Where \(p_{best}^{t-1} = [p_{best_{1,1}}^{t-1}, p_{best_{1,2}}^{t-1}, ..., p_{best_{1,N}}^{t-1}]\) is the best solution achieved for the \(i\)th particle at the \((t-1)\)th iteration, and \(g_{best}^{t-1} = [g_{best_{1,1}}^{t-1}, g_{best_{1,2}}^{t-1}, ..., g_{best_{1,N}}^{t-1}]\) is the best position found for all particles in the swarm at the \((t-1)\)th iteration. \(\varphi_1\) and \(\varphi_2\) are positive real numbers, called learning factors or acceleration constants, which are used to weight the particle individual knowledge and the swarm social knowledge, respectively. \(rand_1\) and \(rand_2\) are real random numbers uniformly distributed between 0 and 1 that make stochastic changes in the \(i\)th particle trajectory. Finally, \(\omega\) is the inertia weight factor, which represents the weighting of a particle’s previous velocity [17].

II. PROBLEM FORMULATION

The problem to be solved involves determining the optimal DNR, taking into account different technical constraints. The objective of the proposed technique is to minimize power loss and voltage deviation as formulated in objective function (OF) below.

\[ \min F \]

Where

\[ F = f_1 + f_2 \quad (3) \]

The first part of the OF is the index of power loss obtained by normalizing the power loss with its initial value as shown in (4)

\[ f_1 = \frac{P_{loss_{recong.}}}{P_{loss_{initial}}} \quad (4) \]

Where \(P_{loss_{recong.}}\) is the power loss after reconfiguration and \(P_{loss_{initial}}\) is the power loss before reconfiguration calculated as;

\[ P_{loss_{initial}} = \sum_{i=1}^{nl} R_i \left( \frac{P_i^2 + Q_i^2}{V_i^2} \right) \quad f o r \ i = 1, 2, ..., nl \quad (5) \]

The second segment of the OF, \(f_2\) is the index of the total voltage deviation. It is similarly obtained by normalizing its reconfigured value, \(V_{dev_{recong.}}\) with its initial value, \(V_{dev_{initial}}\).

\[ f_2 = \frac{\Delta V_{recong.}^{total}}{\Delta V_{initial}^{total}} \quad (6) \]

The total inherent voltage deviation is computed as;

\[ \Delta V_{initial}^{total} = \sum_{j=1}^{NB} |V_j| \quad f o r \ j = 1, 2, ... NB \quad (7) \]

The DNR problem solved by considering the following constraints:-

1. Voltage limit

\[ V_{j_{min}} \leq V_j \leq V_{j_{max}}, \quad j = 1, 2, ..., NB \quad (8) \]

2. Maximum permissible line current carrying capacity

\[ I_l \leq I_{max}, \quad l = 1, 2, ..., nl \quad (9) \]

Where

\[ I_l^2 = A_{ij} |V_i|^2 + B_{ij} V_i V_j - 2 V_i V_j (C_{ij} \cos \beta_{ij} - D_{ij} \sin \beta_{ij}) \quad (10) \]
Radial network structure (RNS), this mean no loop are allow in the network

\[
A_{ij} = g_{ij}^2 + \left( b_{ij} + \frac{b_{shij}}{2} \right)^2
\]

\[
B_{ij} = g_{ij}^2 + b_{ij}^2
\]

\[
C_{ij} = g_{ij}^2 + b_{ij} \left( b_{ij} + \frac{b_{shij}}{2} \right)^2
\]

\[
D_{ij} = \frac{g_{ij}^2 b_{shij}}{2}
\]

(11) (12) (13) (14)

3. Radial network structure (RNS), this mean no loop

\[
\sum_{i=1}^{m} a_i = n
\]

Note that the switch status can be indexed using either the corresponding nodes between which the line is connected as in \( a_{ij} \) or using the line number as in \( a_l \) (implies that the line \( l \) is not connected). Equation (13) is not sufficient, there is need for an additional set of constrains including loop approach, which stipulate that each loop in the meshed configuration has to be open and path-based approach which is based on the identification of reasonable alternative linking each bus to the substation [5].

III. TEST SYSTEMS DESCRIPTION

To ascertain the effectiveness of the proposed method and its practicability on small and medium-scale distribution systems, three IEEE standard test distribution networks are used.

The first system is 16 bus, 3-feeder radial distribution system. The network has total loads of 28.125 MW and 13.53 MVAr on 12.65 kV substation voltage. The lines between each bus has a sectional switch for the buses connected to the same feeder and a tie switch for the buses connected to two different feeders as depicted in Fig 2. There are 3 tie switches and 14 such sectionalizing switches are used in this system [18].

![Fig. 2 IEEE 16 bus test system](image)

The second test system used in the study is 33-bus distribution feeder with a total active and reactive load demand of 3.72 MW and 2.30 MVAr respectively [6]. It has 37 branches, 32 sectionalizing switches and 5 tie switches as shown in Fig 3.

![Fig. 3 IEEE 33 bus test system](image)

A medium scale system having 69 buses, 73 branches and 5 tie switches, is used. The network has a total load demand of 3.80MW and 2.70MVAr. Its topology is shown in Fig. 4 [1].

![Fig. 4 IEEE 69 bus test system](image)

Due to the low R/X ratio of these test feeders considered, the commonly used Newton Raphson load flow program presents lot of convergence problem, hence backward-forward sweep method is used.

IV. RESULTS AND DISCUSSIONS

The performance of the proposed method is evaluated on the aforementioned test systems. The improvement observed in the individual objectives are expressed as the percentage of their respective inherent values.

- 16-bus test system

As mentioned earlier, this test system has 3 tie switches and 14 sectionalizing switches. The algorithm determined optimal configuration by varying open/close status of the switches to minimize the objective function while respecting the RNS and other constraints. The optimal solution is obtained by closing \( s_{14} \) and \( s_{15} \) and opening \( s_{7} \) and \( s_{8} \) while maintaining \( s_{16} \) open as shown in Fig 5.

![Fig. 5 IEEE 16 bus test system](image)
With this reconfigured network, the power loss is found to be reduced by 8.8903% of the total loss established to be 514.0293 kW. The voltage deviation reduced by 12.3364% of its inherent value of 0.2140 pu. Summary of the optimal reconfiguration results are shown in Table I.

### TABLE I

<table>
<thead>
<tr>
<th>Parameters</th>
<th>Before Reconfiguration</th>
<th>After Reconfiguration</th>

<tr>
<td>Voltage dev.</td>
<td>0.2140 pu</td>
<td>0.1876 pu</td>
</tr>
<tr>
<td>Min. Voltage</td>
<td>0.96824 pu</td>
<td>0.9707 pu</td>
</tr>
</tbody>
</table>

Switches that changes status during the reconfiguration has significantly affect the voltages of the neighbouring buses. From Fig. 6, it can be vividly seen that voltages of bus 10, 11 and 14 have greatly improved due to changes in s7, s8 and s15 respectively.

![Fig. 6 16-bus test system voltage profile.](image)

- **33-bus test system**
  
  Unlike the previous case, 33-bus system has one substation, which makes its DNR a little easier. The optimal configuration is tabulated below.

### TABLE III

<table>
<thead>
<tr>
<th>Parameters</th>
<th>Before Reconfiguration</th>
<th>After Reconfiguration</th>
</tr>
</thead>
<tbody>
<tr>
<td>Tie switches</td>
<td>33, 34, 35, 36, 37</td>
<td>7, 11, 14, 28, 32</td>
</tr>
<tr>
<td>Power loss</td>
<td>208.4592 kW</td>
<td>141.6346 kW</td>
</tr>
<tr>
<td>Voltage dev.</td>
<td>1.6610 pu</td>
<td>1.0991 pu</td>
</tr>
<tr>
<td>Min. Voltage</td>
<td>0.9108 pu</td>
<td>0.9413 pu</td>
</tr>
</tbody>
</table>

The optimal solution is obtained by closing s33 - s37 and opening s7, s11, s14, s28 and s32 as shown in Fig. 7.

![Fig. 7 Optimized Configuration of 33 bus test system](image)

As result of this reconfiguration, the power loss is found to be reduced by 32.0564% of the total inherent losses before reconfiguration while the voltage deviation reduced by 33.8290% of the initial deviation established to be 1.6610 pu, much better than those obtained in [14].

![Fig. 8 33-bus test system voltage profile.](image)

Since voltage deviation is included in the OF, buses with higher deviation experienced significant improvement in their respectively profiles. In addition, neighbouring buses to the switches altered, like bus 12, 13, 13 and 15, have appreciable improvement as depicted in Fig. 8 above.

- **69-bus test system**
  
  In spite of the higher number of buses when compared with the previous cases, the algorithm is capable of locating the switches to be opened in order to minimize the OF while maintaining RNS and other constraints. Table III summarizes the optimal configuration.

![Fig. 5 Optimized Configuration of 16 bus test system](image)
The optimal reconfiguration is achieved by closing s71, s72 and s73 and opening s14, s58 and s61 while maintaining s69 and s70 open as shown in Fig 9.

As result of this reconfiguration, the power loss is found to be reduced by 56.1761% of the total inherent losses while the voltage deviation reduced by 64.6758%. This improvement is much better than that obtained in [19, 20].

It is worth-noting to inspect the deterioration of voltages at bus 41–46 as shown in Fig 10. This is caused as result of transferring some loads from middle feeder; loads at bus 15 – 27 and bus 62 – 65. Initially these loads were not on this feeder. For the same reason, voltages at bus 49 and 50 after reconfiguration is less than that before the configuration.

In this paper, the binary swarm optimization algorithm is applied to solve distribution network reconfiguration. The objective of the proposed technique is to minimize the active power loss and voltage deviation. It is carried out subject to some technical constraints in addition to maintaining the radial nature of the network. The decision variables are the open/close status of the sectionalizing and tie switches. IEEE multi-feeder 16-bus and single feeder 33-bus and 69-bus test distribution networks are used for testing the proposed technique. One distinguishing feature of the proposed method is its ability to handle system with single and multiple feeders.

From the simulation result, the technique is capable of reconfiguring the networks effectively and minimized the objectives. With the optimized reconfiguration, the RNS is maintained in all the cases, no mesh network is formed. Even though 69 bus system has higher number of buses, yet the result obtained is much better than the previous cases. While reconfiguring the networks, opening or closing some switches resulted in transferring some loads from one feeder to another, hence overloading it. This can be observed at bus 41–46 due to introduction of loads at bus 15 – 27 and bus 62 – 65 by opening s14 and closing s71. Distributed generation is needed at those overloaded feeders to support its load carrying capacity.

It is envisioned as future work to incorporate distributed generation to support the loaded feeders. Same technique will be used to determine their optimal siting and sizing.

mmutluer@konya.edu.tr

Abstract—Today, the use of permanent magnet synchronous motors has increased in industrial fields and these motors have many different structures. The outer rotor structure is remarkable in terms of ease of design and torque density. This study proposes to design optimization of the outer rotor with genetic algorithm and differential evolution algorithm. The geometric sizes were selected as design parameters and the motor efficiency is used as objective function. The obtained results by using of each algorithm are compared and the industrial conclusions were presented. As a result, the results are satisfactory and the study is useful for academic and industrial technical staff.

Keywords—design optimization, differential evolution algorithm, genetic algorithm, outer rotor, permanent magnet synchronous motor

I. INTRODUCTION

Electric motors consume a large portion of the electrical energy in the world. Therefore, academic and industrial works related to energy consumption and high efficiency motors are more important.

Nowadays permanent magnet synchronous motors (PMSMs) have been preferred because of their high efficiency and torque density. Motor structures affect these merits. Here the outer rotor permanent magnet synchronous motors are remarkable. Generally these motors have common advantages as other permanent magnet synchronous motors for example gearless [1]. In low-speed applications, the surface mounted PMSM with inner rotor is most popular but in high-speeds the outer rotor is more appropriate for the permanent magnets can be protected from centrifugal forces in outer rotors. Moreover their torque density is greater due to the wide diameter of the air gap and the production costs of the outer rotor are suitable.

The stochastic methods have been used for electrical machine design optimization. These methods can give effective results to the very complex problems like motor designs [2], [3]. Some of the most famous of these methods are the genetic algorithm and the differential evolution algorithm. These methods do not require the initial solution or population. The objectives of the design optimization of the PMSMs based on stochastic methods are reduce the torque harmonics or to increase the efficiency of the motor [4].

This study was conducted to optimize the design of the outer rotor PMSM for high efficiency. The genetic algorithm and the differential evolution algorithm were run to provide the optimal efficiency values. As input parameters the structural parameters of the motor were taken. The optimization and the analytical results were compared and eventually the results are sufficiently.

II. DESIGN OPTIMIZATION STAGES OF THE PMSM

A. The Winding Layout

In this study, the investigated PMSM are the surface mounted with outer rotor and the number of stator slots and pole numbers are 12/10 respectively. The concentrated/double layer winding layout is shown in Figure 1. The winding factor is a good value for performance and it is 0.933 [5], [6].

![Fig. 1 The winding layout](image)

B. The Design Parameters and the Objective Function

The design of the permanent magnet synchronous motors is nonlinear study and it has different design parameters. Some of them are variables, invariables and constants. Therefore, the effects of these parameters on the objective are different in terms of ease and accuracy of the design. The design optimization parameters are the rotor diameter for the inner rotor or stator diameter for outer rotor D_r, magnet thickness l_m, air gap length δ, slot wedge height h_w, stator tooth width b_s, stator slot height h_s, ratio of the slot opening over the slot width k_open. The two dimensional geometry of the motor is shown in Figure 2 [7].

![Fig. 2 Two dimensional geometries of the outer rotor PMSM](image)
The diameter, the stack length, and the pole angle are constraints. For each motor the outer diameter is 340mm, the stack length is 120mm, and the pole angle is 126°.

The supply, power, and speed values for the motor are 340V, 2400W, and 250rpm. The remanence flux density and the relative permeability of the permanent magnets are 1.2T and 1.03.

\[
P_{\text{out}} = T \times \omega_{\text{mech}} \quad (1)
\]
\[
P_{\text{Cu}} = 3I^2 \times R_{\text{Cu}} \quad (2)
\]
\[
P_{\text{Fe}} = P_{\text{h}} + P_{\text{e}} \quad (3)
\]
\[
\eta = \frac{P_{\text{out}}}{P_{\text{out}} + P_{\text{Cu}} + P_{\text{Fe}}} \times 100\% \quad (4)
\]

where, \(\omega_{\text{mech}}\) is mechanical angular velocity, \(P_{\text{out}}\) is output power, \(P_{\text{Cu}}\) is copper loss, \(P_{\text{h}}\) is hysteresis loss, \(P_{\text{e}}\) is eddy current loss, \(P_{\text{Fe}}\) is iron loss, and \(\eta\) is efficiency of the motor.

### III. THE OPTIMIZATION ALGORITHMS

#### A. The Genetic Algorithm

Genetic algorithms (GAs) do not produce only one solution for any optimization problem. The aim of the GAs is to find the optimal solution in the solution space. Populations in the genetic algorithm are composed of independent individuals and the individuals have genes reflects the solution of the problem [8].

Genetic algorithms do not guarantee to investigate the optimal result. The GAs may converge to a local solution but also they do not require the solution of the initial solution. Genetic algorithms have three operators; reproduction, crossover and mutation. The reproduction selects the individuals with higher fitness values to keep the struggle for life by using roulette wheel, tournament or any other selection criteria. Crossover operator exchanges randomly the genes of two individuals. Mutation operator changes the string’s bit from a “1” to a “0” or vice versa so the convergence of the algorithm to the local solutions is prevented.

#### B. The Differential Evolution Algorithm

Differential evolution algorithm (DEA) is one of the famous optimization algorithms. The algorithm is basically similar to genetic algorithm. Furthermore the main feature of the DEA is the use of differential operator. Differential action shall be taken to evaluate fitness values on the parents’ genes by the differential operator, thus the quality of the population is tried to be increased. DEA shows superior performance because of very small number of parameters to be set and the understandable actual code sequence [8].

### IV. THE DESIGN APPLICATION AND THE EVALUATION OF THE RESULTS

In this study some assumptions were made about the motor design such as neglect of the mechanical strength, thermal loadability. Obviously, industrial manufacturability of the PMSM was neglected in the design optimization results. The saturation on the stator teeth and stator and rotor yokes were taken only as constraints. The constraint values are 1.8T for the stator teeth and 1T for the stator and the rotor yokes. The geometric parameters were mentioned as input design optimization parameters.

The genetic algorithm has the crossover ratio is 0.85 and the mutation ratio is 0.01 and both algorithms have the population number is 50, the iteration number is 50. The termination criterion of the GA and the DEA is iteration number. The algorithms have binary codes and each gene has ten bits.

According to pre-analytical design and design optimization of the PMSM, the efficiency and losses results were given in Table 1. The investigated outer rotor motor has a good efficiency. It is possible to say that the differential evolution algorithm obtained the better results than the genetic algorithm. At the same time in low frequency ohmic losses are more effective than iron losses.

#### TABLE 1

<table>
<thead>
<tr>
<th></th>
<th>Ohmic Loss</th>
<th>Iron Losses</th>
<th>Efficiency</th>
</tr>

</tbody>
</table>

![Fig. 3 The convergence graphics of the algorithms](image-url)
algorithm may be fallen in a local solution it is absolutely weakness. The graphics of the GA and the DEA were shown in Figure 4. The DEA is more sensitive and strong.

V. CONCLUSIONS

The design optimization of the outer rotor PMSM was investigated by the genetic algorithm and the differential evolution algorithm. The obtained results show that the differential evolution algorithm has better results than the genetic algorithm. The ohmic losses are more important in low frequency application. Eventually, the design optimization study of the outer rotor permanent magnet synchronous motor and the results are acceptable.

Microprocessor Based Antenna Reconfiguration Controller For 5G Communication Systems

Ayhan Yazgan
Karadeniz Technical University
Electrical Electronics Engineering Department 61080 Trabzon TURKEY
ayhanyazgan@.ktu.edu.tr

Abstract— In order to cover wide spectrum with high antenna gain, the reconfiguration process may be proposed as an alternative solution instead of using several antennas which is not efficient considering the size restriction situation. In this study, a microprocessor based antenna reconfiguration controller circuit is designed and fabricated. Designed circuit can be used to reconfigure the antenna frequency, pattern or polarization for the possible 5G communication requirements. Proposed antenna reconfiguration controller has the ability of switching selected PIN diodes in order to cover the desired frequency bands.

Keywords— Antenna reconfiguration, 5G communication

I. INTRODUCTION

The necessity of high speed communication drives researches to figure out new designs and algorithms. These developments may be in hardware or software side. In order to meet the high speed communication requirements, these developments should move on together. For example, considering a mobile phone, suitable software is loaded into different type microprocessors which manage several functions in the phone. On the other hand, electromagnetic properties of the communication device are also important. One of them is the antenna which converts electrical signals into electromagnetic waves and vice versa. The antenna in a mobile phone or base station should send and receive electromagnetic waves in different bands of the electromagnetic spectrum. In order to meet the communication standards, different types of antennas have been designed so far. Some electronics devices have more than one antenna to cover different bands. Another option is to use reconfigurable antennas of which the resonant bands can be rearranged by the operator. Moreover, beside frequency reconfiguration, different properties of the antennas can be reconfigured such as antenna pattern or polarization [1,2]. Several reconfiguration methods are used in literature [3-5]. However, electronic and optical reconfigurations are very topical these days. In this study, a microprocessor based reconfiguration tool is designed fabricated and tested. The designed antenna reconfiguration controller (ARC) can be applied for controlling 64 electronic or optical switches on the antenna surface. For the sake of simplicity, a monopole antenna is used in the testbed. However, considering a cognitive radio process which may be a possible network in 5G, the instant channel state information (CSI) will be necessary in order to focus on the desired frequency band. In this situation, a sensing antenna should be inserted into the system so as to scan and figure out the suitable frequency bands [6]. All these process address the frequency reconfiguration. On the other hand, it should be noted that pattern or polarization reconfiguration may be needed for the future communication standards.

The paper is organized as follows. In Section 2, the fabricated Antenna Reconfiguration Controller (ARC) is given. Section 3 gives and discusses the results. Section 4 concludes the paper.

II. ANTENNA RECONFIGURATION CONTROLLER (ARC)

The fabricated microprocessor based ARC is given in Fig.1. Parallel cables are connected to the one port of the 8 bit microprocessor. LEDs are inserted for testing the signalization correctly. In order to test the ARC, a monopole antenna is designed with one high speed PIN diode as an electronic switch. The aim of this testbed is to use a monopole antenna for two different frequencies. The monopole size can be selected to obtain the desired frequency band. However the bandwidth of the antenna does not change is this method.

![Fig.1. Fabricated Antenna Reconfiguration Controller](image)
III. RESULTS

Designed ARC has been tested for different types of antennas. Here the monopole test results are given. ARC activates or deactivates the switches which are inserted on the antenna surface in the antenna fabrication process. A Microchip brand processor is used and the schematic of the electronic card is designed by using Eagle 6.2 Layout. In this study, only one switch is used for the sake of simplicity. However if the number of switches need to be increased, in this case, a look up table may be designed and inserted into the microprocessor by software. A power supply and LCD screen are also seen in the testbed which is given in Fig.2. The simulated and designed monopole antennas are given in Fig.3.

In Fig.4 and Fig.5, the fabricated antennas on the ground plane are given. Monopole antenna length is 100 mm and the printed surface is Rogers 4350 substrate (\(\varepsilon_r=3.48\)). Designed antenna has special inductors capacitors for electromagnetic isolation and resistors for the current limiting process. Another important device on the antenna surface is the PIN diode. In this study BAP63-02 is selected from NXP company. These electronic devices have to be selected carefully since their electromagnetic effects may change the resonance frequency [7].

According to the results, when the switch is turned on the resonance frequency of the antenna is measured as 900 MHz. Conversely when the switch is turned off, the antenna resonance frequency is measured as 582 MHz. It is clear that the frequency reconfiguration process of an antenna can be realized simply by a high speed PIN diode and cheap electronic components. Pattern and polarization reconfigurations may be experienced for the future antenna studies.
IV. CONCLUSION

An antenna reconfiguration controller (ARC) is designed, fabricated and tested. A monopole antenna which is controlled by the ARC has been fabricated and operated for two different frequencies using a PIN diode. This antenna reconfiguration controller is inevitable part of the cognitive radio which is suggested as possible 5G networks in literature. Using this fabricated ARC, reconfiguration process can be applied up to 64 switches. This number can be increased but considering the complexity it is not suggested.

Abstract — Brain is composed by neurons using electricity to communicate to each other. There is a great amount electrical activity in the brain due to collection of numerous neurons sending signal. Neurons send brainwaves detected by sensitive equipment like electroencephalogram or electroencephalograph (EEG). Beta waves emanates from brains responsible for problem solving or decision making. Some equipment like neurosky biosensor intercepts these brain waves. In this study, neurosky biosensor is used in measuring the meditation level of students in the physics course. Developed program process the data of neurosky biosensor sent and make decision about meditation level of student in the course. Program says that “your meditation level is low to pass another subject or solve the exam”.

Key words – Brainwaves, neurosky biosensor, EEG, education, neurolearning.

I. INTRODUCTION

Our brain is made up of billions of neurons using electricity to communicate to each other. There is a great amount of electrical activity in the brain due to sending signals. This electricity can be detected by equipment such as electroencephalograph (EEG). Electrical activity in the brain composes brainwaves. Brainwaves are produced by synchronised electrical pulses from masses of neurons communicating with each other. Brainwaves are divided into bandwidths to describe their functions as indicated in Fig. 1, however are best thought of as a continuous spectrum of consciousness.

Brainwaves change regard to what we’re doing and feeling. In the case of that slower brainwaves are dominant; we can feel tired, slow, sluggish, or dreamy. On the contrary in the case of that higher frequencies are dominant, we feel hyper-alert. Brainwaves are classified into groups with respect to frequencies in Hertz, like gamma, beta, alpha, theta and delta.

Frequency of delta waves changes between 0.5 and 3 Hz. Delta waves slowest whereas loudest brainwaves. Delta waves generated in deepest meditation and dreamless sleep.

Frequency of theta waves changes between 3 and 8 Hz. Theta waves generated in deep meditation and sleep.

Frequency of alpha waves changes between 8 and 12 Hz. Alpha waves responsible for now and no quite meditation. Alpha waves generated in calmness and learning.

Frequency of beta waves changes between 12 and 38 Hz. These waves are dominant in waking state of consciousness and engaged with problem solving and decision making.

Frequency of gamma waves, fastest changes between 38 and 42 Hz [1, 2].

Neurosky EEG biosensor, which is a non-invasive, dry and low cost, can intercept the brainwaves, measures the attention and meditation level is illustrated in Fig. 2. [3].

Fig. 2 Neurosky Biosensor

Neurosky EEG biosensors can be used in education [4]. Meditation and attention rates shows difference in the case of
different room colour. By changing the room colour these meditation and attention rates can be increased [5]. In order to observe how the rates changes, a lot of game is developed [6]. Neurosky EEG biosensor can be used for identifying the emotion while playing game [7]. In this study, neurosky EEG biosensors are used in measuring the meditation level of students in the course. Developed program process the data of neurosky EEG biosensors sent and make decision about meditation level of student in the exam. Program says that “your meditation level is low to solve the exam or pass to another subject”.

II. EDUCATION WITH NEUROSKY BIOSENSOR

We have developed a program by means of using neurosky biosensor. Firstly, instructors and students have to be sign up this program as demonstrated in Fig.3.

![Fig. 3 Sign up](image)

Instructors sign in the program and load the course materials in the form of text, power point, image and video. Main menu of the developed program is illustrated in Fig.4.

![Fig. 4 Menu of program](image)

As it is seen in Fig.4, average attention and meditation rate while studying is recorded. Instructor can enter the program and upload the course materials. The students can enter the developed program; wear the neurosky biosensor while studying. Firstly, courses are offered as shown in Fig. 5.

![Fig. 5 Offering the courses](image)

Secondly, subjects of courses are entered as depicted in Fig. 6.

![Fig. 6 Subjects of offered course](image)

Thirdly, lesson names, required average attention and meditation rate for subjects are determined as illustrated in Fig. 7.

![Fig. 7 Lessons of subjects](image)

Fourthly, course materials are uploaded into developed program as demonstrated in Fig. 8 a-b for text and video upload respectively.

![Fig. 8 Course material upload](image)

Finally, after course materials are loaded, student can enter the system and study the subjects. During studying period, attention and meditation rates are recorded. When the students want to pass another lesson in the case of lower meditation and attention rate, the system gives the warning like “your attention and meditation level is lower than predetermined value for that reason you cannot pass another lesson”. Also instructor can see the statistical mean of the meditation and attention rate as shown in Fig. 9.
Students study while wearing the neurosky biosensor as shown in Fig. 10.

If the meditation and attention rate of the students are higher than predetermined rates, they can pass to another lesson. Otherwise they are not permitted to pass another lesson as illustrated in Fig. 11.

FIG. 9 Statistical mean of the recorded values

III. CONCLUSION

Brain emanates brainwaves in doing or feeling something. These brainwaves can be intercepted and processed by equipment like neurosky biosensor. In this study, neurosky biosensor used for measuring meditation and attention rates of student. We have developed a computer program. Via the program, we load the course materials into system. Students enter the system with their user name and password. Then study the first subject. If meditation and attention rates are high students pass to second subject. Otherwise, students have to study the subject again. Whenever these rates are high, students pass to second subject.

Adaptive Fault Tolerant Control for a Liquid Tank Process

Mehmet Arıcı, Tolgay Kara

Department of Electrical and Electronics Engineering, University of Gaziantep, 27310 Gaziantep, Turkey
{mehmetarici, kara}@gantep.edu.tr

Abstract—Level control of liquids in coupled tanks is a basic requirement in many industrial processes. Liquid levels in tanks must be controlled accurately regardless of environmental circumstances. Minor faults in sensors, actuators or other system components that take place in processes where liquid level control is required can result in catastrophic consequences. In this case, a fault tolerant control system is needed. The controller must be either passive (passive) or in reconfigurable (active) type in order to compensate for the effect of actuator faults and maintain system reliability and performance. In this study, a water tank level control system and possible valve actuator faults are modelled. By designing different controllers and using modelled failures a simulation is constructed. To test the reconfigurable type controller performance against faults/failures, a model reference adaptive control system is implemented and compared with PI-controlled system.

Keywords—Actuator faults, fault modelling, fault tolerant control, model reference adaptive control, liquid tank

I. INTRODUCTION

Main industries where liquid level and flow control are essential include petro-chemical industries, paper production plants, water treatment industries, food processing industries, pharmaceutical industries, nuclear power generation plants, and automatic water drainage systems. Due to increasing demands on system performance and product quality as well as economic benefits, modern technical processes have become more complicated. These complicated systems are vulnerable to faults in sensors and actuators. Minor faults in sensors, actuators or other system components that take place in processes in which fluid level control is a basic requirement can result in catastrophic consequences. Control system in this case must compensate for the effect of actuator faults and must maintain system reliability and performance.

Failures are difficult to accurately predict in time and can be abrupt, incipient and intermittent [1]. They are classified according to their location of occurrence in the system. The impact of a fault can be a small reduction in efficiency but could also lead to overall system failure and system instability. Therefore, in the design phase of compensators a good actuator failure model that covers all possible cases is crucial and in the application phase, more practical. Different types of actuator models are available in both deterministic and stochastic manners for linear or nonlinear systems. Most of related studies consider deterministic actuator fault models [2]. They use various approaches in deterministic manner [3-15] and generally consider a specific case that once the actuator fails; it will stay at the faulty mode during the rest running process. In other words, the number of actuator failures is finite. However, in practice, especially for safety-critical systems, the failed actuator may recover itself by a self-repairing control system and the actuator may fail more than once during the operation process, that is, the number of actuator failures is infinite. The actuator failures are practically stochastic in nature. For instance, a normally open electrical contact in electrical switches, relays or breakers is required to be open when it is in a de-energized or relaxed state. However, at some moment, the contact may undergo abrupt disturbances, which turns it to be closed, and it may recover to be open again, that is, the contact may jump between closed mode (failure) and open mode (failure-free) in a stochastic manner. Several studies design compensators with stochastic actuator failure [17-25]. In [17-19], actuator failure model output represented with a failure or faulty matrix. This diagonal matrix takes ‘1’ and ‘0’ values, which correspond to total failure and normal operation conditions. Also values between ‘1’ and ‘0’ are considered which represent loss of effectiveness. The diagonal matrix is stochastic with a known distribution. Generally Bernoulli distributed sequences and Gaussian distribution are used to model failure behaviours. In [20-25], the aforementioned abrupt changes are modeled as a Markovian process. Markovian process is a stochastic model that can be used to model a random system that changes states according to a transition rule that only depends on the current state. [26] shows that for given adequate historical data, the abrupt changes can be modeled as Markovian process. In the studies cited above, the stochastic functions related to Markovian variables are employed to denote the failure scaling factors for each actuator.

It is needed to design control methods capable of ensuring nominal performance considering the occurrence of failures. This control is referred to as fault tolerant control (FTC) which has become of significant importance in the last decades. There are lots of approaches in FTC area and individual research has been carried out extensively. However systematic concepts, design methods and even terminology are still not standardized [2, 3]. In FTC systems, the achievable system performance depends on the availability of redundancies in the control system as well as the design approaches used in synthesis of fault-tolerant controllers. Recently, FTC systems are classified into two categories, namely, active FTCs, and passive FTCs. These two approaches use different design methodologies for the same control objective. However, due to the distinctive design
approaches used, each method can result in some unique properties. A general requirement for both methods is the existence of system redundancies which can be analytical or applied on hardware and difference is how the redundancy is utilized.

In passive approach, a list of potential malfunctions is assumed to be known a priori as design basis faults, and all failure modes as well as the normal system operating conditions are considered at the design stage. An active FTC reacts to system component malfunctions (including actuators, system itself, and sensors) by reconfiguring the controller based on the real-time information from a Fault Detection Diagnosis (FDD) scheme. The term “active” represents corrective actions taken actively by the reconfiguration mechanism to adapt the control system in response to the detected system faults. Adaptive control methods are very suitable for active FTC. Due to their adaptation ability in the case of system parameter changes, these methods are in self-reconfigurable type. In other words, they do not require the reconfiguration mechanism and FDD components if component and actuator faults are considered.

In this study, firstly, a general model for actuator fault/failure is given. Then, a simple single input single output water level control system with valve actuator is chosen as testbed since it is widely used in process industry. The level control process is modeled and simulated in order to show the effect of actuator faults/failures on closed loop system performance. A conventional PI controller is chosen to track reference water level. Then, in random time and mode, various fault/failure scenarios are taken into account. Conventional PI controller cannot compensate the failure effects since it has not a reconfiguration structure. Therefore a controller with that property is needed. A model reference adaptive controller is designed in this case and fault accommodation property is compared with PI controller.

II. PROBLEM FORMULATION AND SYSTEM DESCRIPTIONS

A. Actuator Failure Model

Faults are not a reduction in efficiency only; they also include other cases such as stuck/frozen/hard-over failure of control valves in the case of process control. To represent the actuator faults in a more general formulation, the following mathematical model can be used [26]:

\[
\begin{align*}
\dot{u}_i(t) &= \sum_k u_k(t) + (I - \sum_k) f_i(t) \\
\Sigma_i &= \text{diag}\left[\sigma_{i1}^*, \sigma_{i2}^*, ..., \sigma_{in}^*\right]
\end{align*}
\]

where \(u_i(t)\) is faulty actuator output, \(f_i(t)\) contains the values at which the actuators are stuck or floating or hard-over. \(I\) is the identity matrix and \(\sigma_{i0}^* = 0\) represents a total fault (i.e. a complete failure) of the \(i\)-th actuator of the system so that the control action coming from this \(i\)-th actuator becomes equal to the \(i\)-th element of the uncontrollable offset function \(f_i(t)\) , i.e., \(u_i(t) = f_i(t)\). On the other hand, \(\sigma_{i1}^* = 1\) implies that \(i\)-th actuator operates normally ( \(u_i(t) = u(t)\) ). The quantities \(\sigma_{ij}^*\) can also take values in between 0 and 1, making it possible to represent partial actuator faults. For different types of fault conditions the above model can be specified in detail as:

\[
\begin{align*}
\sigma_i' &= \begin{cases} 
0 & t < t_f \\
1 & t \geq t_f
\end{cases} \quad \text{Fault free} \\
\sigma_i' &= \begin{cases} 
0 & t < t_f \\
1 & t \geq t_f
\end{cases} \quad \text{Partial fault} \\
\sigma_i' &= \begin{cases} 
0 & t < t_f \\
1 & t \geq t_f
\end{cases} \quad \text{Stuck fault} \\
\sigma_i' &= \begin{cases} 
0 & t < t_f \\
1 & t \geq t_f
\end{cases} \quad \text{Hard-over fault} \\
\sigma_i' &= \begin{cases} 
0 & t < t_f \\
1 & t \geq t_f
\end{cases} \quad \text{Floating fault}
\end{align*}
\]

Practically, considered faults in (2) occur randomly with unknown size and mode. Some probabilistic properties can be added to the model to represent randomly occurring phenomenon. In this case, the failure model can also represent the failures occurring intermittently.

Faults are further classified as additive and multiplicative with respect to the way they are modelled. Additive faults are suitable for representing component faults in the system while sensor and actuator faults are mostly multiplicative by nature. Possible actuator faults in multiplicative type can be represented by:

\[
\begin{align*}
\dot{x}(t) &= \sum_k x_k(t) \\
\dot{y}(t) &= \sum_k y_k(t)
\end{align*}
\]

Such multiplicative actuator faults do not directly affect the dynamics of the controlled system itself, however they can significantly affect the closed-loop system and may even affect the controllability of the system.

B. System Model

In water level control system given in Fig. 1, water is pumped into the tank at the top through an actuated valve and at the bottom of tank the water drains through a pipe. The objective is to control the water level in the tank with zero steady-state error.
According to Bernoulli equation, the rate of flow of water through the pipe is given by:
\[ q_s = a \sqrt{2gh} \]  (4)

where \( h \) is the level of the tank, \( a \) is the pipe cross-section area and \( g \) is the acceleration of gravity. Conservation of mass yields the equation:
\[ \frac{dh}{dt} = q_s - q_e = q_e - a \sqrt{2gh} \]  (5)

where \( A \) is the bottom area of the tank, \( q_e \) is the inflow rate through the valve.

If we linearize the system around an operating point and ignore the pressure of the tank outlet, the system can be assumed to be first order but by taking valve dynamics into account, system dynamics become second order. The first order system transfer function between inflow rate and water level is:
\[ H(s) = \frac{R}{Q(s)} = \frac{R}{ARs + 1} \]  (6)

where \( R = h/q_e \) is the resistance at the outlet and the valve dynamics can be given with a first order transfer function between controller output \( U(s) \) and system input \( M(s) \):
\[ G_e = M(s)/U(s) = \frac{K}{T_s + 1} \]  (7)

Here gain \( K \) represents steady-state relation between input and output and \( T_s \) is the time constant of valve actuator.

C. Fault Tolerant Control Design

In normal operation conditions, a PI controller is able to track reference while in actuator fault case; an adaptation mechanism is needed because of changing closed loop system parameters. Therefore MRAC is integrated into the system such that PI-controlled system model in normal operation is the reference model of MRAC. PI controller can be represented by the following transfer function:
\[ G_{PI} = \frac{U(s)}{E(s)} = K_p \left( 1 + \frac{1}{T_s} \right) \]  (8)

Reference model is chosen such that valve dynamics and system parameters are unknown. In this case, the closed loop transfer function that has one zero and three poles with unknown coefficients of known signs can be written as follows:
\[ G_{r1}(s) = \frac{Y(s)}{R(s)} = \frac{b_3 s + b_0}{s^3 + a_3 s^2 + a_2 s + a_1} \]  (9)

In order to meet MRAC objective with a control law that is free of differentiators and uses only measurable signals, plant and reference model must satisfy some requirements such as plant numerator polynomial is monic, plant degree is known, plant relative degree is known; reference model numerator and denominator are monic Hurwitz polynomials and relative degree is the same as that of plant. In other words, reference model must be chosen to be strictly positive definite (SPR) to obtain a stable controller. Following the certainty equivalence principle, the controller given below can be used [27]:
\[ u = \theta^T \alpha(s) \left( \frac{y_p + \theta^T y_p + c_i \Gamma}{\Lambda(s)} \right) \]  (10)

where \( \alpha(s) \) is an arbitrary monic Hurwitz polynomial of degree \( n \). The controller given in (10) has known parameters \( \theta' \) i.e., the controller is designed for a known plant transfer function therefore it is named as model reference controller (MRC). However, by using certainty equivalence, we can define an update law and use the same controller with unknown parameters. We can write the equation in compact form as follows:
\[ u = \theta^T \omega \]  (11)

Let us define the parameter error as:
\[ \tilde{\theta} = \theta(t) - \theta' \Rightarrow \theta(t) = \tilde{\theta} + \theta' \]  (12)

By using (12), (11) can be written as follows:
\[ u = \tilde{\theta}^T \omega + \theta'^T \omega \]  (13)

In order to choose an adaptation law, we have to first find out how the tracking error is related to the parameter error:
\[ e = G_n(s) p' (u - \theta'^T \omega) = G_n(s) (p \tilde{\theta}^T \omega) \]  (14)

where \( G_n(s) \) is reference model transfer function; \( p' \) is the ratio of the plant and reference model high frequency gain. Following Lyapunov function is used to prove system stability:
\[ V(\tilde{\theta}, e) = \frac{1}{2} \tilde{\theta}^T P_n e + \frac{1}{2} p' [\tilde{\theta}^T \Gamma^{-1} \tilde{\theta}] \]  (15)

Here \( P_n = P_n^T > 0 \) and \( \Gamma = \Gamma^T > 0 \). By using Kalman–Yakubovich lemma and Lyapunov function above, adaptive law is obtained as follows:
\[ \dot{\theta} = -\text{sgn} \left( \frac{k_e}{k_n} \right) \Gamma e \omega \]  (16)

In the design procedure of above controller, we assume that system has relative degree 1 which gives the opportunity to design reference model as SPR. The reference model we consider for the plant has relative degree 2. In this case reference model \( G_n(s) \) can no longer be SPR. We can solve this problem by using the fact that \((s + p_0)(s + p_0)^{-1}\) is identity for some \( p_0 > 0 \) and rewrite the error equation:
\[ e = G_u(s)(s + p_0)\phi^* (u_j - \theta^* \phi) \]  
(17)

with \( u_j = \frac{1}{s + p_0}u \), \( \phi = \frac{1}{s + p_0}\omega \), which implies that the control law in compact form is:

\[ u = \theta^* \omega + \theta^* \phi \]  
(18)

The reference model degree is \( n=3 \) hence choosing the degree of \( \Lambda(s) \) as \( n-1 = 2 \), fixing \( \Lambda(s) = s^3 + s + 1 \) and taking \( \alpha(s) = [s \ 1] \) for \( n = 3 \) designed controller takes the following form:

\[
\begin{align*}
\dot{u} &= \theta^*_1(t) \left[ \begin{array}{c} s \\ s^2 + s + 1 \\ s^2 + s + 1 \end{array} \right]^T u + \theta^*_2(t) \left[ \begin{array}{c} s \\ s^2 + s + 1 \\ s^2 + s + 1 \end{array} \right]^T y_r \\
&+ \theta^*_3(t)y_r + \theta^*_4(t) + \theta^*_5 \phi \\
\theta &= -\Gamma \phi \text{sgn} \left( \frac{k_p}{k_m} \right) \\
\phi &= \frac{1}{s + 1} \omega
\end{align*}
\]  
(19-21)

III. SIMULATIONS

In this part, firstly, water level control process is modelled and a PI controller is chosen to track reference water level. Using (5), a simulation model is constructed with the model parameters given in Table I.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Height of tank, ( h )</td>
<td>2 m</td>
</tr>
<tr>
<td>Bottom area, ( A )</td>
<td>1 m²</td>
</tr>
<tr>
<td>Out pipe cross-section, ( a )</td>
<td>0.1 m²</td>
</tr>
<tr>
<td>Initial level height ( h_i )</td>
<td>0.5 m</td>
</tr>
</tbody>
</table>

![Table I: Process Parameters](Image)

Appropriate PI parameters are chosen to achieve good time response characteristics such as 10\% maximum overshoot and 10s settling time. The parameters that meet the time domain specifications are \( K_p = 0.65 \) and \( T_i = 2.86s \). Fig. 2 shows the simulation diagram of the system with valve dynamics. System simulation time is 150s and sample time is selected to be 0.01s. A square wave reference input that changes between 0.7 and 1.7 is applied and the response of the system in normal mode can be seen in Fig. 3.

![Fig. 2: PI-controlled simulated system block structure](Image)

![Fig. 3: PI-controlled system output response in normal mode](Image)

PI controlled healthy system given in Fig. 2 is subjected to least squares system identification process by using reference input data \( u \) and output response data \( y_r \). Plant parameters in the simulation are assumed to be unknown in order to take possible parameter variations and uncertainty in real system into account. As a result of identification the following transfer function is obtained:

\[
G_{eu}(s) = \frac{Y(s)}{R(s)} = \frac{3.65s + 1.32}{s^3 + 6.70s^2 + 4.52s + 1.32}
\]  
(22)

Figure 4 shows model reference adaptive controller integrated system simulation model. Before starting the simulations, an actuator failure block is constructed for valve actuator so that in any time of simulation, random failure mode with unknown size can be applied to closed loop system. A wide range of fault/failure cases of valve are considered such as; hard-over, lock-in-place, stuck open, floating failure, leakage, loss of effectiveness. Fig. 5 shows the structure of failure block integrated water tank model. Faulty actuator block with various failure modes that is integrated into simulation can be seen in Fig. 6.

![Fig. 4: Model reference adaptive controlled system block structure](Image)
In MRAC system simulations, total simulation time is 140s, sample time is 0.01s and a square wave reference input that changes between 0.7-1.7 with a period of 90s is applied. Failure responses of both adaptive and non-adaptive controller are examined from different aspects. Various types of failures considered in Section II are simulated. In addition, fault occurrence types that may differ such as incipient, intermittent and abrupt changes are also considered. Following figures show the performance of PI-controlled system and MRAC system in the case of complete or partly failures.

Simulation results show that adaptive controller can compensate for any partial failure regardless of its occurrence type such as abrupt, intermittent and incipient. It has also a good transient response while PI-controlled system exhibits undesired high amplitude oscillations and bad transient behavior in the case of intermittent faults. Furthermore, in incipient loss of effectiveness fault mode given in Fig. 7, PI controller may dramatically damage a real process. In abrupt loss of effectiveness case given in Fig. 8, MRAC adapts itself to system changes while PI controller exhibits an undershoot. In Fig. 9, an intermittent valve leakage occurs with 20s duration and PI control has an oscillatory transient behavior. In abrupt valve leakage case which response is given in Fig. 10, PI controlled system output oscillates continuously while MRAC keeps tracking the reference input. In abrupt occurrence type lock-in-place and hard-over failure cases given in Fig. 11 and Fig. 13 respectively, both controller types cannot accommodate the failures since the system has loose controllability property and does not have actuator redundancy. As it can be seen from Fig. 12, after an intermittent lock-in-place failure of 5s, both systems has the ability to track the reference signal.
In this study, a brief literature search about actuator failure modeling is given. A simple water tank level control model, which is widely used in process industry, is selected as benchmark system. Possible valve actuator failures of tank process are considered and modeled. A fault tolerant MRAC controller is designed for the system and controller performance is tested and compared with conventional PI control via simulations. Simulation tests reveal good performance of designed MRAC over conventional control in terms of eliminating actuator failure effects in transient and at the steady state. As a future work, designed controller will be implemented on a real system. Furthermore, stochastic failure model will be integrated into the system at the design stage and also a robust adaptive controller will be designed to compensate for the failures.

REFERENCES

Abstract— Wireless Sensor Networks (WSN’s) have been finding to itself new applications continuously. Many of these applications need location information of nodes. The localization of nodes can be made by range based or range free localization methods conventionally. Angle-of-Arrival (AoA), Time-Difference-of-Arrival (TDoA), Received Signal Strength Indicator (RSSI), Time-of-Arrival (ToA) are well known range based methods. Therefore AoA, ToA and TDoA have some hardware and software difficulties for nodes which have limited processing and power sources. However RSSI based localization doesn’t cost high processing resources or complex hardware modifications. Most of the WSN nodes already have RSSI measurement capability. However RSSI measurements is vulnerable to noise and environmental effects. Therefore error of RSSI based localization can be over to an acceptable level.

Centroid, APIT, DV-Hop and Amorphous are some of the range free localization methods. Range free methods can only give location information approximately but they don’t need any extra hardware or high processing capability.

In this study WSN nodes are assumed randomly or regularly distributed on a certain area. Some of the nodes are beacon nodes. The beacon nodes are assumed as having higher power resources and GPS receivers. The locations of nodes are assumed as fixed. The beacon nodes send their location information sequentially. Localization of nodes are made through RSSI and location information of beacon nodes. The mean of RSSI is calculated to reduce effect of noise on it. A rough location estimation made by weighted centroid. A probabilistic based location estimation and flower pollination algorithm (FPA) are used separately to make final decision about the location. Rough estimates are used to limit search area of flower pollination algorithm in order to reduce convergence time.

Keywords— RSSI, FPA, WSN, optimization, probabilistic.

I. INTRODUCTION

Recently, WSN has become popular study in communication. The apps like health, business, military and habitat are the factors which made WSN has been so popular [1]. Nodes which are the elements of the WSN have advantages as operating with low-power, having small physical structure, low-cost and communication capability with adjacent nodes in limited range [2]. These are the other reasons why the WSN is so popular.

One of the main objective about WSN is acquiring location information of the sensor nodes. The localization simply means determining physical coordinates of the nodes which are unknown. Location information of the sensor nodes carry vital weight for many WSN apps. For instance; monitoring and surveillance of volcano activities, tsunami risk in oceans, melting regime of the poles, wild animals under risk of extinction, mobility of civilian and military vehicles and agricultural fields require that.

In WSN’s, there are two typical node types. Anchor node (also is called Beacon) is one of them. Anchor node knows location information of itself and can send data to the adjacent nodes. Other one is called non-anchor node which estimates physical coordinates of itself by various methods through location information of the anchor nodes that are in coverage area of it.

In literature, various localization methods have been classified conventionally into two categories named as range-based and range-free methods. Range-based methods require additional hardware. Naturally, additional hardware makes it costly.

Angle-of-Arrival (AoA), Time-Difference-of-Arrival (TDoA), Received Signal Strength Indicator (RSSI), Time-of-Arrival (ToA) are well known range based methods. AoA needs angle of received signal, time based methods; ToA needs exact synchronization between nodes, TDoA needs multiple receivers and synchronization between these receivers [3]. Therefore AoA, ToA and TDoA have some hardware and software difficulties for nodes which have limited processing and power sources.

Range-free methods generally use hop-counting and local techniques [4]. As a feature Range-free methods don’t require additional hardware but location estimations are rougher than range-based methods. Centroid, APIT, DV-Hop and Amorphous are some of the range-free localization methods [5]-[6]-[7].

If RSSI based localization is taken into account, it is seen that it doesn’t require high processing resources or complex hardware modifications. Even it can be considered the least complex among the range-based methods. Most of the WSN nodes already have RSSI measurement capability. But on the other hand RSSI measurements are under effects of noise and environment. Therefore error of RSSI based localization should be over to an acceptable level. For the RSSI based localization noise and environmental effects are considerable problems. To reduce these effects, there are many methods have been proposed in literature. Some studies are based on
reducing of distance error by estimating of path loss parameters dynamically [8]-[9]. In another study, error is reduced by making a mapping database between RSSI and distance information [10]. On the other hand, particle filter usage may has been another solution for RSSI error. For instance, in reference [11] a new particle filter with a hardware-free initialization phase is presented. In other particle filter approach, multiple antenna arrays and particle filter are used together for reducing of RSSI error [12].

In this study, locations of nodes are assumed as fixed. Namely, environment is assumed as static. Therefore, path loss attenuation is also assumed a fixed value. In simulation scenario, the beacon nodes send their location information sequentially. Location estimations of the nodes are made through RSSI and location information of beacon nodes. The mean of RSSI measurements are calculated to reduce effect of noise on it. A rough location estimation made by weighted centroid. In the next phase, a probabilistic based location estimation and flower pollination algorithm (FPA) are used separately to make final decision about the location. Rough estimates are used to limit search area of flower pollination algorithm in order to reduce convergence time.

II. RECEIVED SIGNAL STRENGTH

RSSI method is based on location estimations of the non-anchor nodes by using signal strength of the anchor nodes where are in coverage area of the non-anchor nodes. Received Signal Strength (RSSI) can be formulated simply shown as (1).

\[
\text{RSSI}(dB) = P_{TX}(dB) - P_{LOSS}(dB)
\]  

(1)

Where, RSSI(dB) is received signal strength acquired at non-anchor node, \( P_{TX}(dB) \) is transmitter power of the anchor node, \( P_{LOSS}(dB) \) is path loss in the channel. Well-known models for path loss are Free Space, Log-normal and Hata [13]. Generally, environment where is WSN modules installed shows distortion effects like diffraction, multipath, obstacles etc. The most convenient path loss model for this kind of environments is Log-normal distance model [14]. In this model, path loss can be calculated through the equation shown as (2).

\[
P_{LOSS}(d) = P_{LOSS}(d_0) + 10 \delta \log\left(\frac{d}{d_0}\right) + X_0
\]  

(2)

Where, \( P_{LOSS}(d) \) is path loss value in dB that occurred at distance \( d \), \( X_0 \) is Gaussian noise with zero mean and standard deviation can vary between 4~10. \( \delta \) is path loss attenuation factor which can vary between 2~5. \( P_{LOSS}(d_0) \) is path loss value in dB that occurs at 1m distance. \( P_{LOSS}(d_0) \) is given 40.3dB in CC2538 catalogue [15]. Therefore we accepted \( P_{LOSS}(d_0) = 40.3\text{dB} \).

In simulations, a fixed path loss attenuation factor (\( \delta \)) is used because of anchor and non-anchor nodes are assumed to be fixed locations. In this conditions, path loss is under effect of Gaussian noise as seen in equation (2).

A. The Improvement of RSS Quality

First phase of proposed system is about improvement of RSS quality. Absolute uncalibrated RSSI/CCA accuracy is ±4dB in CC2538 catalogue [15]. This accuracy means ±8m location error at 25m distance under certain conditions. For some apps that accuracy is acceptable but not always. To reduce noise and improve the accuracy, anchor nodes should send signal sequences to its non-anchor nodes. Each non-anchor node gets RSS sequences from the anchor nodes that are at coverage area of it. Due to nodes are static, distances don’t change. In that case, mean of each RSS sequence is an improved RSS information because of Gaussian noise reduced. This is expressed mathematically in equation (3).

\[
\text{RSS}^{\text{IMP}} = \frac{\sum_{i=1}^{k} \text{RSS}_i}{k}
\]  

(3)

Where, \( \text{RSS}^{\text{IMP}} \) is improved RSS value that is acquired from anchor node, \( k \) is the number of sequence, RSS, is the \( i \)th RSS value that is acquired from anchor node. Improved RSS information is important for the distance information. For the next phase of the proposed system, distance can be calculated shown as equation (4).

\[
d_i = \frac{(P_{TX} - \text{RSS}^{\text{IMP}} - P_{LOSS}(d_0))}{10 \delta}  
\]  

(4)

Where, \( d_i \) is \( i \)th improved distance information of the anchor node which is in coverage area of the adjacent non anchor node.

Improved distance information is one of the important parameter for the applied pre-localization. In this study, we preferred weighted centroid algorithm (because of its simplicity).

III. WEIGHTED CENTROID

Weighted centroid is a RSS based localization algorithm [16]. Weights specify level of proximity of the anchor nodes according to the non-anchor node. Weights can be calculated shown as (5).

\[
w_i = \frac{\sum_{j=1}^{N} d_j}{N d_i}
\]  

(5)

Where, \( w_i \) is the weight of \( i \)th anchor node and \( N \) is the anchor node number in the coverage area. After calculation of the weights, rough coordinates can be calculated shown as equation (6).
\[ \bar{x}_r = \frac{\sum_{i=1}^{N} w_i x_i}{\sum_{i=1}^{N} w_i}, \quad \bar{y}_r = \frac{\sum_{i=1}^{N} w_i y_i}{\sum_{i=1}^{N} w_i} \]  

(6)

Where, \( x_i \) is abscissa of the \( i \)th anchor node, \( y_i \) is ordinate of the \( i \)th anchor node, \( x_r \) is abscissa of the estimated rough coordinates and \( y_r \) is ordinate of the estimated rough coordinates. Even if, the coordinates that are estimated through weighted centroid might be sufficient for many WSN apps, sometimes it might not be sufficient. Hence at the last step, probabilistic and FPA methods are used for the improvement.

### IV. PROBABILISTIC APPROACH

In this approach non-anchor nodes estimate their own location through probability density function (pdf). We can express the probability of non-anchor node location in limited area at two dimensional space as in (7).

\[
P_{k}(x_r,y_r) = \int_{x_{r_{min}}}^{x_{r_{max}}} \int_{y_{r_{min}}}^{y_{r_{max}}} f(x,y) \, dx \, dy
\]

(7)

Where, \( P_k(x_n,y_n) \) is the probability of the non-anchor node, \( x \) can change between \( x_{min} \) and \( x_{max} \) and \( y \) can change between \( y_{min} \) and \( y_{max} \) which are bounding coordinates. \( \Delta x \) and \( \Delta y \) are arbitrary small values [17].

The first phase of this approach is calibration phase. RSS measurements are collected at different distances between anchor and non-anchor node. The mean value of RSS measurements \( \mu_{RSS}(d) \) and standard deviation \( \sigma_{RSS}(d) \) can be calculated from measurements, where \( d \) defines distance. In reference [17] it is mentioned that in theory and experiments \( \sigma_{RSS} \) doesn’t vary significantly with the distance. If \( X_0 \) is 0, RSS probability of any distance \( d' \) is equal to 1.

\[
p \rightarrow P_k \left( d' = 10^{0.05 (P_{RSS} - P_{LOSS}(d_0))} \right) = 1
\]

(8)

Practically, channel is under effect of shadowing. Thereby, distribution of distance for a fixed RSS value is log-normal. Consequently in calibration phase, log-normal mappings of the RSS measurements are acquired [17].

Second phase of the probabilistic approach is localization with positive constraints. In this phase, each non-anchor node estimates its pdf position through the log-normal mappings of the RSS measurements.

At first, each non-anchor sets initial estimation for entire network area. Then, anchor nodes send information which includes their own position information and updated pdf estimations of both their own and non-anchors to the adjacent nodes. Non-anchor receives the information and executes the following algorithm;

- RSS measurement is done from received packets,
- RSS is mapped to the one dimensional pdf acquired from the first phase, and a pdf constraint is generated which is function of the 2D coordinate.
- Old pdf is intersected with generated constraint and update is done.
- At last, non-anchor node sends updated pdf estimation to all its adjacent nodes.

Consequently, final estimations for the non-anchor node coordinates are made according to the maximum probability evaluation.

### V. FLOWER POLLINATION ALGORITHM (FPA)

Pollination process in the nature consists of two different forms called biotic and abiotic forms. Biotic pollination is carried out by pollinator creatures as bird, bat and bee. 90% of all pollination events take place in biotic form. And remaining 10% happens in abiotic form that is occurred by wind or water diffusion. It does not include any pollinators. Pollinators travel to long distances to reach plants that they wish. They maximize the pollination probability of the same-species via flying over other species. Pollination process happens in two main types as self-pollination and cross-pollination. Self and cross-pollination are shown in Fig. 1.

- Cross-pollination is defined as pollination that occurs among different plants in the same species. Thus, pollinators are very effective for the cross-pollination. On the other hand, if the pollination occurs in the same plant, this is defined as self-pollination. While self-pollination might occur in different flowers of the same plant, it might also occur in same flower of the same plant [18].
- Pollinators like bird, bat and bee show Lévy Flight behaviour and flying steps show Lévy distribution [19].
- Pseudo algorithm of the FPA can be expressed as below.

**Rule (1):** Biotic and cross-pollination is accepted as global pollination process. Pollinators who carry pollens show Lévy Flight behaviour.

**Rule (2):** Abiotic and self-pollination is accepted as local pollination process.

**Rule (3):** Flower pollination constancy is proportional with the probability of breeding between two similar species.

Fig. 1 Pollination types
Rule (4): Global and local pollination probability is controlled by a switching probability which is defined as $p \in [0, 1]$. The effects like physical proximity, wind and local pollination are considerable part of the global pollination. As a result, they are also considerable for the switching probability. In other words, these effects can be changed by controlling switching probability.

In global pollination phase, the most convenient pollination can be achieved by pollinators who can travel to long distances. While the most convenient pollination parameter is $g_b$, flower pollination constancy can be expressed mathematically as in (9).

$$\phi_i^{t+1} = \phi_i^t + L(\phi_i^t - g_b) \tag{9}$$

Where, $\phi_i^t$ is the $i$th solution vector in $t$th iteration, $g_b$ is the best solution in $t$th iteration and $L$ is the step size which is characterized by Lévy Flight [18-19].

Flower constancy for local pollination can be expressed mathematically as in (10).

$$\phi_i^{t+1} = \phi_i^t + \epsilon(\phi_j^t - \phi_k^t) \tag{10}$$

Where $\phi_j^t$ and $\phi_k^t$ defines pollens where they come from different flowers of the same plant species. If $\phi_j^t$ or $\phi_k^t$ comes from the same species or selected from the same population, it shows random walk characteristics with uniform distribution as defined $\epsilon [0, 1]$ [18]. Consequently, flow chart of FPA can be drawn as shown in Fig. 2.

In this study unlike the conventional FPA algorithm, rough solutions and improved data are integrated to the algorithm. Objective function of this optimization phase is expressed in equation (11).

$$J(x, y) = \sum_{i=1}^{k} \frac{d_i - \sqrt{(x_i - x)^2 + (y_i - y)^2}}{d_i} \tag{11}$$

Where, $J$ is the cost or objective function, $k$ is the anchor node number in communication range of the non-anchor node, $d_i$ is the improved distance information between $i$th anchor node according to the non-anchor node, $x_i$ is the abscissa of the $i$th anchor node, $y_i$ is the ordinate of the $i$th anchor node, $x$ is the abscissa of the pollen and $y$ is the ordinate of the pollen. In the objective function, $d_i$ is subtracted from the distance between pollen and adjacent anchor node of itself. Then, absolute value of the result is divided to $d_i$ to avoid cumulative optimization error. Consequently, global best is acquired by minimizing the value of sum of dependent errors of the every pollen.

VI. SIMULATIONS AND RESULTS

In simulations, anchor nodes are located edge of the 30x30m square area in equal intervals. Transmitter power of the anchor nodes are assumed to 1mW. Non-anchor nodes are assumed at fixed location and deployed randomly in defined area.

For the channel, path loss attenuation is assumed as fixed ($\delta=2.7$) and previously determined through experimentally. Gaussian noise is assumed as zero mean and standard deviation is 5.

Also, iteration and particle number are selected 20, switching probability is selected 85% for the FPA.

In the light of these assumptions, results are acquired by changing two parameters. The first parameter is physically intervals of anchor nodes. The second parameter is about number of RSS samples that acquired from the anchor nodes.
Number of RSS samples were selected fixed value as 10 and number of the non-anchor nodes were selected as 20 for the first analysis. Intervals of the anchor nodes were changed respectively 10-15-30m. Under these conditions, simulation results which contain mean-errors are shown below separately and respectively.

In second analysis, number of RSS samples are increased to 50. Simulation results for each distance interval are shown below.

Mean errors for each methods are shown in Table I. As can be seen, for each distance interval, FPA localization gives the best results.
increasing the RSS samples to 50 improved the location accuracy approximately 50% for the FPA.

VII. CONCLUSIONS

In this study, two different approaches are analysed which used weighted centroid rough results. Both the methods showed improvement according to the weighted centroid localization. When comparison is made between two methods, it shows us that FPA has more accurate results and lower processing load. As a future work, RSSI based location accuracy improvement for mobile nodes will be examined.

Abstract— in this paper a cascade inverter based on photovoltaic system is proposed and the control method which is used in this inverter is the charge balance control method in order to equalize the amount of power which drawn from each h bridge(except the first one ). As a result the batteries life of the inverter which is consider the most important component of the inverter will increase .Also the magnitude of the dc sources is selected in such a way that the number of levels which are produced is more than symmetrical cascade inverter .All of the expressed theoretical results are confirmed by simulation and experimental results.

Keywords— cascade multilevel inverter, photovoltaic, full wave charge balance control method, buck – boost dc to dc converter, perturb and observe maximum power point method.

I. INTRODUCTION

Today, cascade H bridge multilevel inverters have got more interest according to their essential advantages such as: high voltage and high power ratings applications, excellent power quality, lower order harmonics, reduction in switching losses [1-2] .The output waveform of these inverters is synthesized from several dc voltage sources as inputs.

Generally the multilevel inverters are divided into three types according to the topology structure, diode clamped multilevel inverter, flying capacitor multilevel inverter, cascade H bridge multilevel inverter [3].There is more focus on cascade H bridge multilevel inverter because of its simple design ,simple maintenance, the ability of generating large number of output levels by using the same number of the semiconductor devices as compared with the other topologies [2-3].Depending on the above advantages, the losses and the cost will be reduced, on the other hand the efficiency will be improved [2] .The sub classifications of cascade multilevel inverter are the symmetrical and asymmetrical inverters if one of the input dc sources is different and then we can recognize that inverter as asymmetrical inverter[2-5] which can produce more numbers of output levels and amplitude than symmetrical type[6] .The most distinct feature of cascade multilevel inverter is that it need separate dc sources as an input so it is considered the most suitable way to use with renewable energy sources such as pv panels which increases interest because of the Global increasing demand , reduces the negative impact of the power generations on the environment, needs no fuel cost and reduces the transmission losses in case of off grid which serves the regions far from transmission lines and generation units [4] .

Several methods are used to control the cascade h bridge multilevel inverter .Some of these control methods are : [6]:

- Fundamental frequency control method
- Sinusoidal pulse with modulation method
- Space vector pulse with modulation method

The Fundamental frequency control method is considered the most applicable method. In this method every semiconductor device is turned on one time per fundamental cycle and that leads to reduce the conduction losses and the electromagnetic interference [6]. On the other hand it has the drawback related to the amount of power which drawn from one DC source which is different from the other sources, so the battery life will be different from each other and that leads to high maintenance cost [2] .In order to overcome the disadvantage of this method the charge balance control method is proposed in this work to equalize the amount of power drawn from each Dc source.

In this paper, firstly we introduce the basics of cascade H bridge multilevel inverter, secondly brief description of the pv system and then the simulation and practical results will submit the proposed cascade inverter.

II. CASCADE MULTI-LEVEL INVERTERS

Generally, the key component of cascaded inverter is the full bridge unit which is shown in Fig. 1.[11].it is used to produce three level output waveform (vdc, 0and -vdc) with different duty cycle. It consists of four switches which can conduct in bidirectional power flow and can block unidirectional voltage. This reason is behind the connecting of anti-parallel diode with the switching devices and in case of pure resistive loads we can use the semiconductor switch without the anti-parallel diode due to unique current direction .Each switching device has to switch on in a complementary manner with another switch in the same arm to avoid the short circuit across the source so all the control
strategies are built according to this fact, e.g. when s1 is on s3 is already off and when s2 is on s4 is already off.

These H bridges are connected to distinct DC sources in the supply side while the diode clamped and flying capacitor requires common DC source and connected in series in the output side. We can call it as ac side Fig.2. It Show the single phase diagram of cascaded H bridge inverter[11] according to cascaded inverter configuration, the control and modulation and maintenance are modular.

![Fig.1. Full H bridge (three level output)](image1)

![Fig.2. Single phase diagram of cascaded inverter](image2)

Where \( v_o \) represent the output voltage of the cascaded inverter and it can be calculated by adding the amounts of \( v_1(t), v_2(t), \ldots, v_N(t) \). Where N is the number of the cascaded bridges.

The relationship between the produced number of output voltage levels (n) with respect to the number of connected cells N in symmetric converters is:

\[
n = 1 + 2N
\]  
(1)

and the maximum output voltage \( v_o \) is given as a function with the DC sources that cascaded as:

\[
v_{\text{max}} = N \cdot v_{\text{dc}}
\]  
(2)

From the above two relations, we can recognize the most related disadvantage of this topology which is increased of the DC sources and the semiconductor switches when we aim to increase the output levels, so to reduce the number of DC sources and also the semiconductor switches and the connecting cables the asymmetrical cascade h bridges multilevel inverter is proposed. This produces maximum numbers of levels and by utilizing the same number of the DC sources and H bridges, in [9] and [10] the manner of selecting the DC source voltages is binary progressing in [9] and ternary progressing in [10] and the output levels (n) is given as (3) and (4).

\[
n = 2^{N+1} - 1 \quad \text{in binary progress ratio}
\]  
(3)

\[
n = 3^N \quad \text{in ternary progress ratio}
\]  
(4)

By comparing the equations (3)-(4) by (1) it is clear that the output levels increase in the asymmetrical topological at the same time by keeping the same number of switching device and DC sources. This is just an example to show the difference between symmetric and asymmetric inverter topologies. The dependent way for determining the values of DC sources in this paper is also based on asymmetrical configurations and selected to be as follows [12].

\[
v_{\text{dc}1} = v_{\text{dc}}
\]  
(5)

\[
v_{\text{dc}, m} = 3^m v_{\text{dc}1} \quad m = 2, 3, N
\]  
(6)

And the output levels number is given as:

\[
n = 6N - 3
\]  
(7)

Where N is the number of the series connected H bridges. The reason behind the selection of this manner is according to the fact that we cannot use the charge balance control method in [9] and [10], because of different voltages of the batteries.

The main advantages of this method as compared with the fundamental frequency control method is to equalize the amount of power which drawn from different batteries. As a result, battery life will be equal which will reduce the maintenance cost. Several modulation patterns can be used to implement the charge balance control method, in fullwave pattern the angles will route continuously after one cycle while in halfwave pattern the routating angle will routeate after half cycle. If any pattern is used we will make all the DC sources get charges and be balanced after a specific time of operation expect the battery which is used in the first h bridges so the amount of power will be given as:

\[
P_{\text{DC}, k} = \frac{1}{T} \int_0^T v_{o_k} \cdot idc_k \, dt
\]  
(8)

Where \( T \) is the time duration to equalize the power drawn from the bridges.

In Fig.3, a seven level symmetric cascade inverter is implemented by fundamental frequency control method, full

In this paper we will use the fullwave control pattern. It mean the conducting angle will rotate after every full cycle.

III - Interview of photovoltaic system.
Generally, solar cells generate electric potential from sun energy by photovoltaic module which is built from silicon cells. And always the output of these cells has been low so a photovoltaic array is formed to increase the total potential output. The array can be formed by a series or a parallel connected of solar cells to increase the produced voltage or current of the module, pv cells gives its maximum output power in one specific point. This point is called the maximum power point and it depends on the loads, temperature and irradiance. According to this characteristic the pv cells or the photovoltaic module cannot operate in its maximum power point without an external effects which forced the pv panel to operate in its maximum point so that one of the maximum power point tracing algorithm have to be used with the dc-dc converter to maintain the operating point of the panel near the maximum power point area[4]. Some of these techniques are Constant Voltage MPPT Algorithm, Perturb and Observe (P&O)MPPT Algorithm, Incremental Conductance (INC) MPPT Algorithm[8], and the other important component is the dc-dc converter such as : buck, boost, buck boost converter to be merged with the mppt algorithm to ensure that the module will operate in it is maximum power point tracing and to construct the solar charge controller [7], in this paper we will use the following components:

A- buck-boost dc-dc converter

B- perturb and observe mppt algorithm.

A- BUCK -BOOST DC-DC CONVERTER

Generally, DC-DC converter is an electronic circuitry that is capable of producing different levels of dc voltage, many conversion processes are used in these converters such as switch mode, linear, and magnetic[7].

