosen to use for gas detecting as usual, in that these sensors have an ability to obtain wide range of measurements, from temperature to carbon dioxide. After selecting gas sensors, an ADC converter is required to read binary data. Due to the fact that low power consumption and flexible connectivity applications play important role in measurement systems, a 16-bit Microcontroller Unit (MCU) is chosen which contains 8-bit ADC. Digitalized sensor data are stamped with date and time by using Real Time Clock (RTC) that is connected to MCU with I2C (Inter-Integrated Circuit) protocol. Another connection with MCU is Bluetooth module. To access into MCU from Bluetooth module, UART (Universal Asynchronous Receiver/Transmitter) protocol is used. Bluetooth modules are designed to address the needs of new wireless applications. In this work, Bluetooth module enables end-users to control the stored data through a developed application for smartphones. It works on the baud rate of 9600 and has approximately the range of 12 meter. In the last stage of data management module, data is stored in a Multi Media Card (MMC) which is connected to MCU with Serial Peripheral Interface (SPI) protocol as it provides synchronous data transmission.

OSD module is the last part of the system contains another MCU for retrieving data from data management module. To provide data transmission between management module and OSD, a RF (Radio Frequency) transmitter in management module and a RF receiver in OSD module are used. Both RF modules use ISM (Industrial, Scientific and Medical)-433 MHz band. These RF modules work on the baud rate of 600 and have approximately 300 meter outdoor range. In OSD module, MCU is connected to a single-channel monochrome OSD generator (MAX7456). It is used to create on-screen menus and other video overlays. It is NTSC and PAL compatible and displays up to 16 rows × 30 characters. SPI protocol is utilized for maintaining data transmission from MCU to OSD generator. The main working principle of OSD generator is overlaying received data from MCU onto video signals recorded by a wireless surveillance camera. As a consequence, the security monitor is linked to output of the OSD generator for displaying real-time recordings with date and time stamped sensor data. The whole system is represented in Fig. 2.

![The whole picture of the hardware development.](Image)
B. Software Architecture

Since the core part of the system is MCU, data loggers require full-featured software to improve accuracy. In MCU programming, assembly language is generally utilized. However, writing assembly code is not an easy task. For this reason, high level programming languages are proposed to make complex programming to simpler. Although high level programming languages having increasing popularity, C programming language is still most useful language for MCU programming. In this work, MicroC, which provides best solution for developing C code, is chosen as a compiler for MCU in order to adapt the developed system to currently emerging technologies.

As discussed in previous section, MMC card is connected to MCU for data storage. Yet, in MMC card, there is not any special file system like FAT16 (File Allocation Table 16) or NTFS (New Technology File System). Accordingly, data is written to the sectors of the MMC card. A library, which is provided by MicroC compiler for MCU, is utilized for sector writing. Thus, written data on the sectors of the MMC card is inaccessible by the third person. This contributes to the system as a critical feature.

Software development is initiated with writing simple code tasks. With the passage of time, term by term, improvements on students’ programming skills have been observed. They have gained an ability to complete given code writing tasks, transfer them into the MCU, and carry out simulations. Main steps of the proposed data logger software are depicted in Fig. 3.

C. End-User Application

It is widely known that Android is an open and free software stack and it powers millions of mobile devices. This gives rise to select Android platform as a software application for designed data logger system. Application is developed with Eclipse program. Developed Android application has two main features. One of them is “Send Time and Date” function where the users set time and date in the main panel, and application will send request to data logger. User interface of setting time and date is shown in Fig. 4.

Once user request is transmitted to data logger through the Bluetooth module, which provides two-way communication between the application and the logger, stored data in MMC will be sent back to the end-user application as a response. The main panel of the application and received data log is shown in Fig. 5.
The other feature of the application is “Old Records” that lists the former requests of the end-users and corresponding responses from data logger. It can also send these logs to users as e-mail or SMS (Short Message Service) at any time needed. Fig. 6 shows the recorded requests and responded data logs.

Fig. 6 Recorded data logs in the application

At last, developed application enables instant access to data from the smart phones through the Android application where the end-user can control the stored data by requesting time and date.

D. System Implementation

After designing the proposed wireless data logger system, it is implemented for real-time environment monitoring. Two type of gases, propane and carbon dioxide, considered as harmful for human health, are selected to detect. Before testing phase, a wireless surveillance camera is deployed in an area. A security monitor (LCD) is connected to OSD module to observe real-time gas measurement with surveillance camera recordings. The picture captured from the security monitor is shown in Fig. 7.

![Monitoring on LCD](image)

Fig. 7 Monitoring on LCD

IV. CONCLUSIONS

In this work, a wireless data logger system that monitors real-time environmental data is designed as an undergraduate research project. Considering human health and safety, the system can detect released toxic gases in working places. It also merges time and date stamped sensor data with surveillance records for real-time monitoring. Thus, propagation of toxic gases can be prevented by using developed wireless data logger system. Moreover, an Android application is developed for the data logger system using Eclipse software. Hence, the sensed environmental data can be accessed and controlled by smartphones. The system enables end-users to run data through the system without using wireless remote controller or control unit. This provides low cost solution and instant inquiry transaction.

As a result, it is expected that presented wireless data logger system could fulfill industrial demands. In this context, it can be adapted to various applications such as mining, defense and agriculture system applications. Therefore, in future, the system that is presented in this article may be developed for commercial purposes.

ACKNOWLEDGMENT

This study has been conducted as an industry sponsored undergraduate research. This work is also supported by Atılım University under the LAP grant no: LAP-C-1213-02. The authors would like to thank technician Özgür Özen for his continuous support in prototyping process.

Abstract—in this study, used in GSM1800, Wi-Fi and WiMAX applications, high gain microstrip line feed 2 x 1 patch array antenna design work was done. Antenna simulation of this antenna design made using HFSS 3D gain and directivity characteristics were simulated. Since antenna impedance is greater than line impedance, impedance matching has been made with inset – fed microstrip line and the quarter-wave transformer. The results show that the proposed antenna parameters are sufficient for GSM1800, Wi-Fi and WiMAX applications.

Keywords—2x1 linear array antenna; gain; directivity; microstrip antennas; GSM1800; Wi-Fi; WiMAX.

I. INTRODUCTION

As a result of advances in wireless systems in new generation communications and increasing demand for wireless applications promoted the significance of low profile, integrated and high gain antenna designs. Microstrip antennas used in wireless network services, satellite and missile navigation, radar systems, biomedical field and in diverse applications have a seamless record in providing for these requirements [1]. There are studies that attempt to improve Microstrip antennas by selection of special conductors and modification of geometric structures (array of antennas) because of their disadvantages such as low gain and narrow bandwidth. Microstrip antennas produced with printed circuit technology includes a thin layer of low loss insulator material with a radiating conductive layer on one side and conductive ground layer that completely covers the non-conductive. Microstrip antennas are basically fed by the microstrip or a coaxial line. Along with technological advances, researchers have focused on different feeding structures and developed three different feeding techniques [2, 3, 4]. Several factors play a role in feeding technique selection. The most significant of these is the effective transfer of antenna power between the feed line and radiation structure with the feeding technique. This occurs thanks to impedance compliance between the layers. Unwanted radiation could cause increases in side lobe level and cross polarization amplitude in radiation diagram due to impedance discord [2]. In the present study, a microstrip line feeding technique that is easy to design and produce is presented. Due to certain planar shortages of microstrip line feeding [5], an inset fed microstrip antenna was designed. The side radiating microstrip inset fed antenna is presented in Figure 1.

Various different methods were developed to analyze microstrip antennas. The most popular models among these is transmission line model, cavity model and full-wave model. Although transmission line model is the simplest method among analysis methods, it is proficient in analyzing the physical structure. However, its accuracy is lower than the other methods and it is inadequate in modeling multilayer structures. When compared to transmission line model, cavity model has a better accuracy, however it also entails a complex structure. In addition, the cavity model is effective in physical analysis similar to the transmission line model, but this model is also not adequate for modeling multilayer structures. Full-wave model is the most accurate model among these methods. However, this model is quite complex and has low capability for physical analysis [6]. The present antenna model was designed with transmission line model. Application interface
displayed in Figure 2 was developed in NetBeans IDE 8.0.2 editor [7] using JAVA programming language.

Fig. 2 Transmission Line Mode developed using JAVA

Microstrip antennas usually have low gain. In some cases, a singular antenna could not provide the desired requirements (e.g. gain, shifting the radiation to the desired direction). Thus, to improve the performance of the antenna, an array of antennae that are formed by placing more than one antennas geometrically are utilized [2 – 8]. Due to simplicity of design and their geometrical structures, microstrip antennas are one of the most frequently used antenna arrays [9]. Each component of an antenna array could be selected from elements with different structures, but to calculate the total radiation pattern of the array, similar elements are preferred. To obtain a radiation pattern in the desired direction, radiation emitted from each antenna should be added to each other in the desired direction and should eliminate one another in undesired directions. Demand for multi-frequency antenna terminals that have the capacity to receive multiple services provided by different wireless technology networks today is increasing along with the available high gain antennas. In the present study, GSM1800 technology that contains 1.8GHz GSM frequency, Wi-Fi that contains 2.4GHz ISM frequency, and WiMAX that contains 2.9GHz ISM frequency were referenced [8].