Some of the most famous topologies is buck, boost, buck-boost converters, in buck converter the output voltage is less than its input while in boost converter the output voltage is greater than the input voltage. In buck boost type as it is clear from the title of this converter it is able to work as buck mode and boost mode. As mentioned above, we will use this type of converters together with mppt algorithm so our big attention will be around the buck-boost converter, two operation mode can be used in this converter, the continuous conduction mode (ccm) if the current of the converter never reaches the zero region while the other operating mode is called the discontinuous operating mode (dcm) when the converter current reaches the zero region during the time period the equation of all calculation is different from one mode to another.

In this paper we will use the continuous conduction mode (ccm) the output voltage is calculated as:

$$v_o = vi \frac{b}{1-b}$$ (9)

While in discontinuous conduction mode (dcm) the output voltage is calculated as:

$$v_o = vi \frac{b^2}{2Io}$$ (10)
Where \( D \) is the duty ratio which will feed the controlling switch and \( V_o \) in both modes in average values.

\( I_o \) is the current through the load.

In continuous conduction mode (ccm) when \( D < 0.5 \) it will operate in buck mode while when \( D > 0.5 \) it will be in boost mode.

In Fig. 4, it shows the diagram of the buck boost converter [7]

![Buck-boost DC-DC converter diagram](image)

Fig. 4. Buck-boost DC-DC converter

The basic idea of operating is that when the switch is closed then the inductance \((L)\) will charge while when the switch is open the inductance polarity is reversed and the current path will be through the diode \((D)\) and capacitor \((C)\).

In this paper buck-boost dc-dc converter is used and there are several reasons behind the selection of this model of buck-boost converter in this work some of them are:

- ability of operating buck mode and boost mode
- easy to design
- reduce the cost
- reduce power losses
- less component required

One feature of this type of converters is the output of this converter has the opposite polarity with respect to its input.

B. perturb and observe maximum power point tracking algorithm (p&o mppt)

Pv cells are considered the most adverts source of renewable energy because of its availability and the positive impact of this energy in the environment, on the other hand some of disadvantage of this kind of renewable energy its direct effect in the weather condition, temperature, irradiance, etc... So in order to solve this problem and ensure that the pv module operate in its maximum point or nearby of this point, many techniques can be used to do this mission such as Constant Voltage MPPT Algorithm, Perturb and Observe (P&O) MPPT Algorithm, Incremental Conductance (INC) MPPT Algorithm. In this work we will use perturb and observe method according to its simplicity and accuracy. In the Fig. 5, bellow it shows the flow chart of this technique [8].

In this method, the sign of the last perturbation and the sign of the last increment in the power are used to decide what the next perturbation should be. On the left of the MPP, incrementing the voltage increases the power whereas on the right decrementing the voltage increases the power.

![Flow chart for Perturb and Observe Algorithm](image)

Fig. 5. Flow chart for Perturb and Observe Algorithm.

One of the disadvantages of this method is the operating point which will be around the maximum point, not the exact maximum point and one process to increase the accuracy of this method is by decreasing the step time (\( dt \)) but the module will take very long time to operate in its maximum point.

IV-simulation results

Simulation results in matlab 2015A are used to prove the operation of the charge balance control method the pv module which is used to charge the batteries continuously and its type is bpx150. The pv panel generate its maximum power at \( V_{mp} = 34.5 \text{v} \) and \( I_{mp} = 4.35 \text{A} \). So due to control method, e.g, 14 volt is the voltage of first H bridge. The results the dc to dc converter will operate in buck mode \( d < 0.5 \) because the pv module operate at its maximum power point in \( V_{mp} = 34.5 \text{v} \) while the voltage of the second and third H bridges are equal to \((3\times V_{dc1})\) which is equal to \( 42 \text{v} \) so the dc to dc converter will operate in boost \( d > 0.5 \).
Figures (6-7-8) below show the duty cycles of the first, second and third bridges respectively.

From the above figures it is clear that the first pv module operates in buck mode and its duty cycle around 0.36 (less than 0.5) according to the buck-boost dc-dc converter characteristic while the second and the third H bridges operate in boost mode and its duty cycle = 0.56 (greater than 0.5).

The battery voltage of the first, second and the third is as follows: vdc1 = 12.5 - 14 v

Vdc, 2, 3 = 41.5 - 42 v

We put this range according to the control which is merged with the mppt algorithm to control the battery voltages.

The voltage of the batteries is shown in the figures (13-14-15):

Figures (16-17-18) show the output of each H bridge and the final waveform (15 levels) is shown in fig 19 which represents the summation of the three H Bridges voltages.
An anti-parallel diode is connected to each semiconductor switch to allow bidirectional current flow and block unidirectional voltage. The diode type used is (In4007). The voltage which is used in the first H bridges is 6 v while the second and the third are 18 volts the output of the three H bridges is shown in figures (21-22-23)

**V-EXPERIMENTAL RESULTS**

The laboratory setup consists of a single phase 15 level cascaded asymmetrical multilevel inverter. This inverter consists of three H bridges which is able to produce 15 level output with a maximum output voltage equal to 7 vdc.

Each H bridge consists of six semiconductor switch. Four of them build the H bridge frame and the type of this transistor of the prototype are tip142 (nnp bjt) for the upper Q1,Q3 and tip147(pnp bjt) Q2,Q4 for the lower while the other two transistors are used for controlling and the type of them are 2n3904(npp) Q5,Q6. Fig . 20 shows one H bridge diagram in hardware configuration.
VI-Conclusions
In this work an improvement in the cascade inverter is done. This improvement includes two points: the first is related to the number of the output levels which is increased by using the asymmetrical topology with minimum number of dc sources and semiconductor switches and the second concern with the amount of power which is drawn from each DC source (except the first source) is equalized by using the charge balance control method. This inverter works perfectly with direct connected batteries and pv panels as shown in the simulation result, also experimental work shows the performance of the proposed inverter.

The output wave form of the inverter (15 level, 7 positive, 7 negative, 1 zero) is shown in Fig.24.

SVDD Based Data-Driven Fault Detection

Yusuf SEVİM

Karadeniz Teknik Üniversitesi
Elektrik-Elektronik Mühendisliği Bölümü 61080 Trabzon/TURKEY
ysevim@ktu.edu.tr

Abstract— Conventional data driven process monitoring algorithms are limited to Gaussian process data for principal component analysis (PCA) algorithm and non-Gaussian process data for independent component analysis (ICA) algorithm. This paper provides a comparison study between the conventional data driven methods and support vector data description (SVDD) algorithm for fault detection (FD). Different from the traditional methods, SVDD algorithm has no Gaussian assumption. Thus the distribution of process data is not important for SVDD method. In order to compare their FD performances of the proposed methods from the application viewpoint, Tennessee Eastman (TE) benchmark process is utilized to compare the results of all the discussed methods. Simulation results on TE process show that ICA and SVDD methods perform better for false faults than the PCA method.

Keywords— Process Monitoring, Fault Detection, Support Vector Data Description, Independent Component Analysis, Principal Component Analysis, Statistical Process Control

I. INTRODUCTION

In statistical process control (SPC) systems there exist many variables need to be monitored. These measurements provide useful information about the status of the systems. So applying the univariate SPC methods on that systems may produce false alarms. Using multivariate SPC (MSPC) methods can overcome that problem. MSPC has several advantages over univariates, for example, showing relationships between variables which cannot be detected with univariate statistics, and help to understand the interaction between variables. PCA and ICA algorithms have been widely used as a multivariate statistic intended to find latent variables in the FD field [1-6].

PCA is a well-known algorithm, and depends only on the second order statistics which means that the latent variables capture the most variance of the source signals. Unlike PCA, the goal of ICA algorithms is to minimize the statistical dependence between the basis vectors, and there is no closed form expression for ICA algorithms.

Another efficient FD algorithm is SVDD algorithm proposed by Tax and Duin [7]. SVDD algorithm aims at finding spherically shaped boundary around a data set. In this boundary, a hypersphere enclosing most of the data set belonging to the class of interest and rejecting the outliers. SVDD is a new method in the FD area, but it has been used in a wide range of FD applications [8-10]. In this paper, it is employed the one-class SVDD to find the separating boundary the normal data set and faulty data set. In this respect, SVDD is implemented and compared with standard MSPC methods for FD.

The remainder of this paper is organized as follows. Section II describes PCA and ICA algorithms. How to obtain SVDD algorithm is given in section III. Section IV gives monitoring results of the application to TE process. Finally, section V provides a concluding summary of this paper.

II. PROCESS MONITORING BASED ON PCA AND ICA

The basic model considered in PCA and ICA is

\[ x = As \]  

(1)

where \( s = [s_1, ..., s_d]^T \) is a vector of unknown source signals which are independent, and \( x \) is observation vector which is mixtures of the source signals via unknown mixing matrix \( A \). The objective of PCA is to make variables uncorrelated through orthogonal rotation. The orthogonal rotation matrix is obtained by using eigenvalue decomposition on covariance matrix

\[ \Sigma = \frac{XX^T}{m-1} = VAV^T \]  

(2)

where \( \Lambda \) is the diagonal eigenvalue matrix with its diagonal elements in decreasing order, \( V \) is orthogonal eigenvector matrix. The loading matrix \( P \) is formed by a first vector which possesses acceptable percent of data variance. The transformation of \( X \) matrix is called as the score matrix and calculated as follows

\[ T = XP \]  

(3)

The transformation into the original space is achieved by using

\[ \hat{X} = TP^T \]  

(4)

The residual matrix \( E \) is calculated as

\[ E = X - \hat{X} = X - TP^T \]  

(5)

PCA algorithm divides data space into two parts. First part is determined by a first major component and has the greatest data variance. The other part is defined by a small percentage of data variance and shows noise. \( T^2 \) statistic can be used to measure the variation of PCA model for a loading vector.

\[ T^2 = x^TVA^{-1}_aV^Tx \]  

(6)

where \( A_a \) is the first \( a \) rows and columns of \( A \). In PCA the \( X \) data is assumed to follow a multivariate normal distribution so \( T^2 \) follows an \( F \) distribution with degrees of freedom \( A \) and \( A - M \), and confidence limits can be calculated as follows

\[ T_{a}^2 = \frac{A(M^2 - 1)}{M(M - A)} f_{A,M-A,a} \]  

(7)
Squared Prediction Error (SPE) statistic measures the average size of the residuals corresponding to the lowest \(d - a\) eigenvalues

\[
SPE = x^T(I - PP^T)x
\]  

(8)

The confidence limit of SPE statistic is defined as

\[
SPE_\alpha = \theta_1 \left( \frac{h_\alpha c_\alpha \sqrt{2\theta_2}}{\theta_1} + 1 + \frac{\theta_2 h_\alpha (h_\alpha - 1)}{\theta_1^2} \right)^{\frac{1}{2}}
\]  

(9)

where \(c_\alpha\) is the value of normal distribution with \(\alpha\) level of significance.

ICA tries to estimate source signals without knowing \(A\) and \(s\). In order to achieve that, Hyvarinen introduced a fast-fixed point algorithm (FastICA) [11]. In FastICA, Negentropy method is used to measure statistical independency. The negentropy is defined as \(J(y) = H(y_{gauss}) - H(y)\), which can be approximated by

\[
J(y) = \left[ E[G(y)] - E[G(y_{gauss})] \right]^2
\]  

(12)

where \(G(y)\) is the nonquadric function [12]. The FastICA algorithm is stated as follows

1. Choose an initial weight vector \(w\) of unit norm.
2. Update \(w \leftarrow E[zg(w^Tz)] - E[g(w^Tz)]w\), where \(g(y) = tanh(a,y)\)
3. Normalize \(w \leftarrow w/\|w\|\)
4. If not converged, go back to step 2.

Separating matrix \(W\) is obtained by assembling all the vector \(w\), and the demixing sources are calculated as

\[
\hat{s} = Wx
\]  

(13)

After obtaining \(W\), it is divided into two parts, dominant part \((W_d)\), excluded part \((W_e)\), and using these parts three statistics are calculated as follows

\[
l^2 = S_d^2 \hat{S}_d = x^T W_d^T W_d x
\]  

(14)

\[
l_e^2 = S_e^2 \hat{S}_e = x^T W_e^T W_e x
\]  

(15)

\[
SPE = (x - \hat{x})^T (x - \hat{x})
\]  

(16)

where \(\hat{x} = (\Lambda^{-\frac{1}{2}} P^T)^{-1} B_d W_d x\). In ICA, the latent variables are assumed to be non-Gaussian distributed, hence the confidence limits of tree statistics are calculated by kernel density estimation method [13].

III. PROCESS MONITORING BASED ON SVDD

The SVDD is a new method in the FD that constructs a univariate monitoring statistics for variables [14]. The aim of SVDD is to transform original variables into a high dimensional feature space by using kernel. The transformed variables fall into a minimal sphere of radius \(R\) [7]:

\[
\min_{\hat{s},a,c} R^2 + C \sum_{i=1}^{n} \varepsilon_i s.t. \|\phi(\hat{s}_i) - a\|^2 \leq R^2 + \varepsilon_i
\]  

(17)

\[
\varepsilon_i \geq 0 \quad \forall 1 \leq i \leq n
\]

where \(a\) is the center of hypersphere, \(C\) is the trade off between the volume of the hypersphere and the number of transformed samples outside the hypersphere, and \(\varepsilon_i\) is slack variable. The \(a\) and \(R\) are obtained as follows

\[
a = \sum_{i=1}^{n} \alpha_i \phi(\hat{s}_i),
\]

(18)

\[
R = \sqrt{K(\hat{s}_p,\hat{s}_p) - 2 \sum_{i=1}^{n} \alpha_i K(\hat{s}_p,\hat{s}_i) + \sum_{i=1}^{n} \sum_{j=1}^{n} \alpha_i \alpha_j K(\hat{s}_i,\hat{s}_j)}
\]

(19)

where the sample points \(\hat{s}_p\) is support vector. Using (17), the univariate monitoring statistic is calculated as

\[
d^2(\phi(\hat{s}_i)) = \|\phi(\hat{s}_i) - a\|^2
\]  

(20)

If the square distance \(d^2(\phi(\hat{s}_i)) = \|\phi(\hat{s}_i) - a\|^2 \leq R^2\), sample is accepted as a normal sample. The decision based on SVDD can be precisely described as

\[
d^2(\phi(\hat{s}_i)) = K(\hat{s},\hat{s}) - 2 \sum_{i=1}^{n} \alpha_i K(\hat{s},\hat{s}_i) + \sum_{i=1}^{n} \sum_{j=1}^{n} \alpha_i \alpha_j K(\hat{s}_i,\hat{s}_j) \leq R^2
\]  

(21)

IV. COMPARISION STUDY BASEN ON TE

In this section PCA, ICA and SVDD methods will be applied to TE process for a comparison study. TE simulator was developed by Downs and Vogel which produces two products from four reactants [15]. It has five major units, i.e. reactor, condenser, compressor, separator, and stripper. There are 41 measured variables and 12 manipulated variables. In TE process, 20 process faults and an additional valve faults were defined by Downs and Vogel [15]. The sample length of the training data set is 500 under normal operating conditions. Each testing data set for one fault mode consist of 960 samples, and fault was introduced at sample 160 for each data set. All the data were autoscaled prior to application of the algorithms. To obtain better effect of simulation, 52 variables are selected for analysis. The confidence limit of kernel density estimation is selected as 99%. Fault detection rate (FDR) and false alarm rate (FAR) are considered to evaluate FD performance [16,17]. FDR and FAR rates are defined as

\[
FDR = \text{No. of samples} \ (f > J_{th} | f \neq 0)
\]  

(22)

\[
FAR = \text{No. of samples} \ (f > J_{th} | f = 0)
\]  

(23)
If one of the test statistics exceeds threshold, a fault can be detected successfully. The FD performances of the methods are investigated for 11 typical fault modes in TE process, and the results are calculated and tabulated in Table I. Also, in Table I the fault types and fault modes can be seen. As it can be seen in Table I, FDRs are almost the same, and are lower than PCA. Therefore, ICA and SVDD algorithms can be preferred to PCA to obtain lower FARS, and may provide the process operator with more reliable information. The drawback of the ICA algorithm is that using the kernel density estimation method is computationally expensive. Unlike the ICA, SVDD does not suffer from a high computational load, so using SVDD is more appropriate for FD applications.

V. CONCLUSIONS

In this paper, PCA, ICA and SVDD methods have been introduced, which was based on linear (PCA, ICA) and nonlinear process monitoring techniques (SVDD). Then, all the methods were implemented on TE process to compare the sensivity of the algorithms quantified by calculating the FARS.

According to Table I, all the tested methods give similar FDRs but different FARS (Table II). However FARS of ICA and SVDD have almost the same, and are lower than PCA. Therefore, ICA and SVDD algorithms can be preferred to PCA to obtain lower FARS, and may provide the process operator with more reliable information. The drawback of the ICA algorithm is that using the kernel density estimation method is computationally expensive. Unlike the ICA, SVDD does not suffer from a high computational load, so using SVDD is more appropriate for FD applications.

Abstract— The knowledge of Line of Sight (LoS) probability is crucial to estimate signal attenuation correctly in mobile wireless communication. Especially in built-up areas, more accurate LoS probability determination helps to obtain more realistic propagation models or path loss models. Geographic Information Systems (GIS) and City Information Systems (CIS) are used to provide a necessary data to calculate the LoS probability. In this study, LoS analyses are made via Arcgis software for the most well-known streets in Trabzon, Turkey. For these analyses, the Earth’s surface is accepted as flat and a simple geometrical approach is used for calculations in this paper. A Matlab algorithm was created to calculate LoS probability depending on the elevation angle which is an important parameter for satellite services. LoS probability vs. elevation angle is presented for interested streets. As a result, LoS probability for Trabzon dependent elevation angle is estimated and presented.

I. INTRODUCTION

The increasing demand for higher data rate in wireless mobile communications services has expedited the need for more innovative and flexible communications infrastructures. Terrestrial ground-based systems and satellite systems are used for providing mobile communications services [1]. To overcome some of the disadvantages of both terrestrial ground-based systems and satellite systems, high altitude platform stations (HAPS) technology can be used to provide cellular communication. So, there is plenty of research in this area [2]. In [1], researchers obtain propagation models and performance analyses for HAPS systems. It is obvious that elevation angle is the dominant parameter on the propagation models in [1]. The simplest definition of Line of Sight (LOS) is the straight path between two fixed points in two or three dimensional space when unobstructed by the horizon. On the other hand, non-line of sight (NLOS) is indirect path from one point to the other points in two or three dimensional space. LOS is an ideal condition for mobile ground communication because transmitted signal is received with best possible signal strength without exposing any obstacles [1]. In NLOS, there are many obstacles such as buildings, trees, forest, poles, tunnels and traffic lights. In this case, transmitted signal reaches the receiver weakened. Apart from these, transmitted signal also get attenuated due to rain. In urban type environment, the signal gets attenuated especially by buildings. Urban type environment is covered dense buildings which are closely located to each other and streets. Therefore, transmitted signal gets attenuated as a result of diffraction and reflection caused by these buildings.

In urban type environment, when examined it was observed that signal quality in mobile communication systems is significantly affected on the streets for LOS and NLOS cases [1]. Therefore, the height of the buildings, transmitter height, receiver height, elevation angle from receiver to transmitter, street widths and lengths are most important factors to determine the LOS and NLOS conditions created by buildings. In terrestrial mobile communications, above mentioned characteristics of the building and the street can be obtained via digital maps which is used in geographic information systems (GIS) [3]. Transferring the entire city to digital map is a difficult and sensitive process. This has led to the emergence of City Information Systems (CIS) [4]. In Turkey, all municipalities are gradually creating their City Information Systems (CIS). Some of these cities are İstanbul, İzmir, Eskişehir, Konya, Kayseri, and Trabzon. In this study, City Information Systems of Trabzon Municipality is used to obtain LOS probability values [5].

A lot of software is available in the GIS and many of them are paid. ARCGIS [6] and MAPINFO [7] could be given as an example for most commonly used paid software. Also, NETCAD [8] can be given as an example national paid software. Some of the most commonly used free software is GRASS [9], QGIS [10] ve SAGA GIS [11]. Urban Information System of Trabzon Municipality was created by the NETCAD
software. In this study, GIS data sets received from Trabzon Municipality is adapted to ArcGIS software.

In her study [1], Hasırcı used direct sight (LOS) and non-direct sight (NLOS) probability values from Holis and Pechac [12]. Depending on this probability values, propagation models have created and performance analyses of communication channels are made in [1].

In this study, the most well-known streets and avenues for the city of Trabzon were considered. For each street and avenue LOS and NLOS probabilities were calculated depending on the elevation angle through a code written in Matlab. After that, calculated LOS probabilities for streets were combined with Bayes conditional probability theorem [24] by performing simulation to create Trabzon city LOS possibilities.

Realistic LOS probability values calculated in this study will be put in LOS probability equation (1) from [12] and HAPs propagation models and performance analyses will be obtained for Trabzon. Also, these calculated real probability values can be used to estimate propagation and coverage area for Trabzon.

This LOS modelling idea is not new. Actually, LOS analyses were used in the military fields. First LOS analyses were made at the beginning of the 18 century by the French military engineer Prestre de Vauban (1603-1707). LOS analyses slowly began to gain importance over the following years because of increasing military activities as a result of wars [13]. LOS analysis has played an important role in military especially for the placement of an optimum observation tower, selection of military areas, and preparation of war plans.

ArcGIS software one of most commonly used GIS software. ArcGIS™ technology, developed by ESRI, is a scalable integrated Geographic Information System (GIS) software. ArcObjects is a development environment of the ArcGIS family of applications [14]. In this study, ARCMAP which is one of the module of ArcGIS software is used. ARCMAP has provided visualisation of available graphical and verbal data, data update, query and analysis, charting and reporting tools and, it also has high quality cartographic production functions. In ArcGIS 3D analysis tool, there are functions such as LOS (places visible and not visible among a line), Viewshed (visible areal places and not visible areal places for desired specific point of view) and drawing LOS profile [14].

Height of buildings and the distances between the buildings are important parameters for radio propagation models and LOS probability calculations [1]. In the literature, it was shown that building height distributions have similarities with some known probability distributions.

When these studies were analyzed, it is clear that rayleigh distribution is most commonly used distribution. Log-normal distribution is also used in some studies. Some references state that building height densities are similar to log-normal distribution rather than Rayleigh distribution while creating radio propagation models [16,17]. The distributions related to the height of the building are also investigated thoroughly in [15], [17] and [18].

Cheng and Wu have represented the LOS calculation model which determines security and route for vehicles traveling at highway [19]. Led and Pechac, using the ITU-R P.1410 model, use the data from existing GIS to calculate the LOS coverage probability in Prague capital city of the Czech Republic [20]. Oestges and Janvier have represented the physical and statistical model of LOS coverage probability calculation for HAPs [21]. Saunders and Evans has provided a physical model which calculates the probability LOS for land mobile satellite systems derived from a simple geometric model [22]. RamaSarma, in his research, has calculated the probabilities of LOS for interested regions and stated it analytically [23]. RamaSarma is used two models in his research namely CRABS and PLEXTEK which estimate visibility [23]. Both models have a structure that will be an alternative to the ray tracing method in the literature. In both models, required parameters are produce by statistical methods from existing GIS data. Using these parameters, the radio propagation models were estimated.

II. LINE-OF-SIGHT PROBABILITY MODELLING APPROACH

In this section, propagation modelling and statistical study for channel performance analysis on HAPs systems in [1] were investigated. In above mentioned study, the analytical LOS probability expression depending on elevation angle was obtained. In her research, Hasırcı emphasizes propagation modelling of HAPs and gives performance analysis [1]. All possible propagation environments were divided into four groups: suburban (SU), urban (U), dense urban (DU) and urban high rise (UHR) area. These propagation environments were modeled using well-known statistical models with a dependence on elevation angle. Focusing only urban areas in this study provides a more detailed examination. With rapidly growing metropolitan areas, more detailed studies that have become much more important in signal attenuation will help to solve this problem. Statistical models were combined with free space path loss, and full formulations of total path loss for the four possible HAPs propagation environments and different conditions at 2-6 GHz frequency band were obtained [1].

Elevation angle and propagation environment are the most important parameters to determine propagation characteristics for HAPs systems.

First, using ITU-R Rec. P.1410 [17] statistical model, LOS and NLOS probability distributions corresponding to each elevation angle in each propagation environment were calculated [12], the data has been created to be used in the produced model.

Probability distribution for LOS and NLOS corresponding to each elevation angle have been created on the following geometry for four propagation environment [see Fig. 1]. This geometry is essential scenario for simulation result in this paper.
A 2 x 2 km size city area was considered in analyses and the layout of the building sampled every meter in simulation setup. Simulation were separated in two group. In first group simulations, LOS probability in the streets was analyzed as a function of elevation angle for different propagation environment filled with buildings. A much simpler geometry was shown in Fig.1 for LOS and NLOS conditions of area. Calculations were made every 9 degree increments for azimuth angles in a range of from 0 to 360 degrees. Initially, buildings were randomly generated by the statistical models. After that, to implement and analyze a large number of scenarios, HAPs location were determined separately for each sampled point of the street for given elevation and azimuth angles. LOS probability for a given elevation angle were set to the median value of data obtained for all azimuth angles. Thus, the results have become independent from the azimuth angle because buildings in the real world are usually not located regularly. These simulations were applied from 1 degree to 90 degrees for all elevation angles and a distribution was obtained as in Fig. 2.

Equation (1) depending on the elevation angle was obtained with the help of the data in Fig. 2.

\[ P_{LOS}(\theta) = 1 - \frac{t-n}{\theta-k} \]

Table 1 shows parameter change of equation 1 according to propagation environment.

Where \( P_{LOS}(\theta) \) is the probability of LOS in percent, \( \theta \) is an elevation angle in degrees and \( t,n,k,l,p \) are the empirical parameters given in Table I for the four typical environments.

III. OUR EMPIRICAL LOS PROBABILITY MODELLING APPROACH

Flat unobstructed path from the transmitter to the receiver is called free line of sight. Line of Sight is very important for transmitted signal in wireless communication. Even there is not line of sight in the signal path, the signal can still reach its target. Actually, if all transmitted signals move through free Line of sight path, the best propagation occurs. The high-frequency signals need more free line of sight path than the low frequency signals. Infrared communication is particularly sensitive to obstacles which is in the free LOS fields.

In this study, firstly, it was opened Trabzon data set which have binalar.shp, yollar.shp and mahalleleri.shp file. After that, they were compiled via ARCMAP module of ARCGIS software. The most well-known streets and avenues were selected in the city center of Trabzon, Turkey. After that, the buildings which is on the north side of these streets and at a certain distance from these streets were selected. Finally, various operations which use some ARCMAP tools were applied for selected buildings and streets. As a result of these processes, the knowledges such as the height of the buildings, the area occupied by the buildings, the edge lengths of the buildings and the distance to the road from buildings are extracted from the attribute tables which are obtained from Trabzon GIS dataset. It was created a Matlab algorithm that calculates LOS probability depending on the elevation angle for interested streets. Input variables of this algorithm are the height of the building, the edge lengths of the building and the distance from building to the road. Firstly, LOS probability was calculated for every building on the interested street. After that, Additive LOS probability which consists also building spaces.
was calculated and this additive LOS probability was added to pre-calculated LOS probability created by building. As a result of this, Elevation angle dependent LoS probability for interested street were estimated. When it was examined LOS probability graphs in this study, it has been seen that they are similar to some known probability distributions in the literature [25]. This study has been no analysis of similarity to known probability distributions in the literature [25].

A. ARCGIS and Trabzon City GIS Data

In this study, it was used ARCGIS 10.1 software version [6]. In ARCGIS software, basic file extension is ‘shp’. ‘Shp’ file extension name is obtained by shortening ‘shape’ word. The streets which LOS probability was calculated was created by using the necessary analysis and operations in ARCMAP. ARCGIS have many modules. The input data which will be entered to the the geometric-based algorithm is obtained by using ArcMap. Fig. 3 illustrates the ARCMAP module screenshots of Trabzon GIS data.

B. Our LOS Probability Model and Calculation Algorithm

LOS probability prediction models use Ray Tracing (RT) methods mostly. Ray tracing techniques are applications that require large computational load and time. Ray Tracing techniques is used in electromagnetics applications, radio communications, cellular communication systems, radar applications, image processing applications, etc. In RT, rays from transmitter are sent to all angles in medium and all calculations are accomplished.

LOS prediction algorithm in this study has geometrical approaches and it is flexible because it can be applied for all cities in Turkey. Firstly, LOS probability of every building in the street was calculated. After that, LOS probability of street was calculated by using LOS probability of every building. Finally, LOS probability of every street was combined conveniently according to the Bayes' conditional probability theorem [24]. After these operations, LOS probability of Trabzon city was calculated. The more streets taking into account for calculation, the more realistic the LOS probability values of Trabzon city will be obtained. Fig. 5 illustrates typical LOS scenario used in this study.

Fig. 4 illustrates a simple LOS scenario in Urban city. When Fig.4 is examined, it can be seen that there are buildings, trees and cars that prevent direct sight (LOS) between the transmitter and the receiver. They are common obstacles that may exist in all the typical urban-type settlements.
As seen in Fig. 5, Hi is observation height, Li is distance of LOS, $\theta_i$ is elevation angle, Gi is distance to the receiver from building edge which is parallel to road, ‘i’ is building index which helps to differentiate buildings from each other in the street and ‘e’ index represents elevation angle ranging from 1° - 90°. Relationship between elevation angle, $\theta_i$ and distance of LOS, Li can be stated as shown in equation (2).

$$\tan(\theta_e) = \frac{H_i}{G_i} \quad \text{and} \quad L_i = \sqrt{H_i^2 + G_i^2} \quad (2)$$

First, NLOS probability was calculated in this study. After that, LOS probability was calculated. Relationship between these probabilities was shown below.

$$S_{all} = S_{los} + S_{nlos} \quad (3)$$

where $S_{all}$ is total area of the interested region in square meters, $S_{nlos}$ is area of NLOS region in square meters, and $S_{los}$ is area of LOS region in square meters. Relation between area of regions is was given in equation (3). NLOS probability can be calculated by using equation (4).

$$P_{nlos} = \frac{S_{nlos}}{S_{all}} \quad (4)$$

where $P_{nlos}$ is NLOS probability.

Substituting $P_{nlos}$ in equation (4), LOS probability can be calculated using equation (6).

$$P_{los} + P_{nlos} = 1 \quad (5)$$

$$P_{los} = 1 - P_{nlos} \quad (6)$$

where $P_{los}$ is LOS probability.

C. Our LOS Probability Model and Calculation Algorithm for Trabzon City

After LOS probability of N number streets was calculated, LOS probability values depending on the elevation angle for Trabzon was obtained by utilizing Bayes' conditional probability theorem [24].

If elevation angle of between the receiver and the transmitter is known previously, LOS probability for Trabzon ($P_{los}$city) for arbitrary angle can be calculated using equation (7).

$$P_{los}(\theta_i) = \frac{1}{L} \sum_{n=2}^{N} L_i * P_{los}(L_i; \theta_i) \quad (7)$$

where $P_{los}(\theta_i)$ is LOS probability of Trabzon, $P_{los}(L_i; \theta_i)$ is LOS probability of i-th street when $\theta_i$ elevation angle between the receiver and the transmitter is known previously, $L_i$ is length of i-th street, $\theta_i$ is elevation angle, and $L$ is total length of N number streets (given by equation (9)).

The clearest expression of equation (7) is given by equation (8).

$$P_{los}(\theta_i) = \frac{L_1 * P_{los}(L_1; \theta_i) + L_2 * P_{los}(L_2; \theta_i) + \ldots + L_N * P_{los}(L_N; \theta_i)}{L} \quad (8)$$

$L$ in equation (7) and (8) can be calculated as below:

$$L = L_1 + L_2 + L_3 \ldots \ldots + L_N \quad (9)$$

In above equations, $L_i$ and $L$ are easily obtained by using ARCGIS attribute tables.

D. Our LOS Probability Graphics for Trabzon street and city

In this section, LOS probability figures vs. elevation angle were presented for four streets. The LOS probability figures were plotted in Matlab software. LOS probability of four streets were given this section (Fig. 6, Fig 7, Fig. 8 and Fig. 9). After that, LOS probability figure of Akif Saruhan street was examined and discussed. Fig.6 illustrates LOS probability figure vs. elevation angle of Akif Saruhan street.

Fig. 6 illustrates LOS probability figure vs. elevation angle of Akif Saruhan street. Fig. 7 illustrates LOS probability figure vs. elevation angle of Deliklitaş street. Fig. 8 illustrates LOS probability figure vs. elevation angle of Ahmet Barutçu Küütphanesi street. Fig. 9 illustrates LOS probability figure vs. elevation angle of Moloz street. Fig. 10 illustrates LOS probability figure vs. elevation angle of Trabzon city.

![Fig. 6. LOS probability of Akif Saruhan street](image-url)
To illustrate, when LOS probability figure in Fig. 6 is examined, it is clear that even if elevation angle is very low, LOS probability of Akif Saruhan street value is about 0.55. This indicates good quality of wireless communication at low elevation angles.

When LOS probability figure in Fig. 10 is examined, it can be understood clearly that even if elevation angle is very low, LOS probability of Trabzon city is about 0.25. This indicates that low quality of wireless communication at low elevation angles. LOS probability of Trabzon at low elevation angles is low because of Trabzon’s irregular building structures and settlements. It can be seen clearly that LOS probability figures in this study show similarities with other LOS probability figures in [12] and the other studies in literature.

IV. CONCLUSIONS AND SUGGESTIONS

Trabzon GIS data was analysed by using ARCIS software. As a result of this analyses, it was obtained building heights, road, street widths, distances between buildings, building floor area, etc. These obtained knowledges were used as an input data for geometrical algorithm and LOS probability of interested streets in Trabzon city were calculated.

As a future study, it will be investigated that the LOS probability values complies with which well-known cumulative distributions. As result of this, empirical formulas which represents LOS probability depending on the elevation angle will be derived. Instead of flat terrain in this study, rough terrain can be taken into account. LOS probability values obtained in this study can be used for HAPs propagation modelling and wireless channel modelling in Trabzon.

A Simple State Observer Design for Linear dynamic Systems by Using Taylor Series

Saadettin Aksoy
Department of Electrical & Electronics Engineering, Architecture & Engineering Faculty, Siirt University, Siirt, Turkey, aksoy@siirt.edu.tr

Abstract— In this study, an estimation algorithm is proposed to estimate the state variables of linear time-invariant multi input-multi output systems. The proposed recursive algorithm is based on the orthogonal Taylor series approximation and uses some important properties of the Taylor series. It has an analog solution which can be obtained easily by a computer program. It is not affected by rounding errors. When the number of elements of series is sufficiently large, the Taylor series approximation gives results very close to exact solution.

Keywords -- State Estimation, Taylor series, State Observers, Curve fitting

I. INTRODUCTION

State variables that determine a system’s dynamics should be known for analysis and control of dynamical systems [1,2]. Specifically, dynamics feedback for pole placement is required. Furthermore, estimation of state variables in real time is a very important problem in adaptive control applications [3]. Unfortunately, all of the state variables cannot be measured in practice. As a result, use of a suitable state observer or estimator is unavoidable in order to obtain immeasurable state variables. There exit a variety of state observers in the literature [4,5]. Implementation of state observers that use only input and output measurements of the systems are carried out via solution of the observer state integral equations pertinent to the observer. There are several numerical solution algorithms for a solution of the observer state integral equations in the literature [6]. Even though the Runge-Kutta numerical integration algorithm is frequently used for this purpose, it has several drawbacks that depend on the step-size h. First, accuracy gets poorer as h increases. Second, computation time becomes an issue if h is too small. Third, round-off errors may become important for small values of h because the number of cycles required to cover the desired time interval [0,t] increases. Note that equations are evaluated for each t in the interval [0,t] in all of the above mentioned algorithms.

In this study, a simple general algorithm is proposed for state variables estimation of linear, time-invariant multi-input multi output systems. The proposed algorithm is based on Taylor series approximation and has an analog solution. The solution that results from the proposed algorithm gets closer to the true solution when more and more terms are kept in the Taylor series. Finally, the proposed method gives the approximate solution of the estimation vector $\hat{x}(t)$ as a function of time in the interval [0,t]. Consequently, computation of the state integral equations for each t is eliminated. The Taylor series are defined on the interval $t\in[0,1]$ and have the orthogonality property like the Walsh, Chebyshev and Legendre series [7,8]. The proposed algorithm uses some important properties such as the operational matrix of integration for Taylor vector [9,10]. The algorithm consists of four steps. In the first step, the feedback gain matrix $G$, which will force the estimation error to go to zero in a short time, is determined by using a suitable method [4]. In the second step, the observer state equation is converted into integral equation by integrating the terms on either side of the equation. After some algebraic manipulations, the time dependent terms on either side of the integral equation are removed. Hence, the problem is reduced to a set of nonlinear equations with constant coefficients. System outputs are used by the observer equations. Therefore, we have to calculate it’s as the function of time. They can obtained from plant output measurement by using curve fitting methods such as Linear Least Squares, Levenberg-Marquardt and Gauss-Newton [11]. Finally, in the last step, nonlinear equations for unknown state vector are converted into a recursive form whose solution can be obtained easily by a computer program. The proposed estimation algorithm was implemented in MATLAB™ and it was applied to different cases. Results obtained by the proposed algorithm are in harmony with the real results.

II. PROPERTIES OF THE TAYLOR POLYNOMIALS

The Taylor series expansion of an analytic function $f(t)$ in the neighborhood of the point $t=t_0$ can be written as

$$f(t) = f(t_0) + a_1(t-t_0) + a_2(t-t_0)^2 + \ldots + a_k(t-t_0)^k + \ldots$$ (1)
Thus, substituting Eq. 1 relation the following equalities can easily be obtained:

\[ f(t) = \sum_{k=0}^{r} a_k \lambda_k(t) \] (3)

where \[ \lambda_k(t) = t^k \] (4)

By truncating the series given in Eq. (3) after the \((r+1)\)th term, the approximate analytic function \(f(t)\) can be written as

\[ f(t) \approx \sum_{k=0}^{r} a_k \lambda_k(t) = a^T \lambda(t) \] (5)

where \(a\) and \(\lambda(t)\) are the Taylor polynomial coefficient vector and the Taylor series basic vector, respectively defined as

\[
a^T = [a_0, a_1, ..., a_r, 1]
\]

\[
\lambda^T(t) = [\lambda_0(t), \lambda_1(t), ..., \lambda_r(t)] = [1, t, ..., t^{r+1}]
\]

The Taylor series basic functions satisfy the following recurrence relations:

\[ \lambda_k(t) = t \lambda_{k-1}(t), \quad k=1,2, ..., r-1. \] (8)

Also, one may easily show that

\[ \int_0^t \lambda_k(t) \, dt = \frac{t^{k+1}}{k+1} \lambda_{k+1}(t). \] (9)

By using expression (3), the definite integral of an analytic function \(f(t)\) in the interval \((0,t)\) can be approximated as

\[ \int_0^t f(t) \, dt \approx \sum_{k=0}^{r-1} \int_0^t a_k \lambda_k(t) \, dt \]

\[ \approx \sum_{k=0}^{r-1} \left( \frac{a_k}{k+1} \right) \lambda_{k+1}(t) \sum_{k=0}^{r} b_k \lambda_k(t) \] (10)

where \(b_k, \quad k=1,2, ..., r\) are real numbers. From the last relation the following equalities can easily be obtained

\[ b_0 = a_0, \quad b_1 = \frac{(a_1)}{2}, ..., \quad b_r = \frac{(a_r)}{r}. \] (11)

Thus, substituting Eq. (11) in Eq. (10) leads to

\[ \int_0^t f(t) \, dt \approx a^T \mathbf{P} \dot{x}(t) \] (12)

where the square matrix \(\mathbf{P}\) is called the Taylor series operational matrix of integration, and is given by

\[
\mathbf{P} = \begin{bmatrix}
0 & 1 & 0 & 0 & \ldots & 0 & 0 \\
0 & 0 & 1/2 & 0 & \ldots & 0 & 0 \\
0 & 0 & 0 & 1/3 & \ldots & 0 & 0 \\
\vdots & \vdots & \vdots & \vdots & \ddots & \vdots & \vdots \\
0 & 0 & 0 & 0 & \ldots & 1/(r-2) & 0 \\
0 & 0 & 0 & 0 & \ldots & 0 & 1/(r-1) \\
0 & 0 & 0 & 0 & \ldots & 0 & 0 \\
\end{bmatrix}
\]

in the unique form. It can easily be shown that k-fold integration of \(\mathbf{P}\) is \(\mathbf{P}^k\) [16, 17]. The matrix \(\mathbf{P}\) of size r x r in Eq. (13) is called the integration operation matrix.

III. THE PROPOSED ESTIMATION ALGORITHM

The proposed estimation algorithm can be considered as state observer and its simulation diagram is given in Fig. 1.

![Figure 1. Simulation diagram representation of a state estimator](image)

State and error equations for the state observer shown in Figure 1 are

\[ \dot{x}(t) = M \dot{x}(t) + Bu(t) + Gy(t) \] (14)

\[ e(t) = Me(t), \quad e(0) = x(0) - \dot{x}(0) \] (15)

where

\[ M = (A - GC) \] (16)

In Eq. (14) and (15), \(\dot{x}(t), \dot{u}(t), e(t)\) and \(y(t)\) are the nx1 estimation vector, mx1 input vector nx1 error vector and...
px1 output vector, respectively. \(A, B, C\) and \(G\) are nxn state matrix, nxm input matrix, pnx output matrix and nxp gain matrix, respectively. The gain matrix \(G\) is effective only if \(x(0) \neq \hat{x}(0)\) and it should be chosen such that the estimation error goes to zero in a short period of time. The elements of the gain matrix \(G\) can be determined form the characteristic equation given in (17) by using arbitrary eigenvalues of \((A-GC)\) denoted \(\alpha_1, \alpha_2, \ldots, \alpha_n\) (note that eigenvalues are chosen such that \(e(t)\) goes to zero as quickly as possible) (Kailath, 1980):

\[
[\alpha I - (A - GC)] = 0 \tag{17}
\]

In Eq. (17), \(I\) is nxn identity matrix. Now, let us consider the estimation of \(\hat{x}(t)\). If we integrate both side of Eq. (14) we obtain

\[
\dot{\hat{x}}(t)-\hat{x}(0) = \int_0^t \dot{\hat{x}}(\tau)d\tau = \int_0^t B\hat{x}(\tau)d\tau + \int_0^t G\gamma(\tau)d\tau \tag{18}
\]

Let us assume that \(\dot{\hat{x}}(t), u(t), \hat{x}(0)\) and \(y(t)\) are continuous functions for \([0,t]\). Then, their Taylor series approximations can be given as

\[
\hat{x}(t) = \begin{bmatrix} x_{10} & x_{11} & \ldots & x_{1,n-1} \\ x_{20} & x_{21} & \ldots & x_{2,n-1} \\ \vdots & \vdots & \ddots & \vdots \\ x_{n0} & x_{n1} & \ldots & x_{n,n-1} \end{bmatrix} + \begin{bmatrix} \lambda_1(t) \\ \lambda_2(t) \\ \vdots \\ \lambda_n(t) \end{bmatrix} = \hat{X}(t)\lambda(t) \tag{19}
\]

where

\[
\hat{X} = \begin{bmatrix} \hat{x}_0 & \hat{x}_1 & \ldots & \hat{x}_{r-1} \end{bmatrix}
\]

\[
\hat{x}_k = \begin{bmatrix} \hat{x}_{1k} & \hat{x}_{2k} & \ldots & \hat{x}_{nk} \end{bmatrix}^T, \quad k=0,1,2,\ldots,r-1
\]

\[
\hat{x}(0) = \begin{bmatrix} \hat{x}_1(0) & 0 & \ldots & 0 \\ \hat{x}_2(0) & 0 & \ldots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ \hat{x}_n(0) & 0 & \ldots & 0 \end{bmatrix} + \begin{bmatrix} \lambda_1(t) \\ \lambda_2(t) \\ \vdots \\ \lambda_n(t) \end{bmatrix} = \hat{X}\lambda(t) \tag{21}
\]

where

\[
\hat{X}_0 = \begin{bmatrix} \hat{x}_0 & 0 & \ldots & 0 \end{bmatrix}
\]

\[
\hat{x}(0) = \begin{bmatrix} \hat{x}_0(0) & \hat{x}_1(0) & \ldots & \hat{x}_n(0) \end{bmatrix}^T
\]

\[
\hat{u}(t) = \begin{bmatrix} u_{10} & u_{11} & \ldots & u_{1,r-1} \\ u_{20} & u_{21} & \ldots & u_{2,r-1} \\ \vdots & \vdots & \ddots & \vdots \\ u_{n0} & u_{n1} & \ldots & u_{n,r-1} \end{bmatrix} \lambda(t) = U\lambda(t) \tag{23}
\]

where \(U = \begin{bmatrix} u_0 & u_1 & \ldots & u_m \end{bmatrix}\)

\[
u_k = \begin{bmatrix} u_{ik} & u_{2k} & \ldots & u_{mk} \end{bmatrix}^T, \quad k=0,1,2,\ldots,r-1
\]

\[
y(t) = \begin{bmatrix} y_0 & y_1 & \ldots & y_{pk} \end{bmatrix}^T, \quad k=0,1,2,\ldots,r-1
\]

Output vector, \(y(t)\) can be obtain from output measurements by using curve fitting methods (Steven and Raymond, 2009). If we substitute Eq. (19), (21), (23) and (24) in Eq. (18), we have

\[
\hat{X}\dot{\lambda}(t)-\dot{X}\lambda(t) = \int_0^t \hat{X}\dot{\lambda}(\tau)d\tau + \int_0^t B\dot{\lambda}(\tau)d\tau + \int_0^t G\gamma(\tau)d\tau \tag{25}
\]

From Eq. (12), Eq. (25) can be written as

\[
(\hat{X}\dot{X})\lambda(t) = M\dot{\lambda}(t) + B\lambda(t) + G\gamma(\lambda(t)) \tag{26}
\]

If we remove the time-dependent terms in Eq. (26), the following set of constant coefficient algebraic equations is obtained

\[
\hat{X}\dot{\lambda} = M\dot{\lambda} + B\lambda + G\gamma \tag{27}
\]

The unknown coefficient vectors \(\hat{x}_i, i=0,1,2,\ldots,r-1\) in Eq. (27) are in a complex form. Hence, we need to rearrange Eq. (27). After applying the steps given in Appendix A, the following recursive equations are obtained

\[
\begin{cases}
\hat{x}_{i,0} = \hat{x}_i(0) + f_{i,0} \\
\hat{x}_{i,k} = \left( \frac{1}{k} \sum_{j=1}^{n} (m_i \hat{x}_{j,k-1}) + f_{i,k} \right), \quad i = 1,2,\ldots,n, \quad k=2,3,\ldots,r
\end{cases} \tag{28}
\]
The unknown estimation vectors $\hat{x}_i$, $i=0,1,2,...,r-1$ are obtained by using a computer program. Then, these vectors are substituted in Eq. (19), and the Taylor series approximation of the estimation vector $\hat{x}(t)$ is obtained. For the special case in which $G$ is zero matrix, the algorithm behaves as an open-loop observer. Since the observer error dynamics in open-loop observers is determined by eigenvalues of the system, the system must be asymptotically stable for convergence (Kailath,1980). The proposed estimation algorithm was implemented in MATLAB™ and was applied to different examples.

IV. NUMERICAL APPLICATIONS

Example 1. Consider a system having state equations given by

$$\dot{x}(t) = \begin{bmatrix} 1 & 1 \\ -2 & -3 \end{bmatrix} x(t) + \begin{bmatrix} 0 \\ 1 \end{bmatrix} u(t)$$

$$y(t) = \begin{bmatrix} 1 & 0 \end{bmatrix} x(t)$$

This system has an analytical solution, which can be obtained from the unit-step input response as

$$\begin{bmatrix} x_1(t) \\ x_2(t) \end{bmatrix} = \begin{bmatrix} 2e^{-t} - e^{-2t} & e^{-t} - e^{-2t} \\ 2(-e^{-t} + e^{-2t}) & -e^{-t} + 2e^{-2t} \end{bmatrix} \begin{bmatrix} x_1(0) \\ x_2(0) \end{bmatrix} + \begin{bmatrix} (1/2)e^{-t} + (1/2)e^{-2t} \\ e^{-t} - e^{-2t} \end{bmatrix}$$

From Eq. (17), the gain vectors $[-1 \ 2]^T$, $[1 \ -1]^T$ and $[17 \ 47]^T$ are computed to place eigenvalues of the observer error $p$ at -1 , -2 and -10 , with multiplicity 2 respectively. The analytical expression of $y(t)$ given by Fig. 2 is obtained by using Linear Least Squares curve fitting method as follows:

$$y(t)=0.0266x^2-0.1184x^3+0.3089x^4-0.5827x^5+0.75x^6$$
$$-0.5x^7+0.5, \ for \ 0\leq t<1$$
$$y(t)=0.0021x^2-0.0123x^3+0.0347x^4-0.585x^5+0.043x^6$$
$$+0.0487x^7+0.3838, \ for \ 1\leq t<2$$
$$y(t)=0.0021x^2-0.0013x^3+0.0029x^4-0.0008x^5$$
$$-0.0155x^6+0.0493x^7+0.4415, \ for \ 2\leq t<3$$
$$y(t)=-0.0002x^2+0.0025x^3-0.0099x^4+0.0224x+0.4764, \ for \ 3\leq t<4$$
$$y(t)=-0.0002x^4+0.0013x^2-0.0042x^2+0.0088x+0.491, \ for \ 4\leq t<5$$
$$y(t)=-0.0001x^4+0.0005x^2-0.0016x^2+0.0033x+0.4967, \ for \ 5\leq t<6$$
$$y(t)=0.0002x^2-0.0006x^2+0.012x+0.4988, \ for \ 6\leq t<7$$
$$y(t)=-0.0002x^2+0.0004x+0.4995, \ for \ 7\leq t<8$$

From above expressions for each time subinterval Taylor series approximation coefficient matrix, $Y$ is obtained easily. For example we can write for $0\leq t<1$

$$Y=\begin{bmatrix} 0.5 & -0.5 & 0.7499 & -0.5827 & 0.3089 & -0.1184 & 0.02664 \end{bmatrix}$$

![Figure 2. Output curve for example 1.](image-url)

The analytical solution as well as solution obtained by the proposed algorithm curves for each gain vectors and for unit step input function are given in Figure 3. The initial value of estimation vector, $\hat{x}(0)$ is chosen as zero. In addition the estimation error curves are given in Figure 4. It can be seen that from Figure 3, as eigenvalues of the observer error $p$ move to the left in the left half s-plane, the estimation error curves converge to the zero in a shorter time. Estimation error of the proposed algorithm as a function of time for several values of $r$ is illustrated in Figure 5 from which one can see that estimation error decreases as $r$ increases.
Example 2. Consider a 2 input/1 output dynamic system described by the following state equation:

\[
\begin{bmatrix}
-1 & -1 \\
2 & 0
\end{bmatrix}
\begin{bmatrix}
x(t) \\
\dot{x}(t)
\end{bmatrix}
+ 
\begin{bmatrix}
1 \\
1
\end{bmatrix}
\begin{bmatrix}
u(t)
\end{bmatrix}
= 
\begin{bmatrix}
y(t) \\
x(t)
\end{bmatrix}
\]

By using Eq. (17), feedback gain matrices corresponding to the eigenvalues of the observer error dynamic (at -1, -2 and -5 with multiplicity, respectively) are computed as

\[
\begin{bmatrix}
0.42 \\
0.71
\end{bmatrix}, 
\begin{bmatrix}
0.14 \\
1.42
\end{bmatrix}, \text{ and } 
\begin{bmatrix}
5.28 \\
1.85
\end{bmatrix}
\]

The analytical expression of \( y(t) \) is obtained similar fashion to example 1 from Fig. 6. Thus, Taylor series approximation coefficient vectors are obtained easily for each time subinterval. For example, we can obtain in the interval \( 0 \leq t < 1 \):

\[
\begin{bmatrix}
0.009 & 21.43 & -92.11 & 188.7 & -211 & 126.6 & -31.77
\end{bmatrix}
\]

Simulation results of the observer and the proposed algorithm for each gain matrix and for unit step input functions are given in Figures 7 and 8. Here, the initial value of estimation vector, \( \hat{x}(0) \) is chosen as zero. The Runge-Kutta numerical solution method with \( h=0.01 \) was used for the observer simulation. In the estimation...
algorithm one can deduce from Figure 7 and 8 that the proposed Taylor series approximation based estimation algorithm gives state curves, that are very close to those of the observer when the number of terms in the Taylor series is sufficiently large. Like the results obtained in Example 1, as eigenvalues of the observer move to the left in the left half s-plane, the estimation error decreases.

Estimation error of the proposed algorithm as a function of time for several values of r is illustrated in Figure 9. It is obvious from Figure 9 that estimation error decreases as r increases.
V. CONCLUSION

In this study, a direct analytical algorithm based on the truncated Taylor polynomials and the operational matrix of integration has been suggested to estimate the elements of the state vector for a linear time-invariant multi input multi output system. The algorithm uses the Taylor series approximations of the observer in terms of the unknown coefficients of the state vectors. Thus, integration problem is reduced to solving a set of complex linear equations with constant coefficients. The equations for the solution of unknown coefficients are in a complex form. The algorithm we propose transforms these complex equations to a form, which is solved easily in a recursive manner. Furthermore, the algorithm can be easily implemented by using a computer program. The proposed technique does not suffer from the issues such as a choice of the step-size and the rounding errors that are present in the numerical integration algorithms. Proposed algorithm gives the solution of \( \hat{x}(t) \) as an analytical function of time in the interval \( t \in [0,t_{\text{max}}] \). As a result, numerical computation of the \( \hat{x}(t) \) for each \( t \) in the interval \((0,1)\) is eliminated.

For the special case in which the gain matrix \( G \) is chosen as zero matrices, very small number of operations will be sufficient for the solution since the algorithm behaves like an open-loop estimator. However, the system has to be asymptotically stable for convergence since the eigenvalues of the matrix \( A \) determine the observer error dynamics.

Numerical examples illustrate the fact that exact and approximated values of the state variables are in good agreement.

SHORT CIRCUIT ANALYSIS IN ISLAND MODE USING ETAP

Ridha K. MOHAMMED, Assoc.Prof. Musa AYDIN

Department of Electrical and Electronics Engineering, Selcuk University, Konya, Turkey

Abstract— the requirement of power is very much essential for the development of any country. The simulation and short circuit study of an electrical power system is performed on Electrical Transient Analyzer Program (ETAP). The output of short circuit studies are helpful in order to determine system configuration, protection equipment, system voltage levels, cables size, and switchgears, transformers and grounding. ETAP short circuit analysis software analyzes the effect of 3-phase, 1-phase, line-to-ground, line-to-line, and line-to-line-to-ground fault currents on electrical power systems. In this research, selected a city where a national network connected with four distributed generation. This distributed generation was operated depending upon solar energy, wind power, waterpower and natural gas. In the normal case, the national network operates in parallel with the solar station and the wind station to feed all loads in the city. But, in the case of national network outage from city, feed only task loads in the city in island mode through these four distributed generation. With priority given to the work of the stations, the stations operates at the least cost of operating condition. Short circuit analysis can be done for the two cases mentioned above.

Keywords— Short circuit, ETAP, Distributed generation, Island mode, Grid.

I. INTRODUCTION

The short circuits happened in the electrical grid by the reasons of the urgency high voltage that over from the grid. Lot accidents appear in the general electric grid by this current for example (damage in the grid parts, firing or explosion in the breakers and in the lines).

One of practices to minimize the short circuits in the grid determine the fault region and treatment the problem without stopping the lines and to avoid the problem development.

The high sensitivity protection devices and the high response from the technicians help us to maintain the power supply [1].

In this paper using the ETAP software to illustrate the short circuits analysis and treatment it by simulation the single line diagram of the general grid connected with four distributed generation (wind, hydroelectric, photovoltaic energy and natural gas).

The major aims from applied the short circuits to select the appropriate equipment’s to avoid the accidents in the equipment’s and the employees with continuity power supply. And it collected in:

1) Determination of short-circuit duties on switching devices, that is, high-, medium-, and low-voltage circuit breakers and fuses
2) Calculation of short-circuit currents required for protective relaying and coordination of protective devices
3) Evaluations of adequacy of short-circuit withstand ratings of static equipment like cables, conductors, bus bars, reactors, and transformers
4) Calculations of fault voltage dips and their time-dependent recovery profiles [2].

In the power stations and the industrial facilities and the public buildings the designers take in consideration the safety procedures to maintain the equipment’s and the labour, and provide the systems high reliability in the control of systems parts.

The urgency short circuits in the systems leading to big losses also some person’s loss these lives or at less power supplies loss.

The short circuits caused the isolation collapse in the electrical parts and in some cases can see sparks in the short circuits points and these sparks caused fires in the locations. In first time of the short circuits occur the protection devices will work in the various parts and these devices distributed on the system or buildings parts.

The late response when the short circuits appear lead to raising risks to the systems and huge losses [3]. In the electrical power systems the short circuits happened between the phases itself or between the phases and the ground in this paper explain the four types of short circuits as following:

1) Three phase faults
2) Line to ground
3) Line to line
4) Line to line to ground

In the Electrical Transient Analyzer Program (ETAP) software determined the total short circuit currents in the generators, transformer, lines and the other parts of electrical systems.

ETAP depending on two standards the ANSI and IEC standards [4].
II. SINGLE LINE DIAGRAM

In this paper, four distributed generation working by the sun, wind, Hydroelectric and natural gas connected with the national grid. Single line diagram drawing by using ETAP program [5] shown in Figure 1.

In the normal case the solar station and the wind is working in parallel with the national grid to feed the loads. In the case of network outages, these stations operate in the island mode to feed the task loads.

III. SHORT CIRCUIT ANALYSIS

The short circuit analysis of distributed generation system using ETAP. The IEC standard is used to analyze the short circuit. In this simulation, choose all buses as a fault. ETAP short analysis of the 3-phase, 1-phase, phase-to-ground, phase-to-phase and phase-to-phase-to-ground can be realized [6].

The Line to line to ground short circuit analysis shown in figure 6.

The Line to ground short circuit analysis shown in figure 5.
Definition of Terms
IEC standards use the following definitions, which are relevant in the calculations and outputs of PowerStation.

- **Initial Symmetrical Short-Circuit Current (I”k)**
  This is the rms value of the ac symmetrical component of an available short-circuit current applicable at the instant of short-circuit if the impedance remains at zero time value.

- **Peak Short-Circuit Current (ip)**
  This is the maximum possible instantaneous value of the available short-circuit current.

- **Symmetrical Short-Circuit Breaking Current (Ib)**
  This is the rms value of an integral cycle of the symmetrical ac component of the available short-circuit current at the instant of contact separation of the first pole of a switching device.

- **Steady-State Short-Circuit Current (I_k)**
  This is the rms value of the short-circuit current which remains after the decay of the transient phenomena.

IV. CONCLUSION
The errors determine and data analysis in the power systems help the industrial facilities to determine and support the appropriate protection devices and calculate the minimum and maximum value of the system parts to assurance high safety level.

ETAP software applied in the power systems to make simulation and to maintain the equipment’s and the people lives and the rid on from the short circuits risks.
All the studies in the ETAP applied the various types of the short circuits in the (AC) and (DC) systems
1) I”K (initial AC symmetrical SC current)
2) ip (peak SC current)
3) I_k (study state SC current)
ETAP found the acceptable results for the above types.
The gathering information for the short circuit currents helpful to determine the limits value for the voltage, the protection, transformers, lines or cable and the other system parts.

Abstract—The geometrical dependence of metallic nano-patterns provides adjustable resonance frequencies. Especially, aperture-based nanostructures exhibit resonant behaviors in transmission phenomena with easily accessible ultra-high-field localization characteristics and aperture dimensions influence the spectral response of the structure. We report the transmission and reflection characteristics of fourfold rectangular shaped nanoaperture antennas that exhibit high near field distributions in the mid-infrared regime. Numerical analyses are carried out by using finite-difference-time-domain method to analyze the transmittance and reflectance spectra of the structure. We investigate the geometrical parameters that can enable fine control of the resonance frequencies and tunable optical characteristics are concluded by the parameter sweeps. High SEIRA (surface enhanced infrared absorption) enhancement at resonant wavelength and resonant behavior in mid-infrared regime ensure that the proposed antenna can be utilized for infrared detection applications.

Keywords—Plasmonics, sensors, subwavelength structures, nanostructures, spectroscopy, infrared

I. INTRODUCTION

Dependence on the geometrical parameters of metallic nano-patterns provides adjustable resonance frequencies as observed from the theoretical and experimental studies. Recently, particle- and aperture-based nanoantennas with different geometries have been studied to capture, control and manipulate the light at the preferred wavelengths [1-6]. Especially, aperture-based nanostructures has been the subject of several researches due to their resonant behavior in transmission phenomena with easily accessible ultra-high-field localization characteristics and it has been showed aperture dimensions influence the spectral response of the structure [2-6].

In this study, we present the transmission characteristics of a fourfold rotationally symmetric rectangular nanoaperture antenna arrays operating in the mid-infrared regime. The transmittance spectra of the structure are investigated by using the finite-difference time-domain (FDTD) method [7]. We obtain the field distributions at the resonant wavelength, which indicates the physical origin of the resonant modes. We analyze the parameters that can enable fine control of the resonance frequencies of the structure. High SEIRA (surface enhanced infrared absorption) enhancement [8] at resonant wavelength and resonant behavior in mid-infrared regime ensure that the proposed antenna can be utilized for infrared detection applications.

II. NUMERICAL ANALYSES

Fig. 1 The schematic view of the unit cell: (a) Top view (aperture width W, aperture length H, the width the central square aperture C, the geometrical interference of the rectangles with central square S, periodicities Px and Py), and (b) cross-section view.

Fig. 1 shows a schematic structure of the unit cell of the proposed nanoaperture antenna array. In this figure, W is rectangular aperture width, H is rectangular aperture length, C is the width the central square aperture, S is the geometrical interference of the rectangles with central square, and Px and Py are periodicities of the structure. During the simulations, the unit cell of the proposed resonator antenna array is modeled on a free-standing 100-nm-thick silicon nitride (SiN,) substrate. For the metal overlay, a 30-nm-thick Au layer and a 5-nm-thick Ti adhesion layer are added onto the
dielectric substrate. Excitation the surface plasmon modes on the resonator by $E_x$-polarized normally incident electromagnetic field is simulated. The dielectric constants of the metals used for simulation are taken from Ref. [9]. Periodic boundary conditions are chosen as $x$- and $y$-axes, and perfectly matched layers are used along the $z$-axis. Unless otherwise indicated, the analyses are executed under the $x$-polarization and geometrical parameters are chosen as $C = W = 200$ nm, $H=800$ nm, $P = P_x = P_y = 2000$ nm, and $S = 50$ nm.

![Fig. 2 Transmittance spectra of the structure (a) $C$ variation, (b) $H$ variation, (c) $P$ variation, (d) $S$ variation, and (e) $W$ variation.](image)

To control the spectral response of the proposed nanoaperture arrays, a number of numerical studies are performed to obtain a fine tuning control mechanism for the spectral response of the structure (Fig. 2) versus different parameter sweeps. Fig. 2 shows the transmission spectra of fourfold rectangular shaped aperture arrays for different parameter sweeps. As can be seen from Fig. 2a, resonant wavelength red-shifts while increasing central aperture width $C$. Resonant wavelength red-shifts and transmittance increases significantly while increasing rectangular aperture length, $H$ (Fig. 2b). Fig. 2c shows that there is a small blue-shift in resonant frequency and transmittance changes mostly with increasing periodicity $P$. The changing in the geometrical interference of the rectangles with central square $S$ ensures only a significant frequency shift as observed from Fig. 2e.

![Fig. 3 Reflectance spectra of the structure (a) $C$ variation, (b) $H$ variation, (c) $P$ variation, (d) $S$ variation, and (e) $W$ variation.](image)

Spectral reflectance is also investigated numerically for the proposed nanoaperture design which can operate in reflection mode in order to obtain a fine tuning control mechanism (Fig. 3) versus different parameter sweeps in Fig. 2. As can be seen from Fig. 2a, resonant wavelength red-shifts while increasing $C$. Resonant peak red-shifts and reflectance decreases significantly while increasing $H$ (Fig. 2b). Fig. 2c shows that there is a small blue-shift in resonant frequency and transmittance changes mostly with increasing $P$. Changing $S$ ensures only a significant frequency shift (Fig. 2d). Increasing $W$ leads to frequency red-shift as observed from Fig. 2e.

To detect the reason of resonant mode, we analyze near field distribution on metal-air interface and two critical vertical surface of the unit cell. Fig. 4 shows the near-field analyses of the structure. Frequency of the resonant peak is $f_{res}=57.1$ THz ($\lambda_{res}=5247.2$ nm, $\nu_{res}=1905.8$ cm$^{-1}$) and the SEIRA enhancement ($|E|^2/|E_{in}|^2$) at $f_{res}$ is $\sim11660$ for chosen parameters; $C = W = 200$ nm, $H=800$ nm, $S = 50$ nm and $P =$
2000 nm. This high intensity enhancement at resonant peak is required for increasing sensing resolution and sensor-analite interaction in sensing applications.

![Fig. 4 Distributions of SEIRA enhancements |E|^2/|E|^2]. (a) at air - metal interface (z = 30 nm) from the horizontal field monitor, and (b) y = 50 nm and (c) y = 100 nm from the vertical field monitors (C = W = 200 nm, H=800 nm, S = 50 nm and P = 2000 nm).

III. CONCLUSIONS

In conclusion, we present the transmission and reflection characteristics of a resonator plasmonic nano-antenna based on fourfold rotationally symmetric rectangular shaped nanoaperture array which can be useful for infrared detection applications. We determined the behavior of the spectral response towards geometrical parameter variations. We revealed the physical provenance of the resonant behavior by SEIRA enhancements distribution analysis. Such nanoapertures with tunable spectral response can be capable for comprehensive consequences for infrared detection applications. The proposed nanoaperture design can support a high quality resonant mode with strong near-field enhancement.

sedau@omu.edu.tr

Abstract—Channel estimation algorithms can be grouped into three categories as pilot based, blind and semi-blind. In pilot based channel estimation, some of data symbols are used to estimate channel. In blind channel estimation statistical properties of channel are used. In semi-blind channel estimation information from both data symbols and statistical properties is utilized. In this study, pilot based semi-blind channel estimation are used to estimate the channels with various frequency and time selectivity in multiple input multiple output-orthogonal frequency division multiplexing (MIMO-OFDM) systems. Semi-blind channel estimation is done by using independent component analysis (ICA). Simulation results show that if the channel to be estimated is frequency selective, semi-blind channel estimation technique can be used instead of pilot based channel estimation.

Keywords— MIMO-OFDM, pilot based, semi-blind, channel estimation, ICA.

I. INTRODUCTION

Multiple input multiple output-orthogonal frequency division multiplexing (MIMO-OFDM) which has high spectral efficiency is the key technology of today’s wireless communication systems and it has become popular technique for transmission of signals over wireless channel [1-3]. In order to overcome the adverse effects of multipath fading in mobile communication channels, channel estimation must be performed. Channel estimation algorithms can be categorized into three groups. In pilot based channel estimation, value of previously known pilot bits are inserted into the transmitted signal is compared to the received value in the receiver and in pilot based channel estimation one dimensional pilot placement (block and comb) and two dimensional pilot placement (rectangular and diamond) are used. In blind channel estimation, algorithms often exploit the second-order stationary statistics with high computational complexity. Therefore blind channel estimation isn’t used frequently. In semi-blind channel estimation algorithms both small number of pilot bits and statistical properties of channel are used. In literature there are numerous channel estimation algorithms for example ICA [4], singular value decomposition (SVD) [5], subspace methods [6] and. All algorithms have advantages and disadvantages. But in semi-blind channel estimation, more bandwidth efficiency are obtained than pilot based channel estimation because of less pilot usage.

II. MIMO-OFDM CHANNEL

2x2 MIMO-OFDM communication system using Alamouti illustrated in Fig. 1.

Alamouti’s space time block coding for these structures is given equation 1.

\[
X = \begin{bmatrix}
 x_0 & x_1 \\
 -x_1^* & x_0^*
\end{bmatrix}
\]

(1)

A specific \(t\) time, \(x_0\) and \(x_1\) symbols are respectively transmitted simultaneously from the first and second antennas. The next time \((t+\tau)\), \(-x_1^*\) and \(x_0^*\) are transmitted respectively. The signals reach the receiving antenna at \(t\) and \(t+\tau\) time are given in equation (2-5).

\[
y_{11}(k) = x_0(k) H_{11}(k) + x_1(k) H_{21}(k) + n_{i1}(k)
\]

(2)

\[
y_{21}(k) = -x_1^*(k) H_{11}(k) + x_0^*(k) H_{21}(k) + n_{i2}(k)
\]

(3)

\[
y_{12}(k) = x_1(k) H_{12}(k) + x_0(k) H_{22}(k) + n_{i2}(k)
\]

(4)

\[
y_{22}(k) = -x_1^*(k) H_{12}(k) + x_0^*(k) H_{22}(k) + n_{i2}(k)
\]

(5)

Channel estimation coefficients in the receiver are obtained as shown in equation (6-9).
\[ \hat{H}_x(k) = \frac{x_y(k) - x_E y_m(k)}{|x_y(k)|^2 + |x_E(k)|^2} \]  
\[ \hat{H}_y(k) = \frac{x_y(k) + x_E y_m(k)}{|x_y(k)|^2 + |x_E(k)|^2} \]  
\[ \hat{H}_z(k) = \frac{x_y(k) - x_E y_m(k)}{|x_y(k)|^2 + |x_E(k)|^2} \]  
\[ \hat{H}_w(k) = \frac{x_y(k) + x_E y_m(k)}{|x_y(k)|^2 + |x_E(k)|^2} \]

**III. PILOT BASED CHANNEL ESTIMATION**

In this study a rectangular pilot placement (Fig. 2) is used for the estimation of MIMO channel.

![Fig. 2 Rectangular pilot placement](image)

In rectangular structure, pilot bits are placed periodically in the time and frequency domain. In the pilot based channel estimation, the values of the channel at the position of the pilot can be obtained using least squares (LS) and the minimum mean square error (MMSE) [7, 8].