II. ANTENNA ARRAY DESIGN

Theoretical calculations were calculated based on the transmission model. Since numerical values obtained with theoretical calculations and obtained simulation results were not at the desired level, certain parameters were changed manually to obtain adequate results. For simulation findings, High Frequency Structure Simulator (HFSS) [10] based on full-wave finite elements method and widely used in the analysis of electromagnetic structures was utilized. As insulator material “Rogers Ultralam1217™” was selected for the constructed antenna and dielectric constant ($\varepsilon_r$) was taken as 2.17, dielectric thickness ($t$) was 0.035 mm and dielectric height ($h$) was 3.175 mm. Central frequency of the antenna was designed as 2.45GHz and physical parameters were calculated using equations 1 - 6 used in the transmission line model [1 – 11] and exhibited below.

\[ W = c \sqrt{\frac{(\varepsilon_r + 1)}{2}} / 2 f_0 \]  

(1)

\[ L = \left[ \frac{c}{2 f_0 \sqrt{\varepsilon_r}} \right] - 2 \]  

(2)

\[ \varepsilon_e = \left[ \frac{\varepsilon_r + 1}{2} \right] + \left[ \frac{\varepsilon_r - 1}{2} \right] \sqrt{1 + \frac{12 h}{W}} \]  

(3)

\[ \Delta L = 0.412 h \left( \frac{\varepsilon_r + 0.3}{\varepsilon_r - 0.258} \right) \left( \frac{W}{h} + 0.264 \right) \left( \frac{W}{h} + 0.8 \right) \]  

(4)

\[ y_0 = \frac{L}{(\pi)} \arccos \left( \frac{R_\text{in}}{R_\text{in0}} \right) \]  

\[ x_0 = \frac{c}{\sqrt{2 \varepsilon_{\text{eff}}}} \frac{4.65 \times 10^{-12}}{f_0} \]  

(5)

(6)

Rectangular microstrip feed antenna input and output parameters are given in Table 1 below:

<table>
<thead>
<tr>
<th>TABLE I RECTANGULAR MICROSTRIP FEED ANTENNA INPUT AND OUTPUT PARAMETERS</th>

Where $\varepsilon_r$ is the dielectric constant for the insulator material used in the designed antenna, $\varepsilon_e$ is the effective value of the insulator material, $c$ is the speed of light, $f_0$ is the resonance frequency, $h$ is the height of the insulator material and $\Delta L$ is the line expansion. $W_f$ depicts the width of the feed line, $y_0$ depicts the position of the feeding point, $x_0$ depicts the space between the feeding point and the patch, $R_{in0}$ depicts the antenna input impedance before the feed was added, and $R_{in}$ depicts the target input impedance. In general applications, antenna input impedance is selected as 50Ω. Microstrip antenna obtained with transmission line model was multiplied to create a 2 x 1 antenna array. Microstrip lines where
Radiating patches were connected in the 2 x 1 antenna array were designed to contain a 50Ω input port. During the connection of the designed patches, input impedance of each antenna was selected as 100Ω, and quarter-wave transformer was used for input port connection. Presentation of three-band and 2-element antenna array with HFSS is given in Figure 3.

Fig. 3 Three-band and 2-element antenna array with HFSS

For microstrip transmission line shown in Figure 4, the equation of the impedance that would be measured at ℓ distance from the load impedance is shown in Equation 7.

\[ Z_0 = Z_1 \frac{Z_L + jZ_L \tan \beta \ell}{Z_L + jZ_L \tan \beta \ell} \quad (7) \]

\[ \beta = \frac{2\pi}{\lambda} \] used in the formula is the wave count.

Transformation from 100Ω to 50Ω was provided by 70Ω quarter wavelength lines. It is known that feed of an antenna separately is an adequate method to obtain best results. However, due to reasons such as practical difficulties and cost, instead of using separate sources, it was aimed to stimulate more than one antenna element with the power generated at a central resource. The structure of the 2 x 1 antenna array is presented in Figure 5. Thus, it was aimed to create a dual (2 x 1) antenna array by connecting radiating antennas adequately with microstrip lines.

Fig. 5 The structure of the 2 x 1 antenna array

One of the parameters that affect the antenna performance or demonstrate the performance quality is the return loss [12]. Acceptable return loss (RL) in antennas criterion value is -10 dB. [13]

III. EXPERIMENTAL RESULTS

In the present study, the proposed antenna was tested with HFSS simulation software. RL characteristic (S11) of the single-element antenna is presented in Figure 6 and RL characteristic of the proposed antenna is given in Figure 7.

Fig. 6. RL characteristic (S11) of the single-element antenna

Fig. 7. RL characteristic (S11) of the proposed antenna

When simulation results are analyzed based on 10 dB return loss criterion, it was observed that the maximum radiation of proposed antenna was primarily in 2.45GHz central frequency and in 1.8GHz and 2.9GHz frequencies. At central operating frequency of the proposed antenna VSWR value was obtained as 0.43dB RL -31.98dB. It was also
observed that simulation results were consistent in (RL ≥ -10dB) and (VSWR ≤ 2) interval. One of the important parameters that demonstrate the antenna performance is the gain. Antenna gain (G) given in Equation 8 is defined as a factor represented by antenna direction (D) and radiation efficiency (e) [14].

\[ G = e \times D \]  

Eq. (8)

3D gain and directionality graphs for the proposed antenna in 1.8GHz, 2.45GHz and 2.9GHz frequencies is presented in Figure 8.

![3D gain graph](image1)

![Directionality graph](image2)

Fig. 8. 3D gain (top) and directionality (bottom) graphs for the proposed antenna

Analysis of the above graphs shows that the main lobe was at the direction of z-axis, maximum gain was 10.09dB and maximum directionality was 10.14dB. The difference in gain was due to the imperfection of the utilized dielectric insulator material. Since loss tangent of the material was 0.0009, it caused a loss, albeit small. Antenna output values at the end of the simulation are given in Table 2 below.

<table>
<thead>
<tr>

</tbody>
</table>

Radiation patterns of the single-element antenna and 2 x 1 antenna array are given in Figures 9 and 10, respectively. Graphics demonstrate that antenna array radiated in the same direction at mostly angles and the side lobe levels narrowed.

IV. CONCLUSIONS

In the present study, a 2x1 antenna array suitable for GSM1800, Wi-Fi and WiMAX applications [15-16], with a central frequency of 2.45GHz and 10dB directionality was designed and simulation values were presented. The small-sized and high gain microstrip antenna had a suitable structure for the communication devices used today. S-parameters of the developed antenna array demonstrate that it could serve as a multi-frequency (GSM1800+Wi-Fi+WiMAX) functional antenna when adjusted for communication systems that operate in GSM1800, Wi-Fi, WiMAX bandwidths in outdoors.

Abstract— Wireless technology is the key technology to eliminate the dense wire ropes from hospitals and far access to medical devices. In order to overcome the problem of bandwidth scarcity, cognitive radio driven hospitals are introduced and devices are divided in two categories. The first category is primary devices and the second one is secondary devices. Primary devices have very high priority and their communication is vital for the hospital and patients, so that no interference should be made with such devices. Secondary devices are the ones which have lower priority and they can wait until the primary devices do their communication and then, they begin to use the allocated spectrum. One of the key functions to assure that there will be no interference is a reliable spectrum sensing method. This method should be a simple one to be able to implement it in the secondary devices. Among all the sensing methods, energy detection (ED) based spectrum sensing is very popular. In order to improve the performance of ED, double threshold ED (DTED) method is introduced in literature. In this paper, a new algorithm is intruded for DTED considering previous sensing period results in detection procedure by using a memory stick. Memoryful DTED (MDTED) improves the performance of DTED considerably by only the cost of delay in secondary devices communication which has less value than the improvement of the detection method performance.

Keywords— wireless technology hospitals, cognitive radio driven hospitals, spectrum sensing, energy detection, double threshold energy detection, memory.

I. INTRODUCTION

It has been a long while that biomedical and e-health experts are trying to use wireless technologies in their field. The main purpose of this matter, instead of eliminating the dense wire ropes from the hospital environment, is to provide access from distance to the devices in the environment [1]. To meet this requirement, the number of wireless technology based hospitals grow so fast that after a while the problems began to appear. One of the most important problems was the scarcity of bandwidth. The bandwidth of the medical wireless communication is limited because of static requey allocation which is done by governmental and non-governmental commissions. In united states, the responsibility of spectrum allocation is with Federal Communications Commission (FCC). In order to mitigate the scarcity of the spectrum, cognitive radio driven hospitals (CogMed) are introduced by researchers [2].