**IV. SEMI BLIND CHANNEL ESTIMATION**

In this study a semi-blind algorithm is used for the estimation of frequency selective MIMO channel matrix \( H \). The ICA algorithm is based on a decomposition of the channel matrix \( H \). The aim of ICA is finding the \( x \) signals in equation (10).

\[ y = Hx \]  

For a good results there are two assumptions in ICA. First; source signals \( x \) are independent of each other. The second one is the values in each source signal have non-Gaussian distributions.

ICA’s preprocessing steps are:

1) **Centering:** In this step, the observation vector \( y \) by subtracting its mean vector \( m = E\{y\} \)
\[ y_c = y - m \]

2) **Whitening:** A simple method to perform the whitening transformation is to use the eigenvalue decomposition (EVD) [9] of \( y \). That is, decomposition the covariance matrix of \( y \) as follows:
\[ m = E\{yy^T\} = VDV^T \]  

where \( V \) is the matrix of eigenvectors of \( E\{yy^T\} \) and \( D \) is the diagonal matrix of eigenvalues. The observation vector can be whitened by the following transformation:
\[ y_w = VD^{-1/2}V^Ty \]
\[ y_w = VD^{-1/2}V^THx = H^*x \]

where \( H^* \) is the mixing matrix. Initial value of \( H^* \) is given randomly. Then with a using various algorithms (e.g. fixed point algorithm [10]), the last value of \( H^* \) has obtained.

**V. RESULTS**

In this study, pilot and semi-blind channel estimation are used to estimate the channels with various frequency selectivity. Firstly, two dimensional pilot based channel estimation is performed using rectangular pilot placement. Semi-blind channel estimation is done by using ICA with a 1.2 and 4 pilot bits. In simulations; 20MHz band width, ITU pedestrian (Ch1) and vehicular channels (Ch2), 200 Hz Doppler frequency, 2x2 MIMO structure and 1024 subcarriers are used.

In Figure 3 rectangular pilot placement and ICA based semi-blind channel estimation results are given for K1 channel. In rectangular placement different number of pilots (different pilot ratio (PR)) are used (PR=4, PR=16, PR=64, PR=256) and in ICA methods 1, 2 and 4 pilots are used. It is shown that pilot based channel estimation with a rectangular placement results are better than a semi-blind channel estimation results.

![Fig. 3 Performance of ICA and rectangular pilot placement for K1](image)
So for a pedestrian channel K1 which is less frequency selectivity channel than the vehicular channel K2, pilot based channel estimation results are better than the ICA results. Thus with a using a small number of pilot bits, best performance is obtained.

Pilot based with a rectangular placement and semi-blind channel estimation based ICA results for K2 are given in Figure 4. It is shown that up to 22 dB, rectangular pilot placement is better than the ICA. But after 22 dB, ICA (PR=4) is better than rectangular pilot placement.

VI. CONCLUSIONS
The results show that if the channel to be estimated is frequency selective and SNR>22dB, semi-blind channel estimation technique can be used instead of pilot based channel estimation technique which allows less pilot usage and consequently enhanced more bandwidth efficiency. So it is understood that pilot based channel estimation results aren’t always better than the semi-blind channel estimation results.

{oatila, ksengur}@firat.edu.tr

Abstract—Automatic Modulation Classification (AMC) is carried out as a basic structure between signal detection and demodulation types. Detection of modulation type of a received signal is a challenging task in communication environment. Recently, AMC has gained a paramount importance especially in cognitive radio applications. Most of the AMC methods assume that additive white Gaussian noise contaminates the received signal. There might be degradation in the performance of the traditional modulation classification methods in the impulsive noise condition. In this study, firstly the digital modulation signals are transformed into t-f domain by Short Time Fourier Transform (STFT) and then by the Spectrograms of STFT are used to obtain the t-f images of digital modulation signals. We then use Gray-Level Co-occurrence Matrix (GLCM) method which includes some statistical texture recognition techniques as a feature based AMC. Finally, we use the Support Vector Machines (SVMs) classification technique for classifying the digital modulation types. We use 0, 5 and 10 dB noise levels, respectively. We implement the proposed scheme on MATLAB. QAM, 16-QAM, 32-QAM, 64-QAM, BPSK and 8-PSK signals are considered in the experiments. The method we propose achieves the classification with having very little performance loss in impulsive noise condition compared to the Gaussian noise condition.

Keywords—Automatic Modulation Classification, Statistical Texture Recognition, Support Vector Machines.

I. INTRODUCTION

With the rapid development of wireless communication technologies such as cognitive radio, spectrum surveillance, threat evaluation, interference identification and etc. use of automatic modulation classification (AMC) has gained much attention for both civil and military applications [1], [3]. AMC provides detection of the correct modulation type from the received waveforms having different distinctive characteristics [9]. In a general communication system, receiver knows the prior information including modulation type, carrier frequency, bandwidth, symbol rate, carrier phase, and etc. therefore, the received signal can be demodulated accordingly and then the data can be extracted. AMC, however, can recognize the modulation types without need to this prior information.

In a communication system, transmitted signal is exposed to the disruptive effects of the communication channel. One of the disruptive effects is noise in the environment. Most of the modulation classification algorithms are implemented under additive white Gaussian noise (AWGN) condition for the performance analysis. However, noise types in the communication channel occur as a mix of AWGN and impulsive noise characteristic [8]. The impulsive noise occurs as various natural and man-made sources caused by electromagnetic interference such as automotive ignitions, neon lights and etc. in communication channels and this situation decreases the performance of the classifiers used for AMC [5].

There are usually two methods called the statistical texture recognition and the decision theoretic approach for grouping the modulation classification schemes. In order to formulate the classification problem, probabilistic and hypothesis testing arguments are used in decision theoretic approach and with this way the classification rule can be formed. For it keeps the error rate classification in a minimum level, generally the solution is optimal. Need for prior information can be accepted as the disadvantage of this approach [6], [8].

Texture recognition methods, however, do not need such careful treatment, although choosing the right features set is still an issue. This classification method consists of two steps: the feature extraction subsystem and recognition subsystem. The feature extraction subsystem works as extracting distinctive characteristics that are called features from the receiver signal. Example of features used are higher-order cumulates, signal spectral is prepared from wavelet transform, Fourier transform, constellation shape, signal peaks, power moments etc. [2], [4], [6], [8].
The second subsystem, the texture recognition works as classifying the received signal based on the features extracted. It can be applied in many ways such as maximum likelihood classifier (MLC), K-nearest neighborhood classifier (KNN), artificial neural network (ANN), SVM, Genetic Algorithm (GA) etc. [7], [10]-[12].

In this study we propose feature based automatic modulation classifier using SVM for classification of modulation BPSK, 8-PSK, QAM, 16-QAM,32-QAM in the mix of Gaussian noise and Impulsive noise environment. We use time-frequency texture feature based on the presented GLCM. We also present probability of correct classification for different SNR value between -5 dB to 20 dB.

This paper is organized as follows: we focus on signal models and problem statement for digital modulation signals in Section II. STFT which transformed into t-f domain is explained in Section III. Feature extraction based on GLCM including specific distinctive statistic information is presented in Section IV. SVM for digital modulation classification is explained in Section V. Simulation result is represented in Section VI. Finally, conclusions are drawn in Section VII.

II. SIGNAL MODELS AND PROBLEM STATEMENT

In digital communication, a modulated signal can be generally represented as;

\[ s(t) = A_m G_T \cos(2\pi f_m(t) + \varphi_m(t)) \]  

where \( A_m, G_T, f_m \) and \( \varphi_m \) are the message amplitude, pulse shaping function, message frequency and message phase, respectively.

The received signal can be represented as;

\[ r(t) = s(t) + n(t) \]  

received signal is sum of the transmitted signals and noise signals. where \( s(t), r(t), n(t) \) transmitted signal, received signals and noise signal respectively.

The noise signal can be represented as;

\[ n(t) = w(t) + i(t) \]  

noise signal \( n(t) \) in our noise signal model occurs noise signal \( w(t) \) is the additive white Gaussian noise and \( i(t) \) is the impulsive noise added. The AMC algorithm needs to achieve the classification without being effected by the noise so that the signal coming to the receiver can recognize the modulation type correctly.

III. Spectrogram

The discrete time STFT of \( x[m] \) is defined as;

\[ X(n, \omega) = \sum_{m=-\infty}^{\infty} x[m]w[n - m]e^{-j\pi mn} \]  

The discrete STFT is defined as;

\[ X(n, k) = X(n, \omega)\left|_{\omega=\frac{2\pi k}{T}} \right. \]  

where the window function \( w[m] \) centered at time \( n \) is multiplied with the signal \( x[m] \) before the Fourier transform. The window function is viewing the signal just close to the time \( n \) and the Fourier transform will be an estimate locally around \( n \). The usual way of finding the STFT is to use a fixed positive even window, \( w[m] \), of a certain shape, which is centered around zero and has unity power. Similar to the ordinary Fourier transform and spectrum we can formulate the spectrogram as;

\[ S(n, k) = |X(n, \omega)|^2 \]  

which is used very frequently for analyzing time-varying and non-stationary signals.

IV. FEATURE EXTRACTION

GLCM is known as a popular texture encoder where directional patterns with a specific distance and angle between neighboring image pixel pairs are countered [15]. In other words, GLCM is a square matrix where the number of rows and columns is equal to the number of gray levels of input image [13].

Instead of using the GLCM directly, 20 popular statistical features are extracted from GLCM of input images. These features are autocorrelation, contrast, correlation, cluster prominence, cluster shade, dissimilarity, energy, entropy, homogeneity, maximum probability, sum of squares variance, sum average, sum variance, sum entropy, difference variance, difference entropy, information measure of correlation, inverse difference is homogeneity, inverse difference normalized, Inverse difference moment normalized, respectively.

V. SVM CLASSIFIER

The SVM is a machine-learning algorithm, which uses a flexible representation of the class boundaries in order to solve the classification problems [14]. Given a set of training samples, each marked samples for belonging to one of two classes, a SVM training algorithm builds a model that assigns new examples into one class or the other. SVM model is a representation of the samples as points in space, mapped so that the samples of the separate classes are divided by a gap that is as wide as possible. New examples are then mapped into that same space and predicted to belong to a class based on which side of the gap they fall on [12].
VI. SIMULATION RESULTS AND DISCUSSION

All digital modulation signals are simulated according to Eq. (1), Eq. (2) and Eq. (3) in MATLAB. The simulation parameters are tabulated in Table 1.

<table>
<thead>
<tr>
<th>Parameters</th>
<th>Values</th>

</tbody>
</table>

In simulations, the training and test datasets are constructed with various SNR values. As it was mentioned earlier, we use a mixed noise model where AWGN and impulsive noise are considered. An illustrative example is shown in Fig.1 where an 8-PSK signal was contaminated with the mixed noise model. The SNR of noise level is 15 dB. In addition, a similar illustration is shown for 32-QAM in Fig. 2.

After constructing the gray scale sub-images for digital modulation signals, the texture descriptors were computed. For computing the GLCM, the distance parameter set to 1 and the angle parameter set to the values ranging from 0° to 135° within a 45° increment. Thus, 4 GLCMs were obtained and by computing the contrast, correlation, energy and homogeneity features, a 20-dimensional feature vector was constructed for each sub-image. After concatenation procedure, 80-dimensional feature vector was obtained for each digital modulation signals. For SVM classifier, we experimented with all kernels, and the best result was obtained with radial basis function kernel. The C parameter was set to 10000.

The probability of correct classification for simulated data is shown in Fig. 3. The confusion matrices are also given in Table III and Table IV for Gaussian noise environment and mix of Gaussian noise and impulsive noise environment, respectively. The probability of correct classification for simulated data is more than 83% at 0 dB SNR in mix of Gaussian noise and impulsive noise environment.

VI. CONCLUSIONS

In this paper, we supervised signal feature based automatic modulation classification by using SVM classifier under mix of Gaussian noise and impulsive noise condition. For different modulation techniques including BPSK, 8-PSK, QAM, 16-QAM, 32-QAM, 64-QAM, the simulation results and confusion matrix are presented under different SNR values and magnitudes of impulse noises. We propose a method which achieves the classification in an accuracy similar to the performance in the Gaussian noise conditions without being effected by the impulsive noise. The AMC method we propose has an approximately 1% lower performance in impulsive noise condition compared to the Gaussian noise condition. The proposed system provides a classification accuracy of 83 percent at 0 dB SNR under mix of Gaussian and Impulsive noise conditions. We have also observed that when we use more symbol number for classification, we have better results.

We will investigate how the performance of AMC in frequency selective channels can be improved in our further studies.

REFERENCES

Abstract— Partial Transmit Sequence (PTS) scheme is an effective peak-to-average power ratio (PAPR) lessening tool for Orthogonal Frequency Division Multiplexing (OFDM) system. However, computational complexity for the optimum phase factors searches of PTS scheme entails huge computational requirements and limits its applicability to practical applications especially for high-speed data transmissions. This study proposes a PAPR reduction method with a low computational complexity based on a combination of Cuckoo search optimization algorithm with PTS scheme in OFDM system. In terms of PAPR and computational complexity reductions, the performance of the Cuckoo-PTS scheme is comparatively investigated by performing a set of simulations with different PTS schemes.

Keywords— PAPR, OFDM, partial transmit sequence (PTS), Cuckoo search, phase factor

I. INTRODUCTION

Over the past few decades, due to key features as, high bandwidth efficiency, narrowband interference, efficient implementation and robustness to frequency selective fading [1–2], orthogonal frequency division multiplexing (OFDM) systems have received increasing attention and become one of the promising techniques for high data rate transmissions in digital communication. However, OFDM systems are susceptible to high peak-to-average power ratio (PAPR) [5] which causes significant reductions in radio frequency power amplifiers and yields high complexity in digital-to-analog and analog-to-digital converters. High PAPR also leads to implementation problems for the systems with large numbers of subcarriers. The PAPR can be reduced with the applications of constitutional arrangements and restrictions which in turn adversely affect the operation of the power amplifier and the spectral efficiency of OFDM systems.

Numerous methods with different advantages and drawbacks have been appeared in the literature for the reduction of PAPR in OFDM systems such as selected mapping [4], clipping and filtering [5], clipping [6], partial transmit sequence (PTS) [7-8], coding [9], tone injection [10], tone reservation [11], peak windowing [12], interleaving [13] and active constellation extension [14] have been appeared. Among these methods, the PTS is one of the popular distortionless techniques and provides remarkable PAPR reduction performance. However, the search and combination of phase factors which requires an exhaustive search procedure is the major drawback of PTS technique. The replacement of optimum phase factor search steps of PTS scheme with a suboptimal search technique offers reduction in computational complexity of PTS scheme. Many suboptimal PTS schemes, including the harmony search (HS) [15], parallel tabu search (parallel-TS) [16], artificial bee colony (ABC) [17], differential evolution (DE) [18], particle swarm optimization (PSO) [19] and random search [20], have been presented in the literature and it is reported that PAPR reductions with low computational complexities are successfully obtained.

In this paper, a suboptimal PTS scheme based on Cuckoo Search Optimization Algorithm is proposed for the PAPR reduction in OFDM systems. The Cuckoo Search Optimization Algorithm, proposed by Xin-she Yang and Suash Deb, is a relatively new optimization method that mimics the breeding behavior of some cuckoo species.

II. MODEL OF OFDM SYSTEM BASED ON PTS SCHEME

The OFDM system model based on PTS scheme is given in Fig. 1. First, the incoming bit sequences are interleaved to transform burst errors into random errors. The interleaved signal is modulated with 16-QAM modulation. To recover the original signal at the receiver, side information is transferred. The signal is passed through a high power amplifier and then a cycle prefix (CP) is applied to the signal to combat with intersymbol interference (ISI) induced by communication channel. The CP is removed from the signal at the receiver. The phase of original signal is acquired with the use of phase rotation and side information following the realization of fast Fourier transform (FFT). After 16-QAM demodulation, each demodulated symbol is conveyed to the original place in the bit sequence by means of the deinterleaver [1].
values are as follows:

\[ \text{alternative} \]

rotation \[ \text{represented} \]

signal \[ \text{subblocks} \]

carriers with equal size, \( N \), such that \( v \) multiplication of subblocks with optimized phase rotation distortionless PAPR reduction algorithm based on

The block diagram of a typical partial transmit sequence is shown in Fig. 2.

III. CONVENTIONAL PTS

Partial Transmit Sequence (PTS) is a promising distortionless PAPR reduction algorithm based on multiplication of subblocks with optimized phase rotation vectors. In a typical PTS scheme, the input signal is partitioned into \( M \) disjoint subblocks each of which have a set of subcarriers with equal size, \( N \), such that

\[ X = \sum_{m=0}^{M-1} X^{(m)} \quad (11) \]

Oversampling is implemented to subblocks by padding \( L(N - 1) \) zeros to original OFDM blocks. Oversampled subblocks are transformed into time domain and mathematically expressed by

\[ x = \text{IFFT} \left( \sum_{m=0}^{M-1} X^{(m)} \right) = \sum_{m=0}^{M-1} x^{(m)} \]

The goal of PTS scheme is to obtain a combination of \( x \) signal with a rotational phase vector \( b = [b_1 \ b_2 \ \ldots \ b_{M-1}]^T \) to offer the lowest PAPR that is represented by

\[ \bar{x} = \sum_{m=0}^{M-1} b_m x^{(m)} \]

The individuals of rotational phase vector is \( b_m = e^{i \theta_m} \), where \( \theta_m \) is selected freely between 0 and \( 2\pi \). The allowed rotational phase vector combinations is \( W^N \), where \( W \) is the number of allowed phase factor. However, the phase factor for the first subblocks is taken as \( b_0 = 1 \), then there are \( W^{M-1} \) alternative rotational phase vector combinations. The \( b_m \) values are as follows:

\[ b_m = \pm 1 \quad \text{for} \quad W = 2 \]

The block diagram of a typical partial transmit sequence is shown in Fig. 2.

IV. CUCKOO SEARCH OPTIMIZATION ALGORITHM

The Cuckoo Search (CS) Algorithm, proposed by Yang and Deb [ 7 ], is a recently developed promising optimization algorithm that utilizes the offensive reproduction tactics of the cuckoo bird. The CS algorithm is built on the following basic assumptions: each cuckoo can lay only one egg in a randomly chosen nest at a time, high-quality eggs in best nests can receive more chances to survive in next generation, the number of convenient host nests is limited and possibility of discovering cuckoo egg is defined in a range between 0 and 1. In the case of cuckoo egg detection, the host bird can either abandon the nest or throw out the cuckoo egg. The cuckoo eggs in CS algorithm represent the potential solutions.

The replacement of a host bird egg (not so good solution) with a cuckoo egg (better solution) is the goal of the CS algorithm. The assumption of each nest has only one cuckoo egg provides no distinction between egg, nest and cuckoo, and makes the application of CS algorithm simpler. The CS algorithm starts with the generation of initial population of nests with the size \( n \). In this initial population, nests are randomly distributed over the search space and randomly selected design variables are bounded by the lower and upper boundaries in the search space.

A new solution, \( x_i^{(t+1)} \), for the \( i^{th} \) cuckoo is generated using Levy flight according to the following law:

\[ x_i^{(t+1)} = x_i^t + \alpha \Theta \text{Levy}(\lambda) \]

where \( \alpha \) is the step size and is defined with respect to scale of the problem of interests. The step size must be greater than 0, and in most cases, can be unity or some other constant. Levy Flight is a random walk in which Levy distribution determines the random step size.

\[ \text{Levy} \sim u = \tau^{-\lambda}, 1 < \lambda \leq 3 \]

V. SIMULATIONS

The randomly generated OFDM signals with \( N = 256 \) subcarriers with 16 – QAM modulation were used in computer simulations. The number of the population, \( NP \), number of the
generation, number of sub-blocks, $M$, and the number of the phase factor, $W$, was selected as 20, 50, 16, 4 respectively. The complementary cumulative density functions (CCDFs) of the PAPR were obtained with the use of 10000 random OFDM symbol generations. The solid state power amplifier (SSPA) with input back-off factor, $IBO = 9 \text{ dB}$, and smoothness factor, $p = 2$ was used as an amplifier. The additive white Gaussian noise (AWGN) channel was chosen as communication channel. The simulation parameters were summarized in the Table 1.

Figure 3 illustrates the CCDFs of PAPR of PTS scheme based on cuckoo search optimization algorithm (CS), random search (RS) and optimum PTS. The PAPR values of the OFDM system are 10.96 dB for original, 7.62 dB for random search algorithm, 7.45 dB for PSO algorithm, 6.8 dB for cuckoo search algorithm, 6.37 dB for Optimum algorithm, at $CCDF = 10^{-3}$. It is seen that random search yields the worst performance while cuckoo search optimization algorithm yields the best performance for the PAPR reduction of OFDM system.

Figure 4. Comparison of the PAPR0 (dB) versus CCDF for CS-PTS with different values $G$ for $W = 4$, $M = 16$, $NP = 20$, and $G = 50$.

According to Figure 5, the PAPR is $7.28 \text{ dB}$, $7.04 \text{ dB}$, $6.93 \text{ dB}$ and $6.81 \text{ dB}$ at $CCDF = 10^{-3}$ for $P = 25$, $P = 50$, $P = 75$ and $P = 100$, respectively. It is observed that an increment in population yields an increase in PAPR reduction performance.

Figure 5. Comparison of the PAPR0 (dB) versus CCDF for CS-PTS with different values $G$ for $W = 4$, $M = 16$, $NP = 20$, and $NG = 25$.

VI. CONCLUSION

In this paper, PTS based on cuckoo search optimization algorithm in OFDM system is proposed for the PAPR reduction with less computational load. In order to evaluate the PAPR reduction performance of the proposed CS-PTS scheme, the CCDF simulations are performed. Also, its performance is compared with the performances of original PTS, O-PTS, PSO-PTS and RS-PTS in the OFDM systems. Simulation results show that the PAPR reduction performance of the CS-PTS in the OFDM system is better than that of O-PTS, PSO-PTS and RS-PTS in the OFDM system.

Abstract—Recently, utilization of mobile robots has increased substantially. Accordingly, wireless communication is preferred in mobile robots. QBot 2 is an autonomous ground robot which is a new product of Quarc. The QBot 2 utilizes an onboard data acquisition card and a wireless embedded computer to measure the onboard sensors and drive motors. In this study, QBot 2 mobile robot is evaluated in terms of its ability to maneuver. In this way, controlling QBot 2 mobile robot in real time is planned while a command recognition system is developed. Connection with the QBot 2 is carried out in a wireless environment. A Simulink model is developed in MATLAB® environment. The created model is built with Quarc control software. Compiled model is downloaded with TCP/IP connection to QBot 2 and the application is carried out on an embedded computer. The QBot 2 mobile platform consists of two central drive wheels mounted on a common axis. This drive configuration is known as differential drive. The two drive wheels are independently driven forward and backward in order to actuate the robot. Motion of the wheels is realized using high performance DC motors. When the results are analyzed, 13 different motion types are observed in total. The observed motion types could be used as references in future works since many practical applications, such as the remote control of QBot 2 mobile robot via the human voice, require the availability of different motion types.

Keywords—Intelligent robotic systems, Mobile robots; Wi-Fi based remote control.

I. INTRODUCTION

The first major mobile robot development effort was Shakey, developed in the late 1960s [1]. Recently, utilization of mobile robots has increased substantially. Mobile robot systems are designed for research, education, commercial, industrial, space missions or different purpose. Today researchers are focusing on mobile robots owing to their potential applications in hazardous environments [2], household tasks [3], in the field of agriculture [4], medical [5], and military applications [6-7].

The basic technologies involved in these applications are a suitable robotics platform equipped with enhanced sensors and a software framework for fast validation of concepts. The existing robotic platforms are presented for different applications [8-9]. The significance of developed software algorithms on computers is the increase in robotic control. Quanser has developed Quarc real time control software for MATLAB® Simulink [10].

The QBot 2 is ideally suited for research applications such as differential drive kinematics, forward and inverse kinematics, dead reckoning and odometric localization, path planning and obstacle avoidance, 2D mapping and occupancy grid map, image acquisition, processing and reasoning, simultaneous localization and mapping (SLAM), high level control architecture of mobile robots and, vision-guided vehicle control. Applications of QBot which is previous generation of Quanser ground robots are mentioned in the literature [11-13].

The QBot 2 mobile platform consists of two central drive wheels mounted on a common axis that bisects the robot. The two drive wheels are independently driven forward and backward in order to actuate the robot [14]. This drive configuration is known as differential drive [15]. There are different applications of wheeled mobile robots [16].

In this study, QBot 2 mobile robot is evaluated to explore its ability to maneuver. In this way, controlling QBot 2 mobile robot in real time is planned while a command recognition system is developed.

Interacting with mobile robots using speech is of particular interest to researchers since verbal communication is the most natural way of communication for human beings. Speech has been previously used to perform different tasks, such as command based voice teleoperation of a mobile robot [17-18].

The paper is organized as follows. Section II. introduces how to be teleoperated mobil robot QBot 2. Then, differential drive kinematics is described in Section III. The simulation results and analysis are described in details in Section IV. Finally, Section V. concludes the paper.
II. THE TELEOPERATED MOBILE ROBOT QBot 2

The QBot 2 utilizes an onboard data acquisition card and a wireless embedded computer to measure the onboard sensor and drive motors. Connection with the QBot 2 is carried out in a wireless environment A Simulink model is developed in MATLAB® environment. The created model is built with Quarc control software. Compiled model is downloaded with TCP/IP connection to QBot 2 and the application is carried out on an embedded computer.

A. The Hardware Platform

The QBot 2 is an autonomous ground robot which is a new product of Quanser. The QBot 2 is comprised of a Yujin Robot Kobuki platform, a Microsoft Kinect RGB camera and depth sensor and a, data acquisition card (DAQ) with a wireless embedded computer. The embedded computer system mounted on the mobile robot uses the Gumstix DuoVero [19] to run QUARC and interface with the QBot 2 data acquisition card [20].

B. Establishing Wireless Connection

Between the host computer and the QBot 2 connection can be either wired or wireless communications. In this study, the QBot 2 communicates with the host computer by utilizing an ad-hoc peer-to-peer wireless TCP/IP connection. The network established is called GSAH. The teleoperated mobile robot QBot 2 is shown in Fig.1.

Fig. 1. The Teleoperated mobile robot Q Bot 2

QBot 2 can be combined with other QBot units, QBall 2 and QBall-X4 unmanned aerial vehicles, or third-party autonomous vehicles, and an open-architecture, multi-purpose, multi-agent platform can be built for research [21].

C. Software Framework

Quarc 2.5 must be installed on host computer [10]. Quanser real time control software is a rapid control software to run simulink generated code under Windows. Quarc also provides for users with the ability to arrange the control parameters while the model is running.

D. Control of Software Blokset

The QBot 2 is accessible through different block sets in MATLAB® Simulink. “The Hardware in the Loop (HIL) Initialize” block set is utilized to configure the drivers and hardware interface for the QBot 2. “HIL Read/Write” block set is utilized to read from sensors and/or write to outputs. “Kinect Initialize” block set is used to initialize the Kinect sensor. “Kinect Get Image and Depth Sensor” blocks are used captures RGB and depth data from the Kinect sensor. Display Image” block set is used to transmit the input data (RGB or depth) from QBot 2 to the PC and displays them on the monitor. Other than these blocks, the “Host Initialize” block can be used to make use of external input devices such as a keyboard or joystick.

III. TWO WHEELED DIFFERENTIAL ROBOT MODEL

The QBot 2 mobile platform consists of two central drive wheels mounted on a common axis. The two drive wheels are independently driven forward and backward in order to actuate the robot. Motion of the wheels is realized using high performance DC motors. This drive configuration is known as differential drive [22-23]. Modeling of the QBot 2 is shown in Fig. 2 (a) and top view of the QBot 2 is shown in Fig. 2 (b).

Fig. 2. Left: Illustration of the QBot 2; Right: The QBot 2—top view

When there exist differences between velocities of two driving wheels, the robot must rotate around a point that lies along the common left and right wheel axis. The point that robot rotates about is known as the ICC (Instantaneous Center of Curvature). The trajectory of robot can be controlled by changing the velocities of two driving wheels. The wheel angular speed be denoted \( \omega \), \( R \) be the signed distance from to the ICC to the midpoint between the left and right wheels to the ICC, \( L \) be the distance between the left and right wheels, \( \theta \) be the heading angle of the robot, and \( V_c \) be the (forward/backward) speed of the robot chassis center. The motion of the QBot 2 velocity of the wheels can be summarized in the following equations:

\[
V_R = \omega \left( R + \frac{L}{2} \right) \\
V_L = \omega \left( R - \frac{L}{2} \right)
\]  

Equation 1 and 2 can be solved at any instance of time for \( \dot{V}_c, \dot{\omega}, R \) as follows;
\[ V_c = \frac{(V_R + V_L)}{2} \]  
\[ \omega = \frac{d\theta}{dt} = \frac{(V_R - V_L)}{L} \]  
\[ R = \frac{L(V_R + V_L)}{2(V_R - V_L)} \]  

IV. THE SIMULATION RESULTS AND ANALYSIS

In this study, QBot 2 mobile robot is evaluated to explore its ability to maneuver. For this reason a Simulink model is developed, shown in Fig. 3. In this model, we can command left and right wheel speeds of the QBot 2. When both wheels speeds are set, as shown in Fig. 3 (A), we observe linear and angular velocities, as shown in Fig. 3 (C). We analyzed that the measured and the calculated wheel speeds are different from each other, as shown in Fig. 3 (B). The difference between the calculated velocities and the measured ones as a result of measurement error are caused by load, friction and disturbances to the wheels. This concept is known as Forward Kinematics in the literature [22]. Forward Kinematics is used to determine the linear and angular velocity of the robot in the real space coordinate frame given robot’s wheel speeds.

![Fig. 3. Snapshot of the Simulink Block Diagram](image)

When \(-A, -B, 0, B, A\) speed values are set to the left and right wheels in accordance with the equality \(0 \leq B \leq A \leq 0.65 \text{ m/s}\), 13 different motion types are observed in total. Observed maneuvers information of the QBot 2 is presented in Table I. When both wheels rotate at the same speed, we observe linear motion in a straight line as, shown in the first two rows in Table I. When both wheels rotate at the same speed but in the opposite direction, we observe rotation about the midpoint of the wheel axis and rotate in place, as shown in the third and fourth rows in Table I. When only one wheel speed of the QBot 2 is set, we observe rotation around the non-moving wheel as shown in the fifth, sixth, ninth and tenth rows in Table I. When a wheels turns faster than the other, QBot 2 turns in an arc towards the slower wheel as shown in the seventh, eighth, eleventh and twelfth rows in Table I. When \(\omega\) has a positive value \((\omega > 0)\), it creates a counter clockwise rotation (CCW) whereas a negative \(\omega\) value a clockwise rotation (CW). If \(R\) has a negative value, the linear and angular velocities should have different signs. Specially, If the QBot 2 is moving forward \((V_c > 0)\), it should be rotating clockwise \((\omega < 0)\), and if it is moving backwards \((V_c < 0)\), it should be rotating counter clockwise \((\omega > 0)\).

V. CONCLUSION

In this study, QBot 2 mobile robot maneuvers were analyzed. Determined left and right wheel speed values are entered with a model created in MATLAB Simulink using QUARC control software. When the results are analyzed, 13 different motion types are observed in total.

The difference between the calculated velocities and the measured ones as a result of measurement error are caused by load, friction and disturbances to the wheels.

The observed motion types could be used as references in future works since many practical applications, such as the remote control of QBot 2 mobile robot via the human voice, require the availability of different motion types.

Abstract—Use of landmines in soils is a significant international threat facing the world today. There are no safe and highly reliable methods or inspection systems capable of detecting landmines in all situations. The use of infrared thermography is one of the promising methods for mine detection tasks. In infrared thermography, the investigation is done in either way: actively or passively. In this study, thermal signatures of the active infrared time difference images of buried mines and sand are investigated for different camera angles. It is aimed to find the effects of shot angles of the thermal camera on the performance of landmine detection. The experiments are performed at a sandbox emplaced in an indoor laboratory environment. A metal and a plastic antipersonnel mine are buried at 2 cm depth in sandbox. The sand surface is initially heated homogeneously by an infrared heater (2400 W) for 10 minutes on different days. During the cooling phase of the surface, a sequence of images are captured with an LWIR (8-12 µm band) camera (FLIR T 650 SC), which is 280 cm away from the detection area at different angles (90°, 60° and -60°). Images of the size of 480×640 pixels are taken at 15 seconds intervals during one hour. “Thermal signatures” of the buried mines and soil in three viewing angles are compared in MATLAB® environment. The results show that the locations of landmines are easily detected from the captured images during the cooling phase of the surface since observable differences develop between temperature signatures of landmines and sand, but the observation angle of camera has little affects on the detection performance. In addition, it is found that one hour measurement period is accurate for the detection of landmines at 2 cm depth in active thermography.

Keywords—Landmine detection; Thermal infrared imagery; Active thermography.

I. INTRODUCTION

Infrared (IR) thermal imaging, also often briefly called thermography, is a very rapidly evolving field in science as well as industry owing to the enormous progress made in the last two decades in micro system technologies of IR detector design, electronics, and computer science. Thermography nowadays is applied in research and development as well as in a variety of different fields in industry such as nondestructive testing, condition monitoring, and predictive maintenance, reducing energy costs of processes and buildings, detection of gaseous species, and many more [1]. IR thermal imaging has also been widely used for landmine detection.

The detection of landmines and clearance is still a time consuming and unsafe task. Additionally, efficient and accurate detection of buried mines is still a challenging problem [2].

There is no universal technique capable of detecting landmines in all conditions. Infrared thermography is a promising technique in the detection and discrimination of the landmines. The detection principle is based on the variation of the ground temperature due to the presence of buried or surface landmines.

Sand and mines have different thermal properties and this difference can be observed on the surface through the thermal sensors. Since thermal property is a dynamic behavior driven by radiation from the external heating system, it can change with the temperature in a few minutes and it can be observed better in thermal image time series than a single image.

Active thermography technique can be applied to enhance the contrast between the possible targets and the background. This contrast stems from the difference in radiant characteristics between the landmines and the background soil.

Emissivity value, which is one of these characteristics, plays a significant role in the determination of correct temperature of an object surface [3]. The source of uncertainty in temperature measurement with the infrared camera can be listed as followings: emissivity (ε) of objects, infrared detector-to-surface angle and distance. Those are mainstream technical factors for an accurate infrared thermographic measurement.
Some authors [4] [5] [6] have used analytical, numerical and experimental methods to model the thermal signatures of land mines. But, in our humble opinion, how angle of observation influences the results has not been investigated in detail yet.

Therefore, the main objective of this paper is to evaluate the effect of change in camera angle on detection performance of buried landmines.

II. BACKGROUND

A. Mine Problem

Landmines are explosive devices hidden just below the surface designed to be detonated by contact of people or vehicles, as they pass over or near them. Still some 60 countries around the world are contaminated by landmines and thousands of people continue living with a risk of losing their life or limb. In addition, emplaced landmines hinder the cultivation of large productive areas. Besides, they maintain a sense of insecurity long after conflicts end, delay peace processes and impede countries’ development for years [7].

Because of these horrendous effects, a lot of research and technological developments are needed to solve the detection and clearing of landmines problem. One widely searched solution for this problem is IR thermal imaging.

B. Thermal imaging

Each material shows a characteristic thermal response to a given stimulus, also known as the thermal signature. Thus, the cooling or heating process affects buried objects and the surrounding soil in a different way. This difference is due to the fact that the mines are better insulators than the soil. The general concept of using infrared thermography for mine detection is based on the fact that mines may have different thermal properties from the surrounding material [8]. Thermal imaging devices measure the emissivity of surfaces in an area at various temperature ranges.

Uniquely, IR can work in either way, actively or passively. It can work by accepting only the natural radiation from the object called as passive thermography, or it can provide an extra heat source and receive the artificial radiation created by that heat source dubbed as active thermography [9].

Most thermal detection concepts involve single snapshot of the region of interest. The soil over a mine has different thermal dynamics than homogeneous soil and, as a result, a time sequence of images can often produce better detection than a single image [10].

Consequently, the soil temperature on the ground above the mines is often different from that of the background. This temperature can be measured by an IR imaging system placed above the soil area.

III. EXPERIMENTS

The equipment required for the experiments consists of model anti-personal landmines (plastic and metal), thermal camera, a tripod of camera stand or framework, sandbox and a heating unit.

The landmines can be categorized mainly into two sections according to their materials, metal or plastic mines. The surrogate model mine used in the experimental study is Plastic DM-11 (partly filled with wax whose thermal properties are similar to TNT) and Metal M-16 anti-personnel mines (APM’s) as shown in Fig. 1. DM-11 has a diameter of 0.08 m and a height of 0.035 m. M-16 has a diameter of 0.12 m and a height of 0.20 m.

The mines were buried in a sandbox which has a height of 1.85 m length, a width of 1.55 m and a depth of 0.225 m, filled with sand. The thermographic imaging was performed with a portable infrared camera (FLIR T 650 SC) equipped with an uncooled micro bolometer, a focal plane array infrared detector with a spectral range between 7.5 – 13.0 μm and 480×640 pixels.

The camera was attached to a framework, consisting of a fixed attachment point for the camera. The sandbox was located at the base of the framework and the camera was focused on the center of the sandbox.

Fig. 1. Experimental setup for an assessment of angular variation of emissivity. The FLIR T 650 SC was rotated about the sample and fixed at 30-degree intervals. Plastic APM DM 11 (up) and Metal APM M 16 (down) Positions.

Infrared Heater (UFO-L2300-2400 Watt Power) was used as a heat source. The heating phase (active thermography) is shown in Fig. 2.
All measurements were performed for 1 day for each angle. Images were analyzed with commercially MATLAB and FLIR IR Research Software.

IV. RESULTS

Three types of experiments performed at the viewing angles of 90°, 60° and -60° as it is shown in Fig.3 during three days. The acquired thermal images are stored in a personal computer. The model mines were buried into a depth of 0.02 m beneath the sand surface.

The sand surface was initially heated by an infrared heater (2400 W) for 10 minutes in each day. During the cooling phase of the surface, a sequence of images was captured with FLIR T-650 SC camera placed in 280 cm distance from the detection area. Images of the size of 480×640 pixels were taken at 15 seconds intervals during one hour.

The temperature effect of the presence of the mine on the sand surface at each angles are clearly shown in Fig. 4 (a, b, and c).

As it is shown in Fig.4, the surface temperature of the sand above plastic mine was higher than the surface temperature of the sand beside mine. However, the situation was just opposite when it comes to metallic mine. The hot and cold surface spots caused by the energy reflected from the surface over mines generally became apparent within a similar time frame [4].

The results showed that the amplitude of the surface temperature change above the mine was much greater than that on the surface beside it; this was caused by the heating method. In all tests, the locations of the mines were identified using FLIR T-650 SC thermal camera and Research IR Program. The evolution of the “hot spot” and “cold spot” above the mines can be observed from the results shown in Fig. 4.
Our experiments confirmed that emissivity nearly remains constant from 60° to -60° degrees from the horizontal. These results were in agreement with what reported in the textbook of Infrared Thermal Imaging Fundamentals, Research and Applications [1], which explains the influence of viewing angle on emissivity of a surface.

Angular dependency of emissivity (angle of observation) that has an influence on images was recorded with an IR camera system. However, Figure 5 demonstrates an effect that fortunately holds for nearly all practically important surfaces: the emissivity is nearly constant from the normal direction 0° to at least 40 or 45° [1].

![Fig. 5. The emissivity values at different angles [1].](image)

The study was carried out to understand how the viewing angle was influenced to the emissivity. Changing in the emissivity was recorded in each direction, and the results are shown in Fig. 6 (a, b, and c). The difference between the two temperature signature profiles (sand and mines) was plotted in MATLAB for each test.

![Fig. 6. Thermal signatures of a minefield; images taken at (a) 90°, (b) 60° and (c) -60°.](image)

V. CONCLUSION

In our study the effect of viewing angle is investigated by combining the analysis of temporal IR image sequences, showing the dynamic scene behavior during time variant heating by an infrared heater. The results show that different viewing angles (for 90°, 60° and -60°) have relatively little effect on the temperature at the surface. The emissivity is approximately constant at the viewing angles between 60° and -60°.

Experiments have shown that active thermography has strong positive effect on thermal signature in a short time. It can be especially useful in military tasks.

The thermal properties of the mine itself can play a significant role according to the thermal signatures. Also, it is shown that 60 minutes duration is enough to produce thermal signatures for buried mines at a depth of 2cm from the surface with active thermography.

Abstract—With the rapid development of industrial technology, industrial automation systems will provide safe, quality, fast and competitive product manufacturing. Programmable Logic Controller (PLC) is preferred in industrial automation systems due to its features such as process speed, quality and reliability, small physical size and easy installation. As PLC systems develop, SCADA systems are began to use in a wide area. Industrial plants can be monitored remotely can be controlled by time and past data can be stored using SCADA systems with PLC.

In this study, prototype and implementation of SCADA based mortar mixing automation system with PLC was carried out. The system was controlled by S7-200 PLC and WinTr SCADA interface. All parameters can be entered, monitored and controlled by means of SCADA interface. In the system, mortar mixture were comprised of cement, aggregate, gravel and water. Each material was located in separate hoppers. When material values for mixture were entered, hoppers cover was opened respectively. The amount of entered value and weighed value were compared and when their values were equal, hopper covers were closed thanks to loadcells located at the bottom of the hoppers. Materials were transferred to mixing hopper by means of band system after sand, aggregate and gravel were added. Then, water was pumped from the water hopper to the mixing hopper and all materials were mixed by mixer.

Keywords—PLC, SCADA, mortar mixing automation

I. INTRODUCTION

Industrial automation systems will provide qualified, safe, fast and competitive way for product manufacturing with the rapid development of industrial technology. With the use of automation systems, production desired and planned in plants can be made and also systems can be monitored remotely. Furthermore, automation technology also provides fast and reliable production [1].

Mortar mixed systems work under the control software because they are completely subject to the automation system. Nowadays, Programmable Logic Controller (PLC) is used in almost every area of the industry but it is used especially in automation systems. PLC has a wide range of application in all areas of industry such as air conditioning, elevator, ventilation, cooling, packaging, storage and transportation plants, automobile industry, petroleum filling and washing plants, cement industry, lighting plants, all kinds of machines, electropneumatic and hydraulic systems [2].

SCADA systems are used in wide area as long as PLC systems evolve. They enable to remote communication. Thus, they provide easier intervention to long distance system. Nowadays, SCADA systems are widely used in various fields such as energy, water, gas, cement, climatization, transportation, security and banking [3]. Usage of PLC and SCADA systems has many advantages. For example, quality increases, process monitoring is easier, failure caused by human factor and occupational accidents can be minimized [4].

In this study, prototype and application of mortar mixing automation system which is based on PLC and SCADA was realized. The system was controlled by the S7-200 PLC and WinTr SCADA interface. PLC and SCADA interface has worked simultaneously. Thus, system can be monitored and controlled in real time.

II. PROTOTYPE DESIGN OF SYSTEM

A. PLC Properties used in the System

In this study, Siemens S7-200 CPU 224 was used as PLC. S7-200 includes a compact microprocessor to create a powerful Micro PLC, integrated power supply, input and output circuits. CPU 224 model has 14 inputs and 10 outputs [5, 6]. The block diagram of system is shown in Figure 1.

![Block diagram of system](image)

B. Design of System

Prototype of the mortar mixing automation system is shown in Figure 2 and prototype material list is shown in Table 1.

In the system, mortar mixture were comprised of cement, aggregate, gravel and water. Each material located in separate hoppers. Loadcells were located under each hopper. Loadcell is an analogue sensor and its output voltage is between 0-3.6 mV. However, analogue values can’t be read directly by the PLC which can only detect logic signals. Therefore, an EM-235 analogue module is needed to convert analogue value to digital value. Information coming from loadcells was converted digital value in accordance with PLC. EM-235 module has three inputs in the system and they are shown in Table II. The output value of the EM-235 module is between 0-10 V [5]. However, output voltage of loadcells is lower than the output voltage of the analogue modules and it needs to be amplified. Therefore, an amplifier circuit was designed for this and shown in Figure 3.

Six DC motor was used in order to open and close the hopper covers. Three DC motor provided to open the hopper covers and the other three motor provided to close the hopper covers. Materials for the mixture collected respectively in the conveyor hopper located on the belt system and it was transferred to the mixing hopper. The movement of the belt system was provided with inductive sensors located on belt system.

### C. SCADA Interface

In this study, SCADA interface was designed by using WinTr SCADA software. SCADA interface is shown in Figure 4.

PLC and SCADA interface work synchronously, so system can be controlled from interface in an instant. There are hoppers for the materials used in mortar mixing. When material values for mixture are entered from the interface, hopper covers are opened respectively. Information which comes from loadcells is transferred to PLC via analogue module. When entered value equals to weighed value, hopper covers are closed. Materials are transferred respectively to the conveyor hopper which is on the belt system. Materials in conveyor hopper are transferred to the mixing hopper after all materials are added. Then, water is pumped into the mixing hopper and all materials are mixed by means of mixer.

III. CONCLUSION

Nowadays, automation systems are used for safe, quality and fast industrial production with the rapid development of industrial technology. PLC systems are widely used in automation systems. Usage of SCADA systems has increased with the expansion of the application areas of PLC. Industrial plants can be remotely monitored, controlled using SCADA with the PLC. Moreover, historical data of plants can be stored.

In this study, prototype and application of mortar mixing automation systems were realized. The system was controlled by a PLC and SCADA interface. Furthermore, the system can be remotely monitored and can be controlled with SCADA interface.

Real Time Application of Sliding Mode Controller for Coupled Tank Liquid Level System

Hayriye Tuğba Sekban, Kaan Can, Abdullah Başçi

abasci@atauni.edu.tr

Department of Electrical & Electronics Engineering, Atatürk University
Erzurum, Turkey

Abstract— In this paper, real time application of a sliding mode control (SMC) is used for level control of experimental setup of liquid level system due to its properties such as robustness against large parameter variation and disturbances rejection. A well-tuned conventional proportional integral (PI) controller is also applied to the two coupled tank system for comparison with the SMC controller. Experimentation of the coupled tank system is realized in two different configurations, namely configuration #1 and configuration #2 respectively. In configuration #1, the water level in the top tank is controlled by a pump. In configuration #2, the water level in the bottom tank is controlled by the water flow coming out of the top tank. The performance of controllers is analyzed according to their tracking performance and error elimination capability for different references applied to the system. Experimental results prove that the SMC shows better trajectory tracking performance than PI controller in that the plant transient responses to the desired output changes have shorter settling time and smaller magnitude overshoot/undershoot. Robustness of the SMC with respect to water level variation and capability to eliminate external disturbances are also achieved.

Keywords— Liquid Level Control, Sliding Mode Control

I. INTRODUCTION

Liquid level control is one of the essential problems of process industry. In nuclear power plants, wastewater treatment plants, filling-disposal plants etc., high sensitive liquid level systems must be used to do complex and dangerous processes that are not done by humans. To achieve correct mixture ratio, adjust liquid flow between tanks precisely and to get high level performance from this systems, well-designed controllers must be also used. Due to their nonlinear system dynamics and can be effected disturbances easily, the control of liquid level systems are difficult. To overcome these difficulties and control this kind of systems in a desired efficiency, many control algorithms have been proposed by the researchers. Due to their simple structures, easy parameter adjustment and basic calculation knowledge needed P, PI, PID controllers are used to control liquid level of the tanks [1-3]. In the experimental application, classical P, PI, PID controllers are not sufficient for a precise control where sudden changes occur, parameter adjustment and fast response are needed. For these reasons, conventional P, PI and PID controllers are not a good choice for a nonlinear system. In control engineering and relevant areas, some nonlinear controllers have been developed to apply the systems that have nonlinear system dynamics. As an example, the backstepping controller has been presented to control the systems where system dynamics can be written in a lower triangular form [4-7]. Also, it has a recursive structure and its stability analysis can be proven based on Lyapunov stability theorem, the backstepping controller mostly preferred. On the other hand, all states of the system must be measured and in complex systems, more mathematical processes are needed to calculate the control input signal. Moreover, fuzzy controller is proposed where the system is not well defined and does not have an exact mathematical model [8]. Apart from these advantages, the fuzzy controller is not good enough to stabilize the system where the quick response is needed and the controller’s sensitivity need to be very high. Also, it is a rule based controller and there is no theorem to proof its stability criteria. As an another solution, SMC is proposed to control nonlinear systems. The SMC is a type of nonlinear controller and preferred for the systems where the controller must be very robust to model uncertainties and external disturbances [9-15]. In addition to this advantages mentioned on SMC, it has a simple structure and its stability criteria can be proven using Lyapunov stability theorem.

In this study, the liquid level control of coupled tank system is examined in experimental application using PI and SMC controllers for different reference inputs. Both controllers are compared in term of error elimination capability and robustness against to parameter uncertainty. The results prove that the SMC shows better trajectory tracking performance than PI controller. Also, the results show that SMC is really robust to model uncertainties occur in the system and good at eliminating the errors compared with the PI controller.

II. MODELLING AND CONTROL OF THE COUPLED TANK SYSTEM

A. Single Tank Model (Configuration #1)

Single tank system which consisting of the top tank is shown in Fig. 1. It is reminded that in configuration #1, the pump feeds into tank 1 and that tank 2 is not considered at all. Therefore, the input to the process is the voltage to the pump and its output is the water level in tank 1. The model of the single tank system determined by relating the volumetric inflow rate \( f_{i1} \) into tank and the outflow rate \( f_{o1} \) leaving through the hole at the tank bottom.
The volumetric inflow rate and the outflow rate to tank 1 can be expressed as [19],

\[ f_{i1} = \eta u(t) \]  
\[ f_{o1} = A_{o1} V_{o1} \]  

Where \( A_{o1} \) is the outlet cross sectional area, \( V_{o1} \) is the tank 1 outflow velocity, \( \eta = K_p / A_{i1} \) is constant, \( K_p \) is the pump volumetric flow constant and \( u(t) = V_p \) is the actual pump input voltage. The outflow velocity by using Bernoulli’s equation

\[ V_{o1} = \sqrt{2gL_1} \]  

(3)

where \( g \) is the gravitational constant on earth. As a remark, the cross-section area of tank 1 outlet hole can be calculated by,

\[ A_{o1} = \frac{1}{4} \pi D_{o1}^2 \]  

(4)

In the Eq. (4) \( D_{o1} \) is the tank 1 outlet diameter. Using Eq. (3) the outflow rate from tank 1 given in Eq. (3) becomes,

\[ f_{o1} = A_{o1} \sqrt{2gL_1} \]  

(5)

Moreover using the mass balance principle for tank 1, we obtain the following first-order differential equation in \( L_1 \),

\[ A_{i1} \left( \frac{dL_1}{dt} \right) = f_{i1} - f_{o1} \]  

(6)

where, \( A_{i1} \) is tank 1 inside cross-section area. Substituting Eq. (1) and (2) into Eq. (6) and it can be rearranged in the following form for the tank 1 system,

\[ \frac{dL_1}{dt} = \frac{KpV_p - A_{o1} \sqrt{2gL_1}}{A_{i1}} \]  

(7)

B. Coupled Tank Model (Configuration # 2)

A schematic of the coupled tank plant is depicted in Fig. 2.

In configuration #2 the pump feeds into tank 1, which in turn feeds into tank 2. As far as tank 1 is concerned, the same equation as the ones previously developed in section (2.A) is applied. However, the water level equation of motion in tank 2 still needs to be derived. In the coupled tank, the system states are the level \( L_1 \) in tank 1 and the level \( L_2 \) in tank 2. The outflow rate from tank 2 can be expressed as;

\[ f_{o2} = A_{o2} V_{o2} \]  

(8)

Tank 2 outflow velocity by using Bernoulli’s equation

\[ V_{o2} = \sqrt{2gL_2} \]  

(9)

As a remark, the cross-section area of tank 2 outlet hole can be calculated by,

\[ A_{o2} = \frac{1}{4} \pi D_{o2}^2 \]  

(10)

Using Eq. (9) and (10) the outflow rate from tank 2 given in Eq. (8) becomes

\[ f_{o2} = A_{o2} \sqrt{2gL_2} \]  

(11)

Using Eq. (5) the inflow rate to tank 2 is as follow

\[ f_{i2} = A_{i2} \sqrt{2gL_2} \]  

(12)

Moreover using the mass balance principle for tank 2, we obtain the following first-order differential equation in \( L_2 \),

\[ A_{i2} \left( \frac{dL_2}{dt} \right) = f_{i2} - f_{o2} \]  

(13)

Substituting Eq. (12) and (11) into Eq. (13) and it can be rearranged in the following form for the tank 2 system,
\[
\frac{dL_2}{dt} = -A_{o2} \sqrt{2 \frac{gL_2}{A_{o1}}} + A_{o1} \sqrt{2 \frac{gL_1}{A_{o2}}}
\]

(14)

III. SLIDING MODE CONTROLLER DESIGN FOR THE TANK 1

We assume that flow rates cannot be negative and we agree as follows,

\[
f \geq 0
\]

(15)

Therefore, following equation must satisfy as the flow rate to be above,

\[
L_1 \geq L_2
\]

(16)

Thus, the following equation can be written.

\[
L_1 = z_1, \quad L_2 = z_2
\]

(17)

\[
\frac{A_{o1} \sqrt{2g}}{A_{o1}} = k_1, \quad \frac{A_{o2} \sqrt{2g}}{A_{o2}} = k_2
\]

(18)

\[
k_1 = k_2 = k
\]

(19)

If writing to these assumptions in the dynamic model of the coupled tank system the following equations can be obtained.

\[
\dot{z}_1 = -k \sqrt{z_1} + \eta \mu
\]

(20)

\[
\dot{z}_2 = k \sqrt{z_1} - k \sqrt{z_2}
\]

(21)

\[
y = z_1
\]

(22)

The dynamics model of the coupled tank system is nonlinear. Therefore, in order to define the dynamics of the coupled tank system, the dynamic model subject to a transformation equation as follows.

\[
x = \begin{bmatrix} x_1 \\ x_2 \end{bmatrix}, \quad and \quad x = T(z) \quad if \quad we \quad make \quad the \quad transformation,
\]

(23)

\[
x_1 = z_1
\]

(24)

\[
x_2 = \dot{z}_1 = -k_1 \sqrt{z_1} + \eta \mu
\]

(25)

The above equations will be obtained. Then the dynamics of the coupled tank system can be rewritten as shown below.

\[
\dot{x}_1 = x_2
\]

(26)

\[
\dot{x}_2 = -k \sqrt{\frac{z_1}{2}}
\]

(27)

Thus, the dynamics of the combined form of coupled tank system can be written as follows,

\[
\dot{x}_1 = x_2
\]

(28)

\[
\dot{x}_2 = f + \phi u = \frac{-k}{2 \sqrt{z_1}} (-k \sqrt{z_1} + \eta \mu)
\]

(29)

where,

\[
f = \frac{k^2}{2}
\]

(30)

\[
\phi = -\frac{k}{2 \sqrt{z_1}} \eta
\]

(31)

can be expressed. If we define the sliding surface \( s(t) \) as,

\[
s = \left( \frac{d}{dt} + \lambda \right)^{n-1} e = \lambda e + \dot{e}
\]

(32)

where \( \eta \) is the order of the system to be controlled, \( \lambda \) is a positive constant, \( e \) is the error. We take error as a reference and the measured difference and we obtained the following equation.

\[
e_1 = L_{eq} - L_1
\]

(33)

\[
e_1 = x_{eq} - x_1
\]

(34)

If we take the derivative of both sides of the Eq. (32) the following equation obtained.

\[
\dot{s} = \dot{\lambda} e + \dot{\dot{e}}
\]

(35)

Eq. (35) is employed as the expression written instead of the second order derivative of the error, following equations can be written,

\[
\dot{s} = \dot{\lambda} e + \left( \ddot{x}_{eq} - \ddot{x}_1 \right)
\]

(36)

Ideally, we want to sliding surface to be equal to zero. If sliding surface is zero than derivative of the sliding surface will be zero as following equations.

\[
0 = \dot{\lambda} e + \left( \ddot{x}_{eq} - \ddot{x}_1 \right)
\]

(37)

\[
0 = \dot{\lambda} e - f(x) - \phi(x)u_{eq}
\]

(38)

If \( u_{eq} \) in Eq. (38) left alone than Eq. (39) can be obtained.

\[
u_{eq} = \frac{-f(x) + \dot{\lambda} e}{\phi(x)}
\]

(39)

Considering the system parameters and disruptive we can get our control signal as follows.
Thus, the dynamics of the combined form of coupled tank system can be written as follows,

\[ u = u_{eq} + k_x \operatorname{sgn}(s) \]  \hspace{1cm} (40)

Substituting \( u_{eq} \) into Eq. (40) and it can be rearranged in the following form which is control signal for the tank 1 system,

\[ u = \frac{k \sqrt{L_1}}{\eta} - \frac{2\lambda \sqrt{L_1} \dot{e}_1}{k \eta} + k_x \operatorname{sgn}(s) \]  \hspace{1cm} (41)

IV. SLIDING MODE CONTROLLER DESIGN FOR THE TANK 2

Considering the dynamic of equality for tank 2, the following equations are considered to control tank 2.

\[ L_1 = z_2, \quad L_2 = z_1 \]  \hspace{1cm} (42)

\[ \frac{A_{o1} \sqrt{2g}}{A_{i1}} = k_1, \quad \frac{A_{o2} \sqrt{2g}}{A_{i2}} = k_2 \]  \hspace{1cm} (43)

\[ k_1 = k_2 = k \]  \hspace{1cm} (44)

If writing to these assumptions in place of the coupled tank system dynamic model equations are obtained from the following equation.

\[ \dot{z}_2 = -k \sqrt{z_2^2 + \eta u} \]  \hspace{1cm} (45)

\[ \dot{z}_1 = k \sqrt{z_2^2 - k \sqrt{z_1^2}} \]  \hspace{1cm} (46)

\[ y = z_1 \]  \hspace{1cm} (47)

Let \( x = \begin{bmatrix} x_1 \\ x_2 \end{bmatrix} \), and the transformation \( x = T(z) \) such that,

\[ x_1 = z_1 \]  \hspace{1cm} (48)

\[ x_2 = \dot{z}_1 = k \sqrt{z_2^2 - k \sqrt{z_1^2}} \]  \hspace{1cm} (49)

Thus, the dynamics of the combined form of coupled tank system can be written as follows,

\[ \dot{x}_1 = x_2 \]  \hspace{1cm} (50)

\[ \dot{x}_2 = \frac{k}{2 \sqrt{z_2}} \dot{z}_2 - \frac{k}{2 \sqrt{z_1}} \dot{z}_1 \]  \hspace{1cm} (51)

\[ \dot{x}_2 = \frac{k}{2 \sqrt{z_2}} \left( -k \sqrt{z_2^2 + \eta u} \right) - \frac{k}{2 \sqrt{z_1}} \left( k \sqrt{z_2^2 - k \sqrt{z_1^2}} \right) \]  \hspace{1cm} (52)

\[ \dot{x}_2 = \frac{k \mu u}{2 \sqrt{z_2}} - \frac{k^2 \sqrt{z_2}}{2 \sqrt{z_1}} \]  \hspace{1cm} (53)

\[ \dot{x}_1 = \dot{z}_1 \]  \hspace{1cm} (54)

\[ \dot{x}_2 = f + \phi u = \frac{k^2 \sqrt{z_2}}{2 \sqrt{z_1}} + \frac{k \mu u}{2 \sqrt{z_2}} \]  \hspace{1cm} (55)

Where,

\[ f = -\frac{k^2 \sqrt{z_2}}{2 \sqrt{z_1}} \]  \hspace{1cm} (56)

\[ \phi = \frac{k}{2 \sqrt{z_2}} \eta \]  \hspace{1cm} (57)

It can be expressed. Define a sliding surface \( s(t) \) as,

\[ s = \left( \frac{d}{dt} + \lambda \right)^{n-1} e = \lambda e + \dot{e} \]  \hspace{1cm} (58)

Where \( n \) is the order of the system to be controlled, \( \lambda \) is a positive constant, \( e \) is the error. Error we take as a reference-measured, and we have obtained the following equation.

\[ e_2 = L_{2r} - L_2 \]  \hspace{1cm} (59)

\[ e_2 = x_{2r} - x_2 \]  \hspace{1cm} (60)

If we take the derivative of both sides of the Eq. (58) the following equation obtained.

\[ \dot{s} = \lambda \dot{e}_2 + \ddot{e}_2 \]  \hspace{1cm} (61)

Eq. (61) is employed as the expression written instead of the second order derivative of the error is obtained the following equation.

\[ \dot{s} = \lambda \dot{e}_2 + \left( \ddot{x}_{2r} - \ddot{x}_2 \right) \]  \hspace{1cm} (62)

Ideally, we want to sliding surface to be equal to zero. If sliding surface is zero then derivative of the sliding surface will be zero as following equations.

\[ 0 = \lambda \dot{e}_2 + \left( \ddot{x}_{2r} - \ddot{x}_2 \right) \]  \hspace{1cm} (63)

\[ 0 = \lambda \dot{e}_2 - f(x) - \phi(x)u_{eq} \]  \hspace{1cm} (64)

If \( u_{eq} \) in Eq. (64) left alone than Eq. (65) can be obtained.

\[ u_{eq} = -\frac{f(x)}{\phi(x)} + \frac{\lambda \dot{e}_2}{\phi(x)} \]  \hspace{1cm} (65)

Considering the system parameters and disruptive we can get our control signal as follows.

\[ u = u_{eq} + k_x \operatorname{sgn}(s) \]  \hspace{1cm} (66)
Substituting $u_{eq}$ into Eq. (66) the following equation which is control signal of the tank 2 can be obtained.

$$u = -\frac{kL_1}{\eta \sqrt{L_2}} + \frac{2\lambda \sqrt{L_2} \dot{e}}{k \eta} + k_s \text{sgn}(s)$$

(67)

Where, $k_s \text{sgn}(s)$ is switching control function. $k_s$, is the switching gain and $\text{sgn}(s)$ can be expressed given below [18].

$$\text{sgn}(s(t)) = \begin{cases} 
1 & s(t) > 0 \\
0 & s(t) = 0 \\
-1 & s(t) < 0 
\end{cases}$$

(68)

Using the controller law given in Eq. (41) and (67) in to Eq. (36) and (62), it follows that [17],

$$\dot{s} = -w_s \text{sgn}(s)$$

(69)

The state trajectories associated with this unforced discontinuous dynamics i.e eq (69) exhibit a finite time reachability to zero from any value of initial condition subject to the value of $w_s$ must be positive. Since system driven its states to zero in finite time, the desired level $y = z_1 = h_2$ and $y = z_1 = h_1$ in both tanks are regulated after a finite time by first order dynamics $\dot{y} + a_s(y - H) = 0$. Where $H$ is desired value of the output of tank. Hence, the output of both the tank will asymptotically converge to its desired value since $a_s$ is positive.

V. EXPERIMENTAL RESULTS

In the first experiment of configuration #1, the step+sinusoidal reference signal is applied for PI and SMC controllers given in Fig. 3 and Fig. 4 respectively. For the step reference signal part, PI controller has more overshoot and has longer settling time compared with the SMC. The time varying part of the reference signal, both controllers show the same performance in term of tracking the reference signal, under/overshoot and error elimination capability etc. On the other hand, SMC is generated the pump voltage with more chattering phenomena than the pump voltage generated by PI controller.

For the second experiment of configuration #1, the step+sawtooth reference signal is applied to show the responses and performance of both controllers shown in Fig. 5 and Fig. 7 respectively. The sawtooth reference signal is important due to consisting of the sudden and continuously changing part in the same period. For PI controller, it has more overshoot and longer settling time compared with SMC. Also, PI controller has continued to make overshoot through the continuously changing part of the sawtooth signal. Besides, SMC has no overshoot while tracking the step+sawtooth signal and has better performance in term of error elimination and robustness to parameter variations occur in the system.

The experimental results given for configuration #2, are realized using the step + trapezoidal reference signal for PI and SMC controllers shown in Fig. 6 and Fig. 8 respectively. In this section, the cascaded tank system is used to realize level control for different reference signals. For PI controller, it has longer rising and settling time. Also, PI controller has more overshoot than SMC controller. At the same time, SMC shows better performance for position tracking and also has given fast response the parameter variations.
VI. CONCLUSIONS

In this study, SMC has been designed and applied to two tank liquid level system in order to maintain a stable reference tracking for different reference signals for both configurations. The experimental results indicate that the proposed controller has better performance in term of error elimination capability, good reference signal tracking, robustness to parameter variations. It can be also noticed from the results obtained that SMC is reasonably prior to the classical PI controller for the levels that required to be kept at a constant level and following time varying reference signals very well.

Abstract— The design of the system used for brushless DC (BLDC) motor control in speed and position control is difficult due to the non-linear structure. Therefore, the designed controller is required to respond to these challenges and need high-efficiency operation. This paper presents the experimental validation of a robust speed control structure of a BLDC motor based on continuous sliding mode (CSM) and fractional sliding mode (FSM) controllers. The controllers have been tested for low and medium speed reference signals and amplitude values. Then, both controllers have been compared in term of tracking performance and error elimination and the results have been shown graphically. Experimental results prove that the FSM controller shows better trajectory tracking performance than CSM controller with high precision as well as good robustness against changes of references.

Keywords— BLDC motor, Continuous sliding mode control, Fractional sliding mode control, Speed control

I. INTRODUCTION

Parallel to the developments in the control areas, brushless DC motors are used in computers, automated office equipment, robotic applications, electro-mechanical systems and many precision machines. Brushless DC motors can be controlled more simply than other direct current motors and it has advantages such as high torque, high efficiency and small size. In addition, problems such as mechanical wear occur in the brushes and commutator by changing the position of the stator and rotor in the DC motor. And also maintenance of the brush takes a long time. But instead of brushes and commutator, BLDC motors use Hall Effect sensors [1]. Today, drivers have developed high processing ability and therefore robust control of BLDC motors are successfully carried out. The desired control algorithm is mathematically analysed for robust operation of the controller designed in accordance with, are tested in various computer programs and R & D work done. In the literature, various studies have been made for speed control of BLDC motors. In [2], is described a fuzzy logic approach for BLDC motor controller in variable speeds and the fuzzy logic tuner is used to adjust the gains of the PI controller and the results obtained in the simulation study showed less ripple under variation in system parameters with fast response times. Yu and Hwang have proposed an optimal PID controller and controller parameters are determined by linear quadratic regulator. The successes of the proposed method were compared with conventional PID controller and simulation and experimental results were given. Navidi et al. [4] proposed a method determined by ant colony search algorithm for PID controller parameters. They have demonstrated success with the simulation results of the proposed method in improving the step response characteristics such as reducing the steady-states error, settling and rise time, and maximum overshoot in speed control. Chen and Tang proposed a sliding mode current control scheme for pulsewidth modulation (PWM) brushless dc motor drives in their study [5]. In this scheme, an improved “equivalent control” method is used and they stated that the validity of this scheme is achieved by simulation and experimental results. Moshiri et al. proposed an approach that has the merit to determine the optimal structure and the inference rules of fuzzy sliding mode controller simultaneously [6]. The success of the proposed controller is provided with the simulation results. Wang et al. offered a stable hierarchical sliding-mode control method for a class of second-order under actuated systems [7]. They consider the system as two subsystems and defined a first-level sliding surface for each part. Also they defined a second-level sliding surface for these two first-level sliding surfaces and simulation results have shown the success of the proposed method and adaptive abilities for all kinds of extraneous disturbances.

The main advantages of sliding mode control are demonstrated in numerous examples and simulations. The history of this control structure; In 1977, after V. Utkin [8] compiler work, Sliding Mode Controller - SMC and Variable Structure Control - VSC methods are widely used in control
applications until today [9]-[19]. The aim of sliding mode control methods, especially in the real dynamic system; are
designed to drive the system states onto a particular surface in
the state space, named sliding surface. Once the sliding
surface is reached, sliding mode control keeps the states on
the close neighbourhood of the sliding surface. There are two
main advantages of sliding mode control. First is that the
dynamic behaviour of the system may be tailored by the
particular choice of the sliding function. Secondly, the closed
loop response becomes totally insensitive to some particular
uncertainties. The disadvantage of sliding mode control
method is a control signal that changes direction too much and
it is called chattering. Also chattering causes some problems
in practice such as damaging the component parts of the fast
moving systems, to causes fatigue in the controlled
system, significantly reduce the life of the system and also
cause unnecessary energy consumption. Various methods are
available to reduce this negative effect of chattering such as
filtering, discontinuous approach, saturation function and
fuzzy control. But this time the robustness of the sliding mode
control functionality is lost [12-14].

In this study, a fractional order sliding mode controller is
designed to reduce the effect of chattering and also to
maintain the high robustness and high accuracy features
sliding mode control.

II. BLDC MOTOR MODEL

The electrical and mechanical mathematical equation of
BLDC motor can be expressed as,

$$\frac{d}{dt}\begin{bmatrix} i_a \\ i_b \\ i_c \end{bmatrix} = -\frac{R}{L_1}\begin{bmatrix} i_a \\ i_b \\ i_c \end{bmatrix} - \frac{1}{L_1}\begin{bmatrix} e_a \\ e_b \\ e_c \end{bmatrix} + \frac{1}{L_1}\begin{bmatrix} v_a \\ v_b \\ v_c \end{bmatrix}$$

$$\frac{d\omega_m}{dt} = \frac{1}{J_m}(T_e - B_m\omega_m - T_{Load})$$

$$\phi_e = \frac{p}{2}\phi_m$$

$$\begin{bmatrix} e_a \\ e_b \\ e_c \end{bmatrix} = \begin{bmatrix} f_{a}(\phi)\lambda\omega_m \\ f_{b}(\phi)\lambda\omega_m \\ f_{c}(\phi)\lambda\omega_m \end{bmatrix}$$

$$T_e = T_a + T_b + T_c$$

$$T_e = J_m\frac{d\omega_m}{dt} + B_m\omega_m + T_{Load}$$

$$T_{Load} = n^2f_j\frac{d^2\phi_m}{dt^2} + n^2B_2\frac{d\phi_m}{dt} + nF_c\frac{\phi_m}{|\phi_m|}$$

where ‘n’ is the gearbox reduction ratio, ‘B_m’ is frictional
coefficient of motor and load, ‘J_m’ is the motor inertia, ‘J_f’ is
the gearbox inertia, ‘F_c’ is Coulomb torque constant, ‘f_a(\phi)’,
‘f_b(\phi)’, ‘f_c(\phi)’ are functions having same shapes as back
emfs, ‘\lambda’ is represent the total flux linkage as the product of
number of turns and flux linkage/conductor, ‘\omega_m’ is the
angular speed of the motor, ‘\phi_m’ is mechanical angle of rotor,
‘\phi_e’ is electrical angle of rotor, ‘p’ is number of pole on rotor,
$L_i = L - M$, $L$ is the self inductance of the winding per phase,
$M$ is the mutual inductance per phase. $T_{Load}$ is written in the (6)
and it can be rearranged in the following form for each motor;

$$T_e = (J_m + n^2f_j)\frac{d^2\phi_m}{dt^2} + (B_m + n^2B_2)\frac{d\phi_m}{dt} + nF_c\text{sign}(\phi_m)(8)$$

BLDC motor state equations are written in the following form;

$$x(t) = Ax(t) + Bu(t)$$

$$y(t) = Cx(t)$$

where the states and input vector are chosen as;

$$x(t) = [i_a i_b i_c \omega \phi]^T$$

$$u(t) = [v_a v_b v_c T_{Load}]^T$$

the system matrices are given below,

$$A = \begin{bmatrix}
\frac{-R}{L_1} & 0 & 0 & f_a(\phi)\lambda \\
0 & \frac{-R}{L_1} & 0 & f_b(\phi)\lambda \\
0 & 0 & \frac{-R}{L_1} & f_c(\phi)\lambda \\
0 & 0 & 0 & \frac{-B_m}{J_m}
\end{bmatrix}$$

$$B = \begin{bmatrix}
\frac{1}{L_1} & 0 & 0 & 0 \\
0 & \frac{1}{L_1} & 0 & 0 \\
0 & 0 & \frac{1}{L_1} & 0 \\
0 & 0 & 0 & \frac{-1}{J_m}
\end{bmatrix}$$

$$C = [0 \ 0 \ 0 \ 1 \ 0]$$

III. CONTROL

In this section, the mathematical equations of designed
controller and its block diagram is given.

A. Continuous Sliding Mode Controller
The goal is to drive states of the system given (9), (10) in the set $S$ defined by:

$$S = \{ x: \tau(t) - \xi(x) = \varepsilon(x,t) = 0 \}$$  \hspace{1cm} (16)

where $\tau(t)$ is the time dependent part of the sliding function, containing reference inputs to be applied to the controller. $\xi(x)$ denotes the state dependent part of the sliding function, $\varepsilon(x,t)$. The derivation of the control involves the selection of a Lyapunov function $V(\varepsilon)$ and a desired form of derivative of the Lyapunov function such that closed-loop system is stable. The selected Lyapunov function is [20-22]

$$V = \frac{1}{2} \varepsilon^T \varepsilon$$  \hspace{1cm} (17)

which is positive definite, and its derivative is

$$\dot{V} = \varepsilon^T \dot{\varepsilon}$$  \hspace{1cm} (18)

The solution $\varepsilon(x,t) = 0$ will be stable if time derivative of the Lyapunov function can be expressed as [22]

$$\dot{V} = -\varepsilon^T D \varepsilon$$  \hspace{1cm} (19)

where $D$ is a positive definite matrix. Thus, the derivative of the Lyapunov function will be negative definite and this will ensure the stability. Eq. (18) and (19) lead to

$$\varepsilon^T (D \varepsilon + \dot{\varepsilon}) = 0$$  \hspace{1cm} (20)

A solution for this equation is

$$D \varepsilon + \dot{\varepsilon} = 0$$  \hspace{1cm} (21)

The expression for derivative of the sliding function is

$$\frac{d}{dt} \varepsilon = \frac{d}{dt} \tau - \frac{d}{dt} \xi$$  \hspace{1cm} (22)

where,

$$\xi = G \varepsilon(t)$$  \hspace{1cm} (23)

$G \in \mathbb{R}^{nxm}$ is gain matrices ,and

$$\dot{\xi} = G \dot{\varepsilon}(t)$$  \hspace{1cm} (24)

First, equivalent control is found by $\dot{\varepsilon} = 0$ and using (22) as

$$\dot{\varepsilon} = \dot{\tau} - \dot{\xi} = \dot{\tau} - (G \varepsilon(t) + GB \varepsilon_{eq}) = 0$$  \hspace{1cm} (25)

$$\varepsilon_{eq} = (GB)^{-1}(\dot{\tau} - G \varepsilon(t))$$  \hspace{1cm} (26)

Second, using (23) the control input to the system can be found by following:

$$\dot{\varepsilon} = -D \varepsilon = \tau - \dot{\xi}$$  \hspace{1cm} (27)

$$\dot{\tau} - (G \varepsilon(t) + GB \varepsilon_{eq}) = -D \varepsilon$$  \hspace{1cm} (28)

and the result of the short algebra can be written as

$$u = \varepsilon_{eq} + (GB)^{-1} D \varepsilon$$  \hspace{1cm} (29)

Third, from time derivative of the sliding function

$$\dot{\varepsilon} = \dot{\tau} - (G \varepsilon(t) + GB \varepsilon_{eq})$$  \hspace{1cm} (30)

multiplying both sides with $(GB)^{-1}$

$$(GB)^{-1} \dot{\varepsilon} = (GB)^{-1}(\dot{\tau} - (G \varepsilon(t) - u)$$  \hspace{1cm} (31)

and by using (25)

$$(GB)^{-1} \dot{\varepsilon} = \varepsilon_{eq} - u$$  \hspace{1cm} (32)

and finally when this equation is substituted in (29) the control is found as

$$u(t) = u(t^-) + (GB)^{-1}(\dot{\varepsilon} + D \varepsilon)$$  \hspace{1cm} (33)

$$t = t^- + \Delta , \ \Delta \rightarrow 0$$

The value of the control at the instant $t$ is calculated from the value at the time $t^- + \Delta$ and the weighed sum of the control error $\varepsilon$ and its time derivative. Control (33) is continuous function everywhere except in the points of discontinuity of the function $\varepsilon(x,t)$. When these equations are adapted for BLDC motor control system shown in Fig.1, the following equation can be written for the control loop as

$$u_c(t) = u_v(t^-) + (GB)^{-1}(\dot{\varepsilon}_v + D \varepsilon_v)$$  \hspace{1cm} (34)

![Fig. 1. Continuous sliding mode controller block diagram](image)

**B. Fractional Order Calculus**

The fractional-order differentiator can be denoted by a general fundamental operator $a D_t^p$, where $a$ and $t$ are the limits of operations. The fractional-order differentiator and integral are defined as follows,
it is seen that the CSM controller reference input and Fig. 4 are shown in Figs. 3 comparison of reference reduce the error and for system shown in Fig. 2. When these equations are adapted for BLDC motor control system shown in Fig. 2.

\[
\begin{align*}
\dot{D}_t^p & = \begin{cases} 
  \frac{d^p}{dt^p} & : p > 0 \\
  1 & : p = 0 \\
  \int_{0}^{t}(dr)^{-p} & : p < 0
\end{cases} \\
\end{align*}
\]  

(35)

where \( p \) is the fractional order which can be a complex number, however the constant \( p \) related to initial conditions. There are several mathematical definitions to describe the fractional derivatives and integrals [23],[24]. Between these definitions, here are two commonly used ones, i.e., the Grünwald–Letnikov (GL) and the Riemann–Liouville (RL).

The GL definition is,

\[
d_D^p f(t) = \lim_{h \to 0} \sum_{j=0}^{\left[ \frac{t-h}{h} \right]} (-1)^j \binom{p}{j} f(t-jh)
\]  

(36)

where \([.]\) means the integer part, while the RL definition is given as,

\[
d_D^p f(t) = \frac{1}{\Gamma(n-p)} \frac{d^n}{dt^n} \int_{0}^{t} \frac{f(\tau)}{(t-\tau)^{p-n+1}} d\tau
\]  

(37)

for \( n-1 < p < n \), \( \Gamma(.) \) is the Euler’s gamma function, \( a \) is the initial time and \( t \) parameter is used when the differential and integral are taken.

C. Fractional Order Sliding Mode Controller

In (34), if the derivative term expressed as a fractional order,

\[
u_s(t) = u_s(t^-) + (GB)^{-1}\left( \dot{D}_t^p \dot{e}_v + D \dot{e}_v \right)
\]  

(38)

When these equations are adapted for BLDC motor control system shown in Fig. 2.

Fig. 2. Fractional sliding mode controller block diagram

IV. EXPERIMENTAL RESULT

The performance of the both controllers are evaluated for the tracking capability of the references and the ability to reduce the error and rise time. Sinus and trapezoidal speed references are implemented to BLDC motor for performance comparison of both controllers and the experimental results are shown in Figs. 3-10. In the first experiment, 10 rpm sinusoidal speed reference is chosen for testing CSM and FSM controllers. As shown in Fig. 3 and Fig. 4, the FSM controller has fast rise time at the reference input in comparison with CSM controller. Although both controller have similar reference tracking capabilities and it is seen that the CSM controller is less sensitive to follow the reference. The maximum percentage errors of sine wave reference for CSM is 10.13% and for FSM 4.17% respectively. The results for sinusoidal speed reference at 1000 rpm are given in Fig. 5 and Fig. 8. Due to a reference signal which is slowly changing over time the tracking errors are close to each other. However FSM gives 0.4 sec rise time while CSM is 0.6 sec which is obviously much better.

In the second experiment, trapezoidal wave speed reference at 10 rpm is given for control of BLDC motor. The trapezoidal wave reference is important to test the performance of the controllers for sudden changes. It can be seen from Fig. 6 and Fig. 9 that, CSM gives 0.6 sec rise time while FSM is 0.5 sec. On the other hand, FSM have better performance than CSM when the trapezoidal wave reference sudden changes. The trapezoidal speed reference at 1000 rpm in Fig. 7 and Fig. 10 also shows the success of the FSM. Both controllers have similar reference tracking capabilities and have similar rise time at the starting point of trapezoidal wave. CSM was failed to show adequate performance at the moments of suddenly changes. FSM has been more successful than CSM at the any sudden change after the start.

Fig. 10. Fractional sliding mode 1000 rpm trapezoidal ref.
V. CONCLUSIONS

In this paper, an experimental study on the application of CSM and FSM controllers to a BLDC motor under the different speed references was presented. The experimental results show that the FSM controller shows better steady state performance with better rise time, smaller speed error and having less overshoot when it compared to the responses of CSM. To conclude, the applied FSM controller results in better responses than CSM controller to control the speed of the BLDC motor under changing references.

Abstract— The purpose of this study is to design a 3 axis automated programming machine for programming devices such as microcontrollers, EPROMs and CPLDs. While programming numerous devices, an automated system is needed. For his purpose, a prototype system is designed with 3 axis. The system consists of electronics, mechanics and vacuum parts. All of these are controlled by ATMEL's ATMEGA128 8 bit microcontroller using C language. In this study, microcontrollers are programmed which have 44 pins with TQFP package. With some modifications on hardware and software, the designed machine is able to program the devices which have different packages. Thanks to the user interface software, programming results which of the devices are programmed and which are not) can be seen on PC.

Keywords— Microcontroller, Robotic, Automated programming

I. INTRODUCTION

Robotics is a science that combines the technology and knowledge. Owing to the fast development of technology, the term robot, as an automatic machine that replaces humans, is not so clearly defined anymore. A robot is no longer just a humanoid robot, robotic hand at an auto assembly line, autopilot in aircraft, artificial intelligence built of living neurons or simple cleaning robot; it is also computer software that completes works, meant for humans. It is known that robots are built to replace humans at certain works [1].

The word “robot” was created in the twenties by Czech poet, Karel Capek, in one of his plays, a play that ended tragically. In the forties, another writer, Isaac Asimov, made robots the leading figures in his utopian novels. Since these times, robots have been subjects of imagination. The reality of industrial robots only came in the sixties when Joseph F. Engelberger introduced the PUMA robot as a freely programmable, universal, handling device. With it came automation in manufacturing industry, economic issues, and social concern about human labour replaced by machines. The versatility of these robot machines has been increasing, largely due to their continuously increasing ability of information processing. The main goal was the autonomous robot. But, as the application field for robots is widening, and the robot is coming out of the factory halls, new challenges are seen, and even a change of paradigm is taking shape [2].

It is clear that there are high expectations as to the future potential of robotics, even euphoric ones and somewhat unrealistically utopic [3]. On the other side, there are sceptical views, seeing robotics as one of the most powerful technologies of the 21st century, together with genetic engineering and nanotech [4] threatening to make humans an endangered species. A more moderate and realistic, but still fascinating approach has been taken by a study group, comprising of experts from engineering, medical, philosophical and legal sciences, discussing the provoking question whether humans could be substituted by robots [5].

II. LITERATURE REVIEW

The work shows the application of the manipulator to a printed-circuit-board driller system. The manipulator uses DC motors with permanent magnets. The design of the manipulator is based on microcontrollers to control the speed and position of the motors by using full bridge DC-DC converters with a pulse-width-modulation technique. The designed manipulator includes a PC that works as a user interface to load the file with the numeric control format for the driller. From this information, the PC generates the required position and speed commands for each servomechanism. The works describes in detail the software and hardware designed to measure and control the speed and the position of each servomechanism [6].

This work focuses on hardware and software interfacing for robot arm controller application. The aim of this study is to design and build a control system for position control for robot arm with an FPGA chip. This is closed loop control system. In which controller, drive circuits and the sensor circuit plays important role.

Plus Width Modulation (PWM) is used to control the speed of DC motor. The hardware functional block is to be design in software module with the help of VHDL coding. This hardware and software co-design is for five axes OW1 535 arm robot model for the movement of robot arm for pick and place application. The interfacing of different hardware blocks with software module for real time application is very challenging and demanding in every field to achieve better command over control through software only without disturbing the hardware. It reduced the manufacture time, performance, accuracy and lifetime of the particular system [7].
The position control algorithm for a belt-driven servomechanism of a laser cutting machine is described. A high-accuracy position tracking control procedure for systems with inherent elasticity due to the low-cost belt-driven servomechanism is derived based on a continuous sliding mode technique. The aim to robust position tracking control algorithm was tested by simulations and used in the industrial application of a motion controller for the CNC machine. Simulation and experimental results are also reported [8].

The goal of this study is to design a 3 axis automated microcontroller programming robot (AMPR) design were carried out.

III. MATERIAL AND METHODS

In this study is provided to program automatic way of programmable integrated circuits such as microcontroller, CPLD in. In the figure 1, automatic microcontroller programming robot (AMPR)’s block diagram is shown. Figure 2 shows a completed state.

AMPR consist of three axis; X, Y and Z. The movement of the X and Z axes with DC motor and Y-axis was carried out by using bipolar stepper motor (Figure 3 and Figure 4). Located on the microcontroller to be programmed with the aid of a vacuum tip to get from where it is the task of the Z-axis. In addition to the programming socket and programmed into the microcontroller it is also responsible for the drop to the point where the first received. The task of the X axis, the horizontal axis of the hosts on the Z-axis is to move left and right. The Y axis is to be programmed by moving back and forth on the horizontal axis provides the movement of the tray with the microcontroller.
Automatic operation of the system is generated by the C programming language is provided with the control algorithm.

The typology of the programming of a single microcontroller stages are listed below.

1) Placing the device that is to be programmed microcontroller
2) Initial settings
3) Programming the microcontroller
4) Putting the microcontroller from which it was first
5) The next transition to the microcontroller

In the first of the two leading operations once the single time is made in the initial phase.

IV. CONCLUSIONS

In this study is to design a 3 axis automated programming machine for programming devices. While programming numerous devices, an automated system is needed. For his purpose, a prototype system is designed with 3 axis. The system consists of electronics, mechanics and vacuum parts. Designed as a prototype AMPR instead of the desired functions of the program to the microcontroller has automatically. The modern structure, we can easily modify the possibility of functions and add some our new functions. The price the machine is a good choice for inventions and new applications in human life. We hope that this effort will prove useful for future robotics endeavours.

Abstract — A coplanar waveguide (CPW) fed patch antenna array is proposed in this paper. The resonance frequency of antenna is 2.47 GHz and is inside of ISM 2.45 GHz band. The dimension of proposed antenna is 230 mm x 91.5 mm. For substrate the material used is Roger 5870. The relative permittivity of the substrate material is 2.33. For increasing the gain, an array antenna has been designed. The antenna gain reaches up to 12 dB. The working has been simulated in the HFSS Ansoft. The reflection coefficient has been measured by Agilent Network Analyzer. The proposed antenna can be used in applications necessaries high gain such as wireless power transmission.

Keywords — Antenna, High gain, Antenna array, Microstrip patch antenna

I. INTRODUCTION
Antenna is the transitional structure between free space and a guiding device. The guiding device or transmission line may take the form of a coaxial line or a waveguide, and it is used to transport electromagnetic energy from the transmitting source to the antenna, or from the antenna to the receiver [1]. Antennas are very important element of electromagnetic communication. An antenna performance can be described with some parameters. The resonance frequency describe the antennas working frequency. The researches of antenna are intensive in ISM Bands. Many of ISM Band centre frequencies are, 13.56MHz [2], 433.92MHz [3], 2.45GHz [4], 5.8GHz [5]. In other hand these antennas have different structures.
In the some application bandwidth is an important parameter [6] but in the other applications antenna gain may be more important parameter [7]. An application where antenna gain is important may be done array antenna working [8, 9].
Huang et al. has proposed an antenna design for triple-band biotelemetry with data telemetry (402 MHz), wireless powering transmission (433 MHz), and wake-up controller (2.45 GHz). The prototype of the rectenna was fabricated on a Roger 3210 substrate. The antenna type was PIFA and antenna gains were -7dB @402MHz, -11 dB @433MHz and -15dB @2450MHz [10]. Ali et al. has proposed a circularly polarized (CP) microstrip patch antenna that is function as a WLAN antenna in the 5.15–5.35 GHz and as a rectenna at 5.5 GHz. The antenna is 14.8 mm by 14.8 mm by 3 mm in size which can be readily integrated within a sensor circuit board [11]. Yang et al. presented two-port printed microstrip rectenna with compact structure for communication systems. An aperture-coupled dual polarization patch antenna is utilized as the receiving antenna. The max gain of antenna has been reported 7.0dBi @6.1 GHz [12].

The proposed antenna has been designed and successfully achieved outstanding performance within operating frequency of 2.45 GHz. Moreover, such antenna manage to achieve minimum reflection coefficient of S11 < -10dB which is suitable for industrial, scientific and medical (ISM) band applications. The length of proposed antenna is 230 mm and the width is 91.5 mm.

II. GEOMETRY OF DESIGNED ANTENNA

The antenna has been fabricated on a 1.6mm thick RT/Duroid 5870 substrate with a dielectric constant of 2.33 and loss tangent of 0.0012. Fig.1 is the proposed high gain microstrip patch antenna array. For antenna simulation has been used Ansoft HFSS.
present the second Impedance matching part of prosed antenna.

Fig. 2 Feeding part of coplanar feeded patch antenna array

Fig. 3 First Impedance Matching part of coplanar feeded patch antenna array

Fig. 4 Second Impedance Matching part of coplanar feeded patch antenna array

The parameters in fig. 1, fig. 2, fig. 3 and fig. 4 given is bellow described; a=39mm, b=48mm, c=2.5mm, d=4.25mm, e=12.5mm, f=6mm, g=5mm, h=4mm, i=7mm, j=7mm, k=4mm, l=3mm, m=5mm. The general dimension of proposed antenna is 230 mm x 91.5 mm. The Photograph on fabricated coplanar feeded patch antenna array is given in fig. 5.

III. RESULTS

The high gain microstrip patch antenna array has been fabricated and the S11 (return loss) parameter has been measured with Agilent Technologies Field Fox Microwave Vector Network Analyser N9926A. Fig. 6 shows the S11 results comparatively of the designed antenna as simulated values with Ansoft HFSS and measured values network analyser. The S11 value approximates to -14dB for 2.48 GHz. The Bandwidth is from 2.48GHz to 2.51GHz about 30MHz.

The antenna gain pattern is drawn with Ansoft HFSS. The max gain is 12 dBi for z direction.

The comparatively results with previous works are given in Table 1.

IV. CONCLUSION

In this work, high gain microstrip patch array antenna has been designed and fabricated that can operates at 2.45 GHz for ISM applications. Measured and simulated results show that the designed antenna has good performance over a bandwidth of 2.47–2.5 GHz. The gain has been measured a successful value such as 12 dBi for the designed antenna. The antenna has had an excellent performance of high gain. The proposed antenna can be used for energy harvesting and wireless power transfer applications.

Abstract— Wheat is the main food source of the humankind. After its harvest, it goes through many procedures from its separation from chaff to its packaging. With the development in technology, many of these procedures are realized with automatic systems which saves the manufacturer the cost of labour, time and provides the customer with more quality food. One of the main concerns of quality food production is to provide a customer with the product in its purest form which means the product must be separated from all foreign matters. In this study, type-1252 durum wheat seeds have been separated from junk using the morphological properties of wheat seeds through the uncompressed video image taken with the camera Prosilica GT2000c. The main references for the quality measurement of wheat seeds are the shape and the dimensions of a wheat seed. Aiming for high quality wheat grain storage with no junk, this article has adopted various image processing techniques from image preprocessing to feature extraction. The image processing has been realized in a computer environment and the results show that the image processing is successful and the detection of wheat seeds from junk was accurate.

Keywords— BlobAnalysis, Feature Extraction, Image Processing, Junk, Morphological Properties, Segmentation, Wheat Seed,

I. INTRODUCTION

Food supply is one of the most essential materials for the survival of human beings. Wheat, which is the most fundamental material of amylaceous products like bread and pasta, is also one of the main food supply for human beings. It is important for the food industry to provide quality goods which includes wheat grains. After its harvest, wheat seeds go through many procedures from its separation from chaff to its packaging and they are stored in warehouses to be sold at specified intervals [1]. The inspection and the classification of good quality wheat grains can be done by manually through a series of instrumental or chemical analysis. Obtaining good quality wheat product through these tests and analysis is subjective, time consuming, less efficient, costly and the safe inspection of food without damaging its structure is nearly impossible [2], [3].

In recent years, it has become imperative to use automatic systems in the inspection and classification of wheat seeds to eliminate all those adverse conditions mentioned. With rapidly developing computer technologies, machine vision systems and image processing techniques have become one of the most popular research areas in wheat inspection and classification, because they have the ability to visually characterize wheat grains by their physical attributes and the process is objective, speedy, most efficient, cheap, repeatable and harmless to wheat seeds [2], [3].

Through the last years, many researchers have evaluated machine vision and image processing techniques if they really meet the expectations for the inspection and classification of the quality of wheat. There have been many studies about the determination of the properties of single wheat seed, separation of one type wheat from another or identification of damaged wheat seeds, but there have not been many researches about separating the wheat seeds from non-wheat seeds [1]. In a study conducted by Pourrez et al., nine different wheat classes growing in Iran have been classified according to its textural properties extracted from Gray Level, GLCM (Gray Level Co-occurrence Matrix), GLRM (Gray Level Run-length Matrix), LBP (Local Binary Pattern), LSP (Local Similarity Pattern) and LSN (Local Similarity Numbers) matrices and classified using LDA (Linear Discriminate Analysis) [4]. Xia et al. classified a single type wheat with regards to its quality by accounting its 7 morphological properties and 6 colour properties [3]. In an article written by Gűneş et al., it is explained the varieties of wheat growing in Turkey are classified according to its textural analysis using GLCM and LBP methods and k-Nearest Neighbour type classifier [5]. In a study conducted by Babalik et al., variety of wheat classes are identified with 9 morphological and 3 colour features using M-SVM (Multiclass Support Vector Machines) and BPSO (Binary Particle Swarm Optimization algorithm) [6]. In another study, Farahani tried to determine the best potential morphologic features to classify 5 different types of durum wheat [7]. Manickavasagan et al. tried to measure the ability of a machine vision system with a monochrome camera to classify the different types of western Canadian wheat types by using bulk sample analysis [8]. Williams et al. have evaluated two different digital image analysis (DIA) approaches to quantifying wheat seed shape for exploring trait correlations and QTL (Quantitative Trait Loci)
mapping [9]. All these studies generally have been made with the purpose of classifying different types of wheat. However, there is also a small number of studies about purification of wheat from its chaff and other impurities. One of these studies is made by Ebrahimi et al. to propose a machine vision automatic grading system which separates the wheat from the impurities within [1]. The objective of another study conducted by Paliwal et al. is to develop an algorithm which classifies 5 different types of Canadian wheats and also differentiates the wheats from non-wheat materials [10]. In another study, FN Chen et al. have developed an image processing algorithm which determines black germ wheat [11]. It can be seen from these examples that so few of the studies are about purification of wheat from non-wheat materials. Also, all of these studies are conducted in stationary environment and the possible outcomes are not known for a non-stationary environment.

In this study, our objective is to obtain good quality type-1252 durum wheat grains by separating the impurities from wheat grains in a dynamic system using image processing techniques. The process stages we used in this study are shown in Fig.1.

II. MATERIAL AND METHODS

A. Image Acquisition

The system used consists of a band-wheel system where the durum wheat grains are moving upon, image acquisition camera Prosilica GT2000C, and illumination apparatus with a shady box stand for preventing the shadow formation on the background.

Prosilica GT2000C camera is a 2.2 megapixel, RGB camera with 2048 x 1088 resolution, CMOS type sensor, 53.7fps maximum frame rate at full resolution and efficient operation temperature range between -20 °C and +65 °C [12]. The camera has been placed atop the illumination apparatus and daylight coloured powerleds have been placed around the camera. Under the illumination apparatus there is a ground glass around the camera lens so that the light can refract uniformly. The camera and the light illumination apparatus has been placed above a shady box so that the outside light does not affect the wheat grains and shadow formation can be prevented.

The camera views a 8 cm x 10 cm area inside the box and the 5 sec uncompressed video obtained from the camera is transmitted to the image processing computer software with an ethernet cable. The system used for this study is shown in Fig.2. Also, a frame sample of the video acquired is shown in Fig. 3.

Fig. 1 The process stages that were followed in the study

Fig. 2 Dynamic system used for acquiring video sample of durum wheat grains with impurities

Fig. 3 Frame sample of the video visualizing durum wheat grains with impurities
B. Image Preprocessing and Segmentation

The obtained video has been separated into frames and all the frames have been subjected to same processes. First the colormap of the images adjusted suitably after several trials so that the image segmentation is successful. The image with adjusted colormap is shown in Fig. 4.

![Fig. 4 The frame sample of the video with adjusted colormap](image)

After adjusting the colormap, the images are turned into gray images and subjected to a 5 x 5 median filter. Median filtering is a non-linear filtering process which offers an effective noise reduction without blurring the image [3]. After the filtering process, the background is subtracted from the image with “top-hat” operation so the background noise does not affect the image processing. The median filtered image with background subtraction is shown in Fig. 5. Then, morphologically “open” and “close” operations have been applied to the images to smooth the boundaries of the objects and the images have their contrast values adjusted to reduce edge detection errors. The frame sample after several morphological operations is shown in Fig. 6. Lastly, they were converted to binary images using an appropriate threshold value. The binary image of the frame sample is shown in Fig. 7.

Duru\textsuperscript{m} wheat grains and other non-wheat materials reside on the band in a random order so the grains can touch other grains or the other non-wheat materials. While the morphological operation “erode” can shrink the objects, thus maybe separate them. However, if the objects are touching each other they can still be connected despite the touching area is really small. In such conditions, a watershed algorithm is needed. The watershed transform is a segmentation algorithm that can divide the image into multiple regions where the darker colours represent a region with lower altitude and lighter colours represent a region with higher altitude topologically [13]. Thus, a watershed segmentation algorithm used for properly segment all the objects from each other. To apply watershed transform efficiently for segmentation, the first step is to apply the distance transform which labels each existing pixel according to the distance with the nearest boundary pixel in a binary image [13]. Although the distance transform is successful for segmenting round and simple touching objects, it is not successful for kernels with irregular shapes [13]. The reason why it is not successful to segment kernels with irregular shapes is because large number of local minima occur due to large clusters of objects which causes over-segmentation [14]. So, in our study, we used a watershed segmentation algorithm with extended-minima transform to segment the durum wheat grains where the extended-minima transform can produce markers for objects where local minima with greater depth than \( h \) are marked and where local minima with less depth than \( h \) are eliminated. By using minima imposition technique, we create minima at the specific locations associated with the markers [14]. After this procedure, watershed segmentation is applied which results in perfect segmentation for touching grains. The edge detected binary sample image after watershed segmentation with extended-minima transform is shown in Fig. 8.

C. Feature Extraction

The blob is the region of connected pixels of an object and blob analysis is the method which investigates these regions and provides us the information about the regions’ several properties. It is used for feature extraction processes [15]. The blob analysis algorithm distinguishes the pixels according to their values and labels them into 2 categories. The foreground
category is generally the pixels with a non-zero value and the other category is the background where the pixels with a zero value belong. Thus, the blob analysis algorithm measures several properties of the object regions in the image [15].

After the segmentation process, blob analysis algorithm is used for the feature extraction process to measure the properties of wheat grain regions. In our study, 9 morphological features are used for the separation of durum wheat grains from impurities. These features which are extracted directly by blob analysis are area, major axis, minor axis, perimeter equivalent diameter, eccentricity. Features which can be calculated from the others are roundness, shape factor, compactness [6]. The features used for this study and their definitions are shown in the Table I [6], [7], [16].

III. RESULTS AND DISCUSSIONS

After feature extraction, mean and standard deviation values of the properties have been calculated. Durum wheat grains are separated from the impurities by a simple algorithm which uses the calculated results as ranges. The mean and the standard deviation values of the properties are given in Table II.

The algorithm determines the particles which are accepted as durum wheat grains by comparing the properties of every single object within a range specified using the mean values and standard deviation values of the properties. If all the properties of a single object is within the specified range, then the object is a durum wheat grain. If not, then the object is non-wheat material. The obtained result is 73.52% accuracy for the separation of non-wheat materials from durum wheat grains which is an optimistic result for image processing of a dynamic environment, because it is much more complex than image processing of a single image of a stationary environment. If a more complex and more efficient classification algorithm is used for the separation of durum wheat grains from impurities, than the accuracy result will be improved.

IV. CONCLUSIONS

As it is shown in literature, previous studies conducted are not about the purification of wheat from non-wheat materials generally but about classification of wheat varieties. Also, the studies conducted in a dynamic environment are almost non-existing. In this study, the objective has been to obtain good quality type-1252 durum wheat by separating the impurities from wheat grains in a dynamic system using image processing techniques. These processes are image preprocessing for image enhancement, watershed transform with extended-minima transform for segmentation and blob analysis for feature extraction.

In this study, after segmentation and feature extraction processes, a simple algorithm is used for the separation of non-wheat materials from durum wheat grains. The reason for using a simple algorithm is because it was a start for dynamic environments which is not the case for many researches in literature. However, the obtained result is not bad for a start. In future studies, we will use different and more efficient classification models to obtain perfect classification results.

Abstract—A design of ultra-wideband monopole patch antenna is presented in this study. The design consists of a radiating triangular patch antenna (TPA) fed through a 50 Ohm microstrip transmission line (MTL) and defected ground structure (DGS). The triangular monopole is matched to MTL with inserting a thin strip line. The performance of the proposed antenna is numerically investigated using method of moments (MoM) and verified through measurements. Based on the measured results, the antenna operates over large frequency range of 2.6-18.2 GHz at -10 dB. The proposed antenna has well characteristics in terms of radiation pattern, peak gain and total efficiency across the operating ultra-wideband frequency range. Furthermore, the antenna system is suitable for near-millimetre wave applications, since the operating band reaches to 18.2 GHz.

Keywords—Antennas, patch antennas, antenna designing, ultra-wideband (UWB), defected ground structure (DGS)

I. INTRODUCTION

The ultra-wideband systems have received considerable attention in recent years due to allowing signal transmission in a large bandwidth with a low energy level. Radar imaging, mobile and satellite communications, multimedia streaming, biomedical imaging are the most important application areas of ultra-wideband systems [1-5]. The ultra-wideband systems have been further studied especially since Federal Communications Commission (FCC) approved the unlicensed use of the frequency range of 3.1–10.6 GHz for low power emitting implementations [6].

Patch antennas are widely used in the wireless systems due to various advantages such as low profile, small size, light weight, conformability to mounting host and capability of integration into the arrays. Owing to these advantages, the printed antennas have been integrated to the latest wireless communications of wireless local area network (WLAN), long term evolution (LTE) and worldwide interoperability for microwave access (WiMAX) standards, and ultra-wideband systems. Designing an appropriate antenna is the most important part of ultra-wideband applications because it effects the whole system performance.

There are several antenna structures that can be used for ultra-wideband systems such as the Vivaldi antenna [7], log periodic antenna [8], spiral antenna [9] and monopole antenna [10-18]. Monopole designs show inherently wideband behaviour as well as omni-directional radiation pattern. Therefore the printed forms of that designs can be successfully exploited for ultra-wideband systems. Over the past years, several monopole antenna structures, such as rectangular [10], circular [11], elliptical [12], conical [13], tapered [14, 15], slot-loaded [16-18] and defected ground [19-22] configurations, have been suggested for ultra-wideband applications.

The popularity of defected ground structure (DGS) in antenna study has increased immensely [19-22]. The DGS is basically obtained by properly modifying the ground plane of a patch antenna. Thus compact designs with high characteristics of especially wideband and gain can be achieved.

In this study, an ultra-wideband triangular patch antenna (TPA) that consists of a triangular monopole is designed. The triangular monopole is positioned on a rectangular DGS. The triangular radiating monopole patch is fed through a microstrip transmission line (MTL). The TPA is modelled in HyperLynx 3D EM simulation software based on method of moments (MoM) and fabricated for measurements. The TPA with a small size of 23x31 mm$^2$ operates across 2.6 GHz to 18.2 GHz based on measured results.

II. THE PROPOSED DGS-BASED TPA STRUCTURE

The 3D geometry of the TPA model is depicted in Fig. 1 and its dimensions are given in Table I. The TPA structure is composed of a 14x23 mm$^2$ triangular monopole patch fed by 50 Ohm MTL and a 17x23 mm$^2$ rectangular DGS. The radiating plane is placed over a 1.6 mm height substrate with 4.4 relative dielectric constant on the DGS. Therefore, the TPA has a total dimension of 23x31x1.6 mm$^3$. In order to improve the impedance matching, a 1 mm thin strip line is inserted between triangular radiating patch and the MTL.

<table>
<thead>
<tr>
<th>Dimensions of the TPA (Unit: mm)</th>
</tr>
</thead>
<tbody>
<tr>
<td>h</td>
</tr>
<tr>
<td>1.6</td>
</tr>
</tbody>
</table>

III. THE TPA DESIGN PROCEDURE

In design process, different patch forms are assayed in order to achieve an ultra-wideband operation. To further understand the evaluation of the proposed antenna system, the designing steps are investigated in four cases: Case I, II, III and IV as illustrated in Fig. 2. The simulated $S_{11}$ parameters related to the cases are accordingly shown in Fig. 3. In Case I, the design procedure is started with a 14x23 mm$^2$ rectangular radiating patch fed by 50 Ohm MTL and a DGS. The DGS is obtained by shortening the ground plane size of 31x23 mm$^2$ to 17x23 mm$^2$ so as to obtain an effective radiation. Since the radiation field occurs mainly between the radiating patch and the ground edges facing to each other, modifications on these edges can yield a satisfactory results. Therefore, in Case II, the radiating edges facing to the fixed DGS are triangularly trimmed to increase the impedance bandwidth as can be seen in Fig. 3. Once a better results are achieved by this way, the triangular cut’s angle with the DGS is increased to further improve the impedance matching as in Case III. Note that the 50 Ohm MTL uniformly continues from the port to the input of the triangular radiating patch. Owing the radiation starting from the end of DGS, a thinner strip is needed to match the input impedance of the triangular radiating patch to the MTL. A strip is hence designed between those in Case IV which is the final form of the designed antenna system.

IV. THE CURRENT MECHANISM OF THE TPA

The simulated surface current distributions of the TPA at the frequency points of 2.7 GHz, 8.1 GHz and 11.9 GHz are presented in Fig. 4. From the figure, the current distributions for these frequencies vary in similar to each other. As mentioned above in Section III that the radiation field comes about the facing edges, it can also be observed from the current distributions, the source current of that radiation is mostly concentrated at those edges. In addition, the majority of the current intensifies at the side edges of the matching strip line since it behaves as a resonator. This means that it does not only match the input impedance but also highly contributes to the radiation.

![Simulated S11 plots](image)
Fig. 4. Surface current distributions of the TPA: a) 2.7 GHz, (b) 8.1 GHz, (c) 11.9 GHz

V. FABRICATING A PROTOTYPE OF THE TPA

The prototype of the TPA is shown in Fig. 5. The antenna model is etched with the use of a computer numerical control (CNC) machine on a double side 1.6 height FR4 substrate with a relative dielectric constant of 4.4 and a tangent loss of 0.017. The measurements are carried out by the agency of Keysight Technologies N5224A PNA network analyser. The measured $S_{11}$ parameters in comparison with the simulated ones are plotted in Fig. 6. Based on the measured results, the TPA operates between 2.6 GHz and 18.2 GHz. It should be noticed that discrepancies between the simulated and measured curves might be attributed to the small mismatches of geometry, dielectric thicknesses, copper cladding and feeding between the simulated models and the prototype.

Fig. 5. The photograph of the fabricated TPA

Fig. 6 Measured and simulated $S_{11}$ parameters of the prototyped TPA

VI. RADIATION, GAIN AND EFFICIENCY CHARACTERISTICS

Simulated 2D gain radiation patterns of the TPA at the frequency points of 2.7 GHz, 8.1 GHz and 11.9 GHz are illustrated in Fig. 7. The maximum gains are 2.14 dB (in direction of 180° on x-z plane), 2.2 dB (in direction of 185° on y-z plane) at 2.7 GHz; and 2.42 dB (in direction of 90°/270° on x-z plane), 1.9 dB (in direction of 320° on y-z plane) at 8.1 GHz. Likewise, they are 1.6 dB (in direction of 145°/215° on x-z plane) and 0.2 dB (in direction of 45°/315° on y-z plane) at 11.9 GHz.
VII. CONCLUSIONS

In this work, we presented a compact ultra-wideband monopole patch antenna design operating over a large frequency range of 2.6–18.2 GHz. The monopole TPA fed via a MTL is built on a half-length DGS. The whole antenna system has a small size of 23x31 mm². A thinner strip line is inserted between the triangular monopole and the MTL to improve the impedance matching. The proposed TPA is verified by simulation and validated through measurement. The TPA has superior characteristics of larger bandwidth than the regulated ultra-wideband of 3.1–10.6 GHz, near omnidirectional pattern, uniform gain and high efficiency. In conclusion, since the TPA operates up to 18.2 GHz it can be also utilized for near-millimeter wave applications.

Abstract—Signal denoising approaches on data of any dimension largely relies on the assumption that data and the noise components and the noise itself are somewhat uncorrelated. However, any denoising process heavily depending on this assumption retreats when the signal component is adversely affected by the operation. Therefore, several proposed algorithms try to separate the data into two or more parts with varying noise levels so that denoising process can be applied on them with different parameters and constraints. In this paper, the proposed method separates the speech data into magnitude and phase where the magnitude part is further separated into common and difference parts using common vector analysis. It is assumed that the noise largely resides on difference part and therefore denoised by a known algorithm. The speech data is reconstructed by combining common, difference and phase parts. Using Linear Minimum Mean Square Error Estimation algorithm on the difference part, excellent denoising results are obtained. Results are compared with that of the state of the art in well-known speech quality measures.

Keywords—speech, denoising, cva, subspace, frequency domain

I. INTRODUCTION

For decades, as cognitive science penetrated into automation systems, voice automated applications like voice directed banking, voice signatures, intelligent homes; voice recognizing mobile-phone apps and such became both possible and popular. All voice applications somewhat necessitate high quality voice signals, mostly in digital form, imputering voice denoising algorithms. All naturally collected signals carry some noise energy weather from electronics/transmission or unrelated background signals. Voice denoising aims to improve signal quality, voice intelligibility or do both, achieving that with minimal loss in signal energy.

Although the voice denoising methods can be separated into two as single and multiple channel algorithms, researchers mostly focused on single channel because of incomparably higher number of encounters of such. Spectral subtraction, noise estimation, Wiener deconvolution/filtering, statistical and subspace based methods are considered as mainly single channel, notwithstanding the fact that they can be and are also employed in multichannel systems. In this paper, a method based on common vector analysis (CVA) is proposed. Therefore, brief methodology of other well-known subspace is given for comparisons.

Subspace methods rely on the expectation that the noisy data can be separated into two or more component where noise can be handled more efficiently within. A Singular Value Decomposition (SVD) based approach, proposed by Dendrinos et al. [1], uses the expectation that, after factorization of the data into sub-data, noise energy concentrates in vectors corresponding to smaller singular values. In the simplest denoising approach these are zeroed and voice data is recomposed. This technique is improved by Jensen et al. [2] for colored noise on which the former method has somewhat failed to reduce. On the other hand, their method with high computational complexity had several constraints for controlling residual noise. Ephraim et al. [3] aimed to optimize the estimator that minimizes distortion caused by residual noise. Noisy signal is separated into noise and signal subspaces using Karhunen Loeve Transform (KLT) whereby zeroing the components in noise subspace and restructuring the signal subspace using a gain function. Components in subspaces are recombined again to obtain denoised signal through inverse KLT. Mittal et al. [4] and Rezayee et al. [5] expanded this work for colored noise. They obtained better results by employing different KLT matrices and converging covariance matrix of the noise vectors to a diagonal matrix respectively.

Common Vector Approach (CVA) is a subspace method used in recognition applications. In CVA, training data representing each subject to be discriminated are used to form its own class. In a speech recognition application, ambient noise, ages and genders of speakers result in differences within a class [6]. CVA is based on the common component of those, basically by removing these differences within the class. This component is called the common vector. It has been employed in speaker recognition [7], speech recognition [8]-[10], face recognition [11], fault detection in electrical motors [12], spam e-mail detection [13]. CVA has also been used in image denoising [14].

II. COMMON VECTOR APPROACH

When differences between feature vectors in a class are removed, the remaining vector which consists of features invariant within the class is called the common vector. A
feature vector is then, presumed to be a sum of common and difference components. If the number of feature vectors \( m \) is greater than the dimension \( n \) of the vectors, then this is called a sufficient case \( m > n \). In the sufficient case, the common vector is the mean vector. The insufficient case occurs when the vector dimension is larger than or equal to the number of vectors \( n \geq m \), which is the case in most practical applications where, for example, too few image blocks with many pixels each exist. In general, it covers the setups where number of samples is less than the sample dimension. Since we are interested in such setups, only insufficient case of CVA is described in the following.

Let the feature vectors in a pattern class be linearly independent \( a_1, a_2, \ldots, a_m \). Each vector can be written as

\[
a_i = a_{i, \text{diff}} + a_{i, \text{comm}}, \quad i = 1, 2, \ldots, m
\]

where \( a_{i, \text{comm}} \) and \( a_{i, \text{diff}} \) are common vector of the class and difference vector per \( a_i \) respectively. The covariance matrix for the class is

\[
\Phi = \sum_{i=1}^{m} (a_i - a_{\text{avg}})(a_i - a_{\text{avg}})^T
\]

where \( a_{\text{avg}} = \frac{1}{m} \sum_{i=1}^{m} a_i \) denotes the mean of the vectors in the class. In insufficient case \( n \geq m \), \( n - m + 1 \) of the eigenvalues will be zero and corresponding eigenvectors \( u_j \) span the indifference subspace \( B^\perp \), while the remaining eigenvectors span the difference subspace \( B \) where \( B \) and \( B^\perp \) are orthogonal. The common vector of the class can be found by projecting any feature vector onto the indifference subspace \( B^\perp \) using

\[
a_{\text{com}} = P^\perp a_i, \quad i = 1, 2, \ldots, m.
\]

The projection matrix \( P^\perp \) is calculated using eigenvectors \( u_j \) that correspond zero valued eigenvalues (spans \( B^\perp \)) via

\[
P^\perp = \sum_{j=1}^{n-m+1} u_j u_j^T.
\]

The subspace methods other than CVA requires the inverse of the covariance matrix \( \Phi \) [15]. However, \( n \geq m \) inhibits the calculation of inverse of \( \Phi \) whereas CVA does not have this problem.

It is expected that noise mainly reside within the difference components when it is uncorrelated between class vectors. Therefore, it is imperative to construct classes as correctly as possible. When class information of the vectors is not available, classes should be constructed by collecting similar vectors into a data set matrix for each evaluated vector whose common vector is to be found. When the input data is a stream or can be handled as a stream with bounds, for example, classes can be constructed by searching similar vectors within a reasonable time range.

Since the raw vectors in speech data are selected to be sample frames of length \( n \), the words vector and frame are used interchangeably used within this paper.

### III. PROPOSED ALGORITHM

The denoising algorithm proposed in this paper relies on the intuition that the spectral content of the speech does not abruptly change and changes are mostly noise related. Approach is similar to time averaging of Fast Fourier Transform (FFT) data in digital spectrum analyzers. On the other hand, the overlapping ratio is the highest in the proposed algorithm. As illustrated in the Fig. 1, frames are picked from original speech data stream by a sliding Hamming window of width \( n \)

\[
w_i = 0.54 - 0.46 \cos(2\pi i/(n-1)), \quad i = 1, 2, \ldots, n
\]

which picks 1 sample for each subsequent frame. Although not required, it is logical to select \( n \) to correspond approximately 4 ms speech data since spectral characteristics of speech may greatly change for longer intervals. We conducted some tests for determining optimal frame length, as explained in the following section and concluded that 4 ms is adequate.

For each frame to be denoised, a class is constructed by picking \( m \) most spectrally similar Hamming windowed frames within its neighbourhood. Obviously entire data stream can be used for selecting the frames and constructing the class. In our experiments, it is determined that a neighbourhood size that contains \( 2n-1 \) frames, \( x'_i \), including the current frame to be denoised, is sufficient for both required number of vectors for the class and reasonable computational complexity. FFT of these \( 2n-1 \) frames are calculated and their magnitude and phase components are separated as

\[
b_k = |FFT\{x'_i\}|
\]

\[
p_k = \langle FFT\{x'_i\} \rangle.
\]

\( m-1 \) magnitude frames that are most similar to the magnitude frame of the current frame (the one to be denoised) are picked and the class is constructed with a total of \( m \) frames. When distances to the current magnitude frame calculated using the Euclidean distance

\[
d_k = \sqrt{\sum_{i=1}^{m} (b_{k,i} - b_{\text{cur},i})^2}
\]

where \( b_{\text{cur},j} \) and \( b_{k,j} \) are \( i^{\text{th}} \) dimension components of the current and \( k^{\text{th}} \) magnitude frames, and are sorted from smallest to largest, the \( m \) frames with the smallest \( d_k \) are selected into the class member set \( A \). Since \( b_{\text{cur}} \) would have zero distance to itself, it will be assigned index 1 and called \( a_i \) as indicated in Fig. 1.
Noise largely resides in difference components (\(a_{\text{diff}}\)). Therefore, common component (\(a_{\text{com}}\)) is kept and difference component of the current frame is denoised using a denoising algorithm that involves Principal Component Analysis (PCA) [15]. In fact, any denoising algorithm can be effectively used on \(a_{\text{diff}}\) since large portion of the signal energy is still in the common component, which is considered almost noise-free. After denoising \(a_{\text{diff}}\) and obtaining \(\widetilde{a}_{\text{diff}}\), the denoised difference frame, current denoised magnitude frame is reconstructed via \(\tilde{a}_i = a_{\text{com}} + \tilde{a}_{\text{diff}}\). Time domain speech frame is reconstructed by adding phase information and applying inverse FFT.

After applying the described algorithm on each frame, denoised time frames are combined to build the denoised speech data. Since the frames are overlapping, there are several options at the recombining stage. Just adding them onto the appropriate time location is one of them. Here a weighting window can be used to increase the weight of the center of the frame. In our experiments, we noted that just adding the frames (flat window) is sufficient and have least complexity.

It should be noted here that there are several parameters that can be optimized for the best performance on the speech data to be denoised; \(m\) (number of frames in classes), \(n\) (frame size), PCA parameters, recombining options. However, since we intended an algorithm that requires no data dependent optimisation parameters, these optimizations are performed for a large training speech data set and best logical parameter set is kept for all.

**IV. Experiments**

For the experimental work on the proposed algorithm, NOISEUS (Hu, and Loizou, 2007) speech database is used. NOISEUS is composed of 30 English sentences spoken by 3 male and 3 female speakers. Recordings are sampled by 8 kHz 16 bits with approximately 2 seconds in length. 8 different noise type (airport, crowd, car, exhibition hall, restaurant, train station, street and train) are added onto each speech data to obtain 4 SNR levels (0 dB, 5 dB, 10 dB, 15 dB). Noise data is itself taken from AURORA database. In addition, the database is extended by adding 4 levels of white noise onto the data.

Initial experiments are conducted to determine best or reasonable parameter values for CVA. These are; frame size, overlap ratio and neighbourhood size from which the class member candidates are picked. Fig. 2 shows the performance graphics for various frame sizes and input noise levels. From these tests, it is determined that frame size of 40 samples (corresponding to 4 ms) and highest overlap ratio are adequate for both performance and complexity. Neighbourhood size tests, on the other hand, were inconclusive for widths greater than three frame sizes. It is seen that algorithm becomes data dependent for larger search areas. In the following tests, we...
used $N_\text{w} = 3N$ as the neighbourhood size, where $N$ is the frame size in samples.

1. Perceptually motivated subspace algorithm [16], will shortly be called as sub from now on.
2. Psychoacoustically motivated statistical method [17], will be called as stat.
3. Wiener filtering algorithm based on wavelet thresholding multi-taper spectra [18], will be called as wien.
4. A variant of minimum controlled recursive average algorithm [19], will be named as rec.
5. Continuous spectral tracking [20], will be named as spec in the following sections.

Performance measures used in comparisons are Perceptual Evaluation of Speech Quality (PESQ), Log Likelihood Ratio (LLR) and Euclidean Distance in Cepstral Domain (CEP), most used measures in the literature.

| TABLE 1 COMPARISON OF 6 METHODS ON PESQ MEASURE |
|---------------------|-----|-----|-----|-----|-----|-----|
| sub | stat | wien | rec | spec | cva |
| 0 dB | 1.43 | 1.51 | 1.40 | 1.24 | 1.32 | 1.69 |
| 5 dB | 1.87 | 1.68 | 1.84 | 1.77 | 1.82 | 2.05 |
| 10 dB | 2.23 | 2.09 | 2.24 | 2.20 | 2.26 | 2.40 |

| 0 dB | 1.37 | 1.20 | 1.34 | 1.13 | 1.34 | 1.64 |
| 5 dB | 1.84 | 1.73 | 1.82 | 1.62 | 1.78 | 2.02 |
| 10 dB | 2.23 | 2.16 | 2.25 | 2.24 | 2.24 | 2.39 |
| 15 dB | 2.63 | 2.60 | 2.65 | 2.69 | 2.70 | 2.74 |
| 0 dB | 1.46 | 1.27 | 1.41 | 1.23 | 1.40 | 1.68 |
| 5 dB | 1.91 | 1.92 | 1.92 | 1.67 | 1.86 | 1.97 |
| 10 dB | 2.24 | 2.25 | 2.25 | 2.17 | 2.28 | 2.34 |
| 15 dB | 2.57 | 2.70 | 2.60 | 2.66 | 2.71 | 2.70 |
| 0 dB | 1.42 | 1.39 | 1.39 | 1.15 | 1.31 | 1.62 |
| 5 dB | 1.91 | 1.89 | 1.89 | 1.68 | 1.85 | 1.98 |
| 10 dB | 2.25 | 2.21 | 2.22 | 2.23 | 2.28 | 2.32 |
| 15 dB | 2.62 | 2.61 | 2.60 | 2.64 | 2.64 | 2.67 |
| 0 dB | 1.37 | 1.42 | 1.42 | 1.23 | 1.26 | 1.70 |
| 5 dB | 1.84 | 1.74 | 1.83 | 1.71 | 1.80 | 2.02 |
| 10 dB | 2.24 | 2.24 | 2.22 | 2.22 | 2.22 | 2.41 |
| 15 dB | 2.60 | 2.57 | 2.64 | 2.67 | 2.63 | 2.72 |
| 0 dB | 1.44 | 1.35 | 1.41 | 1.20 | 1.36 | 1.66 |
| 5 dB | 1.88 | 1.87 | 1.89 | 1.75 | 1.83 | 2.07 |
| 10 dB | 2.24 | 2.25 | 2.27 | 2.24 | 2.31 | 2.38 |
| 15 dB | 2.53 | 2.61 | 2.59 | 2.65 | 2.66 | 2.72 |

1) Perceptual Evaluation of Speech Quality (PESQ)

Standardized by ITU-T P.862 (02/01), PESQ is a commonly used in telecommunication. It is defined as a linear combination

$$PESQ = a_0 + a_1 D_{\text{avg}} + a_2 A_{\text{avg}}$$

(8)
of the average disturbance value $D_{avg}$ and the average asymmetrical disturbance values $A_{avg}$ where $a_0 = 4.5$, $a_1 = -0.01$ and $a_2 = -0.0309$ are the optimized for speech processed through networks [21]. Table I gives the results for CVA along with sub [16], stat [17], wien [18], rec [19], spec [20] in PESQ measure. Best PESQ values are marked with boldfaced characters. Each number in the table is the average of PESQ values for 180 recordings (30 sentences spoken by 6 individuals).

2) Log-Likelihood Ratio (LLR)

In LLR, distorted and denoised data are compared statistically [22] and is defined as

$$d_{LLR}(c_s, c_d) = \log \left( \frac{c_s R_c c_d^H}{c_d R_c c_s^H} \right).$$

Here $c_s$ and $c_d$ are Linear Prediction Coefficient (LPC) vectors of the distorted and denoised speech data respectively. $R_c$ is the autocorrelation matrix of the distorted speech signal [23]. Lower LLR values mean higher quality speech signal. In Table II, LLR values for CVA and other 5 methods are compared with boldfaced indicating the best/lowest LLR value for a test input. It is notable that CVA is superior to the compared methods since it generated the lowest LLR for all background noise tests. However, for white noise cases CVA failed to be the best even though the scores are close.

CVA performed best among all methods in all PESQ tests except 5. That indicates about 83% success. In white noise cases, although not the best, CVA performed close to the best.

3) Cepstral Distance Measure (CEP)

CEPT too is based on LPCs and is defined as the distance between LPCs of original and enhanced speech frames as

$$d_{CEP} \left( c_s, c_d \right) = \sqrt{ \sum_{n=1}^{N} \left( c_{s,n} - c_{d,n} \right)^2 } $$

where $N$ is the dimension of LPCs. Lower CEP values indicate higher speech quality [24]. As shown in Table III, proposed CVA method is superior against all other denoising methods for all background noise types and levels applied in tests, except for white noise cases.
V. CONCLUSIONS

Tests conducted on 30 sentences spoken by 6 individuals with added 4 levels of 8 structured background noise recordings (total of 5760 recordings per method per quality measure) let us safely conclude that the proposed CVA method is superior against other 5 methods. In additional tests using white noise, on the other hand, CVA has failed to be the best (total of 720 recordings per method per quality measure). However, in most of the tests that CVA was not the best, its scores were close to the best.

Abstract—Owing to the theory depend heavily on mathematical models in communication lessons, instructors find students lost in all the equations and notations that given. Setting a lab component for students to put together the theory with practical implementations is not very easy in many times because it may cost a large number of equipment that is not low-priced. Yet there are still some solutions which reduce the cost in designing a real-life communication laboratory and effective in teaching. We present the usage of NI-USRP Software Defined Radio (SDR) and Emona DATEx Add-on Board on digital modulation techniques that take part in communication engineering education. Most commonly used digital modulation techniques; Amplitude Shift Keying (ASK), Phase Shift Keying (PSK) and Frequency Shift Keying (FSK) are analyzed in both devices. Both modulations and demodulations of mentioned techniques are done by experimentally.

Keywords— Software Defined Radio, Communication Engineering Education, Digital Modulation Techniques, USRP, DATEx

I. INTRODUCTION

In general most of the students at communication engineering start learning communication systems with the theory and the principles. However learning the theory and principles solely does not help students to design communication systems properly. They need to acquire experimental skills beside the theoretical domain. In order to bridge this gap instructors use several equipments such as function generators, oscilloscopes, spectrum analyzers that is not affordable many times.

With the development of microprocessors and software technology, traditional equipments began to transform into computer hosted devices which are low-cost, flexible and multi-functional. As an example, SDR, offers large number of tools to teach signals and communications [1]. Limits of traditional equipments, students being remained at the level of pre-digital area and the motivation for SDR based communication education is stated clearly in [2]. SDR refers that analog-to-digital (A/D) conversion is performed at the antenna connector, with all following signal processing (upconversion and/or downconversion, intermediate-frequency (IF) filtering, demodulation, etc.) performed in reconfigurable software using digital signal processing (DSP) techniques [3].

There are several examples of SDR based education courses. Domain analyses such as time, frequency, joint time-frequency, code, and modulation discussed in [4]. M-ary PSK modulation and demodulation implemented in [5]. AM implementation presented in [6]. Five week communication applications programme discussed in [7]. Therefore, multipurpose usage of SDR in communication lessons will be educatory and preliminary for real world.

In this study’s first part we use NI-USRP 2922 supporting frequency range of 400 MHz to 4.4 GHz with SBX daughterboard. It’s omni-directional vertical antenna provides 3 dBi gain for two-way high bandwidth communication. A Gigabit Ethernet connectivity provide data streaming to host processors enables simultaneously sending up to 50 MHz RF signal in and out of the USRP device [8].

Another way of using computer hosted device in communication education is Emona DATEx. By using it students can find the opportunity to experiment the real world signals in lessons.

The Emona DATEx, Digital Analog Telecommunications Experimenter, is an add-on which could serve as a basic training board in various concepts of communication lessons [9]. This add-on is fully integrated with the NI ELVIS II platform and is controllable through the NI LabVIEW development environment. All DATEx knobs and switches are manually controllable or programmable from LabVIEW.

The NI ELVIS II is an all-in-one electronics workstation that performs the functions of instruments which are conventionally found in an electrical engineering laboratory. The NI ELVIS II holds a removable prototyping board on which developers can build electrical circuits which connect the different ELVIS's instruments to achieve a particular experimental goal.

In communication education, examples of DATEx usage limited. Practical aspects of Direct Sequence Spread Spectrum (DSSS) communication discussed in [10]. AM/FM/BPSK signal generating experiments over the internet is presented in [11]. Time and frequency domain demonstrations discussed in [12].
II. ASK MODULATION APPLICATIONS

ASK is a form of amplitude modulation that the amplitude of the carrier wave is shifted proportionally to the amplitude of the digital signal. For a binary message sequence there are two levels; a binary “0” is one amplitude and a binary “1” is another amplitude. We can formulate ASK as:

\[ s(t) = A m(t) \cos(2\pi f_ct) \quad 0 \leq t \leq T \] (1)

where \( A \) is a constant, \( m(t) = 1 \) or \( 0 \), \( f_c \) is the carrier frequency, and \( T \) is the bit duration.

A. ASK Implementation with USRP

USRP Hardware Driver works on a variety of programming languages, operating systems, and development environments such as Linux, Windows, Mac and can be used with numerous frameworks such as GNU Radio, LabVIEW, Simulink, OpenBTS, OSSIE, Redhawk etc. In this study all applications done with LabVIEW because USRP devices that we have supported with licensed LabVIEW Framework.

The basic building block of LabVIEW is the virtual instrument (VI). Each VI consists of a block diagram and a front panel. The block diagram describes the functionality of the VI, while the front panel is a top level interface to the VI. Fig. 1 shows front panel of ASK application.

At the top of the front panel bit stream represents digital data that is randomly produced. At the bottom of the front panel ASK signal is located. While generating ASK signal, all we have to do is to connect the subVIs to each other in an order and feed them with the wires properly. But the theories like Nyquist theorem is crucial while establishing symbol rate values via carrier frequency. Moreover for the getting pure ASK, sampling rate and noise impairment values must be chosen punctiliously. In Fig. 2 block diagram of the ASK application is shown.

B. ASK Implementation with DATEx

In DATEx implementation we use Sequence Generator module for the digital data. 100 kHz master signal is quite appropriate for the carrier frequency because in ideal ASK communication system, we want the carrier frequency to be much higher than the bit rate of the digital data. Generating ASK signal is provided by Dual Analog Switch module. In Fig. 3 modulation (Dotted) and demodulation (Lined) scheme of ASK is shown.

In demodulation part of DATEx implementation for getting an envelope detector, rectifier on the Utilities module and the Tuneable Low Pass Filter (LPF) module is used. Experimental setup with DATEx is shown in Fig. 4.

While selecting the carrier frequency there is not so many options in DATEx. In Master Signals module, signals that can
be used in an implementation are; 100 kHz sine/cosine, 2 kHz sine, 2–8 kHz digital. On the contrary in USRP students can use all the frequencies supported by daughterboard (400 MHz-4.4 GHz).

III. FSK MODULATION APPLICATIONS

FSK refers to a type of frequency modulation that assigns bit values to discrete frequency levels. In other words frequency does not fluctuate over symbol time but fluctuates in discrete amounts in response to message. Amplitude remains unchanged. This is a desirable characteristic for improving the power efficiency of transmitters. In FSK modulated signal consist of two different carriers;

\[ s1(t) = Ac \cos(2\pi f_1 t) \]  
\[ s2(t) = Ac \cos(2\pi f_2 t) \]

One of the signal above is in response to “0” and the other is in response to “1”.

A. FSK Implementation with USRP

LabVIEW interacts with the USRP transmitter by means of four basic functions located on the block diagram’s palette. Transmitter session starts with “Open Tx Session” and goes on with “Configure Signal” used to set parameter values in the USRP. “Write Tx Data” writes the baseband signal to the USRP for transmission and your code should be before this function. Then “Close Session” terminates transmitter operation once the while loop ends. It has five basic functions at the receiver part similarly.

While generating FSK signal, if we rewrite the frequencies as a deviation from the carrier frequency then it is called frequency deviation. This is excursion of the signal above and below the carrier frequency and indicates the quality of signal as it has particular importance in relation to bandwidth.

We can define the bandwidth of a pulse shaping filter that we create in LabVIEW as;

\[ BW = (1 + \alpha) * Rs + 2 * \Delta f \]

where \( Rs \) is symbol rate, \( \Delta f \) is frequency deviation and \( \alpha \) is roll-off factor.

In the receiver part of the application beside the time and frequency domain you can use eye diagram demonstration as in Fig. 5.

Depending the value of modulation index distortion on the received signal can be seen on the eye diagram easily.

As in Fig. 6 by changing symbol rate, alpha, filter type etc. you can easily discover conversions in the modulated signal. After mathematical theory, showing their importance on a real life signal would be very beneficial for students.

B. FSK Implementation with DATEx

For generating FSK signal in DATEx, Voltage Controlled Oscillator (VCO) method is used. The Sequence Generator module is used for modeling the digital data and its SYNC output triggering the scope to provide a stable screen. By using a filter we can distinguish one of the sinewave in FSK and then demodulate it with the help of an envelope detector. For this purpose Tunable LPF module is used in recovering part and then DIODE and RC LPF on the Utilities module is used to form the envelope detector. As in Fig. 7 modulation (Dotted) an demodulation (Lined) scheme of FSK is shown.

Comparator is a useful function for restoring distorted signal. In demodulation part of the application if signal that we recover is not clear we can use comparator function in the Utilities module either.
As seen clearly from the block diagram, setting FSK demodulation is more difficult in LabVIEW than the one in DATEx. As we mentioned before some of the functions used in block diagram are standart while designing real signals. And their connections seems little bit complicated. But it is obvious that USRP gives us chance to radiate our signal in the air and demodulating/recovering a signal with additive noise is not so simple.

### IV. PSK MODULATION APPLICATIONS

In PSK, information is encoded on the phase of the transmitted carrier that changed between two values according to the binary signal level. When encoding bits, the phase shift could be 0 degree for encoding a "0," and 180 degrees for encoding a "1," or the phase shift could be –90 degrees for "0" and +90 degrees for a "1," thus making the representations for "0" and "1" a total of 180 degrees difference. PSK is ideal among FSK and ASK in providing the lowest average power needed for a given bit error rate. A binary PSK signal can be defined by:

\[
s_1(t) = A \cos 2\pi f_c t \quad 0 \leq t \leq T \\
s_2(t) = -A \cos 2\pi f_c t \quad 0 \leq t \leq T
\]  

These two signals have the same frequency and energy but they have a correlation coefficient of 1.

#### A. PSK Implementation with USRP

Our laboratory have two USRP radios, one for transmission and the other one for reception. There are two possible configurations:

- Both radios connected to single computer (running both the transmitter and receiver VIs) with a dual-port Gigabit Ethernet interface, or using a data switch.
- Each radio connected to a different computer; one running the transmitter VI, and the other, the receiver VI.

We preferred the first one for our applications because it is better and faster for managing all the process in one screen. Our experimental set up with USRP can be seen on Fig. 9. Connection between the two USRP is provided with the Multiple Input Multiple Output (MIMO) cable.

#### B. PSK Implementation with DATEx

Switching halves of the PSK signal’s envelopes have the same shape as the message. So PSK generation and the recovery of the data can be handled by conventional Double Side Band Suppressed Carrier (DSBSC) modulation and demodulation techniques. The Sequence Generator module is used for modelling the digital data and its SYNC output triggering the scope to provide a stable screen. With the help of Multiplier module, PSK signal generated as shown in Fig. 11.

By using second Multiplier and Tuneable LPF module we can easily carry out demodulation part of PSK signal.
V. CONCLUSIONS

In this study we propose a new dimension for teaching communication techniques and algorithms by focusing on two computer hosted devices, called USRP and DATEx. ASK, FSK and PSK modulation/demodulation processes presented experimentally. Our approach allows students to concentrate their efforts on real world signals by hands-on applications. Using these devices students will be able to observe signal waveforms, study the effect of noise, design components of a digital communication system. In other words replacing USRP and DATEx with the traditional hardware-only platforms will give students a chance to link the theory with practical implementations.

hulya.gokalp@brunel.ac.uk

Abstract—In this study Multiple Signal Classification (MUSIC) algorithm were used to reduce the effect of interference in the frequency modulated continuous wave (FMCW) channel data. Since the interference affects a very wide band including the frequency band of interest, the classical band pass filtering did not reduce the noise level. The challenge was to develop an interference reduction algorithm that reduces the noise floor in the frequency band of interest. MUSIC algorithm was chosen for this purpose. The MUSIC algorithm is the one of the subspace method which is frequency estimation technique and it is more useful for reducing the in-band interference than band pass filter.

Keywords— In-band interference, MUSIC algorithm, band pass filter.

I. INTRODUCTION

An in-band interference occurs when a part of transmission band is simultaneously used by another application. Because of interfering signals and desired signal to be transmitted are in the same frequency band, the interfering signals aren’t suppressed in the receiver. The effect of in-band interference in chirp modulated frequency modulated continuous wave (FMCW) data is to raise the noise floor in the average power delay profiles (APDP) [1, 2]. In channel sounding, although the signal processing can be performed off-the-line, measurement campaigns are expensive and difficult to repeat. Since every channel data is valuable for a sound channel model, a technique that alleviates the effect of in-band-interference in FMCW mobile radio channel data is desirable. The basic method proposed to reduce the effect of in-band interference have included clipping the level of interference or put zero to data which has in band interference [1,3,4]. Also Minimum Norm Method (MN) [5] and Prony modelling [6] of data are used to reduce the effect of in-band interference.

Noise subspace methods are used as a frequency detection methods. For example; MUSIC, Pisarenko harmonic decomposition, minimum norm and Eigen Vector (EV) [7]. The methods that based on an eigendecomposition of the autocorrelation matrix into two subspaces, a signal subspace and a noise subspace. In this study MUSIC algorithm was choose to reduce the effect of interference in FMCW channel data.

II. MUSIC METHOD

The MUSIC algorithm is a frequency estimation technique like Pisarenko’s method. In Pisarenko, only a single eigenvector is used and taken to be a set of autoregressive coefficients, whose zeros can be found analytically or with polynomial root finding algorithms. In contrast, MUSIC assumes that several such functions have been added together, so zeros may not be present. Instead there are local minima, which can be located by computationally searching the estimation function for peaks. MUSIC estimates the frequency content of a signal or autocorrelation matrix using an eigenspace method [8].

We assume the received data, \( x(n) \) is a random process consisting of \( p \) complex exponentials in white noise with a variance of \( \sigma^2_w \). \( R_x \) is the \( M \times M \) autocorrelation matrix of \( x(n) \) with \( M>p+1 \). If the eigenvalues of \( R_x \) are arranged in decreasing order (\( \lambda_1 \geq \lambda_2 \geq \ldots \geq \lambda_M \)) and if \( v_1, v_2, \ldots, v_M \) are the corresponding eigenvectors, then these eigenvectors can be divided into two groups: the \( p \) signal eigenvectors corresponding to the \( p \) largest eigenvalues, and the \( M-p \) noise eigenvectors that, ideally, have eigenvalues equal to \( \sigma^2_w \).

The white noise variance by averaging the \( M-p \) smallest eigenvalues as follow:

\[
\sigma^2_w = \frac{1}{M-p} \sum_{k=p+1}^{M} \lambda_k
\]  

(1)

The MUSIC method frequency estimation function as follows [7]:

\[
\hat{p}_{MU}(e^{j\omega}) = \frac{1}{\sum_{i=p+1}^{M} |k^H v_i|^2}
\]

(2)
where \( v_i \) are the noise eigenvectors and

\[ e = [1 \ e^{jw} \ e^{j2w} \ ... \ e^{j(M-1)w}]^T \]

is an arbitrary vector.