In this cognitive radio driven hospitals, devices are categorized as primary and secondary devices. Primary devices are the ones that are vital and have higher priority to have communication. Secondary devices are the ones which have low priority and they can wait until the frequency band get vacant. So that, primary devices should not be interference by other devices as their data are so valuable. In cognitive radio technology, the secondary users sense the bandwidth and in the case of vacancy, the begin communication, otherwise, they wait for predetermined moment and sense the frequency band again [1]. There are many sensing algorithms including ED, matched filtering, wavelet based detection, cyclostationary detection [8] and covariance based detection [7] methods with their different required parameters, advantages and disadvantages. For instance, cyclostationary sensing methods needs the data about the cyclic frequency of the primary user and in matched filter sensing method, the waveform information is needed [4]. As mentioned before, each sensing method has its own advantages and disadvantages that makes them unique in their kind, but in practice, the most important factor is the simplicity of the used method. Among all the methods mentioned, ED method is the most simplest one to use in devices. ED method is based on comparison of the energy of collected samples with a threshold calculated before [3] – [5]. In order to improve the performance of ED sensing method, cooperative sensing method and DTED are introduced in literature [6]. Cooperative ED spectrum sensing is not practical solution for CogMed as there are many devices and in the case that each device use multiple sensing nodes, too complicated and busy environment will be the result of this process. The second solution is using double threshold instead of single one. In double threshold the detection is made comparison of the energy of the signal with two pre-calculated thresholds [4]. This process has improved the performance of ED method considerably, but for CogMed usage, as the inter symbol interference (ISI) with primary users could cost somebodies life, the performance should be much higher with little additional computational complexity. In this paper we recommend to use memory for the secondary user devices, so that, in the detection procedure, they could consider the result of the previous sensing period. By MTD, in the case of any error in the sensing period, the previously gathered information will help the algorithm to check the status of the channel previously.
The rest of the paper is organized as follows. In section II, the system model, ED method and some background information are provided. In section III, DTED and MTDTE methods are introduced. In Section IV simulation results and analysis is done, followed by concluding remarks in section V.

II. ENERGY DETECTION, SYSTEM MODEL AND BACKGROUND

The spectrum procedure in cognitive radio secondary medical devices is a binary hypothesis. Hypothesis $H_0$ is the condition which the primary user is having a data transfer and in the case of beginning communication, interference will occur. Hypothesis $H_1$ is when the primary user doesn’t use the spectrum and secondary user can use the spectrum [9]. These two hypothesis can be shown as follow:

$$y(t) = \begin{cases} \eta(t) : H_0, \\ h(t)x(t) + \eta(t) : H_1 \end{cases}$$ (1)

where $y(t)$ is the received signal by secondary user, $x(t)$ is the signal used for primary user, $h$ is the communication channel gain and $\eta(t)$ is additive white Gaussian noise (AWGN) which is assumed to be stationary process that satisfy $E(\eta(t))=0$ and $\text{Var}(\eta(t))=\sigma^2_\eta$ [4]. Nakagami-m fading distribution is the most used distribution in real life communication wireless channels. This model can be presented as below:

$$P_r = \frac{2m^m}{\Gamma(m)} \frac{x^{m-1}}{\sigma^2_\eta} \exp\left(-\frac{mx^2}{\sigma^2_\eta}\right), \quad m \geq \frac{1}{2}, \quad x \geq 0$$ (2)

$$\Gamma(m) = \int_0^\infty y^{m-1} e^{-y} \, dy, \quad m > 0$$ (3)

that $m$ varies based on the channel characteristics. A Rayleigh fading channel can be modelled when $m$ is equal to one and the a Gaussian channel can be modelled when $m$ goes to infinity. $\Gamma(.)$ is a gamma function.

Energy detection based spectrum sensing detector is consist of a pre-filtering system, square law device and a finite time integrator. The output of the integrator is normalized and can be shown as follow [3-5]:

$$E(t) = \frac{1}{N} \sum_{n=0}^{N-1} |x(t)|^2$$ (4)

where $N$ is the number of samples collected by the secondary user receiver. As the received signals are unknown, the gathered samples can be treated as random processes. So, the transmitted signal samples follows and independent and identically distributed (i.i.d.) random processes with mean equal to zero and variance equal to $\sigma^2_x$. The received signal $t$ noise ratio (SNR) at the detector which we show it by $\beta$ symbol from now on is equal to $\frac{|h|^2\sigma^2_x}{\sigma^2_\eta}$. Assuming the number of collected signals large enough, using central limit theorem, the probability density function (PDF) of $E(t)$ in hypothesis $H_0$ becomes a normal distribution with mean equal to $N\sigma^2_\eta$ and variance equal to $N\sigma^2_\eta$. PDF of $E(t)$ in hypothesis $H_1$ becomes a normal distribution with mean equal to $N(1+\beta)\sigma^2_\eta$ and variance equal to $(1+2\beta)N\sigma^2_\eta$. The probability that the detector detects the presence of signal under hypothesis $H_0$ is $P_d$ and the probability that the detector detects the presence of signal under hypothesis $H_1$ which is called probability of detection ($P_d$) can be shown as follow:

$$P_{d_0} = \text{prob}(E(t)> \lambda |H_0) = \Gamma(u)^{-1} \Gamma(u)$$ (5)

$$P_{d_1} = \text{prob}(E(t)> \lambda |H_1) = \frac{Q\left(\sqrt{2\beta \sqrt{\lambda}}\right)}{\sqrt{2\beta \sqrt{\lambda} \Gamma(u)^{-1} \Gamma(u)}}$$ (6)

In IEEE802.22, the $P_{d_0}$ is given but for different values, threshold based on $P_{d_0}$ which we are going to simply call it threshold can be calculated as follow:

$$\lambda_\alpha = \sigma^2_\eta \left(1 + \frac{\sqrt{2Q^{-1}P_{d_0}}}{\sqrt{\eta}}\right)$$ (7)

and the threshold based on $P_{d_1}$ at a given SNR can be shown as follow:

$$\lambda_\alpha = \sigma^2_\eta \left(1 + \frac{\sqrt{2Q^{-1}P_{d_1}}}{\sqrt{\eta}}\right)$$ (8)

Based on ED algorithm, the normalized energy of the gathered signal samples is compared with the pre-calculated threshold and in the case that the normalized energy is equal or bigger than the threshold, cognitive radio based secondary device detects the presence of the primary user and doesn’t start its communication. In the case that the normalized energy is less than the threshold, it begins its communication.

III. DOUBLE THRESHOLD ENERGY DETECTION AND MEMORYFULL DOUBLE THRESHOLD ENERGY DETECTION

DTED method is introduced in literature to improve the detecting performance of ED and make this method more reliable. By a little error, the sample energy can pass the threshold or can be less than the threshold defined. The main purpose in this sensing algorithm is defining a restricted area near threshold that contains these faulty samples and eliminate them from the detection process as they are more likely to cause an error. Restricted area constant (RAC) is shown as $\Delta$ and defined as below [6]:

$$\lambda_1 = (1-\Delta) \lambda \quad \text{As lower boundary}$$ (9)

$$\lambda_2 = (1+\Delta) \lambda \quad \text{As higher boundary}$$ (10)

In DTED algorithm, the samples are lower than $\lambda_1$ and higher than $\lambda_2$ are used for detection process. If the normalized energy of the received signals is lower than $\lambda_1$ the secondary medical device concludes that the spectrum is vacant and in the case that the received signal is higher than the value of $\lambda_2$, the decision is accuracy of it [4]. In DTED method, the probability of the energy be between boundaries in condition of hypothesis $H_0$ is shown as $P_0$ and in the case that the probability of the energy be between boundaries in condition of hypothesis $H_1$ is shown as $P_1$. $P_{d_0}$, $P_{d_1}$, $P_1$ and $P_0$ probabilities can be shown as follow:

$$P_{d_0} = \text{prob}(E(N)> \lambda_0 |H_0) = \Gamma(u)^{-1} \Gamma(u)$$ (11)

$$P_{d_1} = \text{prob}(E(N)> \lambda_1 |H_1) = Q\left(\sqrt{2\beta \sqrt{\lambda_1}}\right)$$ (12)

$$P_0 = \text{prob}(\lambda_1 < E(N) < \lambda_2 |H_0) = \left(\frac{\lambda_1}{\sqrt{2\beta \sqrt{\lambda_1}}} - \frac{\lambda_2}{\sqrt{2\beta \sqrt{\lambda_1}}}\right)$$ (13)

$$P_1 = \text{prob}(\lambda_1 < E(N) < \lambda_2 |H_1) = \left(\frac{\lambda_1}{\sqrt{2\beta \sqrt{\lambda_1}}} - \frac{\lambda_2}{\sqrt{2\beta \sqrt{\lambda_1}}}\right)$$ (14)
As mentioned earlier, reliability is the most important factor in CogMed and having multiple detectors for having cooperative detection is not possible. MDTED is a novel approach to DTED which improves the detection performance of it. This algorithm is based on saving the energy of last T previously sensed signal samples and detection is made considering these energies. Collection of T consecutive energy samples can be shown as follow:
\[ M_i(y) = \{ E(y_{i-1}), E(y_{i-2}), E(y_{i-3}), \ldots, E(y_i) \} \]