The locations of the \( p \) largest peaks of the estimation function give the frequency estimates for the \( p \) signal components.

**III. FMCW CHANNEL DATA**

FMCW channel data is used in radio channel measurements. FMCW is used in radar applications and radio channel propagation measurements with success [9]. Measurements were carried out in Manchester city of up to 5 km away in the transmitter and receiver. Bandwidth is 60 MHz. FMCW channel probe device output is in the form of the sum of sinusoids of different frequencies.

Channel data that there is in-band interference free is shown in Fig. 1.a. In-band interference has let to a sudden change in amplitude shown in Fig. 1.b. and it is also seen that the sum of sinusoidal form is disrupted.

FMCW channel data in the time domain shown in Fig. 2. As it seen in Fig. 2 in-band interference has increased an average of the noise floor.

**IV. RESULTS**

Firstly a classical band pass filter is attempted to reduce the in-band interference. As a filter, third-order Butterworth band pass filter is used. Band pass filtering results in a time domain are shown in Fig. 3. It seems that with a band pass filtering the signals are cleaned in the time domain.
Band pass filtering results in a frequency domain are shown in Fig. 4.

As it seen, after the band-pass filtering in a frequency domain, we saw that the crude data noise floor did not decrease. Because when a desired data is taken by band pass filter, interference is also taken.

The reason of appear to have been cleaned signal in a time domain is the suppression of the high frequency component of the signal which is out of the desired band.

After the band pass filter application, the MUSIC algorithm is used to reduce in-band interference. MUSIC algorithm is applied different values of \( p \) and \( M \). The range of appropriate \( p \) values were between 300-330 and \( M \) values were between 400-450. The best result is taken by \( p=320 \) \( M=440 \) and so noise floor is reduced 8 dB approximately with that \( p \) and \( M \) values (e.g. Fig. 5).

V. CONCLUSIONS

The results show that band pass filtering did not work to reduce the in-band interference. Because with a band pass filtering, both signal and interference are taken. But the MUSIC algorithm performed very good in terms of producing a clean spectrum and reduced the noise floor in APDP more than 8 dB effectively.

Measurement and Evaluation of Electromagnetic Pollution in Samsun City Center Before and After Deployment of 4.5G
Çetin Kurnaz¹, Begüm Korunur Engiz²
¹,²Ondokuz Mayis University
Department of Electrical and Electronic Engineering
Samsun, Turkey
{ckurnaz, bkengiz}@omu.edu.tr

Abstract—There has been a substantial growth in the use of mobile communication services over the last few years. As a result of this growth increase in the number of base stations, and exposed electromagnetic radiation (EMR) levels have become inevitable. Considering the public debate about possible health hazards caused by EMR, in this study, evaluating the effect of establishment of 4.5G systems on existing EMR levels is aimed. For this purpose; the total 536 EMR measurements were conducted in Samsun before and after 1 April 2016 using PMM 8053 EMR meter. It is seen from the measurements that maximum electric field strength ($E_{\text{max}}$) is 6.32 V/m while the maximum average electric field strength ($E_{\text{avg}}$) is 3.26 V/m which are both below the limits (28V/m, 21V/m the minimum values for 100kHz-3GHz band) that are determined by the International Commission on Non-Ionizing Radiation Protection (ICNIRP) and Information and Communication Technologies Authority of Turkey (ICTA). The mean of $E_{\text{max}}$ and $E_{\text{avg}}$ are 1.2111V/m, 0.8892/m before 4.5G, and 1.849V/m, 0.6628 V/m after 4.5G respectively. The results demonstrate that the deployment of 4.5G yielded up to 52.3% increase in $E_{\text{max}}$ while 12.5% in $E_{\text{avg}}$ values. Even though the measured E levels are below the limits; there is a significant increase in them in parallel with 4.5G. It can be also predicted from the measurement results that E levels are likely to increase over forthcoming years, and exceed the lower limits (4 V/m) applied by some countries e.g. Switzerland and Italy.

Keywords—Electric field strength; electromagnetic (EM) measurement; EM pollution; statistical analysis.

I. INTRODUCTION

Electromagnetic (EM) waves are radiated from many sources, both natural and man-made, that produce electromagnetic pollution. In parallel with technological developments, there has been a dramatic growth in the use of cellular systems which based on base stations. Because each base station is an electromagnetic radiation (EMR) source, with the increase in the number of base stations, exposed EMR levels have also increased. Since each base station works within a limited geographical region and for limited number of users, mobile system operators must install more base stations in order to meet growing demand for multimedia services, and communicating from any place. There are around 100,000 base stations in Turkey right now, but with the establishment of 4.5G systems on 1 April 2016, the estimated number of base stations will be around 130,000. Because there is a growing number of base stations being placed into crowded places; measuring, evaluating, the levels of EMR and controlling their compliance with standards/limit values has become more crucial than before. Therefore detrimental effects of EMR on human health have been the subject of many researches [1-9] in the last decade.

There are international standards and limits on effects of EMR on human health. The limits are recommended by an international commission ICNIRP which is recognized by World Health Organization (WHO). The limits of electrical field are shown in Table I based on ICNIRP and ICTA guidelines on exposure limits [10-11].

Table I Reference levels for general public exposure to time-varying electric fields for ICNIRP and ICTA

<table>
<thead>
<tr>
<th>Frequency range (MHz)</th>
<th>Electric field strength (V/m)</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>ICNIRP</td>
</tr>
<tr>

<td>1.375 f¹/²</td>
</tr>
<tr>
<td>2000 - 60000</td>
<td>61</td>
</tr>
</tbody>
</table>

The limits are given for exposure averaged over a six minute interval. Each country has its own determined limits. The USA and some European countries use limits determined by the ICNIRP, while other European countries like Switzerland and Italy use 1/10 of the ICNIRP’s values as a limit. Turkey applies limits that are 75% lower [11] than those suggested by the ICNIRP [10]. There are currently three mobile
communication operators in Turkey and they use 2G (second generation), 3G (third generation) and 4.5G (fourth generation) systems. According to the [11], the limits are 30.9 (V/m) for 900 MHz base station, 43.7 (V/m) for 1800 MHz base station, 45.75 (V/m) for 3G systems, which is 2100 MHz, and also 45.75 (V/m) for 2600MHz base station.

In this study, to evaluate the effects of newly established 4.5G system on EMR levels, extensive EMR measurements were performed before and after 1 April 2016 in Samsun city center, at 67 different locations. Statistical properties of the measured data are determined. The changes in EMR levels which occurred with the deployment of 4.5G systems are visualized through maps.

II. MEASUREMENT OF EM POLLUTION

In order to determine the changes in EMR levels with the deployment of 4.5G, EMR measurements were conducted using PMM 8053 EMR meter, in Samsun city center at 67 different locations considering the number of users, line of sight, distance from a base station. Each measurement location which is separated by a distance of app. 100 meters is shown with red circle in Fig.1.

![Fig.1 Measurement locations in Samsun city center](image)

Total E in the band between 100kHz - 3GHz is measured with PMM–8053 with EP-330 isotropic electric field probe [12] twice in March named as M1, M2 and May 2016, and, named as M3, and M4 respectively. In each measurement, the maximum electric field strength (E_{max}) and average electric field strength (E_{avg}) were recorded. Based on the international standards and ordinances released by ICNIRP and ICTA, the duration of each measurement was six minutes.

III. MEASUREMENT RESULTS

The maximum E (E_{max}) and the average E (E_{avg}) which were measured at 67 different locations are given in Fig. 2.a and Fig. 2.b respectively. Reasons of various E levels may be: the number of base stations in measurement area, output powers of base stations, distances from the base stations, whether there is line of sight (LOS) between the units or not, and the number of users. As seen from the figure that the E_{max} is 6.32 V/m which is measured at 23th location (measurement time 1). The maximum E_{avg} is also obtained at 23th location (measurement time 4) as 3.26 V/m accordingly.

![Fig. 2 a) Maximum (E_{max}) b) Average (E_{avg}) Es versus locations](image)

The statistical properties of measured data are determined and listed in Table II, probability density functions of each measurement are also given in Fig.3. As seen from the Table II that E_{max} varies from 4.49 to 6.32 V/m while E_{avg} varies between 2.78 and 3.26 V/m. Before 4.5G the mean of the E_{max} is 1.2111, it increases to 1.8449 after 4.5G. for the case of E_{avg} corresponding values are 0.5892 and 0.6628 V/m.

Monitoring the Signal Strength of Cellular System Operators on a University Campus

Begüm Korunur Engiz¹, Çetin Kurnaz²
¹²Ondokuz Mayıs University
Department of Electrical and Electronic Engineering
Samsun, Turkey
{bkengiz, ckurnaz}@omu.edu.tr

Abstract— In this study, in order to determine the signal strengths of the existing cellular system operators for 2G, 3G and 4G services drive test measurements were conducted on a specific route on Ondokuz Mayıs University (OMU) Kurupelit Campus. The synchronized measurements were performed using nine same brand and model smartphones with “Android” operating system and “Netmonitor” application. It is seen from the measurements that the received signal strength can change depending on the location, frequency, line of sight, and base stations’ output power. 2G signal strengths are significantly higher than 3G/4G. Considering all operators; the signal strengths vary from -51dBm to -87dBm for 2G, while from -51dBm to -103dBm, and from -67dBm to -130dBm for 3G and 4G respectively. The average signal strengths of 2G, 3G and 4G are -65.97dBm, -80.01dBm and -94.52dBm. The quality of signal is higher than the minimum limit (<-100dBm) determined by Information and Communication Technologies Authority (ICTA) of Turkey for 2G at all measurement locations. However, for 3G lower than the limit at 8.33% of all measurement locations for operator C while for 4G 69.71% for operator A. Using these results help to have foresight on needed improvements/enhancements.

Keywords—Cellular System; Signal Strength; Drive Test Measurement; Netmonitor.

I. INTRODUCTION

Communication has an important role in human life, and has been developing each day in parallel with the technological improvements. As a result of these improvements many new generation communication devices have been developed and presented. Mobile communication systems especially mobile phones have become the most common tool of communication over recent years.

In cellular systems, the coverage area is divided into a number of elementary areas called cells, and a base station is placed center of the cell. Each active mobile unit within a cell uses assigned frequencies to communicate with the serving base station. With the movement of mobile user the cell boundaries may be crossed from time to time. In such case new channels are assigned, and call could continue without any interruption. Theoretically each cell is hexagonal; and the design of a cellular system begins with the classification of the coverage area [1-2]. With the growth in the capacity of mobile communications, the size of a cell is becoming smaller and smaller: from macro cell to microcell and to picocell [3-4].

In mobile communication systems, modulated electromagnetic waves arrive at the receiver either Line of Sight (LOS) path or through different paths. Along these paths the transmitted signal undergoes reflection, scattering, diffraction because of the surrounding objects (buildings, mountains, trees etc.), and the received electric field strength varies as a result. This phenomenon is known as multipath fading, and if the receiver position moves the destructive effect of multipath becomes more complicated [5].

In Turkey, currently 2G (second generation), 3G (second generation) and 4G (fourth generation) cellular systems are used, by means of three different Cellular System (CS) operators. In order to maintain customers’ loyalty and gain new customers the CS operators mostly emphasize on “coverage area”, “signal power”, and “signal quality” in commercials. Some recent customer surveys on CS operators show that a high level of satisfaction is strongly correlated with signal strength. Therefore CS operators must improve the provided signal quality in order to meet customers’ demands and fulfill the requirements determined by ICTA. For this reason, in this study, measuring the signal strengths of existing three operators (named as A,B,C) in Turkey for 2G, 3G and 4G systems on a specific route on OMU Kurupelit Campus, transferring them on a map are aimed.

II. MATERIAL AND METHOD

In this study, the signal strengths of 2G, 3G and 4G services of the three CS operators were measured, and the results were transferred on a map. In measurements nine same brand and model smartphones with “Android” operating system and “Netmonitor” application, and nine sim cards whose three are for each CS operator were used. After the determination of measurement route, required mobile network settings were adjusted then Netmonitor application was started. According the type of connection mode measured, the network mode of the each smartphone was adjusted to “2G only”, “3G only”, or “LTE only”. In order to determine the exact measurement locations GPSs’ of all phones were turned on. Drive test measurements were conducted the busiest times of a day, at a speed of 30km/h, during 25min. with 5sec. intervals. The signal quality of each operator was measured in terms of dBm.

Fig.1 shows an image for a measurement conducted with Netmonitor application. Netmonitor application which is an
Android based network software, shows the information of connected base station, signal strength, and location instantly, and save these in CLF (list) as well as KML (map) format. Fig.2 a and b illustrate examples of screen shots of 2G and 3G measurements at a measurement location respectively. In figure, Operator shows the connected CS operator’s MCC-MNC number and name, Type represents the connection type, LAC defines the connected cell number while CID indicates connected sector number. RNC also indicates radio network controller.

![Fig. 1. Netmonitor application and its operation](image)

![Fig.2. Examples of Netmonitor measurements for a) 2G, b) 3G](image)

According to communique [6-7] released by Information and Communication Technologies Authority of Turkey coverage area related signal strengths of CS operators were determined. In accordance with this communique minimum signal level for coverage obligation to the operators will be -104 dBm for GSM 900, -102 dBm for GSM 1800 and -104 dBm for the networks using both GSM 900 and GSM 1800. Beside this, the classification can be made according to Table I.

<table>
<thead>
<tr>
<th>dBm equivalent</th>
<th>Classification</th>
</tr>
</thead>
<tbody>
<tr>
<td>-101 or less</td>
<td>Very weak</td>
</tr>
<tr>
<td>-100…-91</td>
<td>weak</td>
</tr>
<tr>
<td>-91…-81</td>
<td>average</td>
</tr>
<tr>
<td>-80 or more</td>
<td>Good</td>
</tr>
</tbody>
</table>

### III. RESULTS

Drive test measurements that performed for 2G, 3G and 4G systems using Netmonitor are given in Fig.3.a, b, c for the operators A, B, C respectively. As seen from the figure that 2G signal strengths are significantly higher than those for 3G and 4G. It is seen from the 2G measurements that neither very weak nor weak signals concurred, and the operator C has worst signal strength. The main reason of this case may be; the change in the signal strength inversely proportional to frequency (Friis transmission equation [5]), and using 1800 MHz for 2G while the others use 900 MHz. It is also seen from the measurements that the received signal strength can change depending on the location, frequency, line of sight, and base stations’ output power for all operators.

The overall assessments for the measurements are given in Table II. As seen from the Table that the average signal strengths of 2G are -63.36 dBm for operator A, while 64.88dBm and -69.69dBm for operator B and C respectively. Corresponding signal strengths of 3G are measured as -85.27dBm, -76.67dBm and -78.33dBm. As a result of newly establishment of 4G; very weak signals are recorded at many location whose averages are -104.21dBm, -89.55dBm, and -89.80dBm for the operators A, B and C respectively.

<table>

Fig. 6. Netmonitor measurement results of operator C for a) 2G, b) 3G, c) 4G
IV. CONCLUSIONS

In this study, the signal strengths of existing three operators (named as A, B, C) in Turkey for 2G, 3G and 4G systems on a specific route on OMU Kurupelit Campus are measured and transferred on a map. It is seen from the measurements that 2G signal strengths are significantly higher than those for 3G/4G. Because of being established on 01/04/2016 4G signal strengths are inadequate. Beside this, the received signal strength can change depending on the location, frequency, line of sight, and base stations’ output power. With the use of the measurement results and/or the maps the lower/higher signal strength locations, and the regions required enhancement, and the operators to improve their signal quality can be determined for 2G/3G/4G systems.

afboz@sakarya.edu.tr

Abstract—In this study, the mathematical equations of five phase segmental switched reluctance motor (SARM) was established by using basic electrical motor model. This five phases SARM has a different rotor and excitation structure than classical ARM, and its phase currents and magnetic field variations with respect to inductance were calculated by means of magnetic equivalence circuit. The value of inductances was calculated by stating the visible inductance profiles of different phases instantaneously in order to emphasise the difference between two motors. In addition, the momentum equation of SARM was obtained by determining the situations of different phases. The inductance values were calculated by assuming the current applied to phases created from an ideal current source and by determining the situations of different phases. It was revealed that the SARM produced much more momentum than the classical ARM having the same phase number by using a mathematical model.

As a result of this study, it was understood that the magnetic flow equations depend not only on the function of rotor position, but also the changing current

Keywords—Switched Reluctance Motor, Mathematical Model, State Equation

I. INTRODUCTION

Switched reluctance motors (SRM) are electrical machines with simple structure but superior properties which converts electrical energy into mechanical energy with changing reluctance effect changes and which are in need of convertor power electronics while performing this action. Although SRMs first put forward in the 1800s, the driving motor depending on developments in power electronics in the early 1960s has become possible. Although it is the engine type based on the old, the examination and investigation of these engines are new. In particular, the studies on this motor are seen to be focused after 1980 [1] [2] [3].

ARMs are increasingly being used in changing-rate and servo-type industrial applications due to mechanical structures and low rotor losses [4]. These motors have many different application areas such as electric cars, spacecraft, household appliances, radars, automatic door systems and water pumps.

The most important characteristic of SRM’s is having magnetic circuit in non-linear form depending on phase circuit and rotor position. That’s why SRM’s need a strong controller in order to produce maximum torque [5].

The difference of new 5-phase bipolar excitation SARM from classic SRM is that the rotor structure has been altered completely and contains variations in excitation method. In case of being used of the same resource, flux distributions produced by the winding of both engines per phase and torque amounts produced depending on this show changes due to inductances of the windings and the mutual inductance value occurs between phases [6]–[7].

Besides the successful results obtained in motor structure and performance of classic switched reluctance, in also the studies on switched reluctance motors (SARM) based on segmental and two-phase energizing essence forming the basis of this study important progresses have been made. In order to model the non-linear structure of SARM and in case of the installation of motor, different structure were suggested by many researchers in motor and actuator circuit design in order to eliminate the fluctuations in the current varying due to time. The first study about this subject was conducted by Lawsonson and Agu in literature in 1964 [8]. Meerow et al. examined the performances of SARM’s with various polarity and winding structure [9]. Uygun et al. performed the analysis of linear model of magnetic circuit by designing U-type segmental type SRM [10]. Belhandi and Koli showed the comparative simulation results of speed and torque parameters of the classic SRM and SARM by using the finite element method [11]. In other studies, the flux distribution topologies of SARM was developed on magnetic structure by changing pole, rotor and winding structures and engine driver optimizations were arranged.

In this study, a control algorithm including PI control for a new segmental switched reluctance motor with bipolar excitation, 5 phases and 10/8 pole configuration, which was designed as segmental rotor (SARM), and entered in the literature has been developed and presented.

Also in this study, the actuator circuit including PI control option developed for controlling bipolar driven segmental rotor and computer-controlled management, monitoring interface will be discussed.
II. STRUCTURAL FEATURES OF BIPOLAR EXCITED SEGMENTAL ROTOR 5-PHASE AND 10/8 SWITCHED RELUCTANCE MOTOR

In this section, it has been mentioned briefly the structural features of the new design segmental type of engine belonging to SARM.

In Fig. 1. (a), newly designed bipolar excited segmental type SRM using short flux paths and the cross sectional view of 5-phase classical switched reluctance motor with 10/8 configuration to be used in performance comparisons were given. The case that occurs in case of being energized of this phase is shown in Fig. 2 (b).

The new developments obtained in newly designed switched reluctance motor having 5 phases and 10/8 stator/rotor configuration which is detailed in Fig. 2. can be summarized as follows. 10/8 SRM has a different rotor structure from conventional SRM. The rotor consists of both the packages created from siliceous plates and an aluminum block where these packages are placed in. as well as the package that was created from a block of aluminum and silicon steel consists of the placement of the package. The reasons of using the aluminum block is the limiting feature of magnetic field that comes out and is being a very light metal compared to other metals (e.g., stainless steel, etc.) [6].

Thus, torque value produced per Nm/kg weight taken into account in the engines, Nm / kg will be automatically increased. In the engine, the two-phase energizing method was used instead of the single phase energization method used in a conventional SRM. The reason for using such a method is to see that the magnetic poles of the engine follow the short flux paths when the windings are properly installed and simultaneously two phases of SARM is energized. This case (reduction of flux path) will lead the reduction in both sheet losses and the temperature of motor sheets.

As it can be understood in Fig. 2 (b), segmental SRM operates by using short current paths instead of long flow paths unlike conventional SRM. Since in every time, two phases remain with power, it is clear that common inductance occurred between the phases and this case will create complexity for the finding of non-linear models of the engine.

III. STATUS EQUITIES OF SARM

In order to be comprehended better of the running of machines like engine and generator, it is required to be prepared mathematical models with the aim of realizing simulation and experimental studies. In this section, running of the new design 5-phase segmental switched reluctance engine, mathematical model belonging to the driver is taken as a basis by using basic motor equities [5].

While the design is being performed, it is stressed on the assumptions that the flux produced by any of the phases in different polarity passes through air range, the circuit is completed briefly; leak flux status is ignored; stator and rotor steel magnetic permeance is accepted as infinite and when stator and rotor poles are overlapped, it is maximum.

In Fig. 3, magnetic equivalent circuit belonging to 5-phase SARM has been given.

In Fig. 3, magnetic equivalent circuit belonging to 5-phase engine is given. Here, $e$ represents opposite electromotor power, $\Phi$ represents flux, $G$ represents magnetic permeability of phases and $U_p$ represents voltage drop. By using this
magnetic equivalence and basic electric machines, the following processes have been realized.

According to ARM basic knowledge, when angular change is considered, it is possible to write the equivalent moment expression for the moment produced by the engine depending on the co-energy produced by the motor as seen in Fig. 1:

\[ T(\theta, i) = -\frac{dW_c(\theta,i)}{d\theta} \quad (\lambda = \text{Sabit}) \]  

(1)

If the moment produced by SARM is calculated from general moment energy by using Equation 1, the following is obtained;

\[ T = \frac{1}{2} \left( \frac{dI_a}{d\theta} V_a + \frac{dI_b}{d\theta} V_b + \frac{dI_c}{d\theta} V_c + \frac{dI_d}{d\theta} V_d + \frac{dI_e}{d\theta} V_e \right) + i_{1a} \frac{dM_a}{d\theta} + i_{1b} \frac{dM_b}{d\theta} + i_{1c} \frac{dM_c}{d\theta} + i_{1d} \frac{dM_d}{d\theta} + i_{1e} \frac{dM_e}{d\theta} \]

(2)

Here, \( T \) represents the produced moment (Nm), \( L \) represents overlapped location phase inductance (mH), \( \theta \) represents rotor location angle (degree), \( M \) represents common inductance (mH), \( i \) phase flow (amper). The following equation can be written according to Kirşof’s flux rule:

\[ \phi_a + \phi_b + \phi_c + \phi_d + \phi_e = 0 \]

(3)

\( \phi_x \) (as being \( x=a, b, c, d, e \)) represents phase fluxes. Depending on magnetic conductivity, flux change belonging to each phase depending on conductivity (as being \( \phi_x(a, b, c, d, e) \)) is expressed as in Equation 4:

\[ \phi_x = G_x(\theta)u_x \]

(4)

Here, the thing expressed is \( G_x(\theta) \) (as being \( x=a, b, c, d, e \)) represents magnetic permeability of phases while \( u_x \) (as being \( x=a, b, c, d, e \)) is representing voltage drop. Besides, the values of the sources are calculated as in Equation 6:

\[ e_x = Ni_x \]

(5)

\( e_x \) (as being \( x=a, b, c, d, e \)) represents the value of the source, \( N \) represents the wrapping number belonging to each phase and \( i_x \) (as being \( x=a, b, c, d, e \)) represents flow belonging to each phase. If it is considered as the value of \( u \) potential;

\[ u_x = e_x - u_p \]

(6)

is obtained. With the widened expression, phase fluxes can be calculated as in the Equation 7.

\[ \phi_x = G_x(\theta)\left(e_x - u_p\right) \]

(7)

Flux connections belonging to each phase can be expressed as follows;

\[ \lambda = N\phi_i \]

If it is used for the Equation 4 flux connection, it is written as follows;

\[ \lambda_a + \lambda_b + \lambda_c + \lambda_d + \lambda_e = 0 \]

(9)

If the magnetic permeability of the phases is expressed as a function of phase inductances, (as being \( x=a, b, c, d, e \)), it is obtained as follows;

\[ G_x = \frac{L_x}{N^2} \]

(10)

When flux connections are widened depending on this expression (as being \( x=a, b, c, d, e \)), it becomes;

\[ \lambda_x = L_x(\theta)\left(e_x - u_p\right) \]

(11)

An arbitrary flow is described as \( i_p = \frac{u_p}{N} \) (as being \( x=a, b, c, d, e \));

\[ \lambda_x = L_x(\theta)(i_x - i_p) \]

(12)

is obtained. If this equity obtained is places in the Equation 9, it becomes;

\[ L_x(\theta)(i_a - i_p) + L_x(\theta)(i_b - i_p) + L_x(\theta)(i_c - i_p) + L_x(\theta)(i_d - i_p) + L_x(\theta)(i_e - i_p) = 0 \]

(13)

If the value of \( i_p \) is taken from this equity, it is obtained as follows;

\[ i_p = \frac{L_x(\theta)\phi_a + L_x(\theta)\phi_b + L_x(\theta)\phi_c + L_x(\theta)\phi_d + L_x(\theta)\phi_e}{L_x(\theta) + L_x(\theta) + L_x(\theta) + L_x(\theta) + L_x(\theta)} \]

(14)

If the Equation 10 is rearranged according to Equation 12, Equation 15 is obtained for phase \( \lambda \):

\[ \lambda = \left(L_x(\theta)\frac{L_x^2(\theta)}{L_x(\theta) + L_x(\theta) + L_x(\theta) + L_x(\theta) + L_x(\theta)}\right)i_p \]

(15)
This expression can be written as the same for the other phases. As it is easily understood from the expression, core inductance value belonging to phase A is seen as follows;

\[
L_{aw} = L_a(\theta) - \frac{L_a^2(\theta)}{L_a(\theta) + L_b(\theta) + L_c(\theta) + L_d(\theta) + L_e(\theta)}
\]  

(16)

Similarly, common inductance values are found between phases A and B as;

\[
M_{ab} = -\frac{L_a(\theta)L_b(\theta)}{L_a(\theta) + L_b(\theta) + L_c(\theta) + L_d(\theta) + L_e(\theta)}
\]

(17)

A. Visible Inductance Profile of SARM

In order to be comprehended of running of the Segmental ARM more clearly, it is required to examine visible inductance profiles. In this method, thinking that the phases of segmental ARM are run with ideal flow source and by revealing the status of different phases at each moment, the values of inductances will be calculated. In this calculation method, phase switches were ignored and phases were connected as star like in Fig. 4.

At any running moment of the designed engine, the phases given in Table I will run together. Accordingly, if only B and C phases are thought to be energized at the first sight, the circuit in Fig. 5 will be obtained.

| A Phase | 0 | + | 0 | 0 | - |
| B Phase | 0 | 0 | - | 0 | + |
| C Phase | - | 0 | + | 0 | 0 |
| D Phase | + | 0 | 0 | - | 0 |
| E Phase | 0 | - | 0 | + | 0 |

At any running moment of the designed engine, the phases given in Table I will run together. Accordingly, if only B and C phases are thought to be energized at the first sight, the circuit in Fig. 5 will be obtained.
\[ i_b = -i_c \]
\[ i_a = 0 \]
\[ i_d = 0 \]
\[ i_e = 0 \]

If flux connections are written for this energizing status again, it is written as;
\[ \lambda_b = \left( \frac{L_b^2(\theta)}{L_a(\theta)+L_b(\theta)+L_c(\theta)+L_d(\theta)+L_e(\theta)} \right) + \frac{L_c^2(\theta)}{L_a(\theta)+L_b(\theta)+L_c(\theta)+L_d(\theta)+L_e(\theta)} i_b \]  \hspace{1cm} (18)

\[ \lambda_c = \left( \frac{L_b(\theta)+L_c(\theta)}{L_a(\theta)+L_b(\theta)+L_c(\theta)+L_d(\theta)+L_e(\theta)} - \frac{L_c^2(\theta)}{L_a(\theta)+L_b(\theta)+L_c(\theta)+L_d(\theta)+L_e(\theta)} \right) i_b \]  \hspace{1cm} (19)

Since the value of the flux flowing from A phase to B phase through the airgap is \( \lambda_{ab} = \lambda_a - \lambda_b \), if Equations 19 and 20 are rearranged, the following is obtained;
\[ \lambda_{bc} = \left( \frac{L_b(\theta)+L_c(\theta)}{L_a(\theta)+L_b(\theta)+L_c(\theta)+L_d(\theta)+L_e(\theta)} - \frac{L_b^2(\theta)+L_c^2(\theta)}{2L_a(\theta)L_b(\theta)+L_c(\theta)+L_d(\theta)+L_e(\theta)} \right) i_b \]  \hspace{1cm} (20)

By using the flux expression expressed above, “visible” inductance value called as \( L_{bc} \) can be calculated by using \( L = \lambda/i \) equity. This value is the common inductance equity between; b and c phases;
\[ L_{bc} = L_a(\theta)+L_c(\theta)-\frac{L_b^2(\theta)+L_c^2(\theta)}{2L_a(\theta)L_b(\theta)+L_c(\theta)+L_d(\theta)+L_e(\theta)} \]  \hspace{1cm} (21)

B. Produced Moment Equitity in SARM

Similarly, if it is thought that only B and C phases are energized and \( i_b = -i_c \) status is considered, moment expression takes these values for both phases [6];
\[ T = \frac{1}{2} \left( \frac{dL_{nb}}{d\theta} i_b^2 + \frac{dL_{nc}}{d\theta} i_c^2 \right) + i_b i_c \frac{dM_{bc}}{d\theta} \]  \hspace{1cm} (22)

\[ T_{bc} = \frac{1}{2} \left( \frac{dL_{nb}}{d\theta} i_b^2 + \frac{dL_{nc}}{d\theta} i_c^2 \right) - i_b i_c \frac{dM_{bc}}{d\theta} \]  \hspace{1cm} (23)

If visible inductance that has been given for B and C phases is used;
\[ L_{bc}(\theta) = L_{nb}(\theta) + L_{nc}(\theta) - 2M_{bc}(\theta) \]  \hspace{1cm} (24)

is obtained. Moment value obtained with this equivalent inductance is as follows:
\[ T_{bc} = \frac{1}{2} \left( \frac{dL_{nb}}{d\theta} i_b^2 \right) \]  \hspace{1cm} (25)

\[ T_{bc} = \frac{1}{2} \left( \frac{dL_{nb}}{d\theta} i_b^2 + \frac{dL_{nc}}{d\theta} i_c^2 \right) - i_b i_c \frac{dM_{bc}}{d\theta} \]  \hspace{1cm} (26)

IV. CONCLUSIONS

In this study, by considering the running conditions of five-phase segmental type switched reluctance engine (SARM) and using basic electrical engines model, status equities have been obtained.

Popularizing the engine structure of the complexity of SARM and comprehending its difference compared to classical ARM, visible inductance profiles of the system have been examined. Considering that the phases of new type SARM is run by ideal flow source and the status of the different phases at each moment, inductance values have been calculated. It has been explained that the engine designed through models produces more moment than classical switched reluctance engine having the same phase number.

Phase flows of this new five-phase SARM having a rotor and stimulation structure different from classical ARM and magnetic flux changes in the type of inductances have been found by using magnetic equivalent circuit.

In order to be understood of this difference more clearly, by revealing common inductance profiles and the status of...
different phases at each moment inductance values have been calculated. Finally, moment production of the engine has been obtained by using the inductance equity

Lean Six Sigma Applying to Reduce the Maintenance Time in Power Plants

Muqdad Khaleel*, Nurettin Çetinkaya*

*Electrical & Electronics Engineering Department, Engineering Faculty, Selcuk University, Konya, Turkey
muqdad_hammad@yahoo.com

Abstract— This paper aimed to illustrate the use of the Lean Six Sigma (LSS) methodology in power plants maintenance. LSS has become the indeed method for process performance improvement in many industrial companies and LSS has been gradually increasing its acceptance in electric power generating that confronts challenges, such as, how to decrease maintenance time, increase quality, better use resources etc. Consequently, the quality of any process may be enhanced by utilizing Lean Six Sigma in any climate and it has the potential to offer a useful approach in term of improving quality and reducing costs. Lean Six Sigma is an exclusive method that helps identify possible improvement areas. The study includes the plant maintenance cycle time from request writing to work finished. Improvement opportunities were identified from a high-level value road map. The Define, Measure, Analyses, Improve and Control (DMAIC) approach was applied to a treat the identified opportunities for improvement. The result shows that the maintenance time was reduced from 180 days to 95 days.

Keywords— Lean Six Sigma, maintenance Time, DMAIC, CTQs, DPMO

I. INTRODUCTION

We are sense the huge development of the maintenance programs. It is leading to mend raising power plant reliability and assuring plant capacity by applied the deferent maintenance kinds. The LSS methodology was firstly developed and implemented by Motorola in 1985[1, 2].

Motorola knew that there was a modality of betterment which would be classification to the five phases of problems treatment applied by manufacturers, i.e., DMAIC. DMAIC is the mainly five steps for every maintenance planners of the power plant.

Leant Six Sigma is a controlled, depends on the data methodology used to remove and minify the practices hence the job faults and squandering (time and sources) [3].

To obtain Six Sigma goodness and practices of a job must be no more than 3.4 defect per million opportunities (DPBO). The researchers submit new ways to monitor data and analyse to appear (DPMO). Six Sigma essential offer amount is that rules for maintenance practices improvement, statistical process, alertness in the work, and maintenance management framework central on high-return improvement power plant generation result in persistent improvement and considerable economic earning [4]. When the power plants applied the Six Sigma, it can discover the factors affect on the maintenance in power plant operation, recognize the optimal scale of allowance and betterment chances. In this paper, the DMAIC practices of the Lean Six Sigma was going ahead to obtain goodness and generation improvement in power plants. The studying of LSS and practice it gives us more opportunities to improvement the equipment operation. These opportunities to be noticed for everything for improvement and confirm the requirement for study driving to improvement and placing methodologies that like LSS [5]. Now the question is when deciding the maintenance procedure when the lean six sigma start? And lean six sigma application starts. All the current studies are leading to when power plants want to minimize these equipment's maintenance time and cost, it must apply the lean six sigma methodology. In the lean six sigma methodology waste is a very important factor affect on the maintenance process of improvement equipment operation [6].

II. SIX SIGMA STEPS (DMAIC)

to improve and increase the quality the maintenance practices to obtain a high level of power plant operation, must arrive at the standard specification by using six sigma (Define, Measure, Analyses, Improve, Control) as shown in Fig. 1. These steps are[7, 8]:

1) Define: First of all, the problem should be defined and requirements of the customers need to be identified. This step is set the guesses to development the maintenance requirements and concentrate on the applications of six sigma methodology but not forget the customer demands.

2) Measure: This step is illustrating the errors in maintenance applications and schedules the information to use it to confirm the improvement targets.

3) Analysis: this step is important in every program to minimize the errors, and studying the information collected and put it in tables. And in next period set the targets and planning to reach the wanted level.

4) Improvement: in this step planners confirm the changes in the maintenance practices and measured it's affecting on the equipment quality (CTQ), and find acceptable rules to minimize change errors and measure affecting on (CTQ) to find the best solutions.

5) Control: this is the final step of six sigma applications, in it the planners find the advantages of applied six sigma and schedule the results of the practices.
Today Six Sigma methodology applied widespread in the world such us (engineering, markets, industrial, management). Particularly, the widespread applications of Six Sigma were possible because organizations were able to articulate the benefits of Six Sigma presented.

III. LEAN

Lean is a process improvement methodology, used to deliver products and services better, faster time and at a lower cost. Womack and Jones (1996) defined lean as “a way to specify a value, line up value-creating actions in the best sequence, conduct those activities without interruption whenever someone requests them and perform them more and more effectively. In short, lean thinking is lean because it provides a way to do more and more with less and less—less human effort, less human equipment, less time, and less space—while coming closer and closer to providing customers with exactly what they want”.[9]

IV. LEAN SIX SIGMA

Lean tools focus on improving maintenance flows and standardizing work processes. To improve the flowing maintenance and job operation by concentrate the lean methods. The classics saw to the lean six sigma is depend on decrease the waste and the losses time in the maintenance operation and the spender money in this operation, and finished maintenance work in the set time. The six sigma methodology sight have the measurement to decrease errors in the operation changes and confirm it's in maintenance works quality and spenders. Lean six sigma is represents the strong sets to increase the speed maintenance works and decrease the waste to obtain the better solution of maintenance engineering management [3].

V. CASE STUDY

In this paper, we will apply the lean six sigma methodology to decrease the maintenance request time. Our work executed in Baiji thermal power plant in Iraq through practice lean six sigma steps from taking the maintenance requests during one year (2012) and the requests rate about 180 day. The purpose of maintenance requests in the power stations is too useful to confirm the maintenance efficiency and productivity. Essentially the request helps maintenance technical to obtain vital power plant data and set every equipment work. The request avoids an incompatible utilization of oral statement. The principles of request system aimed to make a regular shape for data collected and work to equipment rehabilitation.

For this work, we suggest integrated methodology of lean six sigma. In first we must put the road map for this study to define the opportunities amendment and progressing it to the maximum level. And we must fix all the changes in the road map without pay attention to defects type. Six sigma methodologies must apply in this process on these chances. Six sigma methodologies is a strategic way to keep the maintenance on the right road. In this paper, we can use lean six sigma methodology practice or one of them depending on the errors type[10].

VI. DMAIC STEPS

1) Step 1: Define. The critical execution variables of request cycle time were defined. Furthermore, it was determined implementation of every related specification related to all the reasons and confirmed. This means that criticizes the quality of the properties (CTA) of the agreed it was well known as well as the expected performance of their point of view. We are all the reasons we have identified through the process of mapping and data collection that we had more than tripled sessions. Each “bone” appears a group's effect on the troubles, parallel expectations. And to go too far to find the root cause we have implemented a statistical control process parallel to expect. As illustrated in Fig. 2 [5, 6].

We find the major reason of troubles. We showing in the figure the mechanical process (rehabilitation, soldering, water treatment, lubrication and planners state) a huge difference. Then we continued studying each variable by statistical and supposition tools.

![Pareto chart of maintainance days](image-url)
2) Step 2: Measure. Each CTQ’s of measurable enable us to confirm work basis. In this step, to confirm the maintenance requirements we must collect the information around the happened process in the maintenance wait and anticipation and ultimately valiantly the measurement by using modern technical to measure and detect the errors such as Pareto chart.

3) Step 3: Analyze. The concentrate in an analysis for the practice holes in every procedure in CTQs, the intention in this steps dividing the defects to "do it, not do it ". We seek for the style of lean behavior also the style of best behavior in power plant maintenance. Such must in this style the hard work continued on effort confirm and navigable. As well, we take all the input and output variation between the input and output of CTQs. moreover, we tighten to concentrate to some subjects and find an appropriate mechanism for data analysis. Also, we found the different reasons of the troubles. When using the method of statistical analysis at this stage, depending on the type of items will wait a few days.

4) Step 4: Improve. If we wish to examine closely a strong improvement in the process must underestimate the ability gaps in CTQ steps. Also, we support every supposition of cause root to the errors and confirm the substitution solutions and in a parallel way obtain the better solution. Work on these securities began based on the data obtained in 2012.

The recommendations, as described below:

- Resettlement the planners and managers offices to maintenance location in power plants.
- Identify the people responsible for managing the stores that contain maintenance materials.
- Give adequate space for planners to management raw Material.
- Writing a periodic report to the requests of maintenance in order to be classified.
- Prevent acts of direct equipment maintenance without a request order.
- Continuous work development courses for planners to work in order to stay within the set in plans.
- Emergency notices that are written by the operations shift leader.

5) Step 5: Control. We desire to control the better setting of each better solution. The behaviors of all the CTQs able do steady over time to a normal nonrandom low point in maintenance troubles concentrating. Furthermore, we have to assure the reformative process are taken and moving the control of the hot process to the maintenance holder. We are also in parallel using special techniques to maintain the performance of maintenance and monitoring work, this is done by scheduling maintenance requests that require more than 3 months in key process indicator (KPI) and submit them to the maintenance manager. Furthermore, for the next study the reformative process are scheduled. It is controlled maintenance works and monitor the progress of work by the maintenance departments chiefs and submit periodic reports on the progress of business to the maintenance head manager in the power plant.

VII. RESULTS

These papers focus on the major faults in the mechanical, electrical and other taking into account the resulting acts of disparate maintenance process to get the desired results of the right request planning procedure. This work and collect data started in 2012; after 6 months showed signs of success by %50 as we see in Fig. 3. As in Fig. 3, we were able to reduce the average time required for maintenance from 180 days to 105! Furthermore, we have improved the response to urgent requests for maintenance at the station and overcome the difficulties related in terms of adjusted a time for maintenance, as it is shown in fig 4. Follow-up development and success of our work to develop a system to identify actions that need further scientific studies.

VIII. CONCLUSION

Lean Six Sigma is not an enchantment solution that you can use for quick success. It is a methodology, which has to be slowly integrated into the culture of the organization. It can be applied to any process and we as Maintenance Plants need to make the best out of this methodology.

Abstract—In this study, permanent magnet axial-flux coreless synchronous generator is designed as single stators and double rotors and its electromagnetic and structural characteristics are analyzed. Core is not used in the stator of the machine intended to be designed. Aim of this study is to provide reduction of iron loss. Moreover, easiness in the production stage of the machine is provided. Three-dimensioned electromagnetic analysis of the designed machine has been done through finite element method and transient solutions are suggested based on this. Within this study, arrangements have been made depending on certain standards in order that permanent magnets and coils obtain direct alternating current. The designed new axial-flux generator move as permanent speed of 500 rpm and so maximum voltage of approximately 100 V per phase is obtained. Furthermore, this machine does not need a gear system due to its design structure.

Keywords—Axial-flux generator, Permanent magnet, Generator, Single stator, Double rotor

I. INTRODUCTION

Electrical machines have started to be used almost within all areas nowadays. Every passing day, new studies take place in literature. New models are developed in these studies done. Within these developed models, increases in power density of the machine, change in the shape of design as well as size reductions and studies done depending on excitation types have gained speed. Studies have centred on axial-flux permanent magnet machines as different excitation types recently. Permanent magnet axial machines have been aimed to be analyzed due to reasons such as being highly efficient and economic and having ability to produce energy at low cost [1]. Micro wind turbine application has been conducted in a study by Pop et al. Here it has been found that after a comparison of axial and radial-flux permanent magnet generator, axial-flux permanent magnet has shown the best result. It has been discovered that axial-flux generator is less costly [2]. Reducing no-load momentum of the generator has been possible using skewed magnets in axial-flux permanent magnet [3]. It is a huge advantage that axial flux permanent magnet generator (AFPMG) has high efficiency, compact size and light weight compared to other applications. Main purpose of this type of machine design is to obtain the best of output power [4]. Furthermore, axial-flux permanent magnet generator with coreless stator is considered as machines having high power density for energy-generating systems [5].

What has been aimed to reveal within this study is that iron losses have reduced using coreless stator. Moreover, the machine has been made lighter. As core has not been used in the stator windings of the designed machine with coreless stator, stator iron losses have been eliminated completely. As there has not been use of the core in the stator, stator windings will not be influenced by core warm-ups. As the surfaces of the windings are in contact with air, it will be able to take the heat on the surface out more quickly. As the core is not used for the stator windings in this type of axial machine, production difficulty to arise from applications in such type of machines has been reduced. Though copper losses have increased here as the core has not been used in the stator, this newly designed machine provides production convenience. This design can be used to obtain alternating current without need for gear system during wind turbine applications. Besides, it is intended to be used in electric vehicles both as in-wheel motor and generator. Finite element method has been used for analysis in this study. Finite element method is a numerical method used in solving linear and nonlinear partial differential equation [6]. Design features of the designed machine have been given within the second chapter. The third chapter consists of electromagnetic analysis results of the machine. Consequences related to simulation depending on time have been given within the fourth chapter. The final chapter includes the conclusion.

II. THE DESIGN FEATURES OF THE MACHINE

Main purpose of the machine design is to obtain the best of output power. Estimated value of the output power belonging to the designed machine can be calculated using the equality below;
In order that output power of the machine reaches maximum, rate between its dimensions should be as in \( k_d = \frac{1}{\sqrt{3}} \) [7]. Statement related to the relationship between the dimension and power in axial flux permanent magnet synchronous generator has been given within equality 1 [8]. The \( k_p \) here is electric wave form factor and calculated as 0.5 in sinusoidal designs where \( k_i \) is current wave form and calculated as \( \sqrt{2} \) for sinusoidal wave forms [9]. \( B_g \) refers to maximum flux density within the air gap. \( P \) refers to dipole number and \( f \) refers to the frequency. \( D_o \) and \( D_i \) refers to inner and outer diameter respectively where \( R_d \) refers to the ratio of the inner diameter to the outer diameter. The designed axial-flux coreless permanent magnet synchronous generator is given in Figure 1. There are one coreless stators and two rotors within this design.

There exist two rotor discs in Figure 1. 12 permanent magnets have been placed into the single end of the lower and upper rotor discs. The stator winding has been placed between two rotor discs. The stator winding consists of 9 coils in total. Each phase in windings corresponds to three coils.

Rotor steel used for the machine has been made up of M19. There are 12 magnets in rotor steel. Magnets placed upon the rotors have been placed between each other with 30 degrees each. Do and Di values are 145 mm and 85 mm.

Geometric structure of the magnets is as shown in Figure 3. These types of designed magnets are more advantageous to prevent the heat and more suitable to obtain a straight sinusoidal wave. Permanent magnet used in axial flux permanent generator is Neodymium. Length of the neodymium magnet is 50mm and its thickness is 8mm. Representation of flux paths of the magnets have been given in Figure 4.
Generator stator designed within this study has a coreless structure. For the rotor core, steel which is of M-19 class and frequently used in electric machines. The steel used for core is not a linear material. While making solution, the analysis program applied makes solution using B-H curve. B-H curve of M19 steel is shown in Figure 5.

![Fig. 5 B-H curve of M19 core material.](image)

24 trapezoidal permanent magnets (NdFeB) and 9 coreless coils in total have been used in the machine shown in Figure 1. 12 magnets have been placed into the single end of the two rotors for each. There an air gap of 1mm between the magnets placed upon the stator and rotor. Average magnetic flux density is approximately 0.68 Tesla. As a consequence of all these parameters, power estimated according to equality 1 is approximately 770 W.

### III. ELECTROMAGNETIC PROPERTIES OF THE MACHINE

Distribution of magnetic flux density for 3D model is given in Figure 6. Flux density values formed around the magnet have been given. Flux density in windings and steels has been measured as 0.8-0.9 Tesla.

![Fig. 6 Distribution of magnetic flux density for axial flux permanent magnet generator.](image)

Direction of the flux path within the arrangement of the magnets is shown in Figure 7. Arrangements of the permanent magnets here are in the form of N-S-N-S and S-N-S-N. Accordingly, while flux path of the dual magnet group on z plane is mostly up, flux path of the permanent magnet group both at its right and left is the opposite. For a clearer appearance of the flux path, it had been shown in Figure 5 without steel and permanent stator.

![Fig. 7 Appearance of magnetic flux path for axial flux permanent magnet generator.](image)

### IV. THE SIMULATION RESULTS FOR THE MACHINE

Current and voltage values according to the simulation results of the new designed machine have been given below. They have been given according to the angular velocity at 500 rpm of the machine.
Within the Fig. above, coils belonging to each phase and their relationships with each other have been given. There are three coils per phase for each stator winding here. 3 coils in total have been used for each phase. Resistance has been determined as 1.72 ohm in total for one phase of stator. The permanent magnets used are trapezoidal, phase voltage and current wave form to be obtained time-dependently have been demonstrated in Figure 10, 11 respectively.

![Fig. 10 Voltage value for A-B-C phase of axial-flux permanent magnet generator.](image)

![Fig. 11. Current value for A-B-C phase of axial-flux permanent magnet generator](image)

It is observed that within the simulations results the output signal is in the form of alternating current. One of the advantages of the new designed machine is that generated wave form is at quite a good level. Data to be obtained at speed of 500 rpm, roughly 100V voltage and roughly 5A current are in Figure 10, 11 respectively.

V. CONCLUSION

Aim of this study is to analyze the structurally different and alternating-current generating axial-flux coreless permanent magnet synchronous generator design through the finite element method and to present its performance. Application of axial-flux coreless permanent magnet synchronous generator with two rotors and single stators has been given. Within this study, due to the form of design there will be much convenience in production. Though the designed machine is coreless, a high power density has been obtained. That the output wave forms are close to sinusoidal reveals that design data related to the machine have been properly chosen. 9 coils and 24 magnets have been used in the machine and according to the simulation results at 500 rpm, the machine generates approximately 750 W power. The designed generator within this study offers a solution for both in-wheel motor-generator in electric vehicles and wind power applications.

Abstract—This study presents the structure of the Direct Digital Frequency Synthesizers (DDFSs) which have several advantages compared to conventional synthesizers such as high frequency, fast switching speed and low power dissipations. In order to lessen the physical area and power dissipation, ROM compression techniques are applied in designs. Bipartite Table Method (BTM) and Multipartite Table Method (MTM) are utilized in this study because of the fact that they provide high compression rates. By using MTM, the compression rates of 157.54:1, 726.71:1 and 3463.29:1 are obtained at 58.40 dB, 75.30 dB and 84.66 dB SFDR levels, respectively.

Keywords—DDFS, CORDIC, MTM, BTM.

I. INTRODUCTION

Direct Digital Frequency Synthesis is one of the most popular techniques to synthesize frequency for the systems requiring specific frequencies, fast switching, low power dissipation and small silicon area. There are several methods using table based or iterative approaches to implement Direct Digital Frequency Synthesizers (DDFSs). In addition to natural advantages of the approaches, ROM compression techniques are applied to reduce the ROM size. Furthermore, the approaches are enhanced with some modifications offering trade-off between Spurious Free Dynamic Range (SFDR), switching speed and the used silicon area.

Direct Digital Frequency Synthesizers (DDFSs) are commonly used in several areas such as defense industry, satellite systems, radars, test and measuring equipments, etc. As distinct from analog or indirect synthesizers, DDFSs provide high frequency resolution, fast switching speed, continuous phase switching, small physical area and low power dissipation [1]. For the last 10 years, works on the frequency synthesizers are focused on minimizing the used area and power dissipation while keeping the spectral purity above an acceptable level [2], [3] and [4]. High frequency synthesizers are also studied with some recently offered approaches [5], [6] and [7].

A DDFS consists of three sub blocks which are phase accumulator, phase to amplitude converter and the digital to analog converter. Fig. 1 illustrates the principle parts of a DDFS.

Fig. 1 Principal parts of DDFS

A. Phase Accumulator

Phase accumulator is used in DDFS for an adjustable frequency output. It is controlled by an N bit Frequency Tuning Word (FTW). Several frequencies can be obtained by using this digital control word with one clock source.

Phase accumulator works as an N bit counter and a digital phase wheel is created. Each of the $2^N$ points on this wheel correspond the amplitude value of the related phase. The increment of the counter is determined by the FTW. Fig. 2 illustrates the digital phase wheel idea.

Fig. 2 Digital Phase Wheel [1]

The frequency of the output signal is

$$f_{out} = FTW \times \frac{f_{ref}}{2^N} \quad (1.1)$$

The frequency of the output signal is
B. Phase to Amplitude Converter (PAC)

There are two main approaches for phase to amplitude conversion in a DDFS. The corresponding amplitude value of the related phase can be obtained by using Look Up Tables (LUTs) or iterative calculations. While table based methods allow operating at higher frequencies, iterative methods provide better spectral purity. Many studies have done about both methods for the last decade [2, 9], [11] and [12]. The works about table based methods have generally aimed to reduce the ROM size and to increase the Spurious Free Dynamic Range (SFDR) which shows the spectral purity of the generated sinusoid. On the other hand, COnordinate Rotational Digital Computer (CORDIC) based iterative methods have been proposed to achieve better SFDR levels.

C. Digital to Analog Converter (DAC)

DACs are used to convert the digital data taken from the PACs to analog signals. DAC part is one of the most important parts of the DDFS and directly related to its performance.

The resolution and sampling frequency of DAC are able to determine the limits of DDFS. While delta-sigma and R-2R type DACs are beneficial when high resolution is required, current steering type DACs have sampling rates up to GSPSs with comparatively lower resolution. The lower resolution comes with higher quantizing errors and this cause a decrement in SFDR but oversampling may lessen the decrement a little. Addition to all these, the AC and DC characteristics of the DAC are also important and need to be considered at the implementation stage [8].

II. METHODS

A. CORDIC Based DDFSs

CORDIC is a structure that was proposed by Volder to calculate basic trigonometric functions in 1959 [10]. In CORDIC based algorithms, two-dimension vector rotation idea is used. The vector rotation idea is shown in Fig. 3, and the related trigonometric equations are

\[ x_0 = x_1 \cos \theta - y_1 \sin \theta \]  
\[ y_0 = x_1 \sin \theta + y_1 \cos \theta \]  
\[ \frac{x_0}{y_0} = G [\tan \theta \frac{1}{1}] \frac{x_i}{y_i} \]  

As mentioned earlier, CORDIC is applied as an iterative method to calculate some trigonometric functions. Angle (\( \theta \)) of rotation is completed after \( T \) sub rotations and evaluated as in Eq. (2.4) where \( \delta_i \) is the direction of the rotation.

\[ \theta = \delta_0 \theta_0 + \delta_1 \theta_1 + \cdots + \delta_t \theta_t \]  
\[ \delta_k \epsilon \{-1,0,1\} \]  

\[ \tan \theta \] is chosen as multiple of \( 2^{-1} \) so that (2.3) is easily applied digitally. The equation can be rearranged as

\[ x_{i+1} = x_i - y_i \delta_i 2^{-i} \]  
\[ y_{i+1} = y_i - x_i \delta_i 2^{-i} \]

The gain constant is generally applied as the initial end point. \( P(G, 0) \) is used instead of \( P(0, 0) \) as the initial end point of the vector where \( G = \prod_{i=1}^{T} \frac{1}{\sqrt{1+2^{-i}}} \) [11].

B. Table Based DDFSs

Table based methods originally have a simpler idea. ROMs/RAMs are used as LUTs. Phase accumulator is utilized as the address counter of the ROMs.

The ROM size determines the resolution of the DDFS. The bigger the ROM size is, the better the resolution is. This was the bottleneck of the traditional table based methods. The bigger ROM size causes much more power dissipation and needs more physical area. ROM compression techniques have been enhanced to overcome this problem. Quadrant compression, Sunderland and Hutchinson methods, Bipartite Table Method (BTM) and Multipartite Table Method (MTM) are some of the most common ROM compression techniques.

Quadrant compression technique uses the symmetric structure of the sinusoid. Instead of a LUT that stores the sine values between \( 0 \) and \( 2\pi \), a LUT that stores the sine values between \( 0 \) and \( \pi/2 \) is used. The most significant two bits of the \( P \) bit phase word determine the quadrant of the phase wheel and the rest include the phase information. The block diagram of the technique is given in Fig. 4.

BTM was proposed by Dinechin and Tisserand in 2005 [4]. The technique depends on partial piecewise linear approach. The \( x \) axis is divided into \( 2^n \) equal pieces and \( f(x) \) is
interpolated separately for each. The equations of the slope and approximated $f(x)$ are

$$m_i = \frac{f(x_{i+1}) - f(x_i)}{x_{i+1} - x_i} \quad (2.7)$$

$$f_{app}(x) = y_i + m_i(x - x_i) \quad (2.8)$$

As distinct from the piecewise linear approach, $x$ axis is divided into $2^b$ larger intervals ($b < a$) and same slope value used for the adjacent pieces in larger intervals. Thus, the ROM size is efficiently decreased. Fig. 5 shows the piecewise linear approach used in BTM.

![Fig. 5 Bipartite Table Method (BTM) [4]](image)

In BTM, there are two tables to store the values required for the interpolation. The $y_i$ values are stored in Table of Initial Values (TIV) with $a$ bits and Table of Offsets (TO) stores information for $m_i$ and $(x - x_i)$ part of Eq. (2.8) with $\beta$ and $\gamma$ bits separately. The ROM is addressed by $2^a + 2^{\beta + \gamma}$ bits [9].

The linearity of $m_i \times (x - x_i)$ provides opportunity to make the ROM size smaller. By using this linearity property (2.10), it can be beneficial to use more than one TO for some SFDR levels. When the number of TOs is more than one, the technique is called Multipartite Table Method (MTM).

$$m_i \times (x - x_i) = m_i x_1 + m_i x_2 + \cdots + m_i x_k \quad (2.9)$$

The study of De Caro and his friends shows that the number of TOs is not proportional to SFDR. The study also indicates that SFDR of the DDFS strongly depends on $x, y, z$ numbers. From the point of this view, it is obvious that an optimization is essential to get best results. If the number of TOs is more than two then the optimization requires more complex algorithms and calculations. Moreover, the higher number of TOs does not ensure smaller physical area in compression with two or three TOs for the SFDR levels less than 90 dBc [9]. Thus, this paper is focused on the table based methods with one or two TOs.

### III. MATLAB RESULTS

There are three main objectives while designing a DDFS. These are maximizing the SFDR, minimizing the ROM size and increasing the maximum operating frequency as much as possible. In this paper, the SFDR and ROM size considerations are investigated.

#### A. BTM Design

As mentioned earlier, BTM uses two different tables to store the sine amplitude information. While one of them is for initial values, the other one is for the offset values. The size of TIV is calculated as

$$TIV_{size} = R \times 2^a \quad (3.1)$$

where $R$ is the amplitude resolution and $a$ is the number of bits that represents $TIV$ values. TO values are represented with $\beta + \gamma$ bits and the size is calculated as

$$TO_{size} = (R - a) \times 2^{\beta + \gamma - 1} \quad (3.2)$$

The sum of $TO_{size}$ and $TIV_{size}$ gives the total ROM size. The compression ratio is evaluated as

$$compression \ rate = \frac{R \times (a + \beta + \gamma)}{TIV_{size} + TO_{size}} \quad (3.3)$$

The $P$ phase information taken from the accumulator includes $\alpha$ and $\gamma$ bits. The ROM size depends on these bits with some $\beta$ bits in $\alpha$ bits. Fig. 6 shows the decomposition of the phase word.

![Fig. 6 Phase Word Decomposition in BTM Design](image)

This paper is focused on the table based methods with one or two TOs.
The BTM design results are given in Table I and allow two significant deductions. Firstly, it is obvious that increasing the length of the phase word does not improve the SFDR and it makes the ROM size bigger. So, determining the best decomposition of the phase word has a great importance. Secondly, increasing the amplitude resolution provides better SFDR but causes a notable increment in the ROM size.

**B. MTM Design**

MTM is originally based on BTM and requires smaller ROM size comparing to it with a negligible decrease in SFDR. It is generally preferred when higher SFDR is required because BTM provides the same SFDR with a very high ROM size. In this part of the paper, some MTM design results are investigated and are compared with BTM.

The TIV size calculation in MTM is similar to BTM. Using more than one TO makes the difference in total ROM size. The phase word decomposition is given in Fig. 7 where $\theta_i = \beta_i + \gamma_i$.

![Fig. 7 Phase Word Decomposition in MTM Design](image)

**Total ROM size in MTM is calculated as**

$$Total\_size = TIV\_size + \sum_i^n TO_{i\_size}$$ \hspace{1cm} (3.4)

where $n$ is the number of TOs and (3.5) is used to evaluate $TO_{i\_size}$.

$$TO_i = [(R - \sum_{k=0}^{i-1} \gamma_k) \times 2^{\beta_{i+1}+\gamma_{i+1}} - 1]$$ \hspace{1cm} (3.5)

The phase word length and the amplitude resolution determine SFDR and ROM size. Some design results are given in Table II. As clearly seen from the table it is possible to reach better SFDR by just rearranging the decomposition of the phase word. The results indicate that minimizing a value allows making total ROM size smaller. It is also clear that increasing $P$ and $R$ values causes a remarkable rise in SFDR.

While closer $\alpha$, $\beta_1$ and $\beta_{i+1}$ values provide the best compression, it is more complicated to offer any condition for the best SFDR. Although there are some algorithms proposed to find out the best decomposition of the phase word for a specific SFDR level, there is not any multi-objective algorithm to optimize both the SFDR and the ROM size. In this paper, any algorithm is not used and the results given in tables show the effect of the parameters.

**Table III shows some design results with different $P$ and $R$ values at SFDR levels around 57, 75 and 84 dB. It demonstrates that increasing the number of TOs is more beneficial at higher SFDR levels. Although the table shows that increasing the number of TOs in all SFDR levels gives better results in ROM size, it is not practical. De Caro and his friends show that the more TO is the better ROM compression ratio but not the smaller required area for DDFS. Table III also indicates that it is not possible to get a remarkable increase in SFDR without increasing $P$ and $R$ values.**

**IV. CONCLUSIONS**

The DDFS structure has been investigated in this study. The phase accumulator, phase to amplitude converter and digital to analog converter blocks of the structure has been mentioned in section I. Later on, CORDIC, BTM and MTM
based DDFS have been explained in section II. In section III, table based methods have been focused and some MATLAB design results have been interpreted. BTM designs are revealed with two different $R$ values. $59.26$ dB SFDR level is achieved with $R=8$ and $272$ bits ROM size. Increasing the resolution to $11$ bits, $81.98$ dB SFDR level is reached with $1056$ bits. $157.54:1$, $726.71:1$ and $3463.29:1$ compression rates are obtained at $58.40$ dB, $75.30$ dB and $84.66$ dB SFDR levels respectively by increasing the number of TOs.

The main problem of the table based methods is that they need much more physical area. When advanced ROM compression techniques such as MTM are applied to minimize the area, a complex optimization algorithm is required at higher SFDR levels. There are some beneficial optimization techniques such as MTM are applied to minimize the area, a complex optimization algorithm is required at higher SFDR levels. There are some beneficial optimization techniques such as MTM are applied to minimize the area, a complex optimization algorithm is required at higher SFDR levels but multi-objective optimization techniques may be considered as a future work to optimize the sampling frequency, ROM size and SFDR.

Abstract— All electrically powered devices cause electromagnetic wave exposure on human body and we use them nearly every moment in a day. Mobile phones, computers, televisions, hair dryers, lighting systems, etc. they all use electricity and naturally radiate electromagnetic waves. Effects of electromagnetic waves are not clear but international organizations define limit values depending on epidemiological studies in this field. In this study we measure high frequency electromagnetic waves in city center of Mus. Measurements are made at mobile phone frequencies and results compared with limit values. All measurement techniques and limit values are appropriate with Information and Communication Technologies Authority (ICTA) standards. Measurement points are selected according to population density in city center.

Keywords— Include at least 5 keywords or phrases

I. INTRODUCTION

Electromagnetic waves were created by motion of electric charges. They have two main component; electric field and magnetic field. Electric field values are generally shown in volt per meter unit and magnetic field values generally shown in Tesla unit.[1]

Communication systems often use electromagnetic waves for data transfer. Each frequency band of electromagnetic spectrum has its own specification and characteristic.[2]

As it shown in Fig. 1 communication systems use radio-frequency band of electromagnetic spectrum. Their frequency is less than 300 GHz. Mobile phones, satellites, radar systems, wireless modems, TV and radio broadcasts use radio-frequency band of electromagnetic spectrum. [3]

Fig. 1 Electromagnetic Spectrum[7]
All electrically powered devices radiate electromagnetic waves. Additionally, some communication devices use electromagnetic waves for their purpose and increases electromagnetic waves they were radiated.

World Health Organization (WHO) researches effects of electromagnetic waves in last three decades. There are a lot of studies about health effect of electromagnetic waves. But most of them could not show health effect of electromagnetic waves clearly. International Commission on Non-Ionizing Radiation Protection (ICNIRP) determines limit values for non-ionizing electromagnetic waves. In Table I, ICNIRP limit values are shown.[4-5]

In Table I, f values indicates frequency values. Limit values of electric field for mobile phone frequencies are more than 40 volts per meter. In Turkey this value is 9.15 volts per meter, so Turkey applies more than four times lowered limit values on non-ionizing radiation protection.[4]

II. MATERIALS AND METHODS

In this paper we measured electric field of mobile phone frequencies (GSM900, GSM1800, UMTS, LTE) in city center of Mus. Measurements are made in main streets of the city. With GPS data we showed measurement results on the map.

A. Measurement Device and Probe

We used Wavecontrol SMP2 electromagnetic radiation measurement device. Device specifications are shown below:

1) **1 Hz to 18 GHz Broadband Measurements**: With RMS and Field probes can measure up to 18 GHz.
2) **Spectrum Analysis**: With a specific probe, spectrum analysis 1 Hz to 400 kHz.
3) **Weighted Peak Method (WPM)**: Real time comparison in percentage with selected limits.
4) **Assessments According to European Directive 2013/35/EU**: In accordance with international standards such as ICNIRP, IEC, EN, IEEE, etc.
5) **GPS Support**: GPS module integrated in the instrument.
6) **Connection Options**: USB and Fibre Optic connection supported by a PC software.

As measurement probe we used WPT mobile frequency probe. This probe measures only total electric field value of 2G, 3G and 4G frequencies. Measurement device and probe are shown in Fig. 2.

B. Measurement Mode and Standards

Measurements are made in mobile measurement type. Measurement device was put on a car and while car was travelling 30 km/h fixed speed, device measured electric field of the medium. Measurement instances are taken in every 5 seconds.

Measurement results were shown on a map according to GPS data and field strength.

III. MEASUREMENT RESULTS

According to measurement results;
- Maximum measurement value is 5.85 V/m and measured in middle of the Ataturk Boulevard.
- Average measurement value is 1.098 V/m during the whole measurement
- Comparison of electric field strength values in main streets from the highest to the lowest: Ataturk Boulevard, Istasyon Street and Cumhuriyet Street.

Measurement results are shown in Fig. 3. Green points show 0-2 V/m electric field strength value. Yellow points show 0-2 V/m electric field strength value.
show 2-4 V/m electric field strength value and Red points show 4-6 V/m electric field strength value.

**Fig. 3** Electric Field Strength Measurement Results in Mus City Center

**IV. CONCLUSIONS**

All measurement values are under the limit values of International Commission on Non-Ionizing Radiation Protection (ICNIRP) and Information and Communication Technologies Authority (ICTA) but some epidemiological shows that electric field values we measured could be dangerous for human being, especially for the children. In countries like Italy and Switzerland limit values for mobile frequencies in some regions are 2 V/m. Especially red points in the map can be dangerous for livings.[6]

Lowering output power of some base stations or moving base stations to less dangerous places in the city center can be a solution for high electric field values.

Simulink Model for Piece Wise Linear Approximation of Memristor

Ahmet Solak*, Saadetdin Herdem*
*Department of Electrical Electronics Engineering, Selcuk University
Konya, Turkey

ahmetsolak@selcuk.edu.tr
sherdem@selcuk.edu.tr

Abstract— Memristor is a passive circuit element which firstly presented to science world by Leon Chua in 1971. Chua showed a missing link among four fundamental circuit variables which generate basic passive circuit elements. Chua described this missing link between charge and flux, named it as memristor. Memristor is firstly realized by Stanley Williams and his team from HP (Hewlett Packard) research laboratories in 2006. In this study, doped and undoped TiO$_2$ are sandwiched between two Pt layers in nano scale. And this element demonstrated voltage-current characteristic like memristor. Physically implementation of memristor is announced with a paper to science world in 2008. The studies about memristor have quite increased along with this study. In this paper, a new PWL (Piece Wise Linear) memristor model is obtained thereby linearizing current-voltage characteristic of memristor. The equivalent circuit is derived from this model, built in Simulink and results are observed. The results are compared with other studies in literature and obtained results have been shared.

Keywords— Control Equations, Equivalent Circuit, Memristor, PWL Model, Simulink Model

I. INTRODUCTION

Memristor is a semiconductor passive circuit element which is firstly proposed to science world by nonlinear circuit theorist Leon Chua in 1971 [1]. Fundamental passive circuit elements defined by four fundamental circuit variables: voltage, current, charge and flux. For instance; resistor is derived from relationship between voltage and current, capacitor is derived from relationship between voltage and charge and inductor is derived from relationship between current and flux. Chua noticed that there is a missing link between charge and flux. And defined this missing link as “$M = \frac{d\phi}{dq}$” and named it “memristor”. Passive circuit elements and definitions of these elements from fundamental circuit variables are shown in Fig.1.

As the name memristor consists of a combination of the words memory and resistor. Theoretically, this element will protect last electrical quantities such as voltage or current even if energy cuts off on it. Therefore, memristor shows memory characteristic. Memristor also has resistor characteristic due to its definition equation which shown in (1). When this equation derived from type of voltage and current, equation (2) is obtained. This equation is a kind of charge dependent resistor like Ohm’s Law. Memristor characterized by “memristance” as shown (1) and has electrical unit “ohm”.

$$M(q) = \frac{d\phi}{dq} \quad (1)$$

$$M(q(t)) = \frac{V(t)}{i(t)} \quad (2)$$

Voltage-current (V-I) characteristic of memristor has a hysteresis curve. In this characteristic, memristance value of memristor changes between high and low resistance values according to applied
voltage. I-V characteristic of memristor is shown in Fig.2. Memristor is also a frequency dependent circuit element which was mentioned before in Chua’s paper [2]. And Chua gave frequency dependent I-V characteristic of memristor in this paper which is shown in Fig.3. According to this figure, when applied frequency is increased, hysteresis curve of characteristic narrows. And when frequency goes to infinity, I-V characteristic becomes linear as resistor characteristic.

In 2008, 37 years after the definition of memristor, Stanley Williams and his team from HP (Hewlett-Packard) announced that the memristor is physically implemented [3]. The team used TiO$_2$ which is a semiconductor material in this study. Pure TiO$_2$ has high resistance and doped TiO$_2$ with oxygen vacancies has lower resistance. These two kinds of TiO$_2$ sandwiched between two Pt layers and so element is obtained. Fig.4 shows HP memristor model. In this model, there is a thin film between pure and doped sides. Position of this film changes depending on energy flows from where. When energy flows from doped side to pure side, memristance value decreases. Otherwise, when energy flows from pure side to doped side, memristance value increases. These changes consist of depending on ion mobility. So, HP memristor model also called as linear ion drift model.

After physically implementation of memristor, interest in memristor is increased dramatically. Studies about memristor have been accelerated by modelling memristor and using these models in various circuits [4]-[12]. Modelling of the memristor could also be a milestone for applications that cannot be done before because of the lack of available circuit elements and for new circuit applications which previously unthinkable but could be considered with existence of memristor.

In this paper, one of the memristor model PWL (Piece Wise Linear) memristor model design will be made using the model in Simulink. I-V characteristic and M-V characteristic of proposed memristor model will be shared. And also these results will be compared with other studies which described in literature. Suggestions and new future studies about memristor and proposed model will be written in conclusion part.
II. METHODOLOGY

A. PWL (Piece Wise Linear) Memristor Model

Linear ion drift model [3], nonlinear ion drift model [4], [5] and Simmons tunnel barrier model [4], [5] are memristor models which are in nano size. PWL model is different from them is a model which depend on I-V characteristic of memristor [12]. The goal of this model, linearization of I-V characteristic of memristor and so obtain new equivalent circuit models for memristor and using this circuit models in memristor based circuit applications and future circuit applications. PWL memristor model is shown in Fig.5.

![Fig.5 PWL memristor model](image)

B. Proposed PWL (Piece Wise Linear) Memristor Model

In this paper, a different PWL memristor model is proposed. Current-voltage characteristic and memristor-voltage characteristic of the proposed model are compared with existing publications in the literature. Proposed PWL memristor model is shown in Fig.6.

![Fig.6 Proposed memristor model in simulink](image)

In Fig.6, memristor model consists of signal generator block, derivative block, embedded matlab function block, to workspace blocks and scopes. Generator block generates sinus signal which has \(v(t)=3.999\times\sin(2\pi t)\) value. Derivative of signal is taken by derivative block. Commands that consist of control equations for operating model are written in embedded matlab function block. The operation of this block as follows: Generated signal and derivative signal which is generated by derivative block are input parameters of embedded matlab function. Processed signals in this block are obtained as output current and memristance. These current and memristance values are transferred to workspace by “to workspace” block. In workspace, current-voltage and memristance-voltage characteristics are achieved by “plot” command. Also time dependent changes of voltage, derivative of voltage, current and memristance values have been observed by scopes. Fig.6 shows voltage and derivative of voltage graphics. Top graph is voltage versus time, bottom graphic is derivative of voltage versus time. Fig.7 shows current and memristance graphics. Top graph is current versus time; bottom graph is memristance versus time.

![Fig.6 v and dv/dt graphics versus t](image)

![Fig.7 i and m graphics versus t](image)
C. Results and Comparisons

In this section, results of proposed model and comparison of this model with other publications will be given.

Current-voltage characteristic and memristance-voltage characteristic of proposed memristor model is shown in Fig.8 and Fig.9 respectively.

I-V characteristic of proposed memristor model is obtained according to control equations. Written control equations for processing of model are as follows:

\[
\begin{align*}
\text{Region} = \left\{ \\
1. \text{region for } -V_2 \leq v \leq V_2 \text{ and } & \frac{dv}{dt} > 0 \\
2. \text{region for } V_1 \leq v \leq V_2 \text{ and } & \frac{dv}{dt} < 0 \\
3. \text{region for } -V_1 \leq v \leq V_1 \text{ and } & \frac{dv}{dt} < 0 \\
4. \text{region for } -V_2 \leq v \leq -V_1 \text{ and } & \frac{dv}{dt} < 0 
\end{align*}
\]

I-V and M-V characteristics of proposed model are compared with other publications [13], [14]. Vourkas& Sirakoulis and Joglekar& Wolf models are based on HP memristor model. Proposed model is based on PWL memristor model so there is a difference between these characteristic because of that. Proposed model has linear characteristics but other models have nonlinear characteristics. The outlines of characteristics are same without this difference. Comparison of I-V and M-V characteristics are shown in Fig.10 and Fig.11 respectively. In Fig.10; red line represents Vourkas& Sirakoulis model, green line represents Joglekar& Wolf model and cyan line represents proposed model. In Fig.11; green line represents Vourkas& Sirakoulis model, red line represents Joglekar& Wolf model and cyan line represents proposed model.

This study is also an improved version of our previous study [15]. The results of previous study and these results are compatible. Also the results of this study are more compatible to Vourkas & Sirakoulis and Joglekar & Wolf models. Previous study had a gap between first and last values of both characteristics but in this study the gap is vanished. And so this model provides more suitable results.

III. CONCLUSION

In this paper, a new PWL memristor model is proposed. I-V and M-V characteristic of this model are obtained and compared with other publications [13]-[15]. The results of proposed model are better than results of [15]. This model will be used different circuit applications for future studies.

Abstract—In this paper, Autoregressive with exogenous input (ARX) and dynamic neural network (DNN) based generalized predictive control (GPC) methods are designed to control of nonlinear systems. ARX and DNN models adaptively approximate the plant dynamics and predict the future behavior of the nonlinear system. While control process goes on, the poles of the ARX and DNN models are constrained in a stable region using a projection operator for structural stability. Simulation results are given to compare the tracking performances of the methods. ARX-GPC and DNN-GPC both yield good tracking performances while keeping the changes in control signal as low as possible. The simulation results show that even though ARX is a linear model, it provides acceptable tracking results as well as DNN model.

Keywords: Generalized predictive control, ARX, dynamic neural network, Kalman filter and extended Kalman filter, nonlinear systems and adaptive learning rate.

I. INTRODUCTION

Identification of systems with unknown mathematical model, control and fault detection studies keep their importance up-to-date [1]. It is a hard task to obtain a mathematical model in complex systems. In addition, need for system modelling emerges due to uncertainty, disturbances and noises. In such cases, robust or adaptive control techniques should be adopted to design a controller [8]. In adaptive control, an appropriate model is selected to approximate the actual system model. Artificial neural network (ANN) and fuzzy networks are widely used as function estimators [25], [2].

GPC is a class of model-based predictive control. When dynamics of the system are not known, the model which identifies the system has a crucial role in both predicting the future behaviour of the system and generating the future control signals. In each sampling instant first one of the produced control signals is applied to the system [3], [4]. The models which are able to adapt to the changing dynamics of systems improve GPC performance. Artificial neural network (ANN) [20], [21] and support vector machine (SVM) [9], [14] can be adopted in GPC studies.

DNNs [19] have a recursive structure. Internal states and external inputs constitute the actual inputs of these networks which are widely used in function approximation. DNNs can approximate complex nonlinear dynamics due to the merits of recursive structure and nonlinear activation function [22]. Usually they are used in prediction [6], fault detection [12], adaptive control [16] and GPC [24].

In this study, particular type DNN and AutoRegressive with eXogenous input (ARX) model based GPC are performed. ARX is a linear model while both linear and nonlinear dynamics exists in the DNN model. Models are trained by extended Kalman filter (EKF). In addition to adaptation of the parameters, poles are adapted such that they are bounded to maintain stability of the model. Thus, quick and stable online identification is obtained. In numerical simulations, bioreactor and continuously-stirred tank reactor (CSTR) benchmark systems are controlled using two methods and results are compared.

Rest of the paper is organized as follows. In Section II, DNN and ARX models are presented, model stability and EKF-based training are introduced. GPC and ARX and DNN based GPC are detailed in Section III. Simulations are given in Section IV. Finally, paper is concluded in Section V.

II. IDENTIFICATION MODELS

In this section, ARX model and the DNN model which is used in continuous time adaptive control in [13] will be studied for discrete time GPC. Section II-A and II-B present the ARX and DNN models while Section II-C introduces the model stability. Finally, EKF-based training of the models is given in Section II-D.

A. ARX Model

ARX model is simple and linear. Consider \( n_u \) and \( n_y \) are the past input and output samples to construct the ARX data. Let (1) give the output equation of a system at time instant \( k \) whose explicit output expression is unknown.

\[
y_k = f(c_k)
\]

\[
c_k = (u_k, u_{k-1}, \ldots, u_{k-n_u}, y_{k-1}, \ldots, y_{k-n_y})
\]

Output can be approximated linearly by a parameter vector \( \theta_k \in \mathbb{R}^{n_u+1+n_y} \) such as

\[
y_k = c_k \theta_k^T
\]

B. Dynamic Neural Network

Figure 1 presents internal dynamics of one neuron in the dynamic NN. States of the neurons are updated in discrete-time as given in (3) and (4).

\[
\dot{x}_{k+1} = Dx_k + AT(\bar{x}_k) + Bc_k
\]

\[
y_k = Cx_k
\]
Here, $\hat{x} \in \mathbb{R}^n$ is state vector, $c \in \mathbb{R}^m$ and $y \in \mathbb{R}^m$ are input and output vectors respectively. Nonlinear activation function $T(.)$ is tangent hyperbolic function and is expressed as

$$T(\hat{x}_i) = \begin{bmatrix} \tanh(\hat{x}_{1i}) \\ \vdots \\ \tanh(\hat{x}_{ni}) \end{bmatrix}$$  \hspace{1cm} (5)

$$\tanh(x) = \frac{e^x - e^{-x}}{e^x + e^{-x}}$$  \hspace{1cm} (6)

$B \in \mathbb{R}^{n \times m}$, $C \in \mathbb{R}^{m \times n}$ and the matrices $D$ and $A$ are as follows.

$$D = \begin{bmatrix} d_1 \\ \vdots \\ d_n \end{bmatrix}_{n \times n}$$  \hspace{1cm} (7)

$$A = \begin{bmatrix} a_1 \\ \vdots \\ a_n \end{bmatrix}_{n \times n}$$  \hspace{1cm} (8)

DNN model consists of linear ARX (AutoRegressive with eXogeneous input) model and nonlinear function $\tanh(.)$. Thus, identification of linear and nonlinear dynamic systems is aimed in a quick and efficient way. This model can be considered as sparsed Hopfield type network in means of inter-neuron connections. Connection of each neuron with itself brings to the network dynamic property. Dashed lines in Figure 1 show nonexisting connections. From this aspect, model is diagonal. Figure 2 presents diagonal dynamic model.

C. Model Stability

The results in [7], [10] were reviewed to analyze the stability of the models and stability conditions given in [15] were followed in this study. First, ARX model stability is analyzed. In the simulations ARX model is used as a second order IIR (Infinite Impulse Response) filter since $n_y = 2$ is taken (see Section IV). Parameters in the parameter vector $\theta_k$ which correspond to the past output samples are constrained with the stability condition as following.

$$\begin{cases} 1 - \theta_{k,n_u+2} + \theta_{k,n_u+3} > 0 \\ 1 + \theta_{k,n_u+2} + \theta_{k,n_u+3} > 0 \\ 1 - \theta_{k,n_u+3} > 0 \end{cases}$$  \hspace{1cm} (9)

Second, DNN model stability is analyzed. State equation belonging to the $i_{th}$ neuron in the discrete-time DNN model is given by

$$\hat{x}_i(k+1) = d_i \hat{x}_i(k) + a_i T(\hat{x}_i(k)) + b_i u_i(k)$$  \hspace{1cm} (10)

$i = 1, ..., n$, $k$ is the time index, definition of the variables and model matrices are given in the previous section. Discrete-time state solution of the model given $\hat{x}(0) = \hat{x}_0$ as the initial state is obtained as follows.

$$\hat{x}(k) = D^k \hat{x}_0 + \sum_{i=0}^{k-1} D^{k-1-i} (A T(\hat{x}(i)) + Bu)$$  \hspace{1cm} (11)

Stability of the DNN model is directly related to the stability of the states since output vector of the DNN model is linearly related to the states as given in Equation (4). Neuron in Equation (10) can be considered as a first order ARX model. Stability of the DNN model expressed in Equation (3) is guaranteed by satisfying the following conditions.

$$|d_i| < 1$$  \hspace{1cm} (12)

$$a_i \neq 0$$

$$b_{ij} \neq 0, i = 1, ..., n, j = 1, ..., m$$

Generally, $b_{ij} \neq 0$ is needed to be satisfied not for the internal stability but for the input to have effect on the output.

D. Inequality Constrained EKF Based Training

Inequality constrained EKF (ICEKF) is used to train model parameters. Parameter adaptation equations of ICEKF will be given in Section II-D.1 and training of models will be detailed in Section II-D.2.

1) ICEKF: State-space representation of a nonlinear discrete-time system is given below.

$$x_k = f(x_{k-1}) + w_{k-1}$$  \hspace{1cm} (13)

$$y_k = h(x_k) + v_k$$  \hspace{1cm} (14)

Here, $x \in \mathbb{R}^n$ is state vector, $y \in \mathbb{R}^m$ is system output, $f(.)$ is nonlinear process function vector, $h(.)$ is nonlinear measurement function vector, $w \in \mathbb{R}^n$ is process noise and $v \in \mathbb{R}^m$ is measurement noise, which both are Gaussian white noises. Extended Kalman filter can be summarized.
in two steps given $Q$ and $R$ are covariance matrices corresponding to process and measurement noises respectively.

**Time Update**

$$\hat{x}_k = f(\hat{x}_{k-1})$$

$$P_k = J_f(\hat{x}_{k-1})P_{k-1}J^T_f(\hat{x}_{k-1}) + Q_{k-1}$$

$$K_k = P_k J^T_f(\hat{x}_k) J_h(\hat{x}_k) P_k J^T_f(\hat{x}_k) + R_k)^{-1}$$

**Measurement Update**

$$\hat{x}_k = \hat{x}_k + K_k (y_k - h(\hat{x}_k))$$

$$P_k = (I - K_h J_h(\hat{x}_k)) P_k$$

(15)

(16)

In (15) and (16), $P \in R^{n \times n}$ is state estimation error covariance matrix and $K_k$ is Kalman gain. $J_f(\cdot)$ and $J_h(\cdot)$ are given in (17) and (18).

$$J_f(\hat{x}_{k-1}) = \frac{\partial f(x)}{\partial x} \bigg|_{x=\hat{x}_{k-1}}$$

$$J_h(\hat{x}_{k-1}) = \frac{\partial h(x)}{\partial x} \bigg|_{x=\hat{x}_{k-1}}$$

(17)

(18)

Let us consider there exist inequality constraints on states as given below in state estimation by ICEKF.

$$M \hat{x} \leq N$$

(19)

Parameters must be within the constraint space to satisfy the constraints. By this reason, projection is taken onto the constraint space [17].

$$\hat{x}_k = \hat{x}_k - P_k M^T (MPM^T)^{-1} (M \hat{x}_k - N)$$

$$d P_k = P_k M^T (MPM^T)^{-1} M$$

$$\hat{P}_k = P_k - d P_k$$

(20)

(21)

(22)

(23)

Projection onto the constraint space is taken as in (20) to satisfy the constraints in (9) for ARX model while in (12) for DNN model. For the DNN case, states are updated as in (3) using the parameters which are updated satisfying the constraints. Thus, states are not the ones which are estimated optimally but parameters in the vector $\theta$ are.

### III. ARX and DNN Based Generalized Predictive Control

Section III-A briefly introduces GPC while Section III-B and III-C detail the ARX-based and DNN-based GPC respectively.

#### A. GPC

Let us have a NARX (Nonlinear Auto-Regressive with eXogeneous input) data model for a nonlinear system [9].

$$y_n = f(u_{n-1}, u_{n-2}, \ldots, u_{n-n_u}, y_{n-1}, \ldots, y_{n-n_y})$$

As $\hat{y}_n$ is the reference signal and $\hat{y}_m$ is the model output, GPC aims to have the model output track the reference signal with minimum tracking error possible while keeping the changes in the control signal as low as possible. Constraints exist on the control signal.

$$\min_{u} f(u) = \sum_{k=1}^{K_u} (\hat{y}[n+k] - \hat{y}[n+k])^2 + \lambda \sum_{k=0}^{K_u} (u[n+k] - u[n+k-1])^2$$

$$= (\hat{Y} - \hat{\gamma}^T \hat{Y} - \hat{\gamma}^T + \lambda u^T \hat{L} u$$

$$- 2 \lambda u[n][u[n-1] + \lambda^2 u[n-1]]$$

Constraints: $u_{min} \leq u[n+k] \leq u_{max}$, $k = 0, 1, \ldots, K_u$

$$||u[n+k] - u[n+k-1]|| \leq \Delta u_{max}, k = 1, \ldots, K_u$$

(24)

(25)

$$\lambda$$ penalizes the abrupt changes in control signal. $K_u$ and $K_y$ are horizon values up to how many future control inputs and model outputs will be calculated. Always, $K_u < K_y$ is satisfied. $\hat{Y} = [\hat{y}_1 \ldots \hat{y}_{K_y}]^T \in R^{K_y}$ and $\hat{Y} = [\hat{y}_1 \ldots \hat{y}_{K_y}]^T \in R^{K_y}$. At each time instant, to make the system output track the reference signal for future $K_y$ samples, control input

$$L = \begin{bmatrix}
2 & -1 & 0 & \ldots & 0 & 0 \\
-1 & 2 & -1 & \ldots & 0 & 0 \\
0 & -1 & 2 & \ldots & -1 & 0 \\
0 & 0 & -1 & \ldots & 2 & -1 \\
0 & 0 & 0 & \ldots & -1 & 1
\end{bmatrix}$$

(26)
vector \( \mathbf{u} \in \mathbb{R}^{K_u+1} \) is generated and first element in the vector is applied to the system. To predict the future behaviour of the system whose output function is unknown, an appropriate model to approximate that system is used. Also that model is utilised for the gradient information which is necessary to update the control signal at each time instant. This update is expressed as follows.

\[
\mathbf{u}_k = \mathbf{u}_{k-1} + \Delta \mathbf{u}
\]  
(27)

When Gauss-Newton modification is employed,

\[
\Delta \mathbf{u} = -\mu \left( \frac{\partial^2 f(\mathbf{u})}{\partial \mathbf{u}^2} \right)^{-1} \frac{\partial f(\mathbf{u})}{\partial \mathbf{u}}
\]  
(28)

is obtained and \( \mu \) denotes the step size. It can be calculated optimally using one of the one-dimensional optimization methods in the literature. Gradient vector is the following.

\[
\frac{\partial f(\mathbf{u})}{\partial \mathbf{u}} = -2 \left( \frac{\partial \tilde{\mathbf{Y}}_n}{\partial \mathbf{u}} \right)^T (\tilde{\mathbf{Y}}_n - \hat{\mathbf{Y}}_n) + 2\lambda \mathbf{L} \mathbf{u} - 2
\]  
(29)

If derivative of (29) is taken to obtain Hessian matrix, a term \( \left( \frac{\partial^2 \tilde{\mathbf{Y}}_n}{\partial \mathbf{u}^2} \right) \) is generated. But it can be ignored since it has small value. Thus, Hessian is approximated as

\[
\frac{\partial^2 f(\mathbf{u})}{\partial \mathbf{u}^2} \approx 2 \left( \frac{\partial \tilde{\mathbf{Y}}_n}{\partial \mathbf{u}} \right)^T \left( \frac{\partial \tilde{\mathbf{Y}}_n}{\partial \mathbf{u}} \right) + 2\lambda \mathbf{L}
\]  
(30)

Considering (24), model output depends on the control signals who have a time index value which is smaller than or equal to that of the model output. Thus, the term \( \left( \frac{\partial \tilde{\mathbf{Y}}_n}{\partial \mathbf{u}} \right) \) is expressed as follows.

\[
\frac{\partial \tilde{\mathbf{Y}}_n}{\partial \mathbf{u}} = \begin{bmatrix}
\frac{\partial y[n+1]}{\partial u[n]} & \frac{\partial y[n+1]}{\partial u[n]} \\
\frac{\partial y[n+2]}{\partial u[n]} & \frac{\partial y[n+2]}{\partial u[n]} \\
\vdots & \vdots \\
\frac{\partial y[n+K_u]}{\partial u[n]} & \frac{\partial y[n+K_u]}{\partial u[n]}
\end{bmatrix}
\]  
(31)

Computational load of the derivatives depends on the model.

**B. ARX Based GPC**

Since the system is approximated by ARX model, \( \frac{\partial \hat{\mathbf{Y}}_n}{\partial \mathbf{u}} \) is obtained based on that model. Considering (2), future output prediction by the model is given by

\[
\hat{y}_{k+l} = \mathbf{c}_k + \mathbf{h}_k^T \mathbf{u}_k, \quad l = 1, \ldots, K_y
\]  
(32)

It can be written explicitly

\[
\hat{y}_{k+l} = \sum_{i=1}^{n_u} \theta_{k,n_u+1+i} \hat{y}_{k+i-1} + \sum_{i=0}^{n_u} \left\{ \begin{array}{ll}
\theta_{k,i+1} u_{k+i-1} & k - K_u < i \\
\theta_{k,i+1} u_{k+K_u} & k - K_u \geq i
\end{array} \right.
\]  
(33)

Thus, partial derivative expression will be

\[
\frac{\partial \hat{y}_{k+l}}{\partial u_{k+h}} = \sum_{i=1}^{n_y} \frac{\theta_{k,n_u+1+i}}{\partial u_k} \frac{\partial \hat{y}_{k+i-1}}{\partial u_k} \delta_1(k - i - 1) + \sum_{i=0}^{n_u} \left\{ \begin{array}{ll}
\frac{\theta_{k,i+1} u_{k+i-1}}{\partial u_k} & k - K_u < i \\
\frac{\theta_{k,i+1} u_{k+K_u}}{\partial u_k} & k - K_u \geq i
\end{array} \right.
\]  
(34)

\( \delta_1 \) is the unit step function. Obtained partial derivative is substituted in (29) and (30) to obtain the gradient vector and Hessian matrix.

**C. DNN Based GPC**

Since the system is approximated by DNN model, \( \frac{\partial \hat{\mathbf{Y}}_n}{\partial \mathbf{u}} \) is obtained based on that model. Using (3) and (4), model output can be written alternatively as following.

\[
\hat{y}_k = \sum_{j=1}^{n} c_j (d_j x_j + a_j T(x_j) + [b_{j1} \ldots b_{jm}] \mathbf{u}_k)
\]  
(35)

\[
v_{jk} = [b_{j1} \ldots b_{jm}] \mathbf{u}_k
\]  
(36)

\[
\hat{y}_k = \sum_{j=1}^{n} c_j (d_j x_j + a_j T(x_j) + v_{jk})
\]  
(37)

And the future output prediction by the model is given by

\[
\hat{y}_{k+l} = \sum_{j=1}^{n} c_j (d_j x_j + a_j T(x_j) + v_{j,k+l}), \quad l = 1, \ldots, K_y
\]  
(38)

where

\[
v_{j,k+l} = \sum_{i=1}^{n_u} b_{j,n_u+1+i} \hat{y}_{k+i-1} + \sum_{i=0}^{n_u} \left\{ \begin{array}{ll}
\sum_{i=0}^{n_u} b_{j,i+1} u_{k+i-1} & k - K_u < i \\
\sum_{i=0}^{n_u} b_{j,i+1} u_{k+K_u} & k - K_u \geq i
\end{array} \right.
\]  
(39)

Thus, partial derivative expression will be

\[
\frac{\partial \hat{y}_{j,k+l}}{\partial u_{k+h}} = \sum_{j=1}^{n} c_j \frac{\partial v_{j,k+l}}{\partial u_{k+h}}
\]  
(40)

\[
\frac{\partial v_{j,k+l}}{\partial u_{k+h}} = \sum_{i=1}^{n_y} \frac{\theta_{j,n_u+1+i}}{\partial u_k} \frac{\partial \hat{y}_{k+i-1}}{\partial u_k} \delta_1(k - i - 1) + \sum_{i=0}^{n_u} \left\{ \begin{array}{ll}
\frac{\theta_{j,i+1} u_{k+i-1}}{\partial u_k} & k - K_u < i \\
\frac{\theta_{j,i+1} u_{k+K_u}}{\partial u_k} & k - K_u \geq i
\end{array} \right.
\]  
(41)

\( \delta_1 \) is the unit step function. Obtained partial derivative is substituted in (29) and (30) to obtain the gradient vector and Hessian matrix.

**IV. COMPUTER SIMULATIONS**

ARX-based and DNN-based GPC controllers were tested on bioreactor [5] and continuously stirred tank reactor [23] systems.
A. Bioreactor Control

Bioreactor is a second order benchmark system to test tracking performance of the controllers.

\[
\begin{align*}
\dot{x}_1(t) &= -x_1(t)u(t) + x_1(t)(1 - x_2(t))e^{(x_2(t) + x_2(t))} \\
\dot{x}_2(t) &= -x_2(t)u(t) + x_1(t)(1 - x_2(t))e^{(x_2(t) + x_2(t))} \\
&\quad \quad \quad + x_1(t)(1 - x_2(t))e^{(x_2(t) + x_2(t))} \left( \frac{1 + \beta}{1 + \beta - x_2(t)} \right)
\end{align*}
\]

(42)

\(x_1(t)\) and \(x_2(t)\) are cell concentration and amount of nutrients per volume. Control signal \(u(t)\) is the flow rate. \(\eta\) is time-varying parameter of the process and has a nominal value of 0.48. Controllers were employed to make the reactor output track desired reference value with minimum tracking error possible. GPC parameters are \(K_y = 10, \quad K_u = 2, \quad \lambda = 0.01, \quad u_{\min} = 0, \quad u_{\max} = 2, \quad \Delta u_{\max} = 0.2, \quad u_n = 2, \quad n_y = 2\). Sampling period is \(T_s = 0.01\) s. For the DNN-based GPC case, number of states is set \(n = 5\). In the simulation, \(\eta(t) = 0.48 + 0.06\sin(0.05\pi t)\) oscillates around its nominal value. Figure 3 shows reference tracking and produced control signal by ARX-based GPC controller while Figure 4 shows time evolution of parameters. Similarly, controllers are compared in terms of Root-Mean-Squared-Error (RMSE) and power of the produced control signal \(P_u = \frac{1}{N} \sum_{k=1}^{N} |u[k]|^2\) in Table I. ARX-based GPC controller tracks the reference signal with little oscillations while DNN-based GPC controller performs smoother tracking as expected. However, it has more overshoot compared to ARX-based GPC. Control signal is less aggressive in DNN-based GPC. ARX-based GPC has still acceptable tracking performance.

**TABLE I**

<table>
<thead>
<tr>
<th>Controller</th>

Fig. 5. Bioreactor reference tracking and control signal produced by DNN-based GPC controller.

Fig. 6. Time evolution of parameters in control of bioreactor by DNN-based GPC controller.

B. CSTR Control

Continuously stirred tank reactor is a third order highly nonlinear system on which tracking performance of the
controllers were tested.

\[ \dot{x}_1 = 1 - x_1 - D_{a1}x_1 + D_{a2}x_2^2 \]
\[ \dot{x}_2 = - x_2 + D_{a1}x_1 - D_{a2}x_2^2 - D_{a3}d_2x_2^2 + u \]
\[ \dot{x}_3 = - x_3 + D_{a3}d_2x_2^2 \]

\[ D_{a1} = 3, D_{a2} = 0.5, D_{a3} = 1, d_2\text{nom} = 1, y = x_3 \]  

(43)

\( u(t) \) is the control signal and \( d_2 \) is time-varying parameter of the process which has a nominal value of 1. Controllers were employed to make the reactor output track desired reference value with minimum tracking error possible. GPC parameters are \( K_y = 10, K_u = 2, \lambda = 0.1, u_{\text{min}} = 0, u_{\text{max}} = 1, \Delta u_{\text{max}} = 0.1, n_u = 2, n_y = 2 \). Sampling period is \( T_s = 0.1 \) s. For the DNN-based GPC case, number of states is set \( n = 5 \). Figure 7 shows reference tracking and produced control signal by ARX-based GPC controller while Figure 8 shows time evolution of parameters. Similarly, Figure 9 shows reference tracking and produced control signal by DNN-based GPC controller while Figure 10 shows time evolution of parameters.

ARX-based GPC controller. After the parameters of DNN-based GPC controller sets approximately to their stationary values, it begins performing as smooth tracking as ARX-based GPC does. This is the reason why ARX-based GPC has little smaller tracking RMSE value.

V. CONCLUSION

This study presents a comparison of ARX and DNN models in GPC scheme. Tracking performance of models were compared on bioreactor and CSTR systems which are both nonlinear benchmark systems. Even though ARX is a linear model, it has proven to be an acceptable model for generalized predictive control of nonlinear systems. Moreover, structural stability is maintained in both models by constraining the poles in a stable region. As a general result,
ARX and DNN models are adopted successfully in GPC scheme for both systems.

Abstract—In this paper, Cuckoo search optimization algorithm is used to select the standard component values for active filter design by means of fitness function and constraints in order to facilitate design tasks of designers. Conventionally after designers solve circuit, they select the nearest standard component values, which are available in the market, instead of calculated one. However, this process causes design errors which have to be recalculated. From this perspective, unlike conventional method, Cuckoo Search uses a set of solution, which is discreet component values and fitness function to minimize the error. As a result of this work, Cuckoo Search algorithm has been successfully implemented to this filter design process for searching the optimum discreet component values of the solution space.

Keywords—Cuckoo search, filter design, optimization

I. INTRODUCTION

In the conventional analogue circuit design methods, component values are generally considered ideal and limitless. However, electronic components are produced in specific standard values in order to reduce the design costs. Consequently, the analogue circuit components to be used are selected from the specific standard components which are available in the market. In the traditional methods, designers make some assumptions when they know the status of the resolution of the analogue circuit in order to facilitate the circuit, to reduce the solution space and to work in the desired circuit status. In these assumptions, some components are fixed or selected in multiples of one another. This process allows us to search the solution in a smaller area by narrowing the solution space. But this gives rise to potential better solution would be ignored. Also these assumptions restrict the designer and cause some components remain constant value. These acceptances cause undesirable product errors to be fixed.

In the design of analogue circuits, to reduce the mathematical operation load and loss of time, it has been proposed different methods correspond to the classical method. Inspired by nature as an alternative calculation methods developed with Genetic Algorithm, Ant Colony Algorithm, Tabu Search Algorithm, Simulated Annealing, Bee Colony Algorithm, Firefly Algorithm, Cuckoo Search, Particle Swarm Optimization and differential evolution etc., heuristic algorithms can be used for such a complex and burdensome problems[1]. These algorithms generally include objective function expressing the problem and solution space. Thus, suitable results can be obtained with such difficult problems.

In the literature, David et al. performed a low pass active filter design using genetic algorithms. They examined the effect of the changing crossover and mutation rates to the results in the genetic algorithm. They also obtained quite successful results in the standard component selection compared with the conventional methods[2]. Turgay et al. have made the design, using genetic algorithms, for the Sallen-Key band pass filter. They made solutions for the desired frequency and filter gain to find out component values regardless of standard components[3]. Adem Kanali made solution to find out standard values of low pass filter and Wien-Robinson filter using Ant Colony algorithm and conventional methods. He compared these algorithms each other and demonstrated that Ant Colony algorithm is more efficient rather than conventional methods[4]. Gandomi and et. showed that Cuckoo Search algorithm can be used at the solution of the basic civil engineering problems[5]. Karagul made plastic waste collection application using different algorithms. He saw that the cuckoo search algorithm provided better results than others[6].

In this study, classical method and cuckoo search algorithm are used to find out standard component values in the active filter design. Finally, results are compared with each other.

II. CUCKOO SEARCH ALGORITHM

Cuckoo Search Algorithm is proposed by Yang and Deb in 2009. Such algorithms typically used in global optimization problems[7-8]. Cuckoo Search Algorithm is based on natural behaviour of some species of cuckoo called brood parasitism. Such types of cuckoo that lays its eggs into the appropriate nests and throws eggs from the nests with the possibility of hatching. When host bird arrive the nest, it may not recognize the foreign egg. Therefore, large number of hosts exposed to brood parasitism. But if host bird recognises the foreign egg, it
may throw the egg from nest or leave the nest to build new one. Yang and Deb used their idealised rules for this fiction [7-8]:

- Each bird can lay one egg and drop one egg in a random nest at a time.
- Quality solutions are transferred to the next generations.
- The number of nests is constant and host can discover foreign egg by probability pa ∊ (0,1). If it happens, host can either throw the egg and leaves in the same nest or abandons the nest to build new one.

Heuristic algorithms reach best solution by means of global and local searching. To reach the best solution, they should discover other potential solutions. From this perspective, Cuckoo search algorithm is developed algorithm by balancing local random walk and global random walk.

Local random walk equation is expressed as below;

$$x_i^{t+1} = x_i^t + as \otimes H(p_a - \varepsilon) \otimes (x_j^t - x_i^t) \quad (1)$$

Local random walk, which is expressed the equation (1), is determined by a random permutation of $x_j^t$ and $x_i^t$. $H(u)$ is Heaviside step function. While $\varepsilon$ is a parameter that comes from gaussian distribution, $s$ is step length.

Global random walk is carried out by Levy Flight as following equation;

$$x_i^{t+1} = x_i^t + \alpha L(s, \lambda) \quad (2)$$

Levy Flight is performed in order to produce new generations. Moreover, not only $\alpha > 0$ is selected but also levy flight can be scaled according to problem size.

When looked over the equations, deduced that next status depends on current status and transition probability. Best solution is obtained by keeping good solutions in the solution set.

Cuckoo Search algorithm is given in Fig 1. Firstly, objective function, which defines problem, is determined. Subsequently, random and limited initial values of solution set of population are assigned and stopcriterion is determined to make the running algorithm stopped. Loop is generated to search until the suitable solution is obtained. In the loop, new potential solution is generated by Levy Flight and if the potential solution was better than old ones, new potential solution was kept by evaluating their fitness. After that, as a part of this algorithm feature, new potential solution is generated by probability of pa and better ones kept again. After the iteration accomplished, stop criteria checked again. If stop criteria was not suitable, then iteration would continue again. Otherwise iteration would be finished and results would be visualised.

begin
Objective function $f(x) = (x_1, \ldots, x_n)^T$
Generate initial population of $n$ host nests $x_i$ ($i=1, 2, \ldots, n$)
while ( stop criterion )
Get a cuckoo randomly by Levy flights
evaluate its quality/fitness $F_i$
Choose a nest among $n$ randomly
if ($F_i > F_j$)
Replace $j$ by the new solution
end
A Fraction ($p_a$) of worse nests are abandoned and new ones are built;
Keep the best solutions
Rank the solution and find current best
end while
postprocess results and visualization
end

Fig 1. Cuckoo Search Algorithm[7]

III. ACTIVE FILTER DESING

Filter circuit is defined as passing circuit of specified part of sent or received signal[9]. While filters are used to be passed the specific band of signal in Communication, Biomedical and Defence Industries, for example in Power Electronic, they are used to maximize active power by reducing Total Harmonic Distortion. Filters are classified to high-pass filter, low-pass filter, band-pass filter and band-stop filter. According to the used components, Passive filters typically are made of the inductor, capacitor and resistance, whereas active filters are made of not only resistors, capacitors, but also amplifiers[10].

A. State Variable Active Filter

In this work, state variable active filter, as known Kerwin-Huelsman-Newcomb, is used and its schematic image is given in Fig 2. This low pass filter is totally specified by band passgain $(H)$, band pass cut-off frequency $(\omega_0 = 2\pi f_0)$ and selectivity factor $(Q)$. These parameters determine the desired operating status of filter. Kerwin-Heulsman-Newcomb Active Filter is used and its parameters are expressed as below [2-4, 10]

$$H = \frac{R_2(R_3 + R_4)}{R_3(R_1 + R_2)}$$

$$\omega_0 = \sqrt{\left(\frac{R_1}{R_3}\right)\left(\frac{1}{C_1C_2R_5R_6}\right)}, \quad (3)$$

$$Q = \frac{R_3(R_1 + R_2)}{R_1(R_3 + R_4)} \sqrt{\frac{C_1R_4R_5}{C_2R_3R_6}}$$

Electronic, they are used to maximize active power by...
B. Implementation

In this work, pa, which is one of the control parameter of Cuckoo Search Algorithm, is determined as 0.25[11]. Later, size of population is determined as 80 for each component variable. 8 different component variables are determined to solve the problem. Standard of resistor was selected E24 and standard of capacitor was selected E12 according to Electronic Industries Association (EIA) norms. Subsequently, solution set was generated by random values within boundary. Afterwards, fitness function (4) and constraint (5) were determined. Fitness function was determined as percentage difference of desired values and results, for selectivity and frequency. Also, constraint was determined that both half gain, which is desired, must be smaller than filter gain and one and half gain, which is desired, must be greater than filter gain.

\[
F(R_n, C_n) = \left[ \frac{Q-Q_{\text{desired}}}{Q_{\text{desired}}} \right] + \left[ \frac{\omega_0-\omega_{0\text{desired}}}{\omega_{0\text{desired}}} \right]
\]

Constraint:

\[
0.5H_{\text{desired}} \leq H \leq 1.5H_{\text{desired}}
\]

After each nest of solution set was evaluated by means of fitness function, algorithm was implemented until stop criteria was obtained. For this work, stop criteria was defined that, either the error of process reaches under 2% or iterations reach to 1000 steps. When the algorithm begins to work, firstly global search was started. After global search finished, good solutions would be kept. Subsequently, local search was started and it would try to approach best solutions among the good solutions. These local random walk and global random walk cause to explore the undiscovered solutions and not to provide to stick in local points.

Both conventional method and cuckoo search algorithm were implemented to this filter called Kerwin-Huelsman-Newcomb Filter. The specifications chosen were selected as 510000Ω, 13000Ω, 820000Ω, 4700Ω, 1.2x10⁻⁷ F, 1x10⁻¹¹ F, 1.4158. Results are given in Table 1 for the Cuckoo Search Algorithm and Conventional Method. Error of Cuckoo Search algorithm was obtained about 0.86%, on the other hand error of Conventional Method was obtained about 14.36%. According to results, error of Cuckoo Search Algorithm has remained within the specified error border. Cuckoo Search Algorithm was provided closer results to the specified parameters, which are frequency (ω₀) and selectivity (Q), than Conventional Method. On the other hand, Conventional Method was provided closer band pass gain (H) than Cuckoo Search Algorithm. The reason for this is that band pass gain was determined as a constraint in Cuckoo Search Algorithm and nevertheless its result was remained specified interval.

IV. CONCLUSIONS

In this work, Cuckoo Search algorithm is used to determine standard component values for active filter design. Mathematical effort and wasting time disappeared by using Cuckoo Search Algorithm compared to conventional method. Results of Cuckoo Search Algorithm have less error and more successful than Conventional Method as given in Table 1. The results are different for each program, although the run can produce the values of the standard circuit components providing the required conditions.

Obtained results showed that the Cuckoo Search algorithm can be successfully applied to this area and it is not dependent on a specific circuit model. Thus, it can be applied to more complex circuits.

Petri Net Modelling of a Smart Building as a Cyber Physical System

Hanife Apaydin Ozkan

Department of Electrical and Electronics Engineering
Anadolu University
Eskisehir, Turkey
hapaydin1@anadolu.edu.tr

Abstract—In recent years, systems consisting of both physical and computational elements, called Cyber Physical Systems (CPSs), have entered into our lives. These systems are becoming increasingly important because of their wide application area such as smart buildings, intelligent manufacturing processes, energy grids, healthcare devices, smart agriculture and etc. In this work, CPSs are considered by means of a smart building application. Firstly, CPSs are introduced and their features are explained. Then, a smart building is considered for emphasizing and illustrating the importance of CPSs. In order to display working mechanism of computational and physical components of the building and to provide easy trace of the evolution of overall system, models of building components are developed via Petri net, which is a mathematical and graphical tool for modelling and analysing discrete event systems.

Keywords—Cyber physical system, Petri nets, smart building, sensors, communications

I. INTRODUCTION

In recent years, systems consisting of both physical process and computational elements, called Cyber Physical Systems (CPSs), have entered into our lives. The physical process is monitored or controlled by the computational (cyber) system, which is a networked system of several devices with sensing, computing and communication capabilities. Developments in sensor and information technology, smaller and cheaper sensor solutions, development of cheap and different communication methods as well as more powerful embedded control system allow CPSs to become widespread rapidly. These systems are becoming increasingly important because of their wide application area such as smart buildings, intelligent manufacturing processes, energy grids, healthcare devices, smart agriculture and etc.

In the literature, many works have been presented on CPSs. Despite its wide-spread use, the term ‘Cyber-Physical System’ does not come with a uniform meaning. It is often used as a synonym for ‘system in which computing interacts with the physical world’ or ‘networked embedded system’, or ‘system of systems’. The disruptive nature of cyber-physical systems has the potential to substantially change the way of addressing the key questions of modern societies, and specifically the European challenges including Well-Being, Clean Energy, Integrated Transport, and Resource Efficiency, by providing smart answers to these questions.

In the CyPhERS project [1], the following five key areas were chosen to illustrate the potential of cyber-physical systems using future scenarios of 2030, and identify strengths, weaknesses, threats and opportunities of Europe: Transport, Energy, Well-Being, Industry, Infrastructure. Authors introduced model-based design methodology for cyber physical systems and evaluated it through the development of the Tunnelling Ball Device (such as automotive engine control) in [2]. In [3] a qualitative and quantitative empirical study of the state of the art in CPS verification and validation is conducted. An approach to increase resilience in a cyber-physical system from errors in the high-level control logic is presented in [4].

This approach, monitors run-time commands in order to maintain a safety invariant. Although this method seems to be general and powerful, the main drawback is the cost of performing part of the checking at run time. Hence, authors also introduce how to perform this operation offline. In [5], Petri net is used as a formal tool for nondeterministic non-interference security model specification of cyber-physical system and is shown to be applicable to abstract pipeline distribution flow network system. A generalized Petri net model is presented in [6] to formulate the manufacturing processes, and a traceability model is automatically built by model transformation. In that work, model-based algorithms are proposed for enabling back-tracking to the source of an item with detailed productive data. Authors of [7] focus on another important human–machine interaction problem for smart building systems, which concerns conflict detection during the interaction process between multiple users and the system. They design a rule conflicts detection algorithm, which can detect conflicts between two rules as well as cycle conflict/multi-cross contradiction among multiple rules. In [8], a smart Air Conditioner scheme is proposed and its adaptation to a Smart Home system is presented. Petri net model of the smart Air Conditioner is developed in order to enable a good general view of the operation of the Smart-Air Conditioner.

In this work, CPSs are considered by means of a smart building application. Firstly, CPSs are introduced and their features are explained. Then a smart building is considered for emphasizing and illustrating the importance of CPSs. In order to display working mechanism of computational and physical components of the building and to provide easy trace of the evolution of overall system, models of building components are developed via Petri net.
II. PETRI NETS

A Petri net (PN) is a directed bi-partite graph which consists of finite set of places represented by circles, finite set of transitions represented by bars and arcs directed from places to transitions or from transitions to places, which express the conditions required for an action to be feasible and its consequences when it occurs. The places from which an arc runs to a transition are called the input places of the transition; the places to which arcs run from a transition are called the output places of the transition. A place may contain tokens denoted by black dots.

The distribution of tokens over the places of a net is called a marking that corresponds to a state of the modelled system. A transition is the marking vector, \( m \), \( m \in \mathbb{N}^P \), presented by bars, \( p \in P \), \( m \) is the marking vector \( m \) taking time, an enabled transition matrix, corresponding to all \( A \) transition \( t \in T \) is the marking vector, \( m \), \( m \in \mathbb{N}^P \), \( m \) is the output matrix that specifies the arcs directed from places to transitions,

\[
O : P \times T \rightarrow N
\]

is the output matrix that specifies the arcs directed from transitions to places and \( m_0 \) is the initial marking. Here, \( N \) is the set of nonnegative integer number. \( M : P \rightarrow N \) is the marking vector, \( M(p_i) \) indicates the number of tokens, represented by black dots, assigned by marking \( M \) to place \( p_i \).

Example 1: The PN model given in Fig. 1 is represented by

\[
P = \{ p_1, p_2, p_3, p_4, p_5, p_6, p_7 \}, T = \{ t_1, t_2, t_3, t_4, t_5, t_6 \} \text{ and } m_0 = [1 \ 0 \ 0 \ 1 \ 1 \ 0 \ 0]^T.
\]

Input and output matrices of this PN are given as follows:

\[
N = \begin{bmatrix}
0 & 0 & 1 & 0 & 0 & 0 & 0 \\
0 & 1 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 1 & 0 & 0 & 1 & 0 \\
0 & 0 & 0 & 1 & 0 & 0 & 1 \\
0 & 0 & 0 & 0 & 1 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 1 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 1
\end{bmatrix}
\]

\[
O = \begin{bmatrix}
1 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 1 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 1 & 0 & 0 & 1 & 0 \\
0 & 0 & 0 & 1 & 0 & 0 & 1 \\
0 & 0 & 0 & 0 & 1 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 1 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 1
\end{bmatrix}
\]

III. CYBER PHYSICAL SYSTEMS

A. General Review

There are mainly two parts called as physical world and cyber world in CPSs. Physical world consists of sensors, devices and actuators as parts of a real physical process, while cyber world consists of a controller used to manage the physical process, a database storing data related to the physical system, an algorithm concerning the usage, safety and process of the data of the physical system, a scenario and security units. Each component of physical world and cyber world communicates through a wireless sensor and appliance (actuator) network. Information regarding physical process is received through various sensors and transmitted to cyber world. In order physical process to work better, this process is controlled in cyber world by means of developed algorithms and scenarios as well as data taken from sensors. In Fig. 2, corresponding structure of a CPS is given.

![Fig. 2 The structure of a cyber-physical system](image-url)
B. Smart Building

In this work, the importance of CPS is introduced by means of considering a smart building as a CPS. Traditional works on smart building systems mainly focus on issues of automatic control and energy efficiency, but omit the human–machine interaction problem. In [9] and [10], the authors address human activity recognition in the home environment, which can inform the smart building systems from the perspective of human–machine systems.

In this work, considered smart building is composed by real and virtual sensors, appliances, a wireless communication network and a controller unit.

Indoor and outdoor conditions of the smart building are detected via various real sensors, such as temperature, occupancy, light intensity and humidity. User requests concerning indoor conditions are taken via virtual sensors, thus user interfaces at different points, such as on-wall control panels, smart phones, tablets or computers.

Data taken from real and virtual sensors are transmitted to the database and the controller unit via wireless communication network. All data related to the building are stored in the cloud database and used when required. Controller unit manages the appliances in the building according to sensor outputs, user requests, developed algorithms and scenarios.

As diversity and number of sensors used in the building and variety of user requests increase, complexity of CPS increases which complicates the control and tracking of the system. In order to provide easy observation and tracing, computational and physical components of the building can be modelled via PNs which allow graphical representation as well as mathematical calculation of the evolution of the system.

In this work, two different PN models are developed for two different types of sensors: True/False sensors (i.e., occupancy, proximity and touch sensors) and sensors which can make wider range measurements (i.e., temperature, humidity and vision sensors).

PN model of True/False sensors is given in Fig. 3(a). In this model, places \( p_1 / p_2 \) represent sensor situations true(exist)/false(non-exist) while transitions \( t_1 \) and \( t_2 \) represent sensor activities.

For example, explanation of places and transitions of the PN model of an occupancy sensor, which is a kind of True/False sensor, are given in Table 1.

<table>
<thead>
<tr>
<th>Element</th>
<th>Explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>( p_1 )</td>
<td>Occupancy exists</td>
</tr>
<tr>
<td>( p_2 )</td>
<td>No occupancy</td>
</tr>
<tr>
<td>( t_1 )</td>
<td>Occupancy is detected</td>
</tr>
<tr>
<td>( t_2 )</td>
<td>Occupancy is lost</td>
</tr>
</tbody>
</table>

PN model of sensors having wide range measurements, is given in Fig. 3(b). In this model, places, thus \( p_1, p_2, \ldots, p_n \) represent the level of sensor measurement, while transitions, thus, \( t_1, t_2, \ldots, t_s \) represent switching the status of the sensor.

As for appliances, 3 working modes and \( n \) program modes (working types), each of which offers different functionality and features, are considered for each appliance inside the building. Similar to sensors, appliances (in other words, actuators) inside the building can be modelled by PN based on the working status of these devices. In Fig. 4(a) and Fig. 4(b) general PN models of working and program modes of an appliance are given: In Fig. 4(a), places \( p_1/p_2/p_3 \) correspond to on/stand-by/off working modes and transitions \( t_1/t_2/t_3/t_4 \) represent switching the working modes of an appliance. In Fig. 4(b), places \( p_1/p_2/\ldots/p_n \) represent the program modes of the appliance and transitions \( t_1/t_2/\ldots/t_s \) represent the switching the program modes of an appliance.

![Fig. 3 PN models of (a) True/False sensors and (b) sensors with wider range measurement capability.](image-url)

![Fig. 4 General PN models of (a) working modes and (b) program modes of appliances](image-url)

Working modes and program modes of any appliance are monitored by the cyber part of the building and controlled according to the predefined algorithms and scenarios. The cyber part of the building uses the information gathered from the sensors and responds quickly to the changes inside the building.
C. Case Study

In this work, Air Conditioner (AC) and lighting processes of the smart building are considered in detail.

The lighting system of the smart building is controlled according to the room usage inside the building. Occupancy sensors and daylight sensors are integrated to the rooms. Users shall use wall control panel, smart phones, and etc. control units to send their request to open the lighting system. When any request to open the lighting system is detected, the controller switches the working mode of the lighting system from off to standby and monitors the status of occupancy and daylight sensor. If the occupancy sensor in the environment senses occupancy, and the daylight sensor detects that the illumination of the environment is insufficient, the controller switches the working mode of the lighting system from standby to on, thus the lamp turns on. As the controller controls the on, standby and off modes based on the user request and the outputs of occupancy and daylight sensors, unnecessary energy use in the lighting system is prevented. Program modes of a lighting system are specified by dimmable levels that are set due to the level of illumination. These illumination levels affect the users comfort. For this reason, the users determine the dimmable levels by using different user interfaces. PN model of lighting system is given in Fig. 5.

Explanations of places and transitions are given in Table 2 and Table 3, respectively.

In this study, the cooling and heating needs of the smart building are provided by an AC, which has 3 working modes as on, standby and off; and 4 program modes as cooling-normal (set value: \( T_{on} \)), cooling-economic (set value: \( T_{co} \)), heating-normal (set value: \( T_{no} \)) and heating-economic (set value: \( T_{he} \)). Note that, compared to the normal program modes, the temperature set value for the economic mode is higher in cooling mode; and lower in the heating mode (\( T_{he} > T_{on}, T_{he} < T_{no} \)).

According to the information received from occupancy sensors, temperature sensors and smart meter, working status, thus working mode and program mode of AC is determined by the controller, for protecting unnecessary operation of the device, thus reducing the cost, and improving user comfort.
Working mode of this AC is determined according to user request and room occupancy. Working mode of AC in off mode is changed to stand-by mode, if user request is received. If room occupancy is detected afterward, working mode is set to on. If the occupancy disappears, while AC is working in on mode, it turns back to stand-by mode. If user request disappears afterward, AC turns back to off; whatever its present working mode is.

Program mode of AC is determined according to outer temperature value taken from outer temperature sensor, tariff rate information taken from grid. If outer temperature is higher than 24°C, AC works for cooling, otherwise it works for heating. Program mode of AC switches between economic and normal modes according to the information taken from the grid (smart meter). If the tariff rate is expensive, AC is switched to economic mode otherwise it works in normal mode. PN model of the considered AC system is given in Fig. 6.

In all PN models used in smart building, the places show the status of sensors and appliances. The transitions represent the actions or changes done by the controller inside the cyber world.

IV. CONCLUSIONS

In this work, CPSs are considered by means of a smart building application. In order to display working mechanism of computational and physical elements of the building, their models are developed via PN formalism, which is a mathematical and graphical tool for modelling and analysing discrete event systems. These models provide easy trace of the evaluation of the system. In future works, other parts of smart building will be modelled by using PNs and all developed models will be used to monitor and control the real applications. Scenarios and the corresponding centralized control algorithms will also be developed.

Abstract— Short term load forecasting is a subject about estimating future electricity consumption for a time interval from one hour to one week and it has a vital importance for the operation of a power system and smart grids. This process is mandatory for distribution companies and big electricity consumers, especially in liberalized energy markets. Electricity generation plans are made according to the amount of electricity consumption forecasts. If the forecast is overestimated, it leads to the start-up of too many units supplying an unnecessary level of reserve, therefore the production cost is increased. On the contrary if the forecast is underestimated, it may result in a risky operation and consequently power outages can occur at the power system. In this study, a hybrid method based on the combination of Artificial Bee Colony (ABC) and Artificial Neural Network (ANN) is developed for short term load forecasting. ABC algorithm is used in ANN learning process and it optimizes the neuron connections weights of ANN. Historical load, temperature difference and season are selected as model inputs. While three years hourly data is selected as training data, one year hourly data is selected as testing data. The results show that the application of this hybrid system produce forecast values close to the actual values.

Keywords— artificial bee colony, artificial neural network, hybrid method, short term load forecasting, smart grids

I. INTRODUCTION

Today existing power system needs to be enlarged so as to meet the future demand for electrical energy. The general purpose of the planning of electric power system is delivering the electric power to end user with some desired features such as continuous, safe, reliable and minimum price. Various plans should be made to achieve these features and load forecasting is one of the most important steps of these plans. In literature, load forecasting is divided into three categories according to the forecasting time horizons. Long term load forecast consists yearly load demand forecasts and it is used for planning future electric generation, transmission and distribution. Generally gross domestic product, population, export, import, etc. are considered as inputs in the long term load forecasting studies. Forecasting which is made in a time period ranging from one week to one year is called midterm load forecasting and it is useful for determining maintenance scheduling, hydrothermal coordination and fuel purchasing strategies [1].

Short-term load forecasting is a subject on which electric utility industry and researchers are studied for several decades and is an important process for the operations of electric power systems and smart grids. It has a critical role on generation scheduling, unit commitment and maintenance plans for generators. Short term load forecast has been made in a time period from one minute to one hour.

The concept of smart grid has become a global trend in the last years and there is not any definition of smart grid acknowledged by all institutions. For example, The Smart Grids European Technology Platform defines smart grid as “electricity networks that can intelligently integrate the behavior and actions of all users connected to it – generators, consumers and those that do both – in order to efficiently deliver sustainable, economic and secure electricity supplies” [2]. Smart grid is an advanced electrical network that uses control, information and communication technologies to monitoring the power system. In smart grids, energy management is performed with using some forecasts which use real time data. These forecasts are renewable production forecast, load forecast and electric price forecast. The power network can be managed efficiently by making these forecasts. Short term load forecast is also crucially important for smart grids. Recently, the demand side management becomes an emerging emphasis in the electric industry with the development of smart grid technologies. Especially in micro grids, short term load forecast helps to meet the objectives of demand side management issues like determining the electric price, determining the amount of the purchases and sales of energy and reducing the peak load value. It answers the questions of load needs such as when, how much, why and which factor effect [3].

There are many studies under the umbrella of short term load forecasting. Studies can be split into different groups according to the methods, data analyzing forms, data sets, the input variable and hourly/half-hour forecast. But, generally in review studies, they are grouped according to the methods. The used methods can be divided into three as statistical methods,
artificial intelligence methods and hybrid methods. The most commonly used techniques are based on Regression models [4], Times series models [5], [6], ARIMA models [7], Artificial Neural Network models [8], [9], Fuzzy models [10], [11], Support vector machine models [12], Particle swarm optimization models [13], Genetic algorithm models[14], [15], wavelet transform [16], ANFIS [11].

This paper focuses on a hybrid method based on the combination of artificial bee colony (ABC) and artificial neural network (ANN) for short term load forecasting. Firstly, the data is analyzed to create an accurate forecasting model and then the system inputs are determined. Historical load, temperature difference and season are selected as model inputs. While three-year hourly data is selected as training data, one year hourly data is selected as testing data.

The rest of the paper is organized as follows. Section II presents data analyzing. While section III presents a hybrid method based on the combination of ABC and ANN and describes the method in details, the testing results are given in Section IV. Section V outlines the conclusion.

II. DATA ANALYSIS

In this study, 2009-2012 hourly load consumption of Turkey and daily mean temperature of some cities which have maximum load consumption is considered for forecasting data. While load consumption data are taken from Turkish Electricity Transmission Company (TEIAS), temperature data are taken from Turkish State Meteorological Service. The data of the first three years which can be seen in Fig. 1 are used for creating the forecasting model and the data of 2012 are chosen for testing the forecasting model. There are some factors affecting the amount of electricity consumption and we can group them as time, historical load, weather conditions, major events and random events.

A. Time Factor

One of the most important factors which affect the load consumption is time factor, and it can be divided into categories such as hour, day and season. Hourly load forecasting is carried out in this study, hour factor is not considered as a model input. While day factor is discussed by grouping the week days, season factor is considered as an input for forecasting model. The hourly load consumptions of three consecutive weeks are shown in Fig. 2. As can be seen from Fig. 2, load consumption trends of each days are similar with the same day which is in the neighboring weeks. But daily load consumption trends are different from each other. The early hours’ consumption of Monday is very low compared to the other days, so Monday is selected as the first day type. Tuesday, Wednesday, Thursday and Friday daily load rhythms are similar with each other, therefore these days are named as Weekday day type. Saturday and Sunday load curves are unlike any other and each other. Thus, more day types named as Saturday day type and Sunday day type are created. So we have grouped the days in 4 day types as Monday type, Weekday type, Saturday type and Sunday type.

Seasons are also acts as time factor for short term load forecasting. Although load consumption changes according to the geography and people’s usage habits, the seasons affects meteorological variables and load consumptions. For example Turkey is a country located in the northern hemisphere. The use of electricity increases for heating purposes in winter with decreasing temperature in the air. On the contrary, the use of electricity decreases with increase temperature. In summer, it also has an opposite relationship. When the temperature rises in summer season people need to cool down and run their air conditioners and as a result electric consumption increases. In autumn and spring season, the season effects seem as a transition condition between winter and summer. In summary, season is also a time factor which affect the load consumption and we consider season as an input for short term load forecasting.
B. Historical Load Factor

The most important factor is historical load for short term load forecasting and the most of the studies in literature use the historical load as an input. As seen in Fig. 2, load curves are similar to load curves of previous week and next week. Forecasting accuracy increases by taking account previous 1-3 week load values in account, because load consumption trend does not change very much in short time period like 1-3 weeks.

C. Weather Factor

Weather factor is also important factor and these are temperature, humidity, wind speed and cloudiness. In literature studies, some various temperature data are used such as daily mean temperature, daily mean temperature difference, hourly temperature and hourly temperature difference. In this study, daily mean temperature difference is chosen as another input.

There are also some random developing major events such as earthquake, disaster and chaos which affect the load consumption, but such conditions are ignored in this study.

III. FORECAST METHOD

A. Artificial Neural Networks(ANN)

Artificial Neural Networks (ANN) is the most used method for load forecasting in literature studies. ANN is a very successful method to find the relationship between inputs and outputs. Multilayer Feed Forward Neural Network has one input, one output and usually one or more hidden layers [17]. Each node connects to each other with weights. Each node has a duty to produce result with a transfer or activation function.

Output function calculation:

\[ y_i = f_i \left( \sum_{j=1}^{n} w_{ij} x_j + \theta_i \right) \]  

Where \( f_i \) is the activation function and \( w_{ij} \) is the weight of between two neuron such as input \( j \) to neuron \( i \), \( x_j \) is the input neuron number, and \( \theta_i \) is the bias neuron \( i \).

Graphics of frequently used activation functions are illustrated in Fig. 3 and Fig. 4.

A system that has multiple input and one output is called neuron. Neurons form the network structure by combining. In this study, we used an ANN structure with two layers. The structure has input neurons, hidden layer neurons and an output neuron. Sigmoid function and linear function are used respectively for the hidden layer and the output layer.

The difference between the result which is produced by the network and the target result contains generic information. Learning in back propagation algorithm provides the calculation of weights of network by adding half of the total error. This procedure continues iteratively until it reaches minimum error [18]. General network structure is shown in Fig. 5.

The formula of the total error is half of the total square error:

\[ E = \frac{1}{2} \sum_{t=1}^{n} (\text{desired}_t - \text{calculated}_t)^2 \]  

The data is divided into two as test and learning data for the execution of the algorithm. The weights obtained at the end of the training have to include the entire training data. The training will be completed when the total error reaches its minimum value.

B. Artificial Bee Colony(ABC)

Artificial Bee Colony (ABC) algorithm is used as an optimization technique with relation between food and bees. There are three types of artificial bees and these are onlooker (observer) bees, employed bees and scout bees. The onlooker bees give information to the employed bees about food source and distance by dancing on the dance area. The employed bees visit the food source and collect nectar from these sources. The scout bees look for better resources by making a random search [19]. The working principle of the algorithm is shown in Fig. 6.
Artificial observer bees consider the probability value \( p_i \) of the food source \( fs \) that is abandoned by the observer bee, which is shown in Eq. (3), to decide the quality of food source [20]:

\[
p_i = \frac{fit_i}{\sum_{n=1}^{N} fit_n}
\]

(3)

\( fit_i \) indicates the fitness value of the calculated solution and it is shown as:

\[
fit_i = \begin{cases} 
1 + x & \text{if } x \geq 0, \\
1 + \text{abs}(x) & \text{if } x < 0
\end{cases}
\]

(4)

The source of nectar that is abandoned by the observer bee is replaced with a new source that is produced by the scout bee. Formula of the produced new source by scout bee is shown as:

\[
x_i = x_{\text{min}}^j + \text{rand}(0,1)(x_{\text{max}}^j - x_{\text{min}}^j)
\]

(5)

The every each food source is processed by employed bee and calculated solution is compared with the previous solutions.

If the new solution is equal or better, the previous solution is replaced by the new solution and saved on memory.

C. The Hybrid Model

Employed bees of ABC use the transfer function and the activation function to produce solution with artificial bee colony inputs. ANN total error value is calculated by the solution of ABC produced. Trained ANN by ABC is shown in Fig. 8.

Artificial Bee Colony and artificial neural network methods are utilized intensely on the literature. In this study, we have used a hybrid method that is combination of artificial bee colony and artificial neural network for short term load forecasting. As we mentioned before, the ANN deduces the relationship between inputs and outputs by updating network’s weights and uses back propagation algorithm such as Levenberg-Marquardt and quasi-Newton for updating network weights. ABC is a swarm based optimization technique and proves their ability for optimization. The learning speed of ANN is increased by ABC since it reaches better resources.

The interface of the developed software is shown in Fig. 7. The software is developed using Borland Delphi programming language which is one of Pascal programming languages and the data is taken from excel file. The number of input neurons, the number of hidden layer neurons and the number of output layer neurons can be changed by the user. User also can choose the activation functions. Then, the weights of the ANN are calculated by the ABC algorithm while the software is running.

ihallas@ktu.edu.tr

Abstract— In this study, a fractional order PID (FOPID) controller is designed and used to control a DC-DC non-inverting buck-boost converter (NIBBC) for a wave/ultra-capacitor (UC) energy system. Because of the energy discontinuities encountered in wave energy conversion systems (WECS), an UC is integrated to the WECS. In order to obtain the best controller performance, particle swarm optimization (PSO) is employed to find the optimum controller parameters. Integral of time weighted absolute error (ITAE) criteria is used as an objective function. Also, an optimized PID controller is designed to test the performance of the FOPID controller. The whole system is developed in Matlab/Simulink/SimPower environment. The simulation results show that the FOPID controller provides lower value performance indices than the PID controller in terms of reducing the output voltage sags and swells.

Keywords— Wave energy, ultra-capacitor, non-inverting buck-boost converter, fractional order PID controller, particle swarm optimization.

I. INTRODUCTION

Alternative energy sources such as renewable energy are highly considered in order to meet increasing energy demands all over the globe. Among the renewable energy sources, wave energy (WE) is a promising energy source. Its energy density is more available than either solar and wind energy [1]. Whereas, it has some design challenges because of the irregular sea or ocean wave characteristics and extreme weather conditions [2].

A wave energy converter (WEC) used for harvesting energy form the waves. It basically includes a turbine and a floating buoy moves up and down on the sea surface. The power production rate of a WEC is mostly depending on both of the wave height and frequency in a direct-driven WEC. So, the amplitude and frequency of the WEC output voltage fluctuates chaotically. Due to the output power of the WEC has a wide variations, it cannot directly connected to a load or grid. To overcome this problem, WECs are integrated with power electronic devices and storage units [3].

An ultra-capacitor (UC) is an electrochemical capacitor with high-capacitance value. Compared to batteries, it has a very long life cycle, high efficiency, high power density and fast charging-discharging capacity [4]. Integration of the UC to WEC with and without power electronic devices can be found in literature [5, 6, 7]. UCs can be directly connected in parallel with an energy source, especially low voltage applications [8]. Also, direct integration of an UC to energy system increases the overall system efficiency by eliminating the converter losses.

Fractional calculus has become highly popular in engineering applications, especially in control systems. One of the fractional order control method is the fractional order PID controller which is the extension of the PID controller and proposed by Podlubny in 1999 [9]. A FOPID consist of 5 parameters: the proportional gain (K_p), integral gain (K_i), order of integral (λ), derivative gain (K_d) and order of derivative (μ). These parameters increases the complexity of the controller and they should be optimized in order to obtain the best controller performance.

One of the tuning method of controller parameters is to use meta-heuristic algorithms with error-based objective functions. One of these algorithms is the PSO algorithm. PSO is developed by Kennedy and Eberhart in 1995 [10]. The algorithm is an iterative optimization method based on the stochastic movements of the swarms such as fishes and birds and it is suitable for global optimization problems.

In this study, irregular wave effects seen on generated power in WEC are regulated by using a UC unit and NIBBC in order to obtain a reliable and sustainable load voltage. The parallel connected UC to the WEC provides energy to the load when the WEC output is insufficient. The converter is controlled by both of FOPID and PID controllers for comparison. Also, PSO algorithm is used to tune the parameters of the both controllers by minimizing the ITAE performance index. Both of the system results with and without UC connection are discussed.

This paper is organized as follows. Wave energy conversion system with the subtitles wave energy converter, NIBB converter and UC modelling are presented in Section II. FOPID controller is described in Section III. PSO algorithm is given in Section IV. In Section V, the simulation results are discussed. Finally, conclusion is stated in Section VI.
II. WAVE ENERGY CONVERSION SYSTEM

The scheme of the whole system is depicted in Fig. 1. The proposed system includes wave energy converter (WEC), 3-phase passive rectifier used for translating produced AC voltage signal from waves to DC signal, UC energy storage unit, NIBB converter and the resistive load.

The aforementioned subsystems are described below, respectively.

A. Mathematical model of the Wave Energy Converter

A permanent magnet linear generator (PMLG) is modelled in this study for simulating the electrical energy dynamics of a WEC [11]. The mathematical description of the induced 3-phase voltages with 120° phase shifts are given below.

\[
V_A = -\frac{2\pi N \Phi_0}{\lambda} \cos\left(\frac{2\pi}{\lambda} x \right) \frac{dx}{dt} \tag{1}
\]

\[
V_B = -\frac{2\pi N \Phi_0}{\lambda} \cos\left(\frac{2\pi}{\lambda} x + \frac{2\pi}{3} \right) \frac{dx}{dt} \tag{2}
\]

\[
V_C = -\frac{2\pi N \Phi_0}{\lambda} \cos\left(\frac{2\pi}{\lambda} x - \frac{2\pi}{3} \right) \frac{dx}{dt} \tag{3}
\]

where \(x\) is the translator displacement, \(\lambda\) is the wave length, \(\Phi_0\) is the induced flux magnitude and \(N\) is the number of coil turns.

B. Non-inverting Buck-Boost Converter

A NIBBC is a type of switched mode DC-DC converter that is used as an interfacing circuit between the wave/UC energy system and the resistive load. Output voltage of the converter which has the same polarity with the input voltage can be lower or higher than magnitude of the input voltage. This means that the converter is able to operate either a buck or boost converter. The proposed converter topology provides a wide input voltage range with low component stress and simplicity [12].

The converter topology pointed out in Fig. 1 consists of an inductor (L), diodes (D1, D2), switching mosfets (S1, S2) and output capacitor filter (Cout). The converter parameters and design criteria are given in Table I.

Using Kirchhoff’s voltage and current laws, dynamics of the converter is described by the following equations.

\[
L \frac{di_l(t)}{dt} = (u-1)V_{out}(t) + uV_{in}(t) \tag{4}
\]

\[
C \frac{dV_{out}(t)}{dt} = (1-u)i_l(t) - \frac{V_{out}(t)}{R} \tag{5}
\]

Where \(i_l\) is the inductor current, \(V_{out}\) is the output voltage, \(u\) is the control signal representing the switches positions. (\(u=1\) means the switches are on and \(u=0\) means the switches are off) [12].

When both of the switches are ON-state, as shown in Fig. 2, both of the diodes are reverse biased. Current coming from the source flows through the inductor and so, the inductor is linearly charged. The load voltage is provided by the capacitor.

When the switches are OFF-state, the diodes are forward biased and the charged inductor supplies energy to the load and capacitor.

C. Ultra-capacitor Modelling

Different type of model topologies of UC can be found in literature. Some of these are R-C parallel branch model [13], R-C transmission line model [14] and R-C classical model [13, 15], etc. R and C are used to symbolize resistor and capacitor of the UC, respectively.

In this study, RC classical model is used to simulate UC electrical dynamics. The classical R-C topology is suitable for slow discharging applications and pulse loads. Also, it is easy to model [16]. The model equivalent circuit is shown below.

![Equivalent circuit of the RC modelled UC](image)

where $V_{UC}$ is the terminal voltage of the UC, $R_{esr}$ is the equivalent series resistance used to simulate internal resistance of the UC, $R_{epr}$ is the equivalent parallel resistance used to simulate leakage currents and $C$ is the capacitance of the UC. The mathematical description between the UC voltage and current are given in (6).

$$V_{UC(final)}(t) = I_{UC}(t) R_{esr} + \frac{1}{C} \int I_C(t) dt + V_{UC(initial)}(t)$$ (6)

Maxwell BMOD0083-P048 ultra-capacitor specifications are used for modelling of the UC. The parameters are given in Table II [17].