In the case that the maximum of these decision energies fall below the threshold \( \lambda_1 \) the detection process decides the hypothesis \( H_0 \) and in the case that the maximum is higher than \( \lambda_2 \) the detection process decides the hypothesis \( H_1 \). If the maximum is between \( \lambda_1 \) and \( \lambda_2 \) in any way, the next maximum value is going to be used until it doesn’t be in the restricted gap. Because of environment in real life doesn’t change rapidly and in high order by time, this method will help our detection system to not only have the results of the time, it will use previously gathered information also that will help decision process in big range. Considering the improvement of detection process performance and reliability, T-1 sensing period delays can be bearable. Also by choosing T small enough, it is possible to make the delay minimum. The algorithm of MDTED is as follow:

**Algorithm 3. MDTED spectrum sensing method**

Input : T, \( \lambda_1, \lambda_2, \sigma_i \)

Output : \( Y_i \)

1: for each sensing period do
2: for \( \zeta = 1:N \) samples do
3: if \( \lambda_0 < \text{sample energy} < \lambda_2 \) then
4: do nothing
5: else
6: \( e_i(t) \leftarrow \text{Energy of sample} \zeta, \zeta \in \{1,2,\ldots,N\} \)
7: end for
8: \( e(t) \leftarrow \text{normalized energy of the selected total} e_i(t) \) samples
9: \( M_i(y) \leftarrow \text{Energy of previous T received signals and} e(t) \)
10: \( M(t) = \text{MAX} \{ M_i(y) \} \)
11: if \( \lambda_0 < M(t) < \lambda_2 \) then
12: \( Q_i(y) = M_i(y) - M(t) \)
13: \( M(t) = \text{MAX} \{ Q_i(y) \} \)
14: end if
15: if \( M(t) < \lambda_1 \) then
16: \( Y_t \leftarrow H_0 \)
17: else
18: \( Y_t \leftarrow H_1 \)
19: return \( Y_t \)
20: end for

**P_0, P_0, P_0 and P_1 can be calculated as follow:**

\[ P_0= p(M(t) > \lambda_2 | H_0) = p(E(\gamma_i) > \lambda_2, E(\gamma_{i-1}), \ldots, E(\gamma_{i-T}) > \lambda_2 | H_0) = \]
\[ p \left( \frac{\lambda_2 - \mu_d^2}{\sqrt{2\sigma_d^2 + \sigma_i^2}} \right) T^{-1} \]

\[ P_0 = p(\lambda_1 < M(t) < \lambda_2 | H_0) = \left( \frac{\lambda_2 - \mu_d^2}{\sqrt{2\sigma_d^2 + \sigma_i^2}} \right) T^{-1} \]

**MBED detection performance is analysed and compared with DTED method in section IV.**

**IV. SIMULATION RESULTS AND ANALYSIS**

In this section the performance of DTED is studied, analysed and compared with very well-known DTED. All simulations are done in MATLAB software using QPSK modulated random signals and i.i.d. noise samples with Gaussian random variables. It is assumed that the channel doesn’t change while sampling in each sampling period. Based on IEEE 802.22, \( P_0 \) should be less or equal to 0.1 and \( P_1 \) be more than 0.9. In the simulations \( P_0 \) is chosen as 0.1 and 10^3 test signals are used and averaged. DTED and MDTED is studied with RAC equal to 0.5 and in memory section, T is equal to 2 unless it is told to be different. T equal to 2 mean the detection method needs 2 previously sensed normalized energies that should be saved in memory and be used in the detection procedure.

Figure 1 shows the performance of ED, DTED and MDTED in Gaussian channel models. Gaussian channel is the simplest channel model among all communication channel models. MBDTED with a memory equal to 2, has a much better performance compared to DTED and ED in all SNR ranges. With only saving 2 previously sensed signals energy in detection process, a high range of performance can be achieved. Unlike DTED, the performance of MBTDN doesn’t diminish suddenly in low SNRs like DTED.

**Figure 1. ED, DTED and MBDTED sensing methods performance over Gaussian channel.**

Figure 2 show the performance of ED, DTED and MBDTED in Rayleigh channel which is known as one of the worst communication channels. In this kind of channel, MBTDN again has a better performance compared to both DTED and
ED also in all SNR ranges by only the delay of 2 sensing periods.

Choosing the value of memory, based on the communication channel estimated in the cognitive radio driven hospitals and acceptable delay in the sensing procedure, we can have the best performance needed in such areas.

V. CONCLUSION

Memory based double threshold energy detection or in other words, double threshold energy detection with memory sensing algorithm is introduced in this paper. It is shown that using memory and saving the previously received signals energy in the defined algorithm can affect the sensing performance and improve the detection performance of the energy detection based spectrum sensing in very high range. DTED was defined in literature to improve the performance and reliability of ED method. We compared the MBDTED with ED and DTED methods in Gaussian and Rayleigh channels by using only 2 previously saved signals and we saw the performance of this method is much higher than both ED and DTED in wide SNR range. Disadvantage of this method is the time delay after the channel is free but considering the improvement of the sensing performance, T sensing period delay for the secondary user in order to detect the vacancy of the signal could be bearable in cognitive radio driven hospitals. Also, by choosing T and periodic sensing distance small enough, we can make the delay minimum. This research findings help to understand the effect of the memory in a sensing method and advantage and disadvantages of that which helps find optimal solutions to fulfill fundamental sensing requirements in IEEE 802.22 WRAN.

Abstract— The aim of this paper is to compare the performance evaluation in terms of the efficiency, coggng torque and manufacturing cost for a permanent magnet synchronous generator (PMSG) with interior rotor of N35 and N42 NdFeB permanent magnets (PMs) having same geometry separately used in a micro wind turbine (MWT). Firstly N35 type PMs have been used on an interior rotor, and then its performance has been measured and calculated by a MWT setup. After that, N42 type PMs have been used on other interior rotor. According to the obtained results, the PMSG with N42 type presented better efficiency than the PMSG with N35 type. But the PMSG with N42 type has induced a bit more coggng torque than the PMSG with N35 type. When comparing in terms of efficiency, a higher efficiency has been obtained by the PMSG with N42 type.

Keywords— PMSG, PM, efficiency, NdFeB, N42, N35

I. INTRODUCTION

Nowadays, the usage of renewable energy resources such as wind, geothermal, tidal and solar in electricity production is gradually increasing. Wind energy is the most popular of these renewable energy resources. In order to convert wind energy into electrical energy, wind turbines are employed [1].

Wind turbines are divided into two classes as large wind turbines (LWTs) and small wind turbines (SWTs) [2]. While LWTs usually are operated as grid-on, SWTs are utilized as both grid-on and grid-off. Furthermore, as given in Table I, SWTs are separated into three different classes [3]. According to the power of SWTs in Table I, there are SWT types employed by direct-drive and gear mechanism systems [1].

Depending on the powers of SWTs, induction generators (IGs) and permanent magnet synchronous generators (PMSGs) are widely preferred [4]. PMSGs used SWTs are more advantageous than IGs because they have more power density, higher torque and direct-drive ability [5]. Structure of PMSG is simple and their maintenance is easy [6]. There is also no copper loss on rotor. However, one of the biggest disadvantages is their coggng torque [7]. Because of the high coggng torque, they do not commence electrical energy generation at low wind speed [2].

SWTs are designed as horizontal and vertical axis. Also, PMSGs inserted in SWTs are manufactured two types as outer and interior rotors [2, 8]. Although the PMSGs with interior rotor have more size than the PMSGs with outer rotor, their power density, moment, and efficiency are high. But, when considering in terms of manufacturing cost and labor, manufacturing cost and labor of the PMSGs with interior rotor are higher than the PMSGs with outer rotor. In addition to these, PMSGs are constructed as axial and radial flux [9-10]. Output voltage and torque of the PMSGs with radial flux are greater than the axial flux [11].

II. PERMANENT MAGNETS

Permanent magnet (PM) forms and elements that are used in PMSGs have a great impact on performance of PMSGs [12-14]. PM forms, which are placed on an interior rotor with four poles, are illustrated in Fig. 1. A surface radial, a parallel, a breadloaf and a ring PM form are presented in Fig. 1. These are classified as the PMSGs with surface PM rotor. Additionally, there are also the types of PMSG with PMs that are embedded in a rotor.

Magnetization profiles also are important during the PM usage. These are sine angle or sine direction, parallel, radial sine and radial profile. In addition, these are illustrated in Fig. 1 and the most popular of which is the parallel magnetization.

PMs are made up of Aluminium-Nickel-Cobalt (AlNiCo), Ferrite, Samarium-Cobalt (SmCo), and Neodymium-Iron-Boron (NdFeB) materials. Their operating temperatures and magnetic flux density-magnetic field intensity ($BH_{max}$) are

different from each other. The values are given in Table II. When Table II is examined carefully, although NdFeB PMs have the highest $BH_{\text{max}}$ value, their operating temperatures are lower than others. Recently, NdFeB PMs are widely preferred in PMSG design. [15-16].

The remanence magnetization value ($B_r$) of AlNiCo magnets among them is quite high. Due to the fact that they are expensive and also can easily lose their magnetization property, they are not preferred lately.