III. FRACTIONAL ORDER PID CONTROLLER

Fractional-order PID controller based on fractional calculus includes more than two additional parameters ($\lambda$, $\mu$) to the conventional PID controller. $\lambda$ is the order of the integrator and $\mu$ is the order of differentiator.

The FOPID controller has five parameters to be optimized in order to obtain the best controller performance. The block diagram representation of the proposed controller is shown in Fig. 4.

![Block diagram of the FOPID controller](image)

A FOPID controller transfer function representation is defined as [18]:

$$G_{FOPID}(s) = \frac{U(s)}{E(s)} = \left( K_p + \frac{K_i}{s^\lambda} + K_d s^\mu \right)$$ (7)

Where $U(s)$ and $E(s)$ are the control and error signals, respectively. In this study, FOPID controller software are performed by FOMCON Toolbox [19].

IV. PARTICLE SWARM OPTIMIZATION

Particle swarm optimization (PSO) is a population based evolutionary algorithm developed from the simulations of bird-flocking. The first step in algorithm is that the specified number of particles are placed randomly in the d-dimensional search space and objective function of the each particle is calculated and saved at their current position [10].

Associated coordinates with the best solution is called $p_{best}$. Then, the obtained best solution is compared to each other to find the global best solution which is called as $g_{best}$. The movements of the particles are updated by using the position (X) and velocity (V) equations given in (8) and (9), respectively [20].

$$V_{i}^{t+1} = w V_{i}^{t} + c_1 r_1(p_{best}^{t} - X_{i}^{t}) + c_2 r_2(g_{best}^{t} - X_{i}^{t})$$ (8)

$$X_{i}^{t+1} = X_{i}^{t} + V_{i}^{t+1}$$ (9)
In (8) and (9), \( i \) is the particle number, \( t \) is the iteration number, \( c_1 \) and \( c_2 \) are the acceleration factors which are set to 2. \( r_1 \) and \( r_2 \) are the random numbers in the range of \([0, 1]\). \( w \) is the inertia weight which balances the global and local search. The value of the \( w \) is linearly decreased from 0.9 to 0.4 as recommended in [21]. Population size (n) and the iteration number (N) for both of the controller tuning processes are set to 10 and 20, respectively.

Since the ITAE criteria of which mathematical description given below provides a smaller overshoot and reduced oscillations than the other error-based performance indexes, it is used as an objective function [22, 23].

\[
ITAE = \int_{0}^{t} |e(t)| dt
\]

(10)

V. SIMULATION RESULTS

The WECS illustrated in Fig 1. schematically is developed in Matlab/Simulink/SimPower environment. Because the small-scale waves are considered in this study, current drawing from the generator is limited by duty cycle (\( d \)) in the range of \([0, 0.65]\). Simulations are performed for 30 seconds. The initial charge voltage of the UC is 12 V and the load resistor is 10 \( \Omega \).

The DC-DC NIBB converter used for load voltage regulation is controlled by both of FOPID and classical PID controllers. PSO algorithm is employed to tune controller parameters and ITAE performance measure is used as an objective function. Also, other error-based performance indexes : integral of squared error (ISE), integral of absolute error (IAE) and integral of time weighted squared error (ITSE) are considered for a better comparison of the designed controllers. The optimized parameters of the controllers and calculated performance measures are given in Table III and Table IV, respectively.

The simulation results are considered with and without UC unit. Since the FOPID provides a lower value performance criteria value, all results are shown with optimized FOPID controller.

The induced irregular 3-phase form in WEC with and without UC unit is depicted in Fig. 5. The converter input voltage and current is shown in Fig. 6.
Fig. 6 shows that the parallel connected UC unit to the WEC output eliminates the voltage drops encountered in a WEC because of the irregular wave effects. As a result, a more stable input voltage is obtained for the NIBBC input. WEC provides energy to the load when the induced voltage value is greater than UC charge voltage.

Fig. 7 shows the load voltage and current with and without UC unit. The WEC is alone inefficient to feed the load. The comparison of the PSO optimized FOPID and PID controllers are given in Fig. 8. The FOPID controller provides a stable voltage with increased quality than the PID controller. Also, the system response without overshoot is obtained with FOPID controller.

VI. CONCLUSIONS

In this study, an initially charged UC unit is connected in parallel with a WEC output. A NIBBC is used as an interface circuit between the WEC/UC side and the load. Thus, it is aimed to regulate the energy irregularities encountered in WEC output.

The designed WECS is tested under irregular wave condition. The rectified variable WEC/UC output voltage is applied to the NIBBC. DC-DC converter is controlled by a FOPID controller. Also, a classical PID controller is used for comparison. In tuning process of the both controller parameters, a well-known optimization algorithm PSO is employed. The ITAE is used as an objective function. The simulation results show that the FOPID provides lower value objective function value than PID controller. This means the higher quality output voltage without overshoot is obtained by using the FOPID controller.

Since the small-scale waves are considered for this study, WEC is alone inefficient to charge the UC unit. A solar or grid charged UC can be considered to increase the overall system sustainability.

Abstract- Epilepsy that occurs suddenly and repeatability of seizure is a chronic neurological disorder and it is estimated that 1% of the world population suffering from epilepsy. Therefore, many studies are carried out for the diagnosis of epilepsy. In this study, we performed to determine the most significant characteristic by using electroencephalography signals (EEGs). EEG recordings that obtained from 10 normal subjects and 10 epileptic patients were conducted from Selcuk University Faculty of Medicine. Different features extraction methods that include Discrete Wavelet Transform, statistical methods were applied for identifying highest success features vectors. Different classification methods were performed for determining success of classifiers. High classification accuracy (CA) was obtained when the statistical methods was used in this new dataset. K-Nearest Neighbors (kNN) method achieved higher CA with 98% than the other classification methods.

Keywords-Epilepsy, electroencephalography, feature extraction, discrete wavelet transform.

I. INTRODUCTION

Epilepsy is a type of neurological disorder disease stemming from temporary abnormal discharges of the brain electrical activity [1] and [2]. The significant characteristic of epilepsy is recurrent seizures. Sometimes seizures may go unnoticed, depending on their presentation [3]. Therefore, automatic seizure detection, particularly if it is performed online, can be very helpful to identify segments of electroencephalography (EEG) likely to have seizures [4]. However, there still exists a need to further improve existing detection methods published in the literature. Elman Classifier was designed to acquire EEG and psycho physiological signals by Hosseini et al.[5], Kumar et al. [6] highlighted the importance of entropy-based features in recognizing EEGs with recurrent Elman Networks. Orhan et al. [7] achieved Multi-Layer Perceptron Neural Network (MLPNN) for classification of EEG signals and feature vectors were clustered by using K-means clustering method. Aydin et al. [8] developed a classification using Multilayer Neural Network (MLNN) architecture with EEG series.

Lee [9] proposed the Neural Network with Weighted Fuzzy Membership (NEWFM) to classify EEG signals. Fu [10] performed the classification of EEG signals using Hilbert–Huang transform (HHT) and Support Vector Machine (SVM) with Radial Basis Function (RBF). Joshi et al. [11] carried out classification of EEG signals using fractional linear prediction. Musselman et al. [12] proposed time-frequency distributions in the classification of epileptic activities by using SVM. Moreover, Valderrama et al. [13] identified via SVM an increased risk of epileptic seizures using a multi-feature EEG-ECG classification. A comparative study of waveform families for EEG signal classification was performed by Gandhi et al. using Probabilistic Neural Network (PNN) with SVM. Whereas Siuly et al. [14] proposed Clustering Technique-based Least q-Square Support Vector Machine (CT-LS-SVM) classification using some feature vectors, Lima et al. [15] used some SVM methods such as Lyapunov the standard SVM. We may reach the conclusion that classifies EEG signal was performed by using different classification and feature extraction methods.

EEG is a complicated and non-stationary signal and its characteristics are spatio-temporal dependent. They were not considered using statistical properties or sub-bands. The suitable feature extraction and accurate classifiers are needed for evaluation of these signals. Therefore, in this study, EEGs have been evaluated with different classifiers by extracting different features from EEGs. We carried out various classification and feature extraction methods in the same work for observing and detecting feature vectors that provide the highest success. At the same time, we observed which feature vectors on the not suitable for this dataset. On the other hand, we aim to increase the success by using determined features by means of new classification methods or hybrid systems in future work.

There is no doubt that the number of inputs is very crucial in the system since the classification method should be selected very carefully. The number of unnecessarily high inputs might decrease performance of the system or the number of unnecessarily low inputs may not give the result accurately and confidently. Due to the fact that in this paper, we used the various feature extraction methods that include statistical features and power of sub-bands features via Discrete Wavelet Transform for detecting epilepsy from EEGs.

II. MATERIALS AND METHODS

1. DATA ACQUISITION

In this study, EEG data recorded in the Department of Neurology is used with decision of Selcuk University Faculty of Medicine Hospital (Non-Invasive Clinical Research Ethics Committee No. 2014/423). We have used a total of 20 subjects (10 epileptics, 10 non-epileptics) that collected between 2012 and 2015. All of EEGs was obtained from
routine EEG recording and all subjects were awake. Their mean age of 10 epileptic patients was 39 (7 male, 3 female) and mean age of 10 non-epileptic patients was 42 (6 male, 4 female) and all EEG tracing has been converted electronically. Meanwhile, EEG recordings in different dates of two patients who are epilepsy and undergo a treatment were included to our work.

EEG recording consist of 20 channels that include 18 channels for EEG, 1 channel for electrocardiography (EKG) and 1 channel for photic stimulation. However, we used 18 channels in this study because of including brain waves. Sampling frequency is 200 Hz and each epoch consists of 15 seconds.

Recording times is different from each other due to the fact that the situation of each subject in record time is different. Moreover, dataset showing epileptic activity that is determined by specialists are selected. These dataset was created EEGs that include various waves such as sharp wave, spike, spike and slow wave, multiple spike and slow wave complex. 5 epochs are used in this study both epileptic and non-epileptic patients and the length of each epoch are composed of 3000 samples. 100 segment data for 20 subjects was obtained as a result of calculations and adjustments. Whereas a value of 1 is given for 50 epileptic data, a value of 0 is given for 50 non-epileptic data in order to classify.

2. FEATURE EXTRACTION

Feature extraction process is an important factor affecting the success of classification. Features should be determined for achieving results faster and more accurately with fewer data. Therefore, the feature vectors were computed by the usage of the Matlab (Version 7.11, R2010b) software package. Feature Vectors (FV) are divided into 3 groups respectively, Feature Vector 1 (FV1), Feature Vector 2 (FV1) and Feature Vector 3 (FV3) as a result of feature extraction as shown in Table I. The number of decomposition levels is chosen based on the dominant frequency components of the signal. The levels are chosen such that those parts of the signal that correlate well with the frequencies required for classification of the signal are retained in the wavelet coefficients [16]. In this study, the EEG signals are filtered with band-pass Butterworth filter to extract four common frequency bands, beta (β), alpha (α), and delta (δ), theta (θ). The power of subbands has been found by using the Discrete Wavelet Transform (DWT) for FV1. The wavelet function selected was Daubechies with order 4, which was also proven to be the best suitable wavelet function for epileptic EEG signal analysis [17]. Eight statistical features are extracted from each EEG channel data as they are the most representative values to describe the original signals. Experiments have shown that computing speed of classifiers and CA decreased with using of combination of all statistical features. Therefore, whereas some statistical features consists of minimum, maximum, standard deviation and variance have been found for FV2, skewness, kurtosis, interquartile range and mean absolute deviation have been found for FV3. Consequently, statistical features were divided into two groups as FV2 and FV3.

| TABLE I. FEATURE VECTORS BY USING DIFFERENT FEATURE EXTRACTING METHODS |
|---------------------------|-----------------------------|
| Name | Description |
| FV1_Pb | Average power of β in each sub-band |
| FV1_PA | Average power of α in each sub-band |
| FV1_PT | Average power of θ in each sub-band |
| FV1_PD | Average power of δ in each sub-band |
| FV2_Min | Minimum of the coefficients in each channel |
| FV2_Max | Maximum of the coefficients in each channel |
| FV2_Var | Variance of the coefficients in each channel |
| FV2_Sgd | Standard deviation of the coefficients in each channel |
| FV3_Skw | Skewness of the coefficients in each channel |
| FV3_Krt | Kurtosis of the coefficients in each channel |
| FV3_Iqr | Interquartile range of the coefficients in each channel |
| FV3_Mad | Mean absolute deviation of the coefficients in each channel |

72 (18x4) features were obtained due to the fact that 4 features were extracted every channel (18). Thus, each dataset consists of 100 segments and 72 features.

3. CLASSIFICATION METHODS

SVM and different Neural Network algorithms are often used in literature for the epilepsy diagnosis. On the other hand, in this study, we carried out different methods that include kNN, Classification Tree, Random Forest, Naïve Bayes in addition to these methods. The parameters of classifier were optimised in order to determine the highest success by various trials. The parameters of all classifier that provide the highest success is shown in Table II.

| TABLE II. LEARNING PARAMETERS OF EACH CLASSIFIER |
|-----------------------------------|-----------------------------|
| Classification Methods | Parameters |
| MultiLayer Perceptron (MLP) | Hidden layer neurons: 20 |
| Naïve Bayes | Probability estimation: Relative Frequency |
| Classification Tree | LOESS* window size: 0.5 |
| SVM | Estimate class probabilities: Yes |
| Random Forest | Normalize data: Yes |
| kNN | Unknown values ignored: Yes |

*LOESS: Local weighter regression (kernel smoothing procedure)

4. STATISTICAL CALCULATION OF PERFORMANCE

The performance of the classifier methods is assessed by the following measures.

1) True positive (TP): It identifies an input as a patient with epileptic diagnosed by the expert clinicians.
2) True negative (TN): It identifies an input as a normal that was labeled as a normal by the expert clinicians.

3) False positive (FP): The detection of epileptic that was labeled as a normal by the expert.

4) False negative (FN): The detection of a normal that was labeled as an epileptic patient by the expert. The performance of the classifier is also assessed in terms of sensitivity and specificity as follows.

Additionally, we can calculate sensitivity, specificity and accuracy values by using TP, TN, FP and FN as shown below.

(1) Sensitivity (Sens): A measure of the ability of the classifier to detect epileptic signal.

\[
\text{Sensitivity} = \frac{TP}{(TP + FN)} \%
\]

(2) Specificity (Spec): A measure of the ability of the classifier to specify normal signal.

\[
\text{Specificity} = \frac{TN}{(TN + FP)} \%
\]

(3) Accuracy

\[
\text{Accuracy} = \frac{TP + TN}{(TN + TN + FP + FN)} \%
\]

III. EXPERIMENTS AND RESULTS

In this study, we tried to find which feature vector that represents better the EEG signal using various classification methods such as MLP, Random Forest, SVM, kNN, Classification Tree and Naïve Bayes. First of all, data was organized and then extracted some feature vectors by using power of subbands and some statistical functions. 5-fold cross-validation is performed on all data when determining the success of classification methods.

It can be seen that kNN is the most successful methods with 98% CA for FV2 and 96% CA for FV3 as shown in Table III. Meanwhile, Naïve Bayes is the most successful method for FV1 with 69%. However, at the same time kNN is more successful for FV1 than other methods except for Naïve Bayes. Consequently, we can say that whereas kNN is the best classifier for this dataset, Classification Tree is the lowest classifier.

Confusion matrix that is true and false predictions in each feature vectors including FV1, FV2 and FV3 are given in Table IV. Whereas Naïve Bayes classifier has been found 40 true, 10 false for 50 non-epileptic data, 29 true, 21 false for epilepsy group in FV1. On the other hand, kNN has been found 49 true and 1 false both non-epileptic and epileptic data in FV2. 49 true and 1 false for non-epileptic data and 47 true and 3 false was found for FV3 by means of kNN. Confusion matrix in Table IV gives number of true and false in detail that this table is also confirmed in Table II.

Note: column represent predictions, row represent true classes

In spite of the fact that SVM and MLP are providing the highest achievement many studies in the literature, the results show that kNN provides the highest CA in our work. Meanwhile, the accuracy of classification has been finding very high with FV2.

Receiver operating characteristics (ROC) graphs that are commonly used in medical decision is a plot of class sensitivity against specificity as a threshold parameter is varied. In this study, the epilepsy/non-epilepsy decision threshold is varied in the range 0–1 as shown in Fig 1.
The ROC area is an effective method in order to compare the performance of different features. As is known, the area under the 1 value in ROC curve shows the excellent test results, whereas the area under the 0.5 value in ROC curve shows the unsuccessful test results. The gathered results showed that statistical features for this new dataset could be tried on similar dataset that includes larger data in order to test and improve. In the next study, it is planned to develop a system that allows distinguishing the differences and similarities between seizures and artifacts because even experts can give wrong decisions besides the computer systems.

**IV. CONCLUSION**

Feature extraction method and number of the features affects to reach accurate results in a faster way as well as the performance of the classifier. Therefore, it will improve the success of the classifier to determine the appropriate number and best features. In this context, different feature extraction methods were tested and the performance of the classifiers was compared. The CA for FV2 and FV3 are more successful than FV1. On the other hand, kNN gives the highest average CA of all feature vectors although Naïve Bayes is the most successful method for FV1.

**ACKNOWLEDGMENT**

This study was produced as a result of Sema Yıldırım’s PhD’s thesis in Selcuk University Institute of Science and Technology. We present our thanks to Selcuk University Faculty of Medicine Hospital for their contributions.

A Comparison of The Programmes Using Finite Element Software in Electrical Machine Design

Murat TÖREN*, Mehmet ÇELEBİ+

* Electronic and Automation Department of Technical Sciences and Vocational School, Recep Tayyip Erdogan University, Rize, Turkey
murat.toren@erdogan.edu.tr

+ Department of Electric and Electronic Engineering, Ataturk University, Erzurum, Turkey
mcelebi@atauni.edu.tr

Abstract—Electrical machines technology has become too dependent on finite element method (FEM) programs in our time. In this study, three programs that are sold commercially are compared over a 4-poles asynchronous machine of 1.1 kW. With this comparison, it is investigated how close the values obtained by convenience, appearance, integration and, in particular, torque calculations with the real values will be. For this, the mechanical torque value of the machine is obtained first by using the machine’s foreknown geometrical parameters and electrical parameters found by tests. Then, the magnetic flux line and density distribution and the obtained reluctance / real torque values are compared between FEM programs.

Keywords—Ansoft /Maxwell, Cedrat /Preflu, Ansys, Ansys Workbench, Induction Machine

I. INTRODUCTION

In recent years, the FE software package has been widely used in applications. The programs using these applications are Ansoft, Ansys and Cedrat. Ansoft is the most common program among these publications although all types of machine and analysis are available in Ansys. Ansys is the world's most widely used FE software package program. Cedrat is not a very popular program.

In this study, FEM software packages were compared starting from real values on a 4-pole asynchronous machine of 1.1 kW [1]. As a result, it is proposed to give an idea for electrical machine designers using finite element technology. Although this test was performed only for the asynchronous machine, it is generally useful for demonstrating the advantages and disadvantages of these programs. As a matter of fact, as a result of the variations and difficulties between theoretical calculation and reality due to the working manner of the asynchronous machine, the closer a simulation program for such a type of machine to the real value the more acceptable performance given by the simpler direct-current machines.

In essence, real criterion is considered to be torque calculation. This is because magnetic flux distributions of this machine, which has been produced commercially, have already been designed within the acceptable limits. In all simulations, the material is used with a BH characteristic given in Fig. 1 The computer system that is used for simulations is given in Table I and specifications of the test machine in Table II.

| Computer type | Laptop |
| Manufacturer   | Dell   |
| CPU            | AMD Turion 64x2 TL-50 1.60 Ghz |
| Physical RAM   | 2 GB   |
| Graphic Card   | ATI Radeon Xpress / Shared system memory |
| OS             | Windows 7 Ultimate 64 bit |
Initially analytical expressions are obtained from the values determined by the company. After calculating emf in the stator as 192 V by using the air gap magnetic flux density as 0.7 T and heyland leakage factor, the number of conductors per slot is found, by taking the equivalent pole length factor α = 0.76, as follows,

\[ z_0 = \frac{2m E_1}{N_1 4.44 f k_w \phi} \]  

(1)

where, \( E_1 \) is the voltage at motor end; \( n_1 \) is the synchronous speed; \( m \) is the phase numbers and \( X_1 \) is the short circuit reactance.

In here, \( z_0 \) is found as 69 and \( N_1 \) is the number of stator slots; \( k_w = 0.96 \) is the winding factor and \( \phi = 0.0022 \text{ Wb} \) is the air gap flux. The stator slot pitch induction is found from Eq (2):

\[ B_{da} = \frac{\tau_0}{k_w b_{da} B_{0}(1 + 0.6667 \sigma)} \]  

(2)

where, \( B_{da} \) is stator slot pitch induction (T); \( \tau_0 \), stator slot pitch; \( b_{da} \), stator tooth width; \( k_w = 0.95 \) is the iron packing factor; \( B_{0} \) is the air gap induction (T) and \( \sigma = 0.0115 \) is heyland leakage factor. The height of the yoke is found by using the below equation.

\[ h_{j1} = \frac{\phi(1 + \sigma)}{2k_w L B_{j1}} \]  

(3)

where, \( L \) is the stack length (mm) and \( B_{j1} \) is the yoke magnetic flux density and assumed to be as 1.4 T. Rotor yoke height is obtained as,

\[ \frac{h_{j2}}{2k_w L B_{j2}} = \frac{\phi}{2k_w L B_{j2}} \]  

(4)

In here, the rotor yoke height is taken as 1.2 T. Leakage reactance of stator winding is,

\[ X_{\sigma 1} = 0.5 \pi^2 \frac{\omega_1^2}{f} \lambda_1 \]  

(5)

where, \( \lambda_1 = 12.46 \) is the leakage conductance of stator winding. Then, the leakage reactance of rotor bars reduced to stator is obtained from (Eq (6)).

\[ X_{\sigma 21} = 1.6u_1 \pi^2 \lambda_2 \]  

(6)

where, \( \lambda_2 = 19.63 \) is the leakage conductance of stator winding and \( u_1 = 6.67 \times 10^4 \) is the conversion rate. The leakage factor of the rotor is obtained as,

\[ \sigma_2 = \frac{X_{21}}{X_1} \]  

(7)

Then, nominal and startup moments found from the equivalent circuit parameters are obtained as follows, respectively:

\[ T_1 = 1 + \sigma_1 \]  

(8)

\[ X_k = T_1 X_1 + T_2 X_{21} \]

By using the above relationships, the nominal moment,

\[ M_{dn} = 60 \frac{m U}{\sqrt{3}} \frac{R_{21} / s}{(R_1 + T_1 R_{21} / s)^2 + X_k^2} \text{ (Nm)} \]  

(9)

and the startup moment,

\[ M_{dy} = 60 \frac{m U}{\sqrt{3}} \frac{R_{21} / s}{(R_1 + T_1 R_{21} / s)^2 + X_k^2} \text{ (Nm)} \]  

(10)

are found as 7 and 16.84 Nm, respectively. Here, \( U \) is the voltage at motor end; \( n_1 \) is synchronous speed; \( m \) is the phase number; \( T_1 \) is the conversion rate; \( R_1 \) and \( X_1 \) are resistance and reactance of stator winding, respectively, and \( X_k \) is the short circuit reactance.

II. THE PROGRAMMES FOR ELECTRIC MACHINE DESIGN WITH FEM

A. ANSOFT

Of the products of Ansoft [2-13], Maxwell v2.6 is investigated for 2D applications, Maxwell v11.1 for 3D applications and the electrical machines module rxmprt v5 was examined. The
Disadvantages of Ansoft / Maxwell;

- **Electrostatic analysis and a geometry module are available for electrical machines:**
  The geometry of the machine is generated with rmxprt integrated as a module by using Maxwell v11.1 2D/3D program and this can be used with the versions 2.4 or 2.6 for 2D analysis. Almost every electrical machine geometry in 2D or 3D can be generated easily by v11.1 developed for Maxwell 3D applications and the rmxprt module integrated into it.

- **A translator module is available for AutoCad file:**
  A useful module, called a translator, is available in Maxwell control panel that converts Autocad DXF files, etc. to sm2.

- **Very easy-to-use:**
  The geometry part can be easily skipped in this program by converting the AutoCAD files to sm2 format with a translator. In addition, any electrical machine generated with rmxprt program can easily be exported in 2D. The BH curve can easily be obtained directly from txt file.

- **Winding tool is available:**
  Winding tool availability in the program provides convenience to the designer.

- **Graphical performance is high:**
  Maxwell 11.1 provides an excellent graphics performance in 2D/3D applications. Drawing can be easily managed with handy shortcuts using the mouse. The size of the shape does not cause much decrease in performance. Even a synchronous generator with an internal diameter of 2 m, an outer diameter of 2.8 m and a depth of 30 cm takes up the space of approximately 600 MB and offers a superior graphics performance.

- **Graphical plotting specifications are sound:**
  Plotting can be performed easily and a plotting form can be obtained including the number of lines.

- **High solution speed:**
  Solution part progress is very fast.

- **Memory and CPU performance is good**
  Program memory is suitable as drawings do not occupy too much space and the processor performances provide the results in a short time.

Disadvantages;

- **Static Analysis:**
  It does not allow professional solutions with respect to the static analysis.

- **DOS view for 2D applications:**
  The graphical interface of Maxwell v2.6 used for 2D applications is similar to the DOS programs.

- **Direct AutoCAD integration is weak:**
  Integration is not possible for direct intervention in the AutoCAD files.

- **Moderate accuracy:**
  Magnetic flux density distribution is shown in Figure 2. Although the reluctance torque values obtained as 5.53 Nm is not the realistic value, Ansoft can easily bring the simplicity together with the mastership. (Torque value is -5.53 Nm).

- **Inadequate help menus:**
  Help files achieved by F1 button on the program menu are inadequate.

In conclusion, opportunities offered by Ansoft[14] will be very useful for the researchers who will begin Magnetic field static analysis with finite elements method for the first time.

**B. CEDRAT**

Preflu2D v10.3.2 program [15-18] of the Cedrat group is analyzed here. Cedrat classifies its products as 2D and 3D. The visual quality, performance, advantages and disadvantages of this program in 2D and 3D applications were investigated and, information was given about them.

Advantages of Cedrat / Preflu:

- **Electrical machines module is available**
  The design part of the electrical machine is the result of an original design. In Cedrat’s design module, the part that is moving or the part which is fixed can be entered and a good machine geometry can be created. The meaning of the parameters in the designed asynchronous machine geometry can be displayed in the figures (with animations) available on the ready overlayers.

- **Armature reaction is taken into account:**
  In Figure 3, it can be seen that the magnetic flux lines are different from the Ansoft and Ansys programs. This is Cedrav taking the armature reaction into account and this really seems to be a significant advantage by itself.

- **Winding tool is available:**
  The winding tool available in the program provides convenience to the designer.

- **Mechanical torque calculation is available:**
  A mechanical torque calculation by Cedrat is a good specification although it can hardly approach the real torque value as can be seen in Table 3.

- **Electrical circuit module is available:**
  The electrical circuit diagram of the machine is handled separately by the Cedrat. The values of circuit elements cannot be seen with these specifications offering the possibility of making any kind of connections. Furthermore, one has to enter resistance and inductance values of each phase into
the program, as external data requires the use of other programs.

- **Graphical interface is good**
  The graphical interface is designed well although it is not as good as Ansoft.

- **Graphics performance is satisfactory:**
  Graphical result unit of Cedrat generates values suitable with what to do. Understanding of the results takes a short time with the help files. Graphics are found as desired and features of the results part make a good impression.

- **Graphical plotting specifications are very handy**
  It is possible to obtain a variety of parameters graphically and animation features are fairly advanced in graphic illustrations. Harmonic analysis can be represented graphically in spectral analysis and this makes Preflu of the Cedrat one-step ahead. In addition, all graphics can be shown in the same axis in a single window.

- **Solution speed is moderate**
  It is observed that the solution speed generates solutions at normal speed compared to other programs when it is considered to make the memory stacked.

Disadvantages:

- **2D and 3D applications are separated:**
  This is disadvantageous for those who wish to work both in 2D and in 3D.

- **Hard-to-use:**
  The web browser is opened by pushing the help button and the help files follow here. In addition, there is no help file on the machine design in 2D applications. This feature is not contained by what to do. Help files contain brief information.

- **Moderate accuracy:**
  Preflu obtains 2.96 Nm with Ansoft results for a quarter of the designed machine and this would be 11.84 Nm for whole machine. 9.68 Nm would be found by using the analytical inputs. Tests show that the torque generated is too dependent on the rotor leakage reactance (resistance and inductance of the portion of end rings between two adjacent bars). Accordingly, rotor leakage reactance values are seen to give improper results.

- **Inadequate help menus:**
  Help files are very useful. When investigating a topic in the help files, there is no need for any program for this. This also provides a possibility to learn about unknown topics. Help files contain brief information.

Advantages of Ansys Multi Physics:

- **Adequate help menus:**
  Help files are very useful. When investigating a topic in the help files, there is no need for any program for this. This also provides a possibility to learn about unknown topics. Help files contain brief information.

- **2D and 3D applications are together:**
  This is advantageous for those who wish to design both in 2D and in 3D.

- **Opening speed of the project is high:**
  Opening speed of your project is very high.

- **Graphical performance is satisfactory:**
  Shape of magnetic flux distribution is the same for tri-shaped meshing while 1-2% change occurs in the resulting values. Magnetic flux distribution is given in Fig. 2. Tri-shaped meshing and this flux distribution are realistic. This is because the torque calculation reaches to its actual value, e.g. 8 Nm. The type of elements are specified in Ansys and all details of FEM are examined. A BH curve of the material can be completely made through “copy and paste” at a time as a text file from a file. This feature is not contained by the other two programs.

- **Very good accuracy:**
  The torque value obtained by ansys for the machine to be designed is 6.43 Nm. The actual torque value, 7.6 Nm, is a satisfactory value for a company that does not develop simulation programs specific for electrical machines such as Cedrat.
- **Solution speed is good**
  Solution speed gives rapid results concerning the generation of realistic values despite the fact that it is not a program developed for electrical machine design.

Disadvantages

- **Graphical plotting specifications are difficult.**
  Integration cannot be satisfied in plotting graphics which results in plotting that is completed in more than one stage. Since the menus of Ansys Multi Physics are inadequate, plotting graphics is a troublesome process.

- **Graphical interface is inadequate:**
  Drawing sizes should be corrected with a scale factor if they are not in meters since Ansys takes geometric sizes in meters. Assigning material properties should be performed one by one as no tree exists for this feature in the program.
  Undo and modify functionalities for the processes made before in a project saved in the program are very complex. Dynamic model mode icon in the menu should be used every time for zooming and dragging of a geometry in the graphical interface and then cancelled.

- **Electrical machines module is not available:**
  There is no electrical machine design module. Design is made by integration with conversion of an Autocad or Solidwork job.

- **Hard-to-use**
  The electromagnetic sample solution in Ansys is discussed through a very simple problem. Therefore, one will definitely have great difficulty in a real project.

- **Intensive memory and disk usage:**
  Two projects cannot be opened at a time in Ansys. Each project takes up approximately 600 MB in virtual memory and about 17 MB in active memory. Ansys occupies nearly 1 GB in the hard disk during simulation. In addition, it uses an excessive part of the memory during simulation. Simulation results of a 1.1 kW motor take up a space of 1.26 GB with the file where everything is saved. This is because one has to work at full scale.
  In conclusion, Ansys Multi Physics program is a difficult multidisciplinary program for initial design although it has rapid and superior features in several points.
D. ANSYS WORK BENCH

Ansys workbench program[20-29] is investigated and its advantages and disadvantages are given in comparison to other programs.

Advantages of Ansys Workbench[30]:

- **Adequate help menus:**
  Help files are very useful. When investigating a topic in the help files, surfing is possible within the program just as in MATLAB and no program is needed for this. This also provides the possibility to learn about unknown topics. Help files contain brief information.

- **3D applications are powerful:**
  Work bench is actually designed as 3D. This is a simplicity for those working in 3D.

- **Opening speed of the project is high:**
  Opening speed of your project is very high.

- **Graphics performance is satisfactory:**
  It has a better graphical interface compared to Ansys Multi Physics. It includes similar features to Autocad. A number of shapes can be formed easily.

Disadvantages:

- **Graphical plotting specifications are difficult.**
  Integration cannot be satisfied in plotting graphics which results in plotting being completed in more than one stage. Since the menus of Ansys Multi Physics are inadequate, plotting graphics is a troublesome process. As given in Figure 4, deterioration can be seen while getting closer to the drawing.

- **2D application is weak**
  As given in Figure 5, points that should be round are taken as flat directly in Workbench. 2D fields generated by Ansys Multi Physics cannot be generated in Work bench. Here, in order to make surfaces from sketches, the shape should be drawn in work bench by proceeding on the shape, and thus generating new construction points. However, this is difficult for a complex shape such as an asynchronous machine. As can be seen from Figure 6, the appearance of strange arrows with 3D because of this process indicates that 2D application has failed.
  After defining the two axis, missing or additional fields/areas should be removed or merged one by one, as can be seen from Figure 7. Although the angle between 28 rotor slots of our machine is 12.857°, a close fit is ensured on the axis while this cannot be provided on other points (Figure 8).

- **Graphical performance is low:**
Total graphical performance decreases as the number of defined surfaces increases even during study in 2D. As can be seen from Figure 10, the geometric shape made in multiphysics and imported in 3D gives face-face inconsistency error.

- **Electrical machines module is not available:**
  The fact that workbench cannot be fully integrated with sat files imported from Autocad is a huge deficiency. Although it has satisfactory specifications, workbench is not useful for electrical machines. At minimum the generation of cores of asynchronous machine is three to four times more difficult due to the Autocad integration problem.

- **Hard-to-use**
  Despite the fact that the Workbench in Ansys provides some convenience for Mechanical engineering activities, obtaining geometries and design creation is difficult for most designers. Most of the conveniences offered by Autocad is not available for lines in Workbench. The pattern command corresponding to polar and angular array command, which is indispensable for electrical machine designers, should be improved.

- **Intensive memory and disk usage:**
  Workbench requires a memory of 2 GB (650 MB ram + virtual memory) for our 3D project shows that the program is definitely a memory monster.

As a result, workbench is considered to be a hard-to-use program for electrical machine designers (even geometry construction is difficult) although it has a handy interface.

III. CONCLUSION
As can be seen from Figure 2a and 2b, the magnetic flux line distribution is similar between Ansoft and Ansys since both Pittsburg companies work together. In addition, a complete symmetry is observed in each simulation while it is not observed in the diagram of Cedrat. This is because armature reaction may also be taken into account with Cedrat. As magnetic flux lines cannot be perfectly symmetrical at this point due to the armature reaction, it can be considered that Cedrat is one-step ahead of the others. The reason why Cedrat’s geometry/drawing appears more realistic with respect to the magnetic flux density distributions may be the fact that Cedrat takes realistic windings values by taking the number of turns into consideration. Magnetic flux density distributions are not exactly true values since the excitation parameter is entered as area-based like A/m² in the other two programs. Based on the torque values given in Table 3 Ansys multi-physics is better than the others. Ansoft shows brilliant performance with respect to ease of use according to Table 4. The Ansys-Ansoft partnership gives clues that the two companies will be able to reach a better position in the future. The subject of which parameters would be accepted as criteria with respect to which program to be used in terms of engineering problems is a controversial point; however it can be considered that Ansys multi-physics is the best if torque values are considered as the most important factors for electrical machines. The fact that Cedrat is able to make mechanical torque calculation is considered a nice feature. Cedrat may be in a very important position in the long term with respect to electrical machines. However, it should give more realistic results for the torque calculation. Ansys multi-physics is seen as being unrivaled regarding multidisciplinary applications. However, its graphical interface needs a lot of improvement. The compatibility of multi-physics with Auto CAD and the closeness of torque values to realistic values stand out as a big advantage although it does not have any electrical machines module. An electrical machines module is available in Ansys and this makes its usage exclusive. Ansys Workbench should get technical support from Ansoft Company in order to eliminate the deficiencies in graphical interface. Electric machines designers cannot choose any software package in its present condition.

In conclusion, Ansoft / Maxwell is a convenient choice for junior engineers using a FEM software package for the first time. For those who desire to achieve more realistic results, Cedrat would be suitable with its superior electrical machines module and outstanding performance. Due to the fact that an electrical machine that will be manufactured commercially must be analyzed mechanically, structurally and with respect to cooling and viscosity when needed. Ansys multi physics which is very successful in achieving realistic results and unrivaled in multidisciplinary applications should be the first choice for professional engineers although it doesn’t have the features for providing great convenience such as in Ansoft and Cedrat and it is hard-to-use.

Abstract—In this study, modelling and simulation studies of DG based fuel cell (FC) and solar cell (SC), connected to the common direct current (DC) bus system to provide energy for various loads. In order to synchronising of energy sources with grid, using three-phase phase locked loop (PLL) technique based park transformation which is one of the most common methods in literature. Power control methods based dq/abc synchronous reference frame (SRF) or proportional resonant (PR) are used in the DG systems. The performances of two controllers are discussed in this paper. Simulation results are obtained for various scenarios at the designed and created simulation model of DG+Grid+Load system. The system is modeled and simulated by using PSCAD/EMTDC software package.

Keywords— Distributed Generation, Renewable Energy Sources, PLL, Synchronous Reference Frame, PR controller

I. INTRODUCTION

Nowadays, environmental issues and growing demand for lower cost electricity with reliability and security, eventuate in an increased use of small electrical power generation located close to end users which are called distributed generation (DG). There is an increasing use of renewable power sources (RES) in DG systems because the growing demands for electrical energy [1]-[20]. The DG systems utilize RES, such as solar cells, fuel cells, wind turbines and micro turbines [2]. Grid connected inverters as one of the most importantly parts in DG systems, their current and power loop controllers are always the investigated [4].

In The grid tied DG systems, should be carefully designed and controlled in order to get an optimal power under fault conditions [21]. The reason to apply PR in DG system design is to eliminate steady-state error [16]. The traditional Proportional Integral (PI) controller in abc/dq- synchronous reference frame (SRF) is the common solution to solve this problem. But the complexity of displacement the ac SRF back to dc SRF where the PI controller can be used is also brought into the control system design. In this case, a transformed regulator known as PR controller is preferred considering the advantage of avoiding modulation and demodulation process in abc/dq-SRF. That is because PR controller is to transform the dc type regulator network into an equivalent ac regulator, which could directly achieve zero steady-state error in stationary frame [14]. Moreover, PR controllers are used in DG systems due to their superior behaviour over the traditional PI controllers, when filtering sinusoidal signals. Due to PR controller could achieve a very high gain around the given resonance frequency, thus being capable to eliminate the steady-state error when this controller tracking sinusoidal reference, which could be suitable for the using of stationary reference frame control strategy. The advantages of the Proportional Resonant (PR) controller in opposition to PI+ dq/abc synchronous reference frame controller are a less complexity of the control structure and a good capability to compensate harmonics. Compared with Proportional Integral + synchronous reference frame (PI+SRF) controller, the PR controller eliminates abc-to-dq and dq-to-abc frame transformations which significantly reduces computation burden and PLL errors. However PI+SRF controller could improve the dynamic response to power change and unbalanced faults [4]-[5].

In this paper, DG system based on RES, such as characteristic of fuel cell and solar cell with maximum power point (MPP) are investigated. It is analysed the performances of PI+SRF (abc/dq) and PR based Power Controllers in grid tied distributed generation systems. Reliable performances of controllers under grid voltage drop and references power change cases are discussed. Simulation results are provided to illustrate the effectiveness of the proposed system. The validity of proposed topology and control methods are verified with PSCAD/EMTDC software package.

II. DG SYSTEM CONFIGURATION

The implemented DG system in PSCAD/EMTDC is shown in Fig. 1 where FC/Solar cell (SC) combined form is the main form of DG system. DG system is connected to DC bus system. Voltage source inverter (VSI) connected AC side with grid and loads. The output voltage from the inverter contains high order harmonics which must be eliminated and thus, a low LC filter and PR current controller are used to reduce the harmonic contents in the phase current and the output voltage. The technical details of each part of the DG system are given in the following subsections.
Fuel Cell System

The stack voltage and the reference power are determined the reference current which is determined for the fuel cell stack current in eq. (2) and (3). The fuel flow is proportional to the stack current. The dynamic model of the FC stack is presented based its electrochemical and thermodynamic characteristics and emphasis on the FC terminal electrical characteristics [11]-[12]. The partial pressure of hydrogen, oxygen and water are determined using the flow rates of hydrogen and oxygen. The stack current and pressure of gases affect the stack voltage [13]. A simulation model is developed for the FC in PSCAD/EMTDC based on the dynamic FC stack. The output voltage of the stack is given by the Nernst equation. The ohmic loss of the stack results from the resistance of the electrodes and to the resistance of the flow of oxygen ions through the electrolyte.

\[ E_0 = N_0 \left( E_0 + \frac{R \cdot T}{2F} \ln \left( \frac{P_{H_2} \cdot P_{O_2}^{0.5}}{P_{H_2O}} \right) \right) - r_{\text{ohmic}} \cdot I_{fc} \]  

(1)

\[ I_{\text{ref}} = \frac{P_{\text{ref}}}{V_{fc}} \]  

(2)

\[ I_{fc} = \frac{I_{\text{ref}}}{1 + \tau_e \cdot S} \]  

(3)

The power output of fuel cell system is the product of stack current and voltage;

\[ P_{fc} = N_0 \cdot V_{fc} \cdot I_{fc} \]  

(4)

Variable DC load tied to the FC system. Fig. 5 shows modelled the fuel cell system in PSCAD/EMTDC under variable DC loads. The fuel cell stacks current and power increase and decrease with the DC load change. However, with the load change, boost converter output voltage (DC bus voltage) is constant.
b. Solar Cell

Fig. 3 shows a simple equivalent circuit of a SC. The current source which is driven by sunlight is connected with a real diode in parallel. In this case, SC presents a p-n junction characteristic of the real diode. The forward current could flow through the diode from p-side to n-side with little loss. However, if the current flows in reverse direction, only little reverse saturation current could get through [14].

\[
I_{cell} = I_{ph}(1 + I_0(T - 273.15)) - I_o \left( e^{\frac{q(V_{sc} + I R_s)}{n k T}} - 1 \right) - \frac{(V_{sc} + I R_s)}{R_{sh}}
\]  

(5)

In this paper, grid tied SC system is modelled and simulated in PSCAD/EMTDC software under various load, radiation and temperature. MPP incremental conductance algorithm is implemented in PSCAD/EMTDC in order to get the maximum output power for any given solar irradiation and temperature. Fig. 4 shows the characteristic (I-V and P-V) of SC and it pointed MPP.
provide SRF-PLL with PI+SRF and PR current controller can enforce orthogonal voltage (Vq) tracking grid voltage with grid voltage drop (30 %) successfully.

**b. abc/dq-SRF**

PI controller cannot eliminate steady-state error for the alternative current (AC) control as in three-phase grid tied DG system. To solve this problem, a mathematical transformation abc/dq-SRF has been universally applied system. Abc/dq-SRF transformation is short for direct quadrature zero transformation which is usually applied to the three-phase AC circuit analysis. The main reason to apply this method is for simplification of analysis. In balanced three-phase systems, abc/dq-SRF transformation transform three AC quantities to two directive current (DC) quantities into two-phase frame such as direct axis (d) and quadrature axis (q) [17]. Simplified calculations can then be carried out on these imaginary DC quantities. In this case, the application of dq0 transformation not only reduces the complexity of system analysis but also provides an available DC operation condition for PI controller [14].

Park’s transformation—which is given in eq. (6) and (7):

\[
I_{dq0} = \begin{bmatrix}
\cos(\theta) & \cos(\theta - \frac{2\pi}{3}) & \cos(\theta + \frac{2\pi}{3}) \\
\sin(\theta) & -\sin(\theta - \frac{2\pi}{3}) & -\sin(\theta + \frac{2\pi}{3}) \\
\frac{\sqrt{2}}{2} & \frac{\sqrt{2}}{2} & \frac{\sqrt{2}}{2}
\end{bmatrix}
I_{abc}
\]  

\[
I_{abc} = \begin{bmatrix}
\cos(\theta) & -\sin(\theta) & \sqrt{2} \\
\cos(\theta - \frac{2\pi}{3}) & -\sin(\theta - \frac{2\pi}{3}) & \sqrt{2} \\
\frac{\sqrt{2}}{2} & \frac{\sqrt{2}}{2} & \frac{\sqrt{2}}{2}
\end{bmatrix}
I_{dq0}
\]

Modelled and simulated the PI+SRF controller based park transformation in PSCAD/EMTDC are given in Fig.7.
c. The Proportional Resonant (PR) Current Controller

Although its popularity, a PI controller is not able to track a sinusoidal reference without the steady-state error (magnitude and phase). PI controller such as lack of tracking a sinusoidal reference with zero steady-state error and poor disturbance rejection capability [6]. To overcome the mentioned problems of conventional PI controllers in SRF, PR current controller is proposed. The PR controller provides a high gain and zero steady-state error. Besides its simplicity, the system dynamics is almost not affected by the harmonic compensation terms. However, the PR controller is difficult to implement in reality. It has two problems. Firstly, the infinite gain introduced by a PR controller leads to an infinite quality factor which cannot be achieved in an analog or a digital system processor (DSP). Secondly, the gain of the PR controller is much decreased at other frequencies and it is not adequate to eliminate harmonic influence caused by grid voltage harmonics [7]-[8].

Fig. 8 shows that $\omega_o$ is grid fundamental angular frequency and $k_i$ is a constant which is carefully selected to shift the controller’s magnitude response vertically [6].

$$G(s) = \frac{k_p}{s^2 + 2w_c s + \omega_o^2}$$ (8)

And $k_p$ and $k_i$ are the proportional and integral gains of PR controller respectively, and $\omega_c$ is cut-off angular frequency. The transfer function shows a no-ideal PR controller which has lower gain and wider bandwidth than ideal PR controller at the resonant frequency [6]. The power/current controller of the DG system with PR controller is illustrated in Fig. 9.

---

Fig. 7 Synchronous Reference Frame with PI Control Strategy.

Fig. 8 PR Current Controller Block Diagram [10]
PR gain is finite, but it is relatively high for enforcing a small steady-state error. The controller's bandwidth can be widened by setting \( \omega_c \) suitably, which helps to reduce sensitivity towards slight frequency variations [9].

IV. SIMULATION RESULTS

To better understand the performances of the controllers and using main parameters in DG system are given in Table 1 and 2. Their graphics and values are given at the same scale in Fig. 9 and 10 for easily comparing the controllers.

Table 1. Main parameters DG system

<table>

</table>

In this case 1, reference power step changes from 1 p.u. to 0.8 p.u. at 1.1 s and the output performance of controllers can be seen in Fig. 10. The reference value of real power and reactive power step change simultaneously at both 1.1 sec, the corresponding output performance of the system with given reference values are shown in Fig. 10. As one can see from Fig. 11, the system keeps stable under step-change conditions. However, the output power of PI+SRF controller is able to track the reference values well in less than 0.015 s, which proves a good dynamic performance than PR current controller (0.125 sec.). In this case 2, when reference power step changes at 1 s, orthogonal currents with PI+SRF (stable with 0.1 sec.) have a good dynamic performance better than PR current controller (stable with 0.175 sec.) in Fig 11.

V. CONCLUSION

DG system based on RES provides a good substitute to the centralised power generation systems which consumes fossil fuels and has imposed several problems on the environment. The most important aspect of DG systems is their proper control methods in order to ensure sinusoidal current injection into the grid. For this proper synchronization with the grid is SRF-PLL. This paper presents PI+SRF and PR based power controllers for grid tied DG systems. In this paper, dynamic performances of control methods are discussed.

Abstract—Optical fibers which have been in human life for 30-40 years, were used in long haul telecommunication links in the first decade. But today, fiber optic is used every distance of communications. Beside communications, fiber optic Technologies are spreading out in optical sensor technologies and networks, industry and medical in today. Classical optical fibers is standardized and has come to limit of refinement. As a new generation of optical fiber, with feature of very flexible design, photonic crystal fibers (PCF) are promising new horizons. PCFs are designed as endlessly single mod fiber in very wide range of wavelengths. Dispersion, birefringence and nonlinearity can be obtained in desired characters by changing geometrical parameters of PCFs.

In this simulation study, fundamental and high order core modes, cladding modes, fundamental space filling mode (FSM) and high order space filling modes were found. Effective refractive indices of the modes were calculated.

Keywords—Fiber optic, Photonic Crystal Fiber, Fiber optic sensor, Effective refractive index

I. INTRODUCTION

Photonic crystal fibers (PCF) are new generation fiber optic waveguides which have different structures and features from classical fiber optics[1,2]. PCFs are produced from a single material. They have air holes around core which are parallel to core and run along the fiber. Air holes are positioned in many rings around core. PCFs with various geometric features (hole diameter, distance of holes, number of rings, etc.) of cross section show different guiding features. PCFs have many advantages over classical fibers. PCFs have wide range of wavelength of single mod guidance, dispersion, non-linearity and birefringence control and endurances to bending[1-7].

PCFs have two dimensions periodicity. At least one characteristic dimension is about to magnitude of wavelength of guided light[8]. PCFs are called as crystal fibers, holey fibers and microstructure optical fibers (MOF), too. Since air holes arrayed in two dimensions in periodic structure, PCFs is a special tip of MOFs[9]. Core of PCF may be solid or air hole (Fig. 1) [10 -13]. Photonic crystal fibers with air hole core is also called hollow core fibers.

Guided light propagate with different mechanism in 2 holey fibers which have different basic structures. In fibers with solid core, light propagate with modified total internal reflection. Cladding that is the section with air holes shows lower refraction index than core and provides guiding of light. That is also called index guiding. In hollow core fibers, light is guided with principle of photonic band gap. Light with some wave length does not propagate in the fiber. Guidance of light in the fiber occurs in certain bands[14].

II. MODES OF PCF

In core and cladding of PCFs, various modes occur due to guidance conditions determined with parameters of geometry and material of PCF and light. A number of modelling methods have been offered to analyse modes, mode properties and propagation characteristics of PCFs[15-23]. Considerable modelling methods are effective-index, the plane-wave expansion, localized basis function, finite-element, finite difference, finite difference time domain (FDTD), beam propagation and multipole method.

Modelling and after modelling processes give patterns of modes, effective refractive indices of modes, mode areas, confinement losses, dispersion characteristics. Effective refractive indices of modes are very important parameters for especially fiber optic sensor systems. Cladding modes are very critical for PCF sensor in respect to analyse interaction liquid or/and gas materials in holes of the PCFs and guided light [24,25].

Fundamental Space Filling Mode (FSM), is fundamental mode which propagates in cladding[3]. FSM is used effective cladding index and the mode with highest refractive index in cladding[26].

\[
\beta_{FSM} \quad \text{and} \quad \beta_{FSM} \text{are supposed to effective refractive index and propagation constant of FSM, respectively.}
\]

\[
\beta_{FSM} = \beta_{FSM} k_0
\]

\[
\beta_{FSM} \quad \text{is valid for index-guided mode in core. Refraction index of silica glass in core of PCF is up to } n_{co} \text{ This inequality is valid;}
\]

\[
n_{co} > n_{eff} = \beta/k_0 > n_{FSM}
\]

Fig. 1 Holey fibers: a) Solid core PCF[28], b) Hollow core fiber [6].
Numerical and analytical methods can be used for calculation and analysis of FSM. Analytical method is two types as scalar and vector methods. In a study, it was seen that results of vector methods was better matched to results of numerical method[26]. Guided modes in section of silica glass out of rings of holes are admitted as FSM. This section is called as FSM layer[27].

III. RESULTS OF SIMULATIONS
Simulation study was implemented by using finite element method (FEM) for PCF of NKT Photonics LMA-20. Properties of LMA-20: d = 6 (µm), p = 12.8 (µm), number of hexagonal rings = 6, outer cladding diameter = 230 (µm). Guided modes and electric field patterns of modes have been obtained. Effective refractive indices (n_{eff}) of the modes have been calculated in those simulations. It was seen that single mode (LP_{01}) guided in core of PCF. Furthermore, low order modes and their effective refractive indices were obtained in cladding of the PCF.

Some modes have been detected at FSM layer in the simulation of large mode area PCF (LMA-20). In FSM layer modes, maximum n_{eff} of PCF modes have been observed.

The simulation study have been implemented for 560-2300nm range of wavelength.

Modes of core, cladding and FSM layer which have found by means of simulations for wavelength of 600 nm are shown in Fig. 2. In this figure, some prominent low order modes are taken part.

Effective refractive indices of the modes have been also obtained over simulations. Graphic of effective refractive indices verse wavelengths have been sketched in matlab. The graphic is shown in Fig. 3.
Effective refractive indices of core, cladding and FSM were obtained. For this 0.45 μm of wavelength range, guided mode LMA based on FEM, one of the PCF modelling method, is used. Fig 3. Variations of effective refractive indices verse wavelengths of guided modes of PCF LMA-20.

Abstract— Tracking mobile objects has always attracted people’s interest and over time it has become a necessity to keep records of them. Various solutions have been developed to meet this need. In particular, the development of GPS and digital mapping system has contributed greatly to this solutions. The developed methods can be divided into two main categories as online and offline systems. Although the online systems provide advanced features, production and operating costs are quite high and have regular expenses. In this study, we propose a microcontroller based offline vehicle tracking system. The proposed system offers a practical, low cost and high capacity approach for vehicle tracking systems. The proposed system calculates the vehicle’s position and speed according to the signals gathered from GPS satellites and records them to an SD card continuously. The stored data, then, can be transferred to a computer easily whenever needed and the routes that the vehicle followed can be tracked on a digital map using google earth. Besides, some visualization techniques like coloring routes with regards to time or speed intervals can be used for advanced analyses of the data. The proposed system allows the GPS data to be recorded as long as 3 months on a 4 GB SD card continuously.

Keywords— GPS; Digital Map; Offline Tracking; Vehicle Tracking; GPS Data Visualizing

I. INTRODUCTION

The free, open, and dependable nature of GPS has led to the development of hundreds of applications in such areas as marine, aviation, agriculture, environment, space, surveying, mapping, public safety, disaster relief, recreation, timing, rail, roads and highways. Although tracking systems was first developed for fleet management and shipping systems, today it is used in many areas of daily life [1], [2].

Vehicle tracking systems used today are generally online systems. That is, the information like location and speed of the vehicle are sent to a management center in real time. Online systems depend on GPRS or SMS technology to communicate with a management center or a central server. Despite the many advantages of this system, they have some regular expenses beside the initial setup costs. These expenses involves monthly subscription fee per vehicle for GPRS services, server and management center operating and maintenance fees, domain name fees and server hosting costs. Moreover, if these services are not owned by self, it is needed to subscribe such services and pay subscription fee monthly for each vehicle to be tracked.

In case of GPRS or generally internet connection loss, there might be data loss if the device on the vehicle does not have a local storage unit.

There might some cases that real time tracking of the vehicles is not essential and having past records might be sufficient. For example, for a school bus debates about following route, timing and obeying speed limits can be illuminated by examining previous records. Similarly, a company can use recorded past data to check its vehicles routes, departure and arrival times and to estimate amount of fuel consumption. This data may also be used as evidence in case of accident or a crime. For such cases, there is no need for real time or online tracking systems and having just an offline tracking record is sufficient.

In this study, a practical and low cost solution is proposed as an alternative to real time or online tracking systems. For this purpose, an offline tracking system which records the data received from GPS satellites to a pluggable SD card is developed. Then, the recorded data can be transferred easily to any computer when needed and can be monitored on a digital map using google earth. Since the GPS data is recorded directly on SD card as standard NMEA format, there is not a dependency to any special or commercial software to monitor the data on a digital map. Any software able to monitor GPS data can be used. In this study google earth is used to visualize the users route on digital maps.

II. GLOBAL POSITIONING SYSTEM

The Global Positioning System (GPS) is a satellite system that provides users with positioning, navigation, and timing information. The GPS system was created by US. Department of Defense and has been available to civilians since 1980. Generally, it is used to track and navigate the mobile objects.

The GPS system consists of three segments: The space segment, the control segment, and the user segment.

- The space segment basically consists of 24 satellites that travel around the earth two times a day. The arrangements of the satellites on 6 planes allow at least four of them to be visible by receivers from any point on the Earth.
• The control segment consists of ground stations which track the satellites, monitor their transmissions and send command and data to keep them in their orbits.
• The user segment is composed of military and civilian applications. The military services use L2 frequency and have a more precise positioning and timing capability than the civilians. [3], [4]

III. SYSTEM DESIGN AND IMPLEMENTATION

The designed system is described in detail in this section. Block diagram of the designed offline tracking system is shown in Figure 1. The three main parts of the system are GPS module, microcontroller and data storage. The GPS receiver module’s function is to calculate the vehicle position according to information received from GPS satellites. The microcontroller processes the data obtained from GPS receiver module and selects desired NMEA sentences. This data is stored to a pluggable SD card. Whenever needed, SD card can be plugged in a computer to monitor the data on a digital map. All components in the circuit require a 3.3V voltage source. The device includes a voltage regulator on board and vehicle’s battery or a separate battery can be used as a power supply.

GPS module transfers data using NMEA 0183 standard. Although there would be device specific communication protocols, NMEA is a standard protocol supported by all GPS receivers. There are several NMEA sentences as GGA, GLL, GSA, GSV, RMC and VTG. These sentences include some common and some sentence specific information. [4]

In this study, RMC sentence is used because it includes all the information required for this application. A sample RMC sentence and message format is as follows:

$GPRMC,053740.000,A,2503.6319,N,12136.0099,E,2.69,79.65,100106,.,A*53

Description of the sample RMC sentence is seen in Table 1.

A. GPS Module

The GPS module is used to get the current position and speed of vehicle. In this study, LINX RXM-GPS-SR receiver module (shown in Figure 2) is used for getting latitude, longitude, altitude, date and time information. Small dimensions (25.2mm-12.4mm-11.9mm) and low cost of this device is the major reasons for selecting the module. It has an integrated antenna and direct serial interface to communicate with host device. The update rate of the module is 1Hz and position accuracy is less than 10 meters. The module is based on the SiRFstar III low power chipset. The module’s high-performance RF architecture allows it to receive GPS signals that are as low as -159dBm. [4]

B. Microcontroller

In this project, PIC18F4620 microcontroller is used. PIC18F4620 has built in UART and SPI hardware for serial communication and has a wide range of operating voltage (2-5.5V) [5]. In this study, both GPS receiver and SD card module requires 3.3V power supply. A microcontroller capable of operating at 3.3V simplifies the circuit design and reduces the number of power supplies required.

The microcontroller has two main tasks. First one is to get NMEA sentences from the GPS receiver. The microcontroller communicates with GPS receiver through RS232 serial communication protocol. The GPS receiver sends 6 different NMEA sentences every second. Microcontroller receives all these sentences and selects the desired ones.

The second task of the microcontroller is to store the selected NMEA sentences to an SD card. The microcontroller uses build in SPI hardware to communicate with SD card. The data is written to a text file in a FAT formatted SD card.

Fig 1. Block diagram of the designed offline vehicle tracking system

Fig 2. LINX RXM-GPS-SR receiver module
Flowchart of the microcontroller software is seen in Figure 3. Microcontroller initializes the SPI and UART communication ports and checks availability of the SD card. If card is not present, led flashes at 2 Hz to warn the user. If the card is available, microcontroller reads the GPS data over UART port in accordance with the flowchart in Figure 4. Flowchart of subroutine running in the microcontroller for selecting NMEA sentence and recording data to SD card is shown in Figure 4. The software is prepared using MikroC compiler. [6]

C. Storage Unit (SD Card)

Secure Digital (SD) is a non-volatile memory card format developed by the SD Card Association (SDA) for use in portable devices. SD cards are available in a wide range of capacity and speed classes. SD cards are preferred due to their high capacity and small size. SD cards used in this project needs to be formatted as FAT or FAT32 file system. While FAT file system is used in SD cards up to 2 GB capacity, FAT32 file system is used in SD cards up to 32 GB capacity [7], [8].

D. Digital Maps

Digital maps are becoming increasingly widespread. Especially, the development of the GPS system has contributed greatly to the development and widen the usage areas of digital maps. Most of the information that comprise digital maps is satellite images as well as street level information. Digital maps has the advantage of being updated through synchronization with updates from company servers [9].

There are many digital maps used today. But most well-known and widely used maps are google map and google earth. Google maps are mostly used for navigational purposes while google earth is used exploring the world in a more detailed 3D maps. Although there are many common features between google earth and google maps, the main difference is that google earth is an desktop application and google maps is an online web application. Google earth is used in this study, since it can examine the GPS data directly.

IV. RESULTS AND DISCUSSION

The prototype device prepared for offline tracking is given in Figure 5. The dimensions of the device are 45 mm x 65 mm x 25 mm.

Fig 3. Flowchart of main program on microcontroller

Fig 4. Flowchart of NMEA sentence selection subroutine

Fig 5. The prototype of the designed system
In order to test the designed system, the device is put into a vehicle and two different routes were followed in Ankara. Meanwhile, the device collected and recorded the GPS data to an SD card. The obtained data were transferred to a computer just by simply copying the GPS data file and the paths followed are imported to google earth and displayed on a digital map (Figure 6).

Various digital map types can be used to monitor and analyze the GPS data. Google earth is a simple and easy to use digital map monitoring tool and can be used to display tracking data like followed route, speed of the vehicle, time and date without need to any conversion. A digital map image as shown in Figure 6 is generated by simply importing the row data to google earth.

Displaying row data on google earth is easy and practical, but in some cases, it might be necessary to make it more user friendly and understandable. For example, it might be necessary to examine whether a school bus exceeded speed limits, followed its route, or arrived to children’s home on time. In these cases, coloring the routes according to speed or time intervals might be useful. It is possible to convert row GPS data to KML format and display it in a better understandable manner. KML (Keyhole Markup Language) is used for formatting 2-D and 3-D geodata for display in earth browsers.

In this study, in order to make detailed analyses of GPS data, GPS Visualizer is used to convert GPS data to KML format and GPS data is colored according to time and speed intervals.

By organizing KML file using GPS Visualizer, the tracked route of the vehicle can be highlighted in different colors according to time or speed intervals [10]. In Figure 7, the followed routes are drawn according to time intervals. In the figure, red, yellow, green, blue and purple points represent the time interval between 12.05-13.30, 13.30-14.45, 14.45-16.21 and 16.21-17.46. For school bus example, highlighting routes according to time intervals enables observers to easily determine the location of the school bus in a specific time interval. Besides, the observer can mark on a data point in order to check speed and location of the user in terms of latitude and longitude.

Another way for detailed analysis of the followed route is visualizing the data in terms of speed of the vehicle. In this visualizing type, data is highlighted in different colors according to speed intervals. In Figure 8, the followed routes are colored according to vehicle’s speed. Five different speed intervals are highlighted in five different colors. The speed intervals can be set easily by observers. Considering school buses, compliance with speed limits is one of the most important issues. This visualizing technique enables observers easily determine the routes at which the speed limits are exceeded by the drivers.

Another important issue with the offline vehicle tracking systems is data storage capacity. Data storage capacity of the designed system is depends on the SD card used. It is a removable media and can be replaced with a higher capacity SD card according to the needs. By using a 4 GB SD card in this study, the system is able to save 6 types of NMEA sentences data for at least 3 months.
V. CONCLUSIONS

Safety is becoming an important requirement in growing and crowded cities. Tracking systems are getting essential tools for traffic safety. Especially for safety and deterrence purposes continuous recording of vehicles movement is a requirement and offline tracking systems are useful and suitable tools for many application. In this study, an offline vehicle tracking system was designed and implemented that can be used to record continuously the movement times, speeds and routes of vehicles. In this context, a circuit was designed to save the GPS data to a storage unit and the routes of the tracked vehicle were visualized on Google Earth.

Offline vehicle tracking systems offer low cost and convenient solution for situations where real time monitoring is not vital. Besides, the proposed system has several advantages such as low hardware costs, high storage capacity. Moreover, the system does not need constant periodic fees.

Presence of such a tracking system on the car will also create a deterrence on the driver. School buses can be thought as good candidate users of this project. In this way, in an unexpected situation, observers easily check whether or not the drivers changed the predetermined route, or the drivers exceeded the speed limits.

In terms of system cost, the proposed offline tracking system has superior advantage compared to online tracking systems. Since map viewing application is free, cost of the system only consists of hardware components. Besides, there is no software fee or update fees. Moreover, it does not occur additional expenses for SMS or internet connection.

Because of small dimensions, low power requirements, and high storage capacity, the designed vehicle tracking system can be adapted to other objects or living things, such as cyclists, pedestrians or animals in the nature.

The proposed system can incorporate with the existing navigation systems as an additional feature. Moreover, the system can be implemented to the vehicles during their production. Dimensions of the module can be minimized by using micro SD cards and surface mount components.

Abstract—This paper presents a practical comparison study on the speed estimation methods for induction motors by using Direct Torque Control in terms of their estimation performances especially at startup. Simulation and experimental test studies on various operations characteristics are achieved and presented together with the evaluations. The estimation techniques are compared in terms of their capabilities of speed tracking and sensitivities for each operation condition. It is concluded that at startup operation and in steady state behavior, dynamic performance of Model Reference Adaptive System (MRAS) is more stable and effective than sliding mode observers and open-loop estimators. However, open-loop speed estimation method has better performance than the others. Dynamic performance of the speed estimators in DTC control algorithm are tested in a laboratory setup. System configuration includes a low cost STM32F407VG Discovery board used for the implementation of the control algorithm, there-phase power inverter which is designed for this purpose and industrial type of 11 kW induction motor.

Keywords—Speed Estimation, Sensorless Control, Direct Torque Control, AC Drives, Sliding Mode Estimator, MRAS, Open-Loop Estimator, Performance Investigation, Induction Motors.

I. INTRODUCTION

In recent years, importance of the adjustable-speed drives used in industrial and electric vehicle applications has been increased. Modern AC motor drives produced in last decades are composed of microcontrollers, electronic components, digital or analog controllers and sensors. However, many control techniques consisted of more complex algorithms based on the sensorless control system are preferred due to high prices of the sensors, their low safety operations and drawbacks of the noise effects. The enhancement in processor technologies, advanced microcontrollers have made it possible to carry out more complex control algorithms with high efficiency.

Due to avoiding of sensor drawbacks and reducing the cost of the inverters, estimation of the actual speed instead of the measurements is more available for the researchers and engineers. In literature, control algorithms designed with feedback are used generally to estimate the speed of induction motors with high accuracy [1-8]. Most of the estimation techniques work on the magnetic flux waves, such as open-loop estimators and close-loop observers used for this purpose. Speed at dynamic performance and steady-state can be calculated properly if parasitic effects are wiped away [9]. Using only motor parameters is easy way to estimate actual speed of the motor. However, the method can be applied in a limited range. In a study, a hybrid mathematical model, which sustains a low-cost proper design for the industrial applications, is presented [10-13]. Also, flux, speed and rotor time-constant can be estimated by using a sliding functions. It guaranteed an accuracy of the parameters when the difference between the actual current and the observed current is zero [14-18]. Moreover, model reference adaptive system (MRAS) based speed sensorless algorithm can be used for controlling an induction machine. In this method, a proportional-integral (PI) controller is employed in the adaption mechanism instead of pure integral because of initial problems [19-23].

In this study, some of these methods used for control of the induction motors with direct torque control (DTC) without any speed sensor, such as open-loop speed estimator, sliding mode observer based speed estimator and MRAS based speed estimator are compared with each other on various conditions. And, the results obtained by the experiments are presented and introduced a discussion on the results accompanied with the evaluations.

II. INDUCTION MACHINE MODEL

Dynamic model equations of the induction motor used in many control algorithm are given by the equations 1 to 5. The equations include not only steady state characteristics but also starting behavior. The model is represented by differential equations referred to d-q reference frame rotating at the synchronous speed with a view to simplify the analysis of three-phase circuits.

The parameters used in the equations are stator winding resistance and inductance ($R_s, L_s$), rotor bar resistance and inductance ($R_r, L_r$) and mutual inductance ($L_m$).

\[
\frac{di_s^d}{dt} = \beta \frac{1}{Tr} \lambda_s^d + \beta \omega_L \lambda_q^d - k_1 i_d + k_2 V_d \quad (1)
\]

\[
\frac{di_s^q}{dt} = \beta \frac{1}{Tr} \lambda_s^q - \beta \omega_L \lambda_d^q - k_1 i_q + k_2 V_q \quad (2)
\]
\[
\frac{d\lambda}{dt} = -\frac{1}{T_e} \lambda_s^2 - \omega_r \lambda_s \lambda_{qs} + \frac{l_m}{T_e} i_d s
\]

Switching any voltage vector considering the voltage vector table (e.g. Table. I) provides keeping the stator flux in the determined hysteresis error band corresponded with the calculated torque behavior. Each of \( V_s \) vectors represents a switching position of VSI. Voltage space vectors, switching positions and sectors are shown in Fig. 2.

\[
T_e = \frac{3P}{2} (\lambda_{dr}^2 i_{qs} - \lambda_{qr}^2 i_{ds})
\]

where,

\[
\sigma = 1 - \frac{l_m^2}{l_s l_r} \quad k_s = \frac{1}{\sigma l_s}
\]

\[
T_r = \frac{l_r}{T_r} \quad \beta = \frac{k_s l_m}{T_r}
\]

\[
k_1 = k_2 (R_s + \frac{l_m^2}{l_r T_r})
\]

III. DIRECT TORQUE CONTROL

Direct Torque Control technique called DTC is defined briefly as a proper selection of stator voltage vector and direct control of stator flux for estimation of the torque by sensing phase currents and DC bus voltage. The main idea of DTC is related with control of the stator flux and electromagnetic torques synchronously. The superiorities of the technique are less sensitive to parameter changes with respect to the other vector control methods, having quite simple algorithm and faster torque response than others. The control algorithm includes only calculating of stator parameters. Fig. 1 shows principle of the DTC algorithm.