Ferrite magnets being another type of PMs that are relatively lower cost and more commonly usage than AlNiCo PMs. They are resistant to the loss of remanence magnetization. $BH_{\text{max}}$ values of both AlNiCo and Ferrite PMs are lower than SmCo and NdFeB PMs.

SmCo and NdFeB PMs are known as rare-earth magnets. Their $BH_{\text{max}}$ values are quite high compared the AlNiCo and Ferrite PMs. One of their biggest disadvantages is that they are fragile. The remanence and demagnetization values are high.

In recent years, the remanence values of the sintered NdFeB PMs are increased above 1.0 T. In Table III, properties of N35 and N45 type NdFeB PMs that are sintered at different grade are listed. Their performance analysis two type PMs were carried out in a micro wind turbine (MWT). The sintered PMs offer up to 150°C operation temperatures. After the operation temperatures, SmCo PMs are preferred. SmCo PMs also have different temperatures. Their operation temperatures rise at 250°C. Studies continue to increase the operation temperatures of NdFeB and SmCo PMs.

**III. APPLICATION**

Two rotors with surface magnet having N35 and N42 NdFeB PMs were designed and manufactured. The dimension of PMs was sized as $20 \times 20 \times 6$ mm. The usage of the rotor together with a PMSG stator is demonstrated in Fig. 2. A designed MWT, the stator and the rotor dimensions are presented in Table IV. To reduce the cogging torque, the used PMs were selected in a breadloaf form. Moreover, to reduce the cogging torque, their placement was fulfilled according to a pole shifting method [7].

After the rotors that manufactured two prototypes had inserted in the PMSGs, they were mounted in the MWT, as given in Fig. 3. Lastly, their performance tests were carried out by means of a truck test [2]. During the truck test, the generated power from the MWT was transferred to a battery group, which was consisted of four batteries of 12 V and 60 Ah. The battery group was charged until 13.5 V. After the charge, two load resistances of 600 W were used to discharge to the battery group. In order to measure the generated power from the MWT with PMSGs used N35 and N42 NdFeB PMs, a data acquisition system, which was described and embedded formulas in detail [2], was operated. The measurement of input power of the MWT was realized by two different calibrated anemometers – one was Prova AVM-03, the other was Kestrel 3000 model. In addition to these measurements, wind speed was also checked by the truck display. The ambient temperature was registered by both the data...

acquisition system and Extect HD200 measurement instrument. To define the cogging torque, Crane Electronics/UTA-451-0020-OP 5 Nm brand/model transmitter and Crane Electronics/TO-890-01CR-0-EUR brand/model display, which was described in detail [7], were utilized.

IV. RESULTS AND DISCUSSION

The truck test was carried out by using of the PMSGs having two rotors with surface magnet separately used N35 and N42 NdFeB PMs in the MWT. The air pressure was taken as 1020 hPa to calculate the input power of the MWT. The air density was obtained 1.221 kg/m³.

In the MWT having the PMSG with the surface magnet rotor used N35 NdFeB PMs, the cut-in was measured 2.7 m/s. In other, which was the MWT having the PMSG with the surface magnet rotor used N42 NdFeB PMs, the cut-in was taken 4.1 m/s.

Depending on wind speed, the generated powers from the MWTs and their power coefficients are presented in Fig. 4 and 5. When Fig. 4 was examined, the nominal power of the MWT that has N35 NdFeB PMs at 11 m/s wind speed was 177 W. Also, the nominal power of the MWT that has N42 NdFeB PMs at 11 m/s wind speed was 210 W. In Fig. 5, the power coefficients of the MWTs having N35 and N42 NdFeB
PMs were defined 0.277 and 0.388, respectively.

The highest cogging torques of the MWTs having N35 and N42 NdFeB PMs were measured as 0.1 Nm and 0.17 Nm, respectively, as shown in Fig. 6. In the MWT with N42 NdFeB PMs, the cogging torque was occurred a quite high value. In order to reduce the value, it is necessary that other cogging torque reduction methods have to be used together with the pole shifting method.

When examining the literature regarding the study, Lee et al. [8] executed a study with outer rotor PMSG. The cogging torque of about 0.18 Nm was measured in their application used PMs of Br 0.43 T. Also, Jang et al. [10] manufactured an MWT of 1.5 kW employed both NdFeB of 1.26 T and Ferrite type PMs. They tried on the usability of Ferrite PM instead of NdFeB PM. Although the PMSGs generated same power, the PMSG with Ferrite type PM had larger volume than the PMSG with NdFeB PM in reference to their results. They saw an increase of manufacturing cost. At low speed conditions, Ani et al. [17] compared six different SWT in terms of the energy yield and the generated electricity cost. Their cut-in speeds were observed between 2.5 and 4.0 m/s. The manufactured MWT with N35 type PM was compared with regard to cut in, manufacturing cost, energy yield and generated electricity cost in [2] in detail. Because of the usage of N42 type PMs, a small increase of 20 € occurred in the manufacturing cost of MWT. The value was below 1%. According these obtained results, these were quite acceptable when the carried out study was compared the other studies in literature.

**V. CONCLUSIONS**

In this study, the performance analyses of both N35 and N42 type PMs for interior rotor PMSGs were carried out. For this purpose, two surface-mounted rotors that had N35 and N42 NdFeB PMs were designed and manufactured. These were tried on an MWT with PMSG inserted in the rotors separately. According to the obtained data, the generated nominal power of the MWT having N35 NdFeB PMs was obtained 177 W. For the other MWT having N42 NdFeB PMs, the generated nominal power was measured 210 W. When compared their power coefficients, an improvement of 18% was calculated in the MWT having N42 NdFeB PMs in reference to the MWT having N35 NdFeB PMs. However, the cogging torque increased 1.7 times in the MWT having N42 NdFeB PMs. On the other hand, the usage N42 NdFeB PMs increased only 1% in the manufacturing cost of MWT.

Abstract—Hodgkin-Huxley (HH) neuronal model has been widely accepted neuronal model in neuroscience. The variation of the ionic currents in neuron cell causes the variations in the membrane potential. The level of membrane potential indicates the activation and inactivation dynamics. In this paper, in order to observe the unmeasurable states and parameters of HH neuron accurately, Runge-Kutta discretization based nonlinear observer is designed. In numerical simulations, the membrane potential is measured and the ionic currents are estimated. The numerical results provide accurate estimation results that can be used both in monitoring and control of neuron dynamics.

Keywords—Nonlinear observer, state estimation, Hodgkin-Huxley neuronal model, discretization based gradient observer, sliding-mode observer, extended Kalman filter, RMSE.

I. INTRODUCTION

Mathematical model of a biological system presents an understanding for the behavior of the system. Recently, mathematical models of the bacteria populations, diseases, microbiological organisms and nerve cells have increasing applications for biology, medicine, biomedical, neuroscience fields. In this work, we have interested on Hodgkin-Huxley neuronal model. In general, nervous systems have very complex structures with largely interconnected neuron cells. These neurons carry out the computational and communication tasks with electrical potentials. The charge ionic distribution of the neuron cell generates of the electrical potential on the membrane potential. When a membrane has enough action potential, then firing threshold can be reached then there exist spikes on the membrane voltage [1]. The communication with neighboring neurons or the information patterns stored on the neurons are occurred based on this membrane potential such that the control of the membrane potential by ionic currents is an important subject of the neuroscience and biomedical engineering.

In neuroscience, Hodgkin-Huxley (HH) model is a first introduced model of the neuron cell [2]. The mathematical model of the HH model explaining the relations between membrane potential and ion channels is experimentally constructed using the electrical behavior of the giant axon in squad. In fact, it is a five state model that are the membrane potential and four ion channel currents modeled as an electrical circuit. Based on the HH model, there are developed electrical circuits to realize its behavior and stimulate under different conditions. At the same time, in order to produce practical and implementable neuron model, different neuron models are developed based on the HH model such as namely FitzHugh Nagumo model (FHN), Morris-Lecar model, Hindmarsh-Rose model and etc. [1]. In order to analyse the behaviour of neuron models, some of models are realized using electronic components [3]-[5].

Nonlinear observers have been used for considerably amount of applications in the subject of such as state estimation, parameter estimation, fault detection and isolation, disturbance estimation, unknown input estimation and other applications. Therefore, in literature, various types of the nonlinear observers can be found for a specific application. As a leading work on state observers have been first published for linear systems [6], and then extended for nonlinear systems [7]. With the requirements on the state estimation, there have introduced several nonlinear observers such as extended-Luenberger observer [8], extended-Kalman filter [9], sliding-mode observer [10], [11], high-gain observer [12], Takagi-Sugeno fuzzy observers [13], Runge-Kutta observer [14]-[16] etc. The nonlinear observers mentioned above are based on the mathematical model of the nonlinear system.

In this study, some of nonlinear observers are chosen to estimate the states of HH neuronal model. For the HH neuronal model, the membrane potential is assumed to be measurable but the currents or auxiliary variables are assumed to unmeasurable. The aim is to estimate the unmeasurable states of the HH neuron model for an observer based future work such as in neuroscience medicine; there exist some mental diseases to treat using external stimulus of the nerve cells. The designed observers are selected purposely such that extended Kalman filter (EKF), sliding-mode observer (SMO), and discretization based gradient observer (DBGO). The chosen and designed nonlinear observers are applied to estimate the states of the HH neuron model then estimation results are plotted and root-mean squared errors (RMSE) are given in Table. As a general result, state estimation results are accurately obtained for the HH

neural model of future applications in neuroscience, biomedical engineering and medicine.

This paper is organized as follows: In Section 2, nonlinear observers, which are designed here, are explained in detail. Section 3 presents the Hodgkin-Huxley neuron model with mathematical dynamics. The Section 4 illustrates the state estimation results of the HH neuronal model using designed nonlinear observers. The discussions about the design conditions and application results of the observers are given in Section 5.

II. NONLINEAR OBSERVERS

Consider a nth order continuous-time nonlinear multi-input multi-output (MIMO) system:

\[
\begin{align*}
\dot{x} &= f(x,u) \\
y &= g(x,u) \\
x_i(t) &\in X_i, u_i(t) \in U_i, \forall t \geq 0 (1)
\end{align*}
\]

where \( x(t) \in X \subset \mathbb{R}^n \) is the state vector, \( u(t) \in U \subset \mathbb{R}^m \) is the vector of measured control inputs and \( y(t) \in \mathbb{R}^p \) is the vector of outputs measurements. Nonlinear dynamics are subject to state and input constraints written as

\[
\begin{align*}
X_i &= \{x_i \in \mathbb{R}^n | x_{i_{\min}} \leq x_i \leq x_{i_{\max}} \} \\
U_i &= \{u_i \in \mathbb{R}^m | u_{i_{\min}} \leq u_i \leq u_{i_{\max}} \}.
\end{align*}
\]

It is assumed that the functions \( f_i \) and \( g_j \) \([i = 1, ..., N] , [j = 1, ..., Q]\) are known and continuously differentiable with respect to the control inputs and the state variables and also the state variables are not available for measurement. The problem is to get the estimates \( \hat{x}(t) \) of the unmeasured states of the system (1) by using only the available input and output measurements. The nonlinear system is given in Eq. (1) is discretized to get samples from the time instants. The Runge-Kutta (RK) discretization method is adopted for obtaining discretized models of the continuous-time nonlinear system. The states and the output values of the system which belong to the next sampling time as in compact form can be predicted as

\[
\begin{align*}
\hat{x}[n+1] &= f(\hat{x}[n], u[n]) = \hat{x}[n] + k[n] \\
\hat{y}[n] &= g(\hat{x}[n], u[n])
\end{align*}
\]

where

\[
k[n] = \sum_{i=1}^{N} \left[ \begin{array}{c}
\frac{1}{6} \left( k_{11} + 2k_{12} + 2k_{13} + k_{14} \right) \\
k_{21} + 2k_{22} + 2k_{23} + k_{24} \\
k_{31} + 2k_{32} + 2k_{33} + k_{34} \\
\vdots \\
1 \end{array} \right]
\]

\[
k_{ij} \text{ variables with } i = 1, ..., N \text{ and } j = 1, ..., N \text{ are explicitly defined as}
\]

\[
\begin{align*}
k_1 &= T_f f(\hat{x}, u) \\
k_2 &= T_f f(\hat{x} + 0.5k_1, u) \\
k_3 &= T_f f(\hat{x} + 0.5k_2, u) \\
k_4 &= T_f f(\hat{x} + k_3, u)
\end{align*}
\]

where it is called as the discretized model of the continuous-time system. For a Lipschitz nonlinear system the stability of RK discretization is shown using sufficiently small step size [17].

A. Extended Kalman Filter

The EKF uses a recursive algorithm consisting of two parts namely prediction and measurement correction [9]. Consider the following state-space model of a discretized nonlinear dynamic system of (1) the states of which are to be estimated,

\[
\begin{align*}
x[n + 1] &= f(x[n], u[n]) + w[n] \\
y[n + 1] &= g(x[n], u[n]) + v[n]
\end{align*}
\]

\[
w \sim N(0, Q) \\
v \sim N(0, R)
\]

where \( x[n] \) is a N-dimensional state vector, \( u[n] \in \mathbb{R}^k \) is the vector of input signals and \( y[n] \in \mathbb{R}^p \) is the vector of output signals. In (6), \( f(\cdot) \) is the discrete model of the nonlinear system. The random variables \( w \) and \( v \) represent the process and measurement noises, respectively, which are assumed to have independent and normal probability distributions with zero mean. Moreover, they have uncorrelated \( Q \) and \( R \) noise covariance matrices. In the measurement correction stage a posteriori state estimates \( \hat{x}[n] \) and the a posteriori error \( P[n] \) are calculated using current measurements and the observer model. Thus, error covariance of the estimator is minimized. Time update equations for prediction stage are as follows,

\[
\begin{align*}
\hat{x}[n] &= f(\hat{x}^-[n-1], u[n-1]), \\
\end{align*}
\]

Similarly, measurement update equations related to correction stage are,

\[
\begin{align*}
P^-[n] &= (1 - Y[n]H[n])P^-[n],
\end{align*}
\]

where \( \hat{x}^-[n] \) is state estimation vector, \( Y[n] \) and \( P[n] \) matrices are Kalman gain and error covariance matrices, respectively. It is assumed that the functions \( f(\cdot) \) and \( g(\cdot) \) are differentiable with respect to \( x \) and \( u \) parameters where \( A[n] \) and \( H[n] \) matrices are the Jacobian matrices as

\[
\begin{align*}
A[n] &= \frac{\partial f}{\partial x} \bigg|_{x=\hat{x}^-[n-1], u=u[n-1]} \\
H[n] &= \frac{\partial g}{\partial x} \bigg|_{x=\hat{x}^-[n-1], u=u[n-1]}
\end{align*}
\]

These matrices, which are updated at every sampling time, are used recursively in prediction and correction update equations of the EKF.

B. Sliding-Mode Observer

The sliding-mode observers are known for robustness to uncertainties and finite-time convergence properties [10], [11]. SMOs construct a sliding-motion of output estimation error between the measured system output and observer output. There are some applications of the SMOs for state and parameter estimation of nonlinear systems [18], [19]. One of the states is measured and the estimated states are corrected using measurement error in a switching function and multiplying by a feedback constant. For the state estimation of
nonlinear system (1), classical sliding-mode observer is designed as follows.

\[
\begin{align*}
\dot{x}_1[n] &= -h_1 e_m[n] + \hat{x}_2 - d_1 \text{sign}(e_m[n]), \\
\dot{x}_2[n] &= -h_2 e_m[n] + \hat{x}_3 - d_2 \text{sign}(e_m[n]), \\
\vdots & \\
\dot{x}_N[n] &= -h_N e_m[n] + \hat{f} - d_N \text{sign}(e_m[n]).
\end{align*}
\]

(10)

where \(e_m[n] = \hat{x}_m[n] - x_m[n]\) is the measurement error and \(x_m\) (\(m = 1, N\)) is the single available measurement. The function \(f(x[n], u[n])\) is an approximation of \(f(x[n], u[n])\).

For bounded input case of the nonlinear DBGO, the DBGO state updates are performed as

\[
\begin{align*}
\Delta \hat{x}[n+1] &= \hat{x}[n] + (\hat{T}[n] \alpha[n+1] + \mu) I , \\
\hat{y}[n+1] &= \hat{g}(\hat{x}[n+1], \hat{u}[n]).
\end{align*}
\]

(17)

where \(I\) is \(N \times N\) identity matrix, and change of the states is

\[
\Delta \hat{x}[n] = (\hat{T}[n] \alpha[n] + \mu) I \hat{e}[n].
\]

(18)

For bounded input case of the nonlinear DBGO, convergence was proved in [15].

III. HODGKIN-HUXLEY NEURONAL MODEL

The Hodgkin-Huxley (HH) model is a mathematical model that describes how action potentials in neurons are initiated and propagated [2]. HH model defines the electro-physiological behavior of a neuron. The interoperability of neuron’s is important for memory, calculation, motion control and diseases such as epilepsy. Also, synchronized activity and temporal correlation are fundamental tools for encoding and exchanging information for neuronal information processing in the brain [2].

It is a set of nonlinear ordinary differential equations that approximates the electrical characteristics of excitable cells. The basic single HH neuron is described by a Markov model as a set of nonlinear ODEs:

\[
\begin{align*}
C \dot{V} &= -g_N a_m h(V - V_{Na}) - g_K n^4 (V - V_K) - g_L (V - \text{in}) \\
&= a_m (V)(1 - m) - \beta_n(V) n, \\
&= a_h(V)(1 - h) - \beta_h(V) h, \\
&= a_N(V)(1 - N) - \beta_N(V) n,
\end{align*}
\]

(19)

where \(C\) is the membrane capacitance and \(V\) is the membrane potential. \(m, h, n\) are the gating variables. They represent the activation of the sodium flow current, the inactivation of the sodium flow current and activation of the potassium flow current, respectively. The spikes are generated with very low current levels. The explicit form of the functions \(a_m(V), a_h(V), a_N(V), \beta_m(V), \beta_h(V)\) and \(\beta_N(V)\), which
describes the transition rates between open and closed states of
the channels in Eq. (19), are given below:
\[ a_m(V) = 0.1(V + 40)/(1 - \exp(-(V + 40)/10)), \]
\[ \beta_m(V) = 4\exp(-(V + 65)/18), \]
\[ a_h(V) = 0.07\exp(-(V + 65)/20), \]
\[ \beta_h(V) = 1/(1 + \exp(-(V + 35)/10)), \]
\[ a_h(V) = 0.01(V + 55)/(1 - \exp(-(V + 55)/10)), \]
\[ \beta_h(V) = 0.125\exp(-(V + 65)/80), \]

The gating variables are described the probability for
appropriate gate to be open. Therefore, these variables take
values between 0 and 1, where 0 means that the gate is closed,
and 1 means that the gate is open. The parameters of the single
neuron based on the HH model are given in TABLE I.

**IV. NUMERICAL RESULTS**

In this section, the state estimation results are plotted
separately and a comparative table is shown to discuss the
estimation performances of nonlinear observers in root-mean
squared errors (RMSE). The main goal of the study is to
provide accurate state estimation results for HH neuronal model
using different nonlinear observers. At the same time, we have
chance to compare and discuss the observer’s estimation
capability. In order to get fair estimation results, the observers
are initialized with same states and the parameters observers are
tuned to get best estimation results for each designed observer.

![Fig. 2 DBG0 estimation results for Hodgkin-Huxley neuronal model.](image)

Fig 2 presents state estimation results using DBG0. The
estimation results are very accurate for all four states such that
the estimated states are rapidly converging to the real neuron
states which are promising to use for real-time control studies.
a) Membrane potential ($V$) estimate (mV)

b) Activation of the sodium flow current ($m$) estimate

c) Inactivation of the sodium flow current ($h$) estimate

d) Activation of the potassium flow current ($n$) estimate

Fig. 3 SMO estimation results for Hodgkin-Huxley neuronal model.

SMO based state estimation results are shown in Fig. 3, respectively. The estimated states are following to the real states slightly late compared to the DBGO estimation results. However, after a few milliseconds, the real states are estimated accurately. The design parameters of the SMO are determined through grid search as follows: $h_1 = 8 \times 10^{-2}$, $h_2 = 1 \times 10^{-4}$, $h_3 = 1 \times 10^{-5}$, $d_1 = 1 \times 10^{-5}$, $d_2 = 1 \times 10^{-4}$, $d_3 = 1 \times 10^{-5}$ and $d_4 = 1 \times 10^{-4}$, respectively.

Fig. 4 EKF estimation results for Hodgkin-Huxley neuronal model.
For the HH neuronal model, EKF observer based state estimation results are obtained and presented in Figure 4, respectively. It is seen that the EKF is slower than the DBGO and SMO. The design parameters of the EKF are determined through grid search as follows: $P_0 = 10^{-4}I_4$, $Q = 0.1I_4$, and $R = 10^{-1}$, respectively.

**Table 2: Comparison results of designed observers**

<table>
<thead>
<tr>
<th>HH Model</th>
<th>DBGO</th>
<th>SMO</th>
<th>EKF</th>
</tr>
</thead>
<tbody>
<tr>
<td>RMSE</td>
<td>0.1723</td>
<td>0.3283</td>
<td>0.5293</td>
</tr>
</tbody>
</table>

The numerical simulations are summarized in Table 2 for the HH neuronal model. The RMSE errors of the estimations are similar with figures. It is seen that the DBGO observer is much better than both SMO and EKF for the model based neuronal model state estimations. DBGO observer is based on the mathematical model of the system such that there is no parameter to adjust. However, SMO and EKF are difficult to design. Neuronal model has fast dynamics and the states have small values. Therefore, it is one of the difficulties for parameter adjustment and the selection of sampling time in integration routine.

**V. CONCLUSIONS**

The designed nonlinear observers can be discussed and compared addressing the design conditions and performance results. The design conditions are mostly about the parameter selection and updating rule of the designed observer. If we want to order the designed nonlinear observers here about structural complexity, the simplest one is the SMO observer, which is designed as a classical sliding mode observer in this study. Beside its simple structure of classical SMO, there is faced very difficult parameter selection problem. For a four state system estimation, there is required to define eight parameters. Second observer is the DBGO observer here which has a complex state updating rule is based on the gradient update. The advantage of the DBGO is that there is no parameter tuning for a state estimation. On the other hand, there is needed to define Jacobian matrix and detailed update rule based on the RK discretization. Third observer is the EKF. EKF has a parametric structure where the estimation accuracy depends on the choice of process and measurement noise covariance matrices. Finally, we can rank the sensing algorithms from the one having the simplest structure to the most complex one as SMO, DBGO, EKF, respectively.

In order to compare the performance of the designed observers for state estimation results of HH neuronal model the Table 2 can be seen in detail. In the experiments, SMO exhibits better estimation performance than EKF. This is mainly because SMO exhibits robustness to the parameter uncertainties such that there could be uncertain or un-modeled dynamics of the systems. Moreover, DBGO does not need parameters which rectify the error dynamics where Levenberg-Marquardt direction is chosen for the faster convergence. There is an important difference between DBGO observer and other observer results in the Table 2. The second order gradient direction of the DBGO observer makes very fast the observer dynamics. However, it has a lack of robustness since any tiny change in the dynamics affect the observer performance.

As a general result, if we want to design a feedback controller or an online fault estimator, we need to check the model uncertainty and noise existence. If there is small unmodeled dynamics, the DGBO is a suitable selection. In the case of noise and uncertainty, the SMO must be chosen.

Abstract—Polar code is one of the major breakthroughs in information theory field by its theoretically proven capacity achieving error correction property and low encoding, decoding complexities. Since Arikan submitted his original paper, researchers have made many improvements on both decoding and encoding sections. Successive cancellation (SC) and belief propagation (BP) is widely used decoding algorithms for polar codes. To reduce the complexity of BP decoder, early stopping methods are studied in literature. In this paper we simplify early stopping method for BP decoder by using channel polarization phenomena and we reduce the complexity of early stopping section by observing only a small cluster of information bits which are polarized to the highest error probabilities. Simulation results shows that early stopping detection algorithm needs to observe only n/8 bits instead of n for considered code length and rates without any performance loss and faulty early stopping detection.

Keywords—Polar code, belief propagation decoder, early stopping detection

I. INTRODUCTION

As the first theoretically proven capacity-achieving error correction code, polar code [1], draw serious attention by its low encoding and decoding complexities. After polar code is introduced researches are focused on developing more efficient encoding and decoding algorithms.

There are two main decoding algorithms for polar code, belief propagation (BP) and successive cancellation (SC) as a special form of BP [1], [2]. Both decoders have their own advantages and disadvantages. SC decoder has a serial structure which increases the latency with low decoding complexity [2], [3]. On the other hand BP has parallel structure which is suitable for parallel hardware implementation with high complexity [2]. Scaled min-sum (SMS) BP decoder proposed in [4] offers a great deal of complexity reduction over original BP decoder.

As all the other iterative decoding algorithms without early stopping detection SMS BP decoder needs fixed number of iterations for decoding [5]. With the help of early stopping methods some of the redundant iterations might be avoided. In [3], two early stopping methods, G-matrix and minLLR, for BP based polar code decoder are proposed. Another simplified early stopping method called worst of information bits (WIB) is proposed in [6]. Unlike G-matrix and minLLR methods, WIB method uses only a small cluster of information bits to detect successful decoding. In this paper we propose simplified minLLR method using this idea of WIB method.

II. SMS BP AND EARLY STOPPING CRITERIA

A. SMS BP Polar Code Decoder

BP is a commonly used algorithm for decoding of block codes [5]. SMS BP is basically the same algorithm with min-sum approach and a scaling factor. SMS BP has a similar performance with BP while having a significantly reduced complexity and a hardware friendly structure. For a (n,k) polar code there is (n = 2^m) m-stage factor graph representation. Factor graph representation of (8,4) polar code and single processing element (PE) showed in Fig. 1 and Fig. 2, respectively. Here, n is the code length and k is the amount of information bits and m is the number of factor graph layer and each layer of factor graph includes n/2 PE. Update equations for decoder are given in Eqn. (1-4). In Eqn. (1-4) log-likelihood ratio(LLR) values for right and left direction referred as R and L LLRs, i is bit index, j is layer index and t is iteration number.

![Fig. 1. Factor Graph Representation for an (8, 4) Polar Code Decoder](image-url)
There are three early stopping criteria used for polar codes, two of them are proposed in [3] and the other one proposed in [6]. First method is called G-Matrix proposed in [3] and has the lowest average iteration amount along with the highest computational complexity. Second method is called minLLR also proposed in [3] with the highest average iteration amount and mid-level complexity. Last method is called WIB [6] and the method has the lowest complexity with mid-level average iteration amount.

1) G-Matrix Early Stopping Criterion: G-Matrix method has a basic approach, after re-encoding the decoded data if the results are equal to input data than decoder assumes decoding is successful. It has three main steps decision of input bits, decision of output bits and encoding of output bits to compare with input bits. If the compare operation does not yield any differences then decoding is assumed successful. This method includes encoding process at each iteration therefore it has a complexity disadvantage.

2) minLLR Early Stopping Criterion: minLLR method has a simpler structure than G-Matrix. This method only check for last layers LLR values magnitude and compares them with a pre-determined constant ($\beta$). If the minimum LLR value is bigger than $\beta$ value then decoding is assumed successful. For high signal to noise ratio(SNR) values, $\beta$ needs to be switched to a higher constant. This method has lower complexity than G-Matrix but has the highest average iteration amounts.

3) WIB Early Stopping Criterion: Polarization phenomena is fundamental of polar code. When a block is encoded with polar code, some of the bits polarize to high error probabilities and others polarize to low error probabilities. These bits then classified as frozen bits which have a fixed value and information bits which carry the information respectively. Third method uses this phenomena. This method called WIB early stopping criterion proposed in [6] and the method uses only small cluster of information bits which are polarized to the highest error probabilities called WIB. As suggested in [6] for $n$ up to 2048 it is enough to use $n/8$ bits to detect successful decoding. Method checks for LLR values sign alterations of WIB. If there is no sign change of WIB LLR values during last $M$ iterations, decoding is assumed successful.

In this study we combine the idea of WIB method with the structure of minLLR method.

C. Proposed Early Stopping Criterion

As we know from [1], polarization occurs at different levels for different bit indexes. While some of the bits polarize well others could not polarize as needed. Semi-polarized bits used as information bits cover the great proportion of error probability according to rate of encoder. In [6] this idea used for simplifying entire early stopping detection. Here we use the idea to simplify minLLR method proposed in [3]. As illustrated with Fig. 3, method has the same structure with minLLR method in [3]. Only difference is amount and index of bits used to detect successful decoding.

According to [6] WIB covers the information bits with the highest error probabilities therefore it makes sense to look up minimum LLR value inside the WIB cluster instead of entire block. To test validity of the idea we provide Table I which gives us the probabilities of minimum LLR values being outside WIB cluster and the average difference from actual minLLR value when minimum LLR is outside the WIB.
For simulation study we use the same methodology as in [3], [6]. During simulations we consider binary-input additive white Gaussian noise (BI-AWGN) channel. We choose code length as 1024 and we provide simulation results for various code rates (1/3, 1/2, 2/3). Scaling parameter for SMS BP algorithm is $s = 0.9375$. In Fig. 4, we provide bit error rate (BER) curves for various code rate and WIB number versus signal to noise ratio (SNR) over 10000 trials.

As illustrated in Fig. 4 there is no performance loss with proposed method along with complexity reduction for early stopping section which is also compared with Table II. Fig. 4 also tells us that $n_{WIB} = n/16$ is not enough to cover the semi-polarized bits.

The most important contribution of an early stopping criterion to an iterative decoder is iteration reduction performance. Since proposed simplified minLLR method has the same iteration reduction performance with original minLLR method we have not provided these results cause these results clearly stated in [3], [6].

IV. CONCLUSIONS

In this study we proposed a simplification to an existing early stopping criterion (minLLR) for BP based polar code decoders by using a theory from another early stopping method (WIB). Simulation results show that there is no performance loss with simplified minLLR method compared to original minLLR or fixed iteration amount. Although this method has the lowest computational complexity for early stopping section, overall performance would be better if it is used with G-Matrix method because of average iteration numbers.

Abstract— Low and medium voltage (LV and MV) distribution networks are operated in a radial configuration, but their topology, especially when highly loaded, is usually meshed in order to improve system reliability and quality of the supply. This makes it feasible to configure the network after an outage to restore the service to affected sites. In addition, by modifying the topology of the network, power loss and node voltage deviation can be minimize. However, this network modification is a non-linear, multi-objective, constrained and combinatorial optimization problem. In this paper, Binary Particle Swarm Optimization (B-PSO) technique is employed for optimal network reconfiguration of primary distribution network. The objective of the proposed method is to minimize the total active power loss and voltage deviation experienced in the network. It is carried out subject to a variety of technical constraints, with the search space being the set of networks branches. To ascertain the efficiency of the proposed method and its practicability on multi-scale distribution systems, standard IEEE 16-bus, 33-bus and 69-bus test distribution networks are used. The proposed algorithm is implemented in MATLAB and MATPOWER environments. The results obtained signify the effectiveness of the proposed technique.

Keywords— Binary Particle Swarm Optimization, Distribution Network Reconfiguration, Loss Reduction, Voltage Deviation.

I. INTRODUCTION

Distribution networks (DNs) carry electrical power right from transmission system to the consumption sites. Being the last stage of the power delivery, DN contributes at least 40% of the total power loss occurring in the entire system [1]. Most DNs are built as weakly meshed but operated radially, for effective coordination of their protection systems [2, 3, 4]. This is done with aid of switches within a feeder or across different feeders as shown in Fig. 1. They are either normally closed (NC) sectionalizing switches; S1-S6 existing within each feeder and normally open (NO) tie switches; S7 and S8 connecting sections of different feeders [5]. DN is vulnerable to number of outages due its radial nature, as a fault on a single line can result in blackout to many customers [6]. As a result, many efforts have been made to suppress these complications and improve the reliability and quality of the supply. Among the techniques proposed is distribution network reconfiguration (DNR).

A. Reconfiguration Techniques

DNR is the process of varying the topology of DN by changing the closed/open status of sectionalizing and tie switches to optimize system parameters while maintaining system constraints [7]. Among the objectives of DNR includes reducing system losses, service restoration and relieving primary feeders either due to overload or allow maintenance activities on that feeder. For instance, in Fig. 1, the first feeder can be relieved by opening S1 and closing S7.

In the same vain, the middle feeder carries the loads on the rest of the feeders if S1 and S2 are open while S7 and S8 are closed. In either case, the radial configuration of network is always maintained.

However, this network modification is a non-linear, multi-objective, highly constrained and combinatorial optimization problem [8]. The complexity of the problem arises from the fact that distribution network topology has to be radial and power flow constraints are nonlinear in nature.

The early studies on the network reconfiguration were directed to the planning stage [9, 10]. The sole objective these researches is to minimize the cost of construction, giving no concern on the quality of the supply. The first recognized work which attempts to solve the problem of distribution system reconfiguration for loss reduction was presented by Merlin and Back [11]. Henceforth, many algorithms have been developed to solve this problem. In the proposed method, all switches in
the DN were closed and then the switches are opened successively to eliminate the loops.

Recently, some researches have integrated both the DNR and DG placement problems to improve the effectiveness of the DN. Thuan Thanh Nguyen et al. applied adaptive cuckoo search for DNR for DG allocation [1]. The objective of this technique is minimizing power loss and improve voltage stability. Similarly, in [12], DNR is applied to distribution feeder to allow increasing the penetration of plug-in electric vehicles and minimizing network cost. Power loss and voltage deviation minimization using DNR is presented in [13].

In this paper, binary particle swarm optimization (B-PSO) is applied for optimal DNR to minimize the power loss and voltage deviation in primary DN. The outstanding performance of the proposed technique is its ability to solve DNR problem on single feeder or multi-feeder DNs.

B. Binary Particle Swarm

Due the non-linearity and combinatorial nature of the DNR optimization problem, various techniques were applied for its solution. It can either be a single or multiple objective problem [6]. Both classical and heuristic optimization methods were applied for DNR problems. Mixed-integer conic programming is formulated in [5] to minimize power loss. In a similar work presented in [14], selective PSO is employed. However, in these studies less concern was given to voltage deviation.

The particle swarm optimization (PSO) was first introduced by Kennedy and Eberhart in 1995 [15]. It was developed through simulation of many simplified work, it has been found to be robust in solving continuous nonlinear optimization problems, PSO is attractive because very few parameters are required for its applicability [16].

The algorithm used in this paper, B-PSO, has an advantage of handling both discrete and continuous parameters. It involves initializing the search space with swarm particles, \(x_i\) randomly. The search space in this problem is the set of all the sectionalizing and tie switches. At each iteration, the position of \(i\)th particle is updated by its previous position in the velocity vector, \(v_i\) according to (1)

\[ x_i = x_i^{t-1} + v_i^t; \quad i = 1, 2, ..., P \quad (1) \]

Where \(x_i = [x_{i,1}, x_{i,2}, ..., x_{i,N}]\) represents the position vector of the \(i\)th particle at the \(t\)th iteration, and \(v_i = [v_{i,1}, v_{i,2}, ..., v_{i,N}]\) signifies the velocity vector of the \(i\)th particle at the \(t\)th iteration, \(N\) being the number of variables of the function to be optimized and \(P\) is the number of particles in the swarm. The velocity vector is updated according to the following equation:

\[ v_i = \omega v_i^{t-1} + \varphi_1 r_1 (p_{best}^{t-1} - x_i^{t-1}) + \varphi_2 r_2 (g_{best}^{t-1} - x_i^{t-1}) \quad (2) \]