![Fig. 1 Schema of Direct Torque Control (DTC) System](image)

**TABLE I**

| \[|\lambda|\] | \[\lambda\] | \[d\lambda\] | \[dTe\] | Region |
|---|---|---|---|---|
| 1 | V_2 | V_3 | V_4 | V_5 | V_6 | V_7 |
| 0 | V_4 | V_5 | V_6 | V_7 | V_8 | V_9 |
| -1 | V_6 | V_7 | V_8 | V_9 | V_10 | V_11 |
| 0 | V_8 | V_9 | V_10 | V_11 | V_12 | V_13 |
| -1 | V_10 | V_11 | V_12 | V_13 | V_14 | V_15 |

Voltage vector selection in the control algorithm is related to the stator fluxes behaviors, instant torque value and sector of stator flux linkage vector. Torque and flux are estimated by using instant value of the phase currents and dc voltage.

![Fig. 2 Space Vectors and sectors](image)

The aim of this paper is to show dynamic performance of the speed estimators used in DTC control algorithm. The estimation techniques are compared with each other in terms of their capabilities of speed tracking performance and sensitivities to the operation conditions.

IV. SPEED ESTIMATION METHODS IN BRIEF

Sensorless control of squirrel cage induction motor have been widely used in industry during the last decade. In the literature, many methods are introduced and investigated to estimate the actual speed of the motors and to produce the best switching for the voltage vectors.

A. Open Loop Speed Estimator

The model consists of four motor parameters; stator resistance, transient inductance, magnetizing inductance and rotor resistance referred to the stator. All other variables used in calculation are also referred to stator.

The relationship among the speed, currents and fluxes are given as follows:

\[
\omega_{mr} = \frac{\lambda_s^2}{\lambda_{dr}^2 + \lambda_{qs}^2} \frac{d\lambda_{qs}}{dt} - \omega_{slip}
\]

\[
\omega_{slip} = \frac{l_m}{T_r} (\lambda_{dr}^2 i_{qs} - \lambda_{qr}^2 i_{ds})
\]

\[
\omega_r = \omega_{mr} - \omega_{slip}
\]

B. Sliding Mode Observer Based Estimator

In this method, sliding-mode-based flux and speed estimation method are used without any speed sensor for DTC algorithm. The method includes speed, rotor time and flux estimations and current observer. Sliding-mode current observer is used to estimate the speed and rotor time constant, as shown in the equations 9 and 10.
\[
\frac{d\psi_d^s}{dt} = \beta \psi_d - k_1 i_{d}^s + k_2 V_{ds}^s
\]  \tag{9}

\[
\frac{d\psi_q^s}{dt} = \psi_q - k_1 i_{q}^s + k_2 V_{qs}^s
\]  \tag{10}

The flux used for calculating observed current is determined by production of \( u_0 \) and sign of the error selected large enough. The sliding equation provide observing the stator current components in the stationary reference frame.

\[
\psi_d = -u_0 \text{sign}(s_d)
\]  \tag{11}

\[
\psi_q = -u_0 \text{sign}(s_q)
\]  \tag{12}

where,

\[
s_d = i_{ds}^s - i_d^s
\]  \tag{13}

\[
s_q = i_{qs}^s - i_q^s
\]  \tag{14}

\[
\psi_{dq}^s = \frac{1}{\mu s + 1} \psi_{dq}
\]  \tag{15}

\[
\frac{d\lambda_{dr}^s}{dt} = -\psi_d^s + \frac{1}{t_r} i_{d}^s
\]  \tag{16}

\[
\frac{d\lambda_{qr}^s}{dt} = -\psi_q^s + \frac{1}{t_r} i_{q}^s
\]  \tag{17}

\[
\lambda = \frac{1}{i_{a}}(-\lambda_{dr}^s \psi_d + \lambda_{dr}^s \psi_q)
\]  \tag{18}

|\lambda| = -\left(\lambda_{dr}^s\right)^2 - \left(\lambda_{qr}^s\right)^2
\]  \tag{19}

C. MRAS Based Speed Estimator

In this method, the estimated speed is calculated by the reference model of the whole system, adaptive model and an adaptation mechanism. Also, measured currents and voltages in a stationary frame of reference are used in the equations.

In order to estimation of the rotor actual speed, rotor fluxes state variables are obtained from the reference model using stator currents and stator voltages and adaptive model using stator currents and the speed.

The model reference equations are written as follows:

\[
\frac{d\lambda_{dr}^s}{dt} = \frac{1}{t_r} (\psi_d^s - R_{ds} i_{ds}^s - \alpha \lambda_{dr}^s \frac{d\lambda_{dr}^s}{dt})
\]  \tag{20}

\[
\frac{d\lambda_{qr}^s}{dt} = \frac{1}{t_r} (\psi_q^s - R_{qs} i_{qs}^s - \alpha \lambda_{qr}^s \frac{d\lambda_{qr}^s}{dt})
\]  \tag{21}

The adaptive reference equations are written as follows:

\[
\frac{d\lambda_{dr}^s}{dt} = -\frac{1}{t_r} \lambda_{dr}^s + \tilde{\omega}_r \lambda_{qr}^s + \frac{1}{t_r} i_{ds}^s
\]  \tag{22}

\[
\frac{d\lambda_{qr}^s}{dt} = -\frac{1}{t_r} \lambda_{qr}^s + \tilde{\omega}_r \lambda_{dr}^s + \frac{1}{t_r} i_{qs}^s
\]  \tag{23}

Rotor actual speed is estimated by using the error, which is the difference between adaptive reference and model reference system, as shown in equation 24. The zero error occurs when the references produce same values.

\[
\varepsilon = \tilde{\lambda}_{dr}^s \lambda_{qr}^s - \tilde{\lambda}_{qr}^s \lambda_{dr}^s
\]  \tag{24}

Generally, MRAS can be used if pure integration is possible. But it is not possible on the microcontroller certainly. To overcome this problem, nonzero-flux initial condition and offset in the voltage/current, low pass filter can be used instead of an integral. In this paper, adaptation mechanism consist of PI as a controller, as given in equation 25.

\[
\tilde{\omega}_r = \left(K_p + \frac{K_i}{s}\right) \varepsilon
\]  \tag{25}

V. EXPERIMENTAL RESULTS

In these experiments, open-loop, sliding-mode and MRAS based speed estimation techniques are compared at starting, ramp based acceleration, reverse operation and instant speed changing with no-load. All algorithms run on STM32F407 discovery kit working at 167 Mhz. Also, the compact design IGBT module, named as 7MBP50VDA-120-50, is used for switching components. The calculated data getting from microcontroller are sent to computer by wireless commutation after the operations.

A. Starting Characteristics

The operation is started at zero speed and finished at 314.16 rad/s. Firstly, open-loop estimation method has an initial problem. On the other hand, it has better performance than the others at steady state. However, MRAS technique is more stable at all time (e.g. Fig. 4).
B. Ramp Reference Operation

On ramp operation, speed estimators performance observed during 2 second are compared at synchronous speed. The ramp value reaches the synchronous speed at 1 second. Minor changes are observed on the starting characteristics. First one, an open-loop initial point is changed. Also, sliding-mode has more oscillation with respect to the previous operation. Also, MRAS based estimation has no significant changes (e.g. Fig. 5).

A. Change in Speed (Speed Tracking)

With sliding-mode technique, rotor speed has some ripples like in the previous operations modes. The best algorithm on the operation can be said to be MRAS method (e.g. Fig. 6).

B. Reverse Operating

The experimental operation is carried out at half of the synchronous speed of the induction motor. At 5.5th second, speed is the same, but rotation is reversed. It is shown that open-loop estimators has the best time for reaching to the reference point. For the reverse directed speed and braking mode, all algorithms have nearly almost the same decelerating time. But MRAS has the most change in speed at positive speed side (e.g. Fig. 7).

VI. CONCLUSION

Open-loop estimation method is more stable at the large part of the operations with the exception of starting point problem. On the other hand, sliding-mode method has more ripples than others. The method, MRAS, is minimized ripples at steady-state and its initial condition is the best on all working operations.

Abstract— After the memristor, which passive electrical component relating electrical charge and magnetic flux linkage and it was known as lost element since 1971, has been found by researchers in Hp Lab, it has been the focus of attention of researchers. For analysis of the memristor, analog circuit model of memristors is generally used. In this paper, using fractional order a memristor model, fractional order adaptive PI controller has been designed. For performance analysis of the controller, it has applied to control of nonlinear system, and compared classical PI controller.

1. Introduction

Memristors are known as the materials representing the link between the charge and flux suggested as the missing element by Chua. It has been known as the missing element since 1971, however it has been found this material's entity at the result of a research in Hp laboratory in 2008 [1-3]. Because of memristor's feature to hold the last resistance value as a passive circuit element (likely to be used as a passive memory element) has increased interest in these materials. Studies on the memristors have risen more and more after 2008. These studies have generally spread into many different scientific fields like; memristor emulator circuits [4-8], production methods [8-14], applications on communication systems [15], nonlinear circuit design [16-18]. In some of these studies, it has been observed that the usage of memristor affects system performance positively. Besides the model of memristor developed in Hp laboratory, the idea of using the emulator circuit in practice is still widespread. One of these studies is the model put through by Muthuswamy [19]. It has been observed that Chua circuit, composed by using this model, demonstrates chaotic behavior.

Memristor are defined as the ratio of the change in raids over the last load changes. It has been known that the change of flux in terms of current is inductance, the change of current in terms of voltage is resistance, and the change of voltage in terms of load is capacitor. According to these definitions, as the element representing to the change rate between flux and load as the fourth relation had not been found, it was called as missing element. After finding this element, studies has determined the relation between load and flux as a function of fractional order, the behavior of this element has begun to be the subject for new researches [20-22].

Modeling of fractional order systems known as the systems having system degree's any real number except whole numbers [20-23] has practices in many fields such as control systems [24-25], effects on chaos behavior [26-27], communication systems [28]. The studies exercised fractional order systems on circuit models have proved that system degree could be changed according to circuit topology made by using passive circuit elements [29]. One of the most common practicing field of fractional order systems is control system. Having wider stability domain at control systems and performing in a good way at controlling nonlinear systems have increased the interest in this type of controllers [30]. The behavior of a controller designed with fractional order memristors which is a fractional order nonlinear element still remains uncertain.

In this study, PI type controller has been designed by using fractional order memristor from model of memristor in literature. The performance of a nonlinear system on control has been measured with this controller designed by using analog circuit designation method. To evaluate controller performance, it has been compared with performance of PI controller occurred with classic memristors. The effect of controller parameters on control system has been investigated.

The study was organized like above. The structure and mathematical model of classic memristors and fractional order memristors have been investigated in II. section. In III. section, the applications of classic memristors and fractional order memristors on control systems has been investigated. In IV. section, simulation results have been given. In conclusion, the results have been investigated.

2. Memristors

2.1. Classic Memristors

Memristors have been found at HP laboratory in 2008 after Chua suggested this as an idea. According to this model, the relation between voltage and current applied to circuit has been given at Equation I. [1-2].
\[
M(q) = \frac{v(t)}{i(t)} = R_{on} \frac{\mu R_{on}}{D^2} q(t) + R_{off} (1 - \frac{\mu R_{on}}{D^2} q(t))
\]

\[
\frac{\mu R_{on}}{D^2} = A
\]

(1)

Here, TiO weight of D memristor is the load mount flowing over q(t) memristor, and R_{on} is defined as on-position resistor of circuit, R_{off} is defined as off-position of circuit. As R_{on} resistor value of memristor model is so bigger than R_{off} resistor value, the statement in Equation 1 would be changed as given in Equation 2[4].

\[
M(q) = \frac{d\phi}{dq} \approx R_{off} (1 - Aq(t))
\]

(2)

The emulator circuits of memristors had been studied before this circuit element was found in Hp lab. With using this mathematical model, the circuit model which was occurred by Muthuswamy has been demonstrated in Figure 1[19].

![Memristor emulator circuit](image)

**Figure 1 Memristor emulator circuit [19]**

### 2.2 Fractional Order Memristors

#### 2.2.1 Fractional Calculus

Fractional order systems are based on fractional calculus. Although fractional order calculus is old mathematical method, researchers are still studying solutions using this method. Fractional order systems have many solution techniques. These techniques are the Grunwald–Letnikov (GL) method (Eq. 3) and the Riemann–Liouville (RL) method (Eq. 4) [20,22]. The GL equation is described as following:

\[
D_t^\alpha f(t) = \lim_{h \to 0} \frac{1}{\Gamma(\alpha)} \int_{t-h}^{t} \frac{(t-\tau)^{\alpha - 1}}{\tau^\alpha} f(\tau) d\tau
\]

(3)

For fractional order systems, another solution technique is Euler method which was given (5), generalized derivative of fractional order systems[20].

\[
D^\alpha f(t) = \frac{\Gamma(n+1)}{\Gamma(n-\alpha+1)} \int_{t}^{f(t)} (t-\tau)^{-(n-\alpha)} d\tau
\]

(4)

For the solution of main fractional order systems, it is a useful method in a lot of studies. Laplace transform method is another very popular solution method in the literature that we used the method in the paper.

Laplace transforms of fractional systems are defined as following:

\[
L \left[ \frac{d^\mu f(t)}{dt^\mu} \right] = s^\mu F(s)
\]

\[
\mu \in \mathbb{R}
\]

There are many approaches to solve s^\mu Laplace operators. Some of these approaches are the Crone, Carlson and Matsuda methods[20,22,29]. The most widely used approximation of s^\mu is Crone. Crone is a French acronym (non-integer order robust control — Commande Robuste d’Ordre Non-Entier) [23]. In the Crone approximation, s^\mu is calculated as;

\[
s^\mu \approx C \prod_{a=1}^{\infty} \frac{s}{\omega_{p,a}^{(2\mu+1)}}
\]

(7)

\[
\omega_{p,a} = \omega_b \left( \frac{\omega_b}{\omega_l} \right)^{\frac{2\mu+1}{2\mu}}
\]

(8)

where C, \omega_b and \omega_l can be chosen as;

\[
0 < \omega_l < \omega_b
\]

\[
C > 0, \mu \in (0,1)
\]

(10)

In fractional order systems, Laplace and Crone approximations are useful methods. Therefore, several research studies use these approximations.

#### 2.2.2 Mathematical Model of Fractional Order Memristors

At previous sections in classic memristors, the change of load according to flux was discussed, in fractional
order memristors this dependence can be defined as fractional order [21].

\[ M^\alpha (t) = \frac{d^\alpha \phi}{dq^\alpha} \] (11)

Fractional order memristor can be defined as mathematical model over classic memristor performed in Hp laboratory as;

\[ M^\alpha (t) = \frac{d^\alpha \phi}{dq^\alpha} \approx R_{off} \left[ 1 - A(D_t^\alpha i(t)) \right] \] (12)

2.2.3. Circuit Model of Fractional Order Memristors

Fractional order memristor can be obtained in the event integrator from the model composed by Muthuswamy is fractional order. Circuit model of this model has been given in Figure 2. When sinusoidal voltage has been applied to this model, the change of current over circuit element has been given in Figure 3. As it can be seen from current and voltage graphic, besides fractional order memristor shows familiar feature like classic memristor on mathematical model, it can be seen exit of circuit model.

3. Application of Fractional Order Memristor to Controllers

3.1. Application of Classic Memristors to PI

In the studies on the applications of classic memristors on PI controllers, it is known that PI controllers with classic memristors perform faster and more powerful. Such a controller model has been demonstrated in Figure 4 [31].

Mathematical model for memristors is given as Equation. 13.

\[ \frac{U_2}{U_1} = \frac{RCs + 1}{MCs} \]

\[ M = R_{off} \left[ 1 - \frac{AC}{1 + RCs} U_2 \right] \] (13)

3.2. Application of Fractional Order Memristors to PI

One of possible application field of memristors is controller system. When using a memristive element at the proportional processing of classic PI circuit, circuit model becomes as shown in Figure 5.

Mathematical model of this circuit model is nonlinear fractional order model.
\[ v_0(t) + \frac{A}{R} v_0(t) D^\alpha v_0(t) \approx \frac{R}{R_{off}} v_i(t) \]  
(14)

Mathematical model occurred from this circuit model (given in figure 5) has been demonstrated in Equation 10.

\[ v_0(t) + \frac{A}{R} v_0(t) D^\alpha v_0(t) \approx \frac{R}{R_{off}} v_i(t) \]  
(15)

4. The Results

In this study, synchronization control of two fractional order Van-der Pol oscillator has been performed for testing performance of control system. Mathematical model of Master and Van der Pol oscillator is like;

**Master**

\[ x^{(1+\lambda)} + \alpha(x^2-1)x^{(\lambda)} + x = 0 \]

**Slave**

\[ x^{(1+\lambda)} + \alpha(x^2-1)x^{(\lambda)} + x + u = 0 \]

\[ 0 < \lambda < 1 \]

\[ \lambda \in R \]  
(16)

Here \( u(t) \) is controller entrance and function produced depending on error with designed controller.

4.1. Simulation Results

Circuit model, used on synchronization of two Van-der Pol chaotic systems with PI controller occurred with fractional order memristor, has been shown in Figure 6. At circuit models; Master chaotic Lorenz oscillator circuit has been shown in Figure 6a, Slave chaotic Van-der Pol circuit has been shown in Figure 6b and fractional order memristor controller has been shown in Figure 6c. According to these parameters, the change of system exit has been given in Figure 7. In this figure, the first graphic (Figure 7a) shows the simulation result obtained from mathematical model of the system. The change obtained from circuit model result has been given in Figure 7b. The similarity of both these graphics can be seen at 2 figures.

5. Discussion and Conclusion

In case of memristor which is very popular element in electronic, can use in control systems, it provide adaptive control performance. In this Study, an effective method to PI
controller based on memristive has been presented and we have generalized the order of the memristor for real number set. It is applied Van-der Pol chaotic synchronization circuit and Simulink model in order to test of controller performance. As the memristors have nonlinear behaviour between current and voltage, the systems based on memristor can have adaptive control performance. The obtained Simulink and circuit simulation results shows that synchronization control of nonlinear Van-der Pol oscillators is performs better results than classical PI controller.

{bilim, nurikapucu, develi}@erciyes.edu.tr

Abstract—This paper investigates the bit error probability (BEP) of dual-hop interleave-division multiple access (IDMA) systems with decode-and-forward (DF) relaying over Nakagami-\textit{m} fading channels. A closed-form approximate BEP expression for the considered system is derived. In particular, we present a detailed performance comparison for binary phase shift keying (BPSK) modulation. Computer simulations are also presented to confirm the analytical results. Our findings show that the results obtained by the derived BEP expression are sustained through computer simulation results.

Keywords—Dual-hop DF IDMA, Nakagami-\textit{m} fading, bit error probability.

I. INTRODUCTION

Dual-hop communications technique in wireless systems has attracted a considerable research attention [1-6]. Most existing studies about dual-hop transmission systems mainly focus on different performance metric, system model and different fading channel conditions. In [1], an analytical framework for the performance evaluation of dual-hop decode-and-forward (DF) systems operating over $\eta-\mu$ fading channels in the presence of cochannel interference and additive white Gaussian noise (AWGN) is provided. Simple accurate analytical expressions for the outage probability, average bit error probability (ABEP), and average capacity are derived. The outage performance of dual-hop DF cooperative systems is considered over an interference-limited Nakagami-\textit{m} fading environment [2]. In [3], the authors analysed the dual-hop DF relaying systems with multiple interferers over Rayleigh fading channels. They derived the closed-form expressions for the outage probability of their system. In another work in [4], the exact closed-form outage probability expression is presented for an L-relays dual-hop system over Nakagami-\textit{m} channels. They concluded that an optimal number of relays should be used depending on the channels conditions. Lee et al. investigate the symbol-error-rate (SER) performance of DF cooperative communications with multiple dual-hop relays and they considered Nakagami-\textit{m} fading for the source-relay and relay-destination links [5]. However, the analytical result for the SER performance of the considered system has no closed-form expression. In [6], the outage probability derivation of the DF dual-hop system with an interference-limited environment is presented. The performance of two-hop DF relaying protocol under mixed faded channels by evaluating outage probability and average bit-error probability was investigated in [7]. Several authors have studied the performance of different communication systems based on dual-hop relaying transmission [8-12]. The end-to-end error probability performance of a dual-hop orthogonal frequency division multiplexing (OFDM)-based relaying system is examined [8]. The other study in [9], the authors study the performance of a dual-hop multiple-input multiple-output (MIMO) wireless communication system using orthogonal space-time block codes. The considered channel model is correlated Nakagami-\textit{m} fading in their work. Xu et al. investigated the outage probability of a dual-hop DF cognitive relay network over Rayleigh fading channels in the presence of the primary user’s interference. Also, the exact and asymptotic outage probabilities for the considered system were derived in [10]. Most recently, in [11], the performance of direct-sequence code division multiple access (DS-CDMA) based on two-hop amplify-and-forward protocol over Weibull symmetric fading channels as well as Rayleigh/Rician, Rician/Rayleigh asymmetric fading phenomenas based on simulations are analysed. Dual-hop $N$-relay assisted transmission scheme for interleave-division multiple access (IDMA) with DF relaying was proposed in [12] to improve the performance of IDMA systems. The authors in [12] are considered Weibull fading channels, but they presented the error performances of their system by means of the simulations.

The existing works on dual-hop relaying in [1-7] are limited to analysing only dual-hop relaying transmission without combination of different communication protocols. The previous works in [8-12] presented the performance metrics with the help of simulations or considered different fading conditions. Although dual-hop relaying has been studied in different wireless communications systems, it has not yet been investigated in the context of dual-hop DF IDMA systems over Nakagami-\textit{m} channels. In this paper, the dual-hop DF IDMA system over Nakagami-\textit{m} fading channel is provided. The bit error probability (BEP) for dual-hop DF IDMA systems is analysed. In particular, an approximate closed-form expression for BEP of dual-hop DF IDMA is derived by employing Rake detector at the relay and destination node. The analytical results obtained by the derived BEP expression are validated by computer simulations.
II. DUAL-HOP DF IDMA SYSTEM MODEL

As shown in Fig. 1, we consider a dual-hop DF IDMA system where the transmissions of user $k$ are assisted by $N$ relays installed with the DF protocol. Two transmission slots are needed to convey source information. The first transmission slot is to transmit information from the user $k$ to all relays in the system. The received signal $n$th relay node is given by

$$r_{SR}(t) = \sum_{j=0}^{T_s-1} h_{SR}(j) d_k(j) \pi_k^j (t - j T_s - \tau_{SR}) + n_{SR}(t)$$

where $h_{SR}$ is the channel gains for source- $n$th relay, $\tau_{SR}$ is delay for source- $n$th relay link, $d_k$ is the $j$-th transmitted symbol of the user $k$. $J$ is the frame length, $T_s$ is the symbol period, $n_{SR}$ is Additive White Gaussian Noise (AWGN) term. $\pi_k^j$ is the combination of the spreading and interleaving waveform of the user $k$ used by $S$ during the $j$-th symbol period.

In the second transmission slot, the $n$th relay decodes the source information, reencodes and then forwards it to the corresponding destination. The received signal at the destination node is expressed as

$$r_{RD}(t) = \sum_{j=0}^{T_s-1} \sum_{i=1}^{K} h_{RD}(j) \hat{d}_k(j) \pi_k^i (t - j n T_s - D_{k,s} - \tau_{RD}) + n_{RD}(t)$$

where $h_{RD}$ is the channel gain for $n$th relay-destination, $\tau_{RD}$ and $D_{k,s}$ are random delay and the transmission delay during the second time slot for $n$th relay-destination link, respectively. $\hat{d}_k(j)$ is the decoded source signal for user $k$ at $n$th relay node. $n_{RD}$ is AWGN term and $N$ is the number of relays in the system. $\pi_k^i$ is the spreading and interleaving waveform of the user $k$ used by $n$th relay during the $j$-th symbol period. Finally, destination node uses a Rake receiver to estimate the data message from different relays. Then, these soft estimates of the data message are combined by using a maximum ratio combiner (MRC).

Assuming perfect channel estimates, the instantaneous signal-to-noise ratio (SNR) at the Rake receiver output for both $n$th relay and destination in the system is written by [13]

$$\gamma_{SR} = \frac{E_s}{N_0} [h_{SR}]^T g_{SR} h_{SR}$$

$$\gamma_{RD} = \frac{E_s}{N_0} [h_{RD}]^T g_{RD} h_{RD}$$

where $h_{SR}$ and $h_{RD}$ are the channel gains for source-$n$th relay and $n$th relay-destination links, respectively. $E_s$ is the transmitted energy per symbol. $g_{SR}$ and $g_{RD}$ are $(1 \times 1)$ matrix for cross-correlation of delayed waveforms due to the single-path propagation. $[\cdot]^T$ is complex transpose operator.

![Fig. 1 Schematic diagram of a dual-hop DF IDMA system model for user $k$.](image)

III. PERFORMANCE ANALYSIS

We now derive an approximate BEP expression for a dual-hop DF IDMA system model described in Section II. In doing so, we begin with the commonly known BEP formulation for the considered system:

$$P_e = \sum_{\alpha} P_{\alpha} p(\alpha)$$

where $\alpha$ is the set of relays which correctly decoded and $P_{\alpha}$ is the conditional error probability at destination node. $p(\alpha)$ that is the error probability for the indirect transmission and is given by

$$p(\alpha) = \prod_{n=a}^{b} (1 - P_{\alpha,n}) \prod_{j=a}^{b} P_{\alpha,j}$$

where

$$P_{\alpha,n} = \int_{0}^{\infty} A Q(B \gamma) p_{\gamma,n}(\gamma) d\gamma$$

Eq. (7) is the average BEP at $n$th relay. $A$ and $B$ are constants that depend on the modulation type (for example $A = 1$, $B = 2$ for binary phase shift keying (BPSK)) [14]. $Q(x)$ is Gaussian $Q$-function defined by $Q(x) = \frac{1}{\sqrt{2\pi}} \int_{x}^{\infty} \exp(-t^2 / 2) dt$. $p_{\gamma,n}(\gamma)$ is the probability density function (PDF) of the total instantaneous SNR at $n$th relay node. $P_{\alpha,n}$ is the same as $P_{\alpha}$ after replacing the subscript $n$ with $j$. In order to find $p_{\gamma,n}(\gamma)$, the moment generating function (MGF) of $\gamma_{SR}$ is given by

$$M_{\gamma,n}(s) = E[\exp(\gamma_{SR})] = \left(1 + s \frac{\gamma_{SR}}{\sigma_{SR}^2}\right)^{-m_{SR}}$$
where \( \overline{\gamma}_{SR} \) is the average SNR and \( \overline{\gamma}_{SR} = \lambda_{SR} \frac{E_s}{N_0} \). \( m_{SR} \) is the Nakagami-\( m \) fading parameter for source-\( n \)-th relay link. \( \lambda_{SR} \) denote eigenvalue of both path delay and the correlation matrix of channel gains related to source-\( n \)-th relay link. Using the fraction decomposition for \( M_{\gamma_{SR}}(s) \), we obtain
\[
M_{\gamma_{SR}}(s) = \omega_{SR} \left( 1 + \frac{s}{\overline{\gamma}_{SR}} \right)^{-m_{SR}} \tag{9}
\]
where \( \omega_{SR} \) is the residue value. By using the inverse Laplace transform of (9), we deduce \( p_{\gamma_{SR}}(\gamma) \) as
\[
p_{\gamma_{SR}}(\gamma) = \omega_{SR} \left( \frac{m_{SR}}{\overline{\gamma}_{SR}} \right)^{m_{SR}} \gamma^{m_{SR}-1} \exp \left( -\frac{\gamma m_{SR}}{\overline{\gamma}_{SR}} \right) \Gamma(m_{SR}) \tag{10}
\]
where \( \Gamma(\cdot) \) is Gamma function. Inserting (10) into (7), we get
\[
P_{e,R} = \int_{0}^{\infty} A Q(B \gamma) \left\{ \omega_{SR} \left( \frac{m_{SR}}{\overline{\gamma}_{SR}} \right)^{m_{SR}} \gamma^{m_{SR}-1} \exp \left( -\frac{\gamma m_{SR}}{\overline{\gamma}_{SR}} \right) \right\} d\gamma \tag{11}
\]
The integral in (11) can be evaluated by using
\[
Q(x) \approx \left[ \frac{1}{12} \exp \left( -\frac{x^2}{2} \right) + \frac{1}{4} \exp \left( -\frac{2x^2}{3} \right) \right] \tag{16}
\]
and using eq. (4). Similar to eq. (16), using the fraction decomposition and inverse Laplace transform evaluation, we can obtain the PDF of total instantaneous SNR. Following to the same steps for (11) and using eqs. (5) and (6), \( P_e \) is derived as
\[
P_e = \sum_{n=1}^{N} \left( \frac{m_{SR}}{\overline{\gamma}_{SR}} \right)^{m_{SR}} \frac{A \omega_{SR}}{\overline{\gamma}_{SR}} \left[ \frac{(Z_1 + \Lambda_2)^{m_{SR}}}{12} \right] \tag{15}
\]
Each integral term in (13) can be evaluated using [17, eq. 3.381.4]. After some mathematical manipulations, an approximate \( P_{e,R} \) expression is derived as
\[
P_{e,R} \approx \frac{A \omega_{SR} \left( \frac{m_{SR}}{\overline{\gamma}_{SR}} \right)^{m_{SR}}}{\overline{\gamma}_{SR} \Gamma(m_{SR})} \left[ \begin{array}{c} \left( -\frac{B}{2} - \frac{m_{SR}}{\overline{\gamma}_{SR}} \right)^{m_{SR}} \\ \frac{4}{12} \end{array} \right] \tag{14}
\]
IV. NUMERICAL EXAMPLES
In this section, the performance of the dual-hop DF IDMA system is evaluated via analytical results and validated through simulations for BPSK modulation. In the considered system, the Nakagami-\( m \) links among the source, relays and destination are independent and identically distributed. Without loss of generality, we assume equal noise powers at all the nodes.
In Fig. 2, the performance of the dual-hop DF IDMA system for $m = 2.5$ and different number of relays is shown. It can be observed that the error performance improves with increasing SNR. Fig. 2 shows, as expected, precise agreement between the results obtained from the theoretical analysis and simulation results at greater than 8 dB.

![Graph showing Bit error probability vs. SNR](image)

Fig. 2 Bit error probability of the dual-hop DF IDMA system versus average SNR for $m = 2.5$ and different number of relays.

The performance of a dual-hop DF IDMA system with $N = 3$ is better than that of a DF IDMA system with $N = 1$. For example, an error probability of $10^{-3}$ happens at SNR $\approx 6$ dB for $N = 3$, while it occurs at SNR $\approx 13.2$ dB for $N = 1$. It can be noticed from the curves in Fig. 2 that dual-hop DF system performances are affected by the number of relays.

V. CONCLUSIONS

New theoretical approximate solution for BEP of a dual-hop DF IDMA network over Nakagami-$m$ fading links have been derived. The exponential-type Gaussian $Q$-function approximation was used to obtain the theoretical results for error probability of the considered system. The effect of increasing the number of relaying nodes in the network were investigated as well as simulation results were used to verify the analytical results obtained by the proposed BEP expression. The results were shown that while the number of relays in the system increases, a notable SNR gain is occurred.

Performance of Dual-Hop DS-CDMA Systems with AF Relaying over Rician Fading Channels

Nuri Kapucu, Mehmet Bilim, Ibrahim Develi
Erciyes University
Department of Electrical and Electronics Engineering, 38039, Kayseri, Turkey
{nurikapucu, bilim, develi}@erciyes.edu.tr

Abstract—This paper presents the bit-error rate (BER) performance of direct-sequence code-division multiple access (DS-CDMA) systems with dual-hop amplify-and-forward (AF) transmission over flat Rician fading channels. In the considered system, a source node communicates with a destination node via N relay nodes. BER results are obtained via extensive computer simulations by varying the number of relay nodes and the value of Rician K factor. It is shown that the performance of a DS-CDMA system is improved by using multiple AF relays.

Keywords—DS-CDMA, amplify-and-forward, Rician distribution, BER, Dual-hop.

I. INTRODUCTION

Recently, dual-hop relaying techniques known as amplify-and-forward (AF) and decode-and-forward (DF) are considered promising solutions due to their possible application in the wireless and mobile communication systems. AF relaying in which the relay (R) amplifies the source (S) information and then sends it to destination (D) is an important method to implement relay systems [1]. Dual-hop relaying techniques provide connectivity when direct transmission from S to D node is not practical because of deep fading conditions [2]. Dual-hop AF relaying can be applied to spread spectrum communication systems such as direct-sequence code-division multiple access (DS-CDMA) systems. Several studies have focused on performance of dual-hop relaying techniques without DS-CDMA systems [3-10]. In [3] and [4], the bit-error probability and outage probability of dual-hop AF relaying protocols are presented when the channels are subject to mixed fading cases such as Rayleigh/Rician and Rician/Rayleigh. The performance of dual-hop AF transmission without DS-CDMA principle is investigated over Nakagami-m/Rician fading channels [5]. Spalevic et al. [6], investigated the performance of a two-hop AF relaying system under asymmetric fading environments. The authors in [7] presented the performance of dual-hop AF relaying systems over Rayleigh/Rician and Rician/Rayleigh fading channels. In [8], the authors proposed exact expressions for probability density function (PDF) and cumulative distribution function (CDF) of dual-hop AF relaying systems over Nakagami-m and Rician fading channels. The performance of two-hop relaying systems was investigated over Rayleigh/Gamma and Rayleigh/Weibull fading conditions in [9] and [10]. Different from [3]-[10], in this work, dual-hop DS-CDMA systems with AF transmission method is investigated over Rician fading channels. In the literature, there are only a few studies dealing with the performance of dual-hop AF relaying based DS-CDMA systems [11-13]. The bit-error rate of a dual-hop DS-CDMA systems with AF technique is investigated over different fading channels by presenting only computer simulations [11]. In another work, the authors analyzed the performance of DS-CDMA system with relaying in the presence of multi-user transmitter pre-processing based on channel impulse responses in [12]. Zappone et al. [13] considered the resource allocation problem in a relaying based DS-CDMA wireless communication system.

In this study, BER performance of N relay assisted dual-hop AF DS-CDMA system is investigated over Rician fading channels. It is considered that the direct transmission between S-D nodes is not possible due to deep fading conditions. In order to maintain the transmission in a conventional DS-CDMA system, N relay assisted dual-hop relaying is adopted. S-R_n and R_n-D channels are subject to Rician fading which provides line-of-sight (LOS) characteristics of a wireless channel. It is shown that BER performance of a conventional DS-CDMA system is improved with the help of dual-hop AF transmission. In addition, increasing the number of R nodes (N) and the value of Rician K factor brings considerable amount of BER improvement.

II. SYSTEM AND CHANNEL MODELS

In Fig. 1, a dual-hop relaying model with N relay nodes is illustrated.

![Illustration of N relay assisted dual-hop relaying system](image_url)

In the considered system, half duplex transmission is considered. The transmission occurs in two transmission phases. Each user is separately considered as an information while the other users are assumed as interference due to the
DS-CDMA principle [14]. In Fig. 2, the structure of $S$ node which consists of $L$ users is shown.

![Fig. 2 Structure of $S$ node with $L$ users](image)

The information of each user, $d_l(t)$, is modulated and spreaded by employing the unique spreading code, $c_l(t)$, for each user. After that, the information of $L$ users is summed and $r_{sr}(t)$ is transmitted to the $R$ nodes. In the first transmission phase, the received DS-CDMA signal at $R_n$ node can be expressed by

$$r_{sr}(t) = \sum_{i=0}^{L-1} \sum_{l=1}^{N} d_i(t) C_t (t - \tau_l - iT_l) h_{sr}(i) + n_{sr}(t)$$  \hspace{1cm} (1)

where $L$ is the number of users, $f$ denotes the frame length, $d_i(t)$ and $C_t$ are the $i$th symbol and the spreading code for the $i$th user, respectively. $T_l$ is the bit period and $\tau_l$ represents transmission delay of the $l$th user. $n_{sr}(t)$ is the additive white Gaussian noises (AWGN) and $h_{sr}$ is the Rician fading coefficient for the $S$-$R_n$ path. The PDF of the instantaneous SNR for $h_{sr}$ can be given according to Rician distribution as

$$f_{\alpha}(\alpha) = \frac{2e^{-K(K+1)}}{\Omega \sqrt{\pi}} \left( \frac{\sqrt{K(K+1)}}{\Omega} \right)^{-\frac{1}{2}} I_0\left(2\alpha \sqrt{\frac{K(K+1)}{\Omega}}\right)$$  \hspace{1cm} (2)

where $\alpha \geq 0$, $K$ is the Rician parameter and $I_0(\cdot)$ is the zeroth order modified Bessel function of the first kind [15]. Then, $R$ nodes amplify the received source information by employing the amplification process as follows

$$\beta = \sqrt{E_s / \left( (E_s | h_{sr} |^2) + N_0 \right)}$$  \hspace{1cm} (3)

$R$ nodes transmits the amplified source information to the $D$ node. In Fig. 3, the structure of $D$ node which consists of $L$ users is depicted.

![Fig. 3 Structure of $D$ node with $L$ users](image)

At $D$ node, the received signal from $R$ nodes, $r_{rd}(t)$ is despreaded by using the unique spreading code of each user's to separate the each user's information. Then, the each user's information is demodulated and decision process is employed to estimate the $l$th user information, $\tilde{d}_l$. In the second transmission phase, the received signal at $D$ node is written as,

$$r_{rd}(t) = \sum_{i=0}^{L-1} \sum_{l=1}^{N} r_{rd}(t - D_l - \tau_l - iT_l) h_{rd}(i) + n_{rd}(t)$$  \hspace{1cm} (4)

where $D_l$ is the time delay, $\tau_l$ is the transmission delay of $R_n$ and $n_{rd}(t)$ is AWGN of the $R_n$-$D$ link. $h_{rd}$ is the Rician channel coefficient of $R_n$-$D$ link and the PDF of the instantaneous SNR for $h_{rd}$ is subject to Rician distribution given by

$$f_x(x) = \frac{2e^{-K(K+1)\chi}}{\Omega \sqrt{\pi}} \left( \frac{\sqrt{K(K+1)}}{\Omega} \right)^{-\frac{1}{2}} I_0\left(2\chi \sqrt{\frac{K(K+1)}{\Omega}}\right)$$  \hspace{1cm} (5)

where $\chi \geq 0$. At $D$ node, maximum ratio combining (MRC) is used to combine received signal from each relays [16]

$$r_{MRC}(t) = \sum_{n=1}^{N} w_n r_{rd}(t)$$  \hspace{1cm} (6)
where $N$ is the number of relays, $w_n$ is the MRC coefficient of the received signal from the $R_n$ node and

$$w_n = \sqrt{E_h \sigma_{sr,d}^2 / \sigma_{sr,d}^2}.$$ 

$h_{sr,d}$ is the conjugate of $h_{sr,d}$ and $\sigma_{sr,d}^2$ is the noise variance of the $S-R_s-D$ link.

### III. SIMULATION RESULTS

This section presents the simulation results for BER performance of dual-hop DS-CDMA systems with AF relaying over Rician fading channels. Number of simultaneous users and spreading length are set to 4 and 32, respectively. Results are plotted versus SNR by assuming binary phase shift keying (BPSK) modulation.

In Fig. 4, BER performance results are illustrated. The simulation results are obtained for different number of relays and different values of Rician $K$ parameter. As can be seen from Fig. 4, increasing the number of relays in the system improves the BER performance of the considered system model.

![Fig. 4 BER performance of dual-hop DS-CDMA systems with AF relaying over Rician fading channels.](image)

For example, the worst performance is obtained when one relay is used with $K = 5$ and the best performance is obtained with $N = 3$, $K = 10$. From Fig. 4, it is evident that the value of $K$ parameter is the major parameter for the performance improvement in the considered system model. As an example, when $N = 3$, $K = 5$ and $N = 3$, $K = 10$, BER results are equal to $\approx 2.8 \times 10^{-3}$ and $\approx 3 \times 10^{-6}$ at 15 dB. Increasing the value of $K$ parameter from 5 to 10 brings considerable BER improvement in this example. In the contrary, using more relays does not bring same improvement for the considered system. This shows that better channel conditions are more important than increasing number of relays in the considered system model.

### IV. CONCLUSIONS

In this study, we simulate BER performance of DS-CDMA systems with dual-hop AF transmission over Rician fading channels. The results are obtained for different number of relays and different $K$ parameter values. It is shown that BER performance of dual-hop DS-CDMA systems is improved with the use of multiple relays and increasing the value of $K$ parameter. From the results, it is obvious that the value of Rician $K$ parameter is more important than the number of relays for the performance improvement in the system.

{gokhankocyigit, ugurcini}@trakya.edu.tr

Abstract—In this work performance limitations of various pulse-width modulation based analog digital converter is analyzed. Then, pulse-count modulation based digital-analog converter is explored. The structures are implemented on Altera™ Stratix III FPGA. A sawtooth test signal is generated to analyze the performance of the DAC structures. Maximum effective resolution is calculated depending on the architecture selected. The paper is especially useful for the practicing engineers who deal with embedded system design and develop pulse-width modulation and pulse count modulation based digital-analog converters on microcontrollers and FPGAs systems.

Keywords—Pulse width modulation (PWM); pulse count modulation (PCM); digital-analog conversion; low pass filter; embedded systems.

I. INTRODUCTION

Pulse width modulation digital-analog conversion is a popular data conversion technique for embedded systems. The advantage of the system is that, the system only requires pulse-width modulator inside the controller and an external RC filtering is required to acquire desired analog signal at the output [1]. Since most of the microcontrollers include pulse-width modulators inside, only an RC filter is required to achieve desired analog signal. The implementation is popular for its low cost and easy configuration [2-5]. The resolution of the PWM DAC is limited by counter range of the PWM generator and switching noise after the filter. As a result, the resolution of the PWM DACs is not adequate for many of the embedded system requirements whenever high resolution is needed.

In [5] an alternative implementation for the PWM DAC, pulse-count modulation (PCM) is defined. The PCM method increases performance; however, the implementation is not possible using internal PWM modules of the microcontrollers. Delta-sigma PWM DACs are provides high resolution [6-8]; however, the implementation of delta-sigma conversion is not possible by using basic PWM modules of general-purpose microcontrollers, rather, it requires digital and analog full custom design blocks which is not suitable for low-cost general-purpose design.

In this work, PWM and PCM DAC structures are implemented using an FPGA board and effective resolution of the DAC structures are analyzed depending on the switching noise at the outputs of the structures.

II. PWM AND PCM DIGITAL-ANALOG CONVERTER

General PWM digital-analog converter (PWM DAC) structure is shown in Fig 1. Here, fsys is the clock frequency of the general system. Duty cycle of the PWM modulator is the input of the system, which is entered as digital value, and analog value at the output is proportional to the duty cycle at the system. PWM modulation frequency must be filtered out to have the desired analog value at the output [2-5]. By employing a simple RC low-pass filter at the output of the PWM modulator, desired analog is output is achieved. A second order RC filter stage provides better implementation of the PWM DAC [5, 9]. Although it is possible to use higher order filters they are not preferred due to increased design cost. Generally, second order filter is sufficient to obtain the desired output [9].

The duty cycle of a pulse width modulator contains the desired analog signal data. The output of the DAC can swing between GND and VMAX. The maximum output voltage at the output node and least significant bit (LSB) amplitude is given as:

\[ V_{\text{MAX}} = V_{\text{DD}} \left(1 - \frac{1}{2^m}\right), \quad (1.a) \]
\[ V_{\text{LSB}} = V_{\text{DD}} \frac{1}{2^m} , \quad (1.b) \]

where \( m \) is the resolution of the \( m \)-bit DAC, i.e., \( m \) is the bit size of the DAC digital input; \( V_{\text{DD}} \) is the supply voltage of the digital system. The normalized value of the analog signal \( s(t) \) can be represented as duty cycle of the PWM:

\[ s(t) = \text{Duty}(t) = \frac{\text{Digital input}}{2^m} \quad (2) \]

Fig. 1. Pulse Width Modulator Structure
The PWM output is composed of two signals, i.e., the desired analog output and pulse-width modulator frequency. Since the analog signal band-width is much smaller than the modulator frequency, the analog signal component of the PWM DAC, i.e. $Duty(t)$ signal is quasi-stationary. Hence, the quasi-stationary part of the signal contains the analog output data. Therefore, the modulator frequency must be filtered out. Fig. 2(a) shows circuit equivalent of PWM DAC. Fig. 2(b) shows the PWM signal in frequency domains, and, Fig. 2(c) shows the time domain switching characteristics. The modulator signal is filtered out using a first order RC filter to have the desired analog output in Fig 2(a). As an example, if the desired analog signal is 0.3V, then the duty cycle of the modulator has to be 30%, if 0.5V analog signal is required, then the duty cycle has to be 50%. The values are normalized to the supply voltage of 1V. The transfer function of simple RC filter at the output of PWM DAC as shown in Fig. 2(a) is:

$$V_{\text{out}}(j\omega) = \frac{1}{1 + j\omega RC}$$  \hspace{1cm} (3)

The cutoff frequency for the desired analog signal can be calculated as:

$$f_{\text{cutoff}} = \frac{1}{\tau} \left( \text{rad/} \text{s} \right)$$ \hspace{1cm} (4)

In Fig. 3, analog outputs are generated using various modulation frequencies. The analog signal is generated by sweeping the duty cycle from %0, %10, ... %90 at each millisecond. Here, supply voltage is selected to be 3.3V. In each of the step outputs, the analog signal band-width is selected to be 20 kHz, and, using (4), $R$ and $C$ values are selected to be 0.8 nF and 10 k\Omega. As can be seen from Fig. 3, removal of modulator noise from the analog signal is very critical to reach a desired output resolution level, if modulation frequency is increased, then output noise level is less at the output. On the other hand, if PWM modulator frequency is increased, then PWM resolution decreases since,

$$f_{\text{PWM, MAX}} = \frac{f_{\text{sys}}}{2^m},$$  \hspace{1cm} (5)

where $m$ is the resolution of the PWM modulator.

The effective resolution of the PWM DAC depends on the pulse-width modulator resolution, desired output frequency band ($f_{\text{cutoff}}$), and the filter performance for the pulse-width modulator frequency suppression. The remaining pulse-width modulator frequency component appears as noise at the output and limits the resolution of the DAC. Even if $m$-bit counter is utilized for the PWM module as shown in Fig. 1, it does not guarantee $m$-bit resolution. The reason is that, if PWM DAC output noise is higher than the $V_{\text{LSB}}$ as given in (1.b), then the effective resolution will be less than $m$-bits.

For most of the applications, a first order RC filter stage is not sufficient for the removal of the PWM noise. In general, second order filter is employed to reach higher resolution levels. Here, in order to reach for the desired resolution requirements an empirical cutoff frequency calculation for a second order RC filter is given. Different types of low-pass
filter structures is also suitable for filtering the switching noise. However, second order RC filter is the simplest topology.

A possible implementation of a second order RC filter is shown in Fig. 4(a). Here, in order to reduce the loading effect, the resistor in the second stage is selected as 2R. Regarding to this, the second stage capacitor value is selected to be C/2. The filter transfer function of the circuit in Fig. 4(a) is:

\[ \frac{V_{out}(s)}{V_{PWM}(s)} = \frac{1}{(RC)^2 s^2 + \frac{5}{2} RC s + 1} \]  

The frequency response of the second order RC circuit in Fig. 4(a) for component values of \( R = 5k \) and \( C = 1nF \) is shown in Fig. 4(b). Here, frequency is 30 kHz. Using the configuration in Fig. 4(a) cutoff frequency can be extracted using SPICE simulations as:

\[ f_{cutoff} \approx \frac{0.1575}{RC} \]  

The calculation is based on the assumption that second order filter asymptotically -40dB/decade amplitude decrease at the output which is represented as in Fig 4.b. The line cut at 0dB point gives empirical equation (7) whenever component values are selected as shown in Fig. 4.a. The calculation eases filter design process.

The second order RC filter shown in Fig. 4(a) has R and 2R resistor values and C and C/2 capacitance values, which provides easy implementation. In addition, the cut-off frequency in (7) provides a fast calculation method without complex filter calculations.

As mentioned, PWM DAC output is severely affected by the switching noise of the pulse-width modulator. As a result, effective resolution of PWM DAC is quite limited. To overcome this limitation, a small modification over the PWM structure can be made to have pulse-count modulation scheme. The pulse count modulation (PCM) scheme is shown in Fig. 5. In this structure, only comparison bits are crossed from MSB to LSB. Equivalent duty cycle is the same as PWM DAC. However, PCM switching frequencies are much higher than PWM DAC. So that, much better effective resolution can be handled. The hardware modification is very easy whenever FPGA implementation or VLSI implementation is available. However, the case is more complicated whenever microcontroller implementation is considered.

PWM and PCM duty cycle scheme for 4-bit modulator is shown in Fig. 6. As the total duty cycle is same over whole period, analog signal output is same for both of the structures. Moreover, switching noise after the RC filter is much less whenever PCM is implemented. PCM switching harmonics are shown in Fig. 7. The switching frequencies of both PWM and
PWM and PCM DACs can be compared. It is obvious that, higher frequency components can be filtered out much easier in PCM since switching harmonics are at much higher frequency points whenever compared to the PWM frequency plot which is shown in Fig. 2.b. Since the harmonics of the PCM modulator resides at much higher frequencies compared to PWM structure, filtering out the switching noise from the desired signal is much effective. As a result, much better effective DAC resolution is possible.

III. EXPERIMENTS AND DISCUSSIONS

To experiment the PWM and PCM DAC, both of the structures are constructed using an FPGA board with Altera’s CycloneIII FPGA. The modulator output is filtered out using second order RC filter as shown in Fig. 4(a). The cutoff frequency of the filter is calculated using (7) as 30 kHz, where $R_1 = 5k$, $R_2 =10k$, $C_1=1nF$ and $C_3 = 0.5nF$. The system frequency $f_{sys}$ is 50 MHz in the system setup.

To compare same structures, a test pattern of sawtooth wave is digitally generated using PWM and PCM DACs with 9-bit PWM and PCM modulators, i.e. $m$ is selected to be 9. The signal outputs of the two of the DAC structures are shown in Fig. 8.

It is obvious that PCM DAC switching noise after the filter gives much better results compared to PWM DAC output. PCM DAC effective resolution is approximately 9-bits. PWM effective resolution is much less, even same size PWM and PCM modulators are implemented. However, PWM effective resolution can also be improved to have better results. To increase effective resolution, $m$ is modified to 7. After that $f_{PWM}$ as given in (5) is increased, then, switching noise is decreased. As a result, 6 to 7 bits of resolution is also achieved using PWM DAC as well. PCM DAC provides 2 to 3 bits of more effective resolution in the provided test setup. The effective resolution is calculated as maximum switching noise measured at the output of the DAC is less than least significant bit amplitude of the DAC.

PCM DAC implementation can also be possible for microcontroller implementations, whenever SPT port is used as PCM modulator source and periodically SPI port is driven by PCM data by reversing the data output as given in the scheme as shown in Fig. 5, which is planned to be next implementation to test the microcontroller performance of PCM DAC structures as well.

IV. CONCLUSIONS

PWM and PCM DACs are constructed using an FPGA development board. Two of the DAC structures requires same hardware resources. However, PCM DAC provided 9-bit effective resolution whereas PWM exhibited up-to 7-bits of resolution due to the fact that PCM switching noise can be more effectively suppressed. PCM DAC can be an alternative solution for FPGA and VLSI implementations whenever a simple and efficient DAC structure with moderate analog frequency band is required.

Abstract—In this study, a new microstrip patch shape, called Seljuk star, is proposed. The performance of the designed antenna is compared with the performance of square and circular microstrip antennas, which are two other popular patch shapes in literature. The design of the antenna is performed in HFSS. Each individual antenna is intended to be working at a single frequency, but during the simulations multiple resonances are obtained for most of the designs. Therefore, the bandwidth comparisons are done for each time one by one. In comparison to the circular patch shape with the same surface area, bandwidth is improved 10.57 times. The shift between the theoretical calculations and simulations is % 1.38. Again, this is the smallest shifting between all results. Based on this, it is observed that Seljuk star shape microstrip patch antenna has a better performance than circular and square shape microstrip antennas which have the same dimensions or same surface areas with it. The new, proposed Seljuk star patch shape is believed to have a high potential to be used in future research.

Keywords—Seljuk star, microstrip antenna, HFSS, bandwidth enhancement

I. INTRODUCTION

Microstrip antennas are one of the most preferred types of antennas because of their small sizes, low power consumption and consumption for mobile applications today. However, the narrow bandwidth of the microstrip antennas is a major disadvantage. In order to overcome this negative side, many studies have been performed on bandwidth enhancement methods [1-3].

One of the bandwidth enhancement methods that is very common in literature is choosing the optimal patch geometry. Thus, resonant frequency and bandwidth values can be chosen for the structure while maintaining a suitable application for the antenna geometry. In addition, the polarization and radiation characteristics can be adjusted by changing the shape of the patch. [1-3,6-8]

In this study, Seljuk star microstrip patch antenna, a new patch shape in literature, is designed with using the traditional square and circular microstrip antennas and their performances are compared. During designs, a two-phase study was performed. In the first phase, patch dimensions were taken equal to each other for all three patch geometries. In the second phase, the dimensions were chosen as surface areas of the patches would be equal. Except patch dimension, all other antenna parameters didn’t change for aiming to present the effects of the patch shape on antenna performance. Study is described in detail below [2,4].

II. ANTENNA DESIGN

Seljuk star is a special geometric shape which can be easily obtained by placing two equivalent squares with a 45° degree relative to one another can be come across through the whole Islamic geography. The reasons of choosing this shape for antenna design are easy calculation of shape dimensions as geometrically and utilizing the circular antenna expressions in literature. Seljuk star microstrip patch antenna (SSMSA) has advantages in many ways according to other patch shapes and gives opportunities to save area, so the new antenna design can be used in more today’s smaller mobile devices. Also, by adding other bandwidth enhancement methods can be applied to this patch shape it can be achieved successfull antenna performances. [2,4,9].

In Figure 1, SSMSA designed on a square substrate is seen. Rogers Duroid 6010 is prefered as substrate material. It has a dielectric constant of 10.2 and a thickness of 3.175 mm.

Coaxial feedlines were used in all designs. The feed point of the antennas were determined by trial and error in simulation.
media. HFSS is used for simulations [5]. Antenna designs can be seen in Table 1.

- **h**: Substrate thickness
- **\(\varepsilon_r\)**: Dielectric constant of the substrate
- **x_f**: Feed point
- **\(f_{r_{Teo}}\)**: The theoretical resonant frequency

In Figure 2, the differences of dimension equality and area equality designs for all three patch shapes are shown.

At first phase, a Seljuk star shape microstrip antenna is designed by choosing the ground plane parameters and resonant frequency as 5800 MHz which are suitable for the available material. Simulations were completed for both dimension equality and area equality designs. After SSMSA was designed, the patch shape was changed into square and circular, respectively. All other antenna parameters were kept constant. They were simulated using HFSS and their performances were compared.

**III. RESULTS**

Simulation results are given in Table 2. From these results, it is obtained that with all patch designs, more than one resonant frequencies are occurred and the largest bandwidth is achieved with SSMSA design. This value of \(1.48\) is not enough for ISM 5800 MHz needs which is \(2.5\), but it is quite larger than the other design bandwidths. From simulation results, it is seen that a bandwidth is obtained which is 10.57 times larger than the other patch shapes. That is the result of Seljuk star design equal area with the circular patch. For the same design, there is only a frequency shift as \(1.38\) between the simulation and the theoretical frequencies. Again, this is the smallest shifting between all results. Based on this, it is observed that Seljuk star shape microstrip patch antenna has a better performance than circular and square shape microstrip antennas which are the same dimensions or same surface areas with it. So, as a new patch shape, Seljuk star will easily find application and study areas in literature.

IV. CONCLUSIONS

A Seljuk star shape microstrip patch antenna is designed then its performance is compared with circular and square shape microstrip antennas that are the popular patch shapes in literature. There are two phases for the designs: First, the patch dimensions of circular and square are taken as the same with Seljuk star. Then the patch surface areas of antennas are fixed to the area of Seljuk star antenna and new patch dimensions are calculated for the new designs. Antenna performances are compared in terms of bandwidth.

As can be seen from simulation results, SSMSA design has superior performance compared to other patch shapes. Also the the target resonant frequency has obtained with a reasonable shifting. However the % 2.5 bandwidth criteria nessecary for WiFi applications could not be matched with % 1.48 bandwidth result. Nevertheless, it’s possible to improve the bandwidth futher by applying the bandwidth enhancement methods.

Effect of junction recombination velocity of electrical parameters of a vertical parallel silicon solar cell under frequency modulation

Electric and Electronic Engineering Department, IĞDIR University
İğdır 76000, Turkey,
* Corresponding author: Gökhan ŞAHİN (g.sahin38@hotmail.fr - 00905535764285)

Abstract—This study investigates a theoretical study based on the determination of electrical parameters in solar cell junction vertical parallel silicon under polychromatic illumination and frequency modulation. From the excess minority carrier’s density in the solar cell, the photocurrent density and the photovoltage are derived. The route of the current vs. voltage density (I = f (V)) that materializes the behavior of the generator; we have a model on the shunt resistor and the series resistor. From their expressions, we study their pace according to Bode and Nyquist then extend the study to other electrical parameter. The Bode diagrams of the diffusion capacitance are shown for different junction recombination velocity

Keywords: Photovoltaic, junction recombination velocity, Nyquist and Bode diagramme, series resistance and shunt resistance, capacitance.

I. INTRODUCTION

In order to improve the efficiency of solar cells, various methods for determining electrical [2] and electronic [1] parameters of a silicon solar cell were studied on regime and different illumination modes. These investigations have identified some adverse effects to the performance of the solar cell. Include among others : the drastic effect of the series resistance and shunt conductance on the performance of the solar cell [3]; the effect of incidence angle on the electrical parameters of a solar cell to vertical parallel junction [4,5]; the effect of the size of the grain boundaries on a solar cell under illumination multispectral [6] etc.

In this present article, we will determine the expression of the density of minority carriers, the photocurrent density and photovoltage. Study of the characteristic photocurrent - photovoltage (I- V) where each point of the shape defines a specific operating state of the solar cell, the electrical parameters (series and shunt resistance) will be deducted.

From Bode and Nyquist diagrams enlargement of the capacitance study, the predominant effects will be listed and analysis will be on the impact of the frequency of these parameters and the effect on junction recombination velocity.

II. MATHEMATICAL DEVELOPMENT

Figure 1 represents parallel vertical junction silicon solar cell under various junction recombination velocity in the base. This study is based on a bifacial silicon solar cell with an n+-p-p+ [7,8] structure (figure 1). Given 20 that the base has a greater contribution to photocurrent, the following analyses have been conducted only in this region.

Under the effect of the exciting light, there is a generation of minority carriers (electrons) and majority (holes) called electron-hole pairs in the database. The contribution of the transmitter (the thickness is 1 µm) is neglected at the expense of the base [9] which is the predominant area of absorption phenomena, generation, recombination and diffusion of the charge carriers. From these phenomena it governs the continuity equation of minority charge carriers in the following basis:

$$D(\omega) \frac{\partial^2 \delta(x,t)}{\partial x^2} - \frac{\delta(x,t)}{\tau} + G(z,t) = \frac{\partial \delta(x,t)}{\partial t} \quad (1)$$

Where $\delta(x,t)$ [10] and $G(z, t)$ [11] respectively represent the density and the generation rate of minority charge carriers as a function of depth $z$ and time $t$. Their expressions are given respectively by the relations (2) and (3):

$$\delta(x,t) = \delta(x) \times \exp( j \omega t) \quad (2)$$

$$G(z,t) = G(z) \times \exp(j \omega t) \quad (3)$$
As the illumination is polychromatic, \( G(z) \) [12] is written as follows:

\[
G(z) = \sum_{i=1}^{i} a_i \times \exp(-b_i z) \tag{4}
\]

With \( a_i \) and \( b_i \) tabulated coefficients of solar radiation defined under AM (air mass) (solar spectrum) = 1.5 [12].

\( \omega, \tau \) and \( D(\omega) \) [13] respectively called by the terms modulation frequency, average duration (in \( \mu s \)) and complex diffusion coefficient of minority charge carriers in the base. This is expressed as follows:

\[
D(\omega) = \frac{D(1 + \omega^2 \tau^2)}{(1 + \omega^2 \tau^2)^2} \left[ 1 - j\omega \tau \right] \tag{5}
\]

Substituting equations (2), (3) and (4) in equation (1) we obtain equation (6):

\[
\frac{\partial^2 \delta(x)}{\partial x^2} - \delta(x) + G(z) = 0 \tag{6}
\]

With \( L(\omega) \) the complex diffusion length expressed as follows:

\[
L(\omega) = L \times \sqrt{\frac{1 - j\omega \tau}{1 + \omega^2 \tau^2}} \tag{7}
\]

From the equation (6) we obtain the solution (8).

\[
\delta(x) = A \sinh \left( \frac{x}{L(\omega)} \right) + B \cosh \left( \frac{x}{L(\omega)} \right) + \sum_{i=1}^{i} \frac{a_i}{1 + \omega^2 (b_i \tau)^2} \exp(-b_i z) \tag{8}
\]

Coefficients \( A \) and \( B \) are determined through the following boundary conditions [14, 15]:

- at emitter-base junction \( (x = 0) \):
  \[
  D(\omega) \frac{\partial \delta(x)}{\partial x} \bigg|_{x=0} = S_f \delta(x) \bigg|_{x=0} \tag{9}
  \]

\( S_f \) is the excess minority carrier’s junction recombination velocity. It has two terms:

- \( S_f = S_{f_0} + S_{f_b} \)

\( S_{f_0} \) or intrinsic junction recombination velocity induced by the shunt resistor and \( S_{f_b} \) the flow of current required by a load imposing the operating point of the solar cell [16, 17].

- at the middle of the base \( (x = H/2) \):
  \[
  \frac{\partial \delta(x)}{\partial x} \bigg|_{x=H/2} = 0 \bigg|_{x=H/2} \tag{10}
  \]

with \( H \): the total thickness of the base (0.03\( \mu m \)).

III. RESULTS AND DISCUSSION

A. PHOTOCURRENT DENSITY

The photocurrent density is obtained by the minority carrier gradient at the junction \( (x=0) \) and is given by the Eq. (11).

\[
J_{ph} = 2 \cdot q \cdot D(\omega) \cdot \left. \frac{\partial \delta(x, \omega, z, \lambda)}{\partial x} \right|_{x=0} \tag{11}
\]

\( q \) is the charge minority carriers. For different excitation frequencies, we represent in the figure 2 the photocurrent density as a function of the junction recombination velocity. Based on the excess minority carrier density, we can determine the photo voltage across the junction.

![Figure 2: Photocurrent density versus the junction recombination velocity for different values of the logarithm of frequency.](image)

The analysis of the figure shows that the photocurrent density increases with increasing the junction recombination velocity for different frequencies. However the amplitude is larger for low excitation frequencies (static regime). In high frequencies the solar cell does not have time to relax and hence the decrease of the amplitude of the photocurrent [18].

For the low values of \( S_f (S_f = 2.10^6 \text{cm.s}^{-1}) \), the photocurrent density is very low because few minority carriers across the junction: the solar cell works in the vicinity of the open circuit while for large values of \( S_f (S_f = 4.10^6 \text{cm.s}^{-1}) \), a large number of minority carriers across the junction where the maximum current. This is the neighborhood of the short circuit.

B. PHOTOVOLTAGE

According to the Boltzmann’s relation, the photovoltage is obtained by the expression. (11) [19, 20]:

\[
V_{ph} = \frac{K \cdot T}{q} \ln \left[ 1 + \frac{N b}{n^2} \delta(x) \bigg|_{x=0} \right] \tag{11}
\]

with

\[
V_T = \frac{K \cdot T}{q}
\]
where q is the electronic charge, $V_T$ the thermal voltage, Nb (10^23cm^-3) the base doping density and $n_0$ is the intrinsic concentration of minority carriers (1.55*10^10cm^-3),
K: the Boltzmann constant (1.38*10^-23 m^2kg/s^2K^-1).
T: the absolute temperature

**C. I-V CHARACTERISTIC**

We present in fig. 3 the profile of the photocurrent density versus the module of the photovoltage for various angular frequency.

![Image](https://via.placeholder.com/150)

**Figure 3** Characteristic current-voltage various incidence angles.

$\omega = 10^2$ rad/s, $H = 0.03$cm, $L_o = 0.02$cm, $D_o = 26$cm²/s, $S_f = 2.10^3$ cm²/s

a) Ideal current generator $J = J_{sc}$ (short circuit current). b) Ideal voltage generator $V = V_{oc}$ (open circuit voltage). c) Ideal photovoltaic cell. d) Generator with constant internal resistance shunt.

When the photocurrent density is maximum and constant, we see that the photovoltage is small: we have a real power generator. The solar cell is characterized by current leakage from which the existence of shunt resistance ($R_s$). By cons when the photovoltage is maximum and constant, the photocurrent density is low: we have a real voltage generator therefore it has a series resistance of existence ($R_s$) that takes into account the difference between the external voltage and the voltage appears across the junction.

**D. ELECTRICAL PARAMETER**

For the first two electrical parameters, characteristics of the parasitic effects, it is based on previous studies in which the equivalent electrical circuit of the solar cell in the vicinity of the short circuit and that in the vicinity of the open circuit are studied [19]. From these studies, the respective expressions are extracted from the shunt resistance and the series resistance given by the equations (12) and (13):

$$R_{sh} (\omega, S_f, z) = \frac{V_{ph} (\omega, S_f, z)}{J_{cc} (\omega, z) - J_{ph} (\omega, S_f, z)}$$ \hspace{1cm} (12)

$$Rs (\omega, S_f, z) = \frac{V_{oc} (\omega, z) - V_{ph} (\omega, S_f, z)}{J_{ph} (\omega, S_f, z)}$$ \hspace{1cm} (13)

With $J_{cc}$, the short-circuit current and $V_{oc}$, open - voltage circuit.

$J_{cc}$ is obtained with the expression of the photocurrent density by letting the junction recombination velocity to a very high limit ( $S_f \rightarrow \infty$ ). While for $V_{oc}$, expression is used the photovoltage density by letting the junction recombination velocity to a very low limit ( $S_f \rightarrow 0$ ).

**E. BODE DIAGRAMME OF THE ELECTRICAL PARAMETERS**

The Bode diagram [20] a method is developed to simplify the obtaining of the variation of the parameter as a function of frequency. Bode is adopted to the amplitude and phase of the parameter is called Bode amplitude and phase of the Bode.

**F. SHUNT RESISTANCE**

Fig. 4 shows the modulus of shunt resistance versus the logarithm of the modulation frequency for different values of the junction recombination velocity.

![Image](https://via.placeholder.com/150)

**Figure 4** Shunt resistance versus the logarithm of frequency Log($\omega$) for different values of the junction recombination velocity.

$H = 0.03$cm, $L_o = 0.02$cm, $D_o = 26$cm²/s, $z = 0.003$cm, $\tau = 10^{-5}$s, $L = (t.D)^{1/2}$

The shunt resistor does not practice varies to a certain value of the junction recombination velocity called $S_{ph}$, from this value. We observed and showed the powerful of the resistance shunt. In fact, when the junction recombination velocity ($S_{ph}$) increases, the fuits also increase. Then the resistance shunt takes high values giving a good quality for the solar cell. We also note that the resistance shunt augment when the angular frequency increases. Indeed, the high frequencies do not promote good carrier mobility within the base. Then the resistance shunt take increasingly large values to ensure good quality in the solar cell. The Bode diagrammes magnitude to determine the cut-off frequency and validate the equivalent circuit model in figure 5.
Figure 5 Module of the shunt resistance versus the logarithm of modulation frequency:
H = 0.03cm, Lo=0.02cm, Do = 26cm²/s, z=0.003cm, τ= 10⁻⁵s, L= (τ.D)¹/²

Figure 5, we observed the same paces: When ω < ωc, the module of the capacitance is independent of frequency : one has a horizontal level for all curves. More Sf is low over this level is maximum. The magnitude of the Bode diagramme to determine the cut-off frequency and confirm the electric model equivalent. When ω > ωc, the module of the capacitance is significantly decreases to tend asymptotically toward zero. Over the junction recombination velocity (Sf) the greater the module of capacitance is low because the little present minority charge carrier’s pass through the junction: we also enlargement of the space charge region ( scr ) or an extension of the space charge region or a spacing of the electrodes [ 21,22 ] the junction can be considered as a plate of capacitor. The analysis of these figures shows the same curve shapes. For ω < 10⁴ Hz, the modulus of the shunt resistance and series that are independent of ω : this is static regime. For an angular frequency ω > ωc, the electrical parameter of the module believes. This frequency ωc corresponds to a so-called cut-off frequency. It is obtained with the intersection of the extensions of each of the two linear portions of the curve. According to Figure 6 or 7, it is seen that the curves have approximately the same peaks of intersection of two linear parts: thus we have the same cut-off frequency for all curves as the electrical parameter studied ( Rsh or Rs ). The figure 8 or 9 respectively phase diagrams of the Rshunt and Rsérie. For the independent of frequency ω < 10⁴ Hz, the phase of the electrical parameter is zero. By cons in high frequencies 10⁴ Hz < ω < 10⁶ Hz, the phase believed ( fig 6 and fig 8 ) and takes positive values , in this area we have the presence of inductive effect or presence of a coil.

G. PHASE OF SHUNT RESISTANCE

The variation of the phase of the shunt resistor with the modulation frequency is shown in Figure 6 below [12].

It can be seen that the phase of the shunt resistance increases with the increase of the modulation frequency. However, it is observed that the phase of the shunt resistor is always positive. Its horizontal junction solar cell has an inductive behavior, and this inductive reaction is greater for high values of data modulation frequency. We can say that when the modulation frequency is high, the response of the photocell is virtually zero. Very high frequencies block relaxation of the solar cell. It is seen that the junction recombination velocity slightly increases the phase of the shunt resistor.

H. SERIES RESISTANCE

The fig. 7 illustrates the profile of the series resistance of the module as a function of the modulation frequency for different junction recombination velocity values [14, 15].
For any given curve, the series resistance increases with the angular frequency especially beyond $\log (\omega) = 10^5$ cm/s. In effect when the angular frequency increases, the provoked current by the generator (Voc) increases. The series resistance is contrasted advantage in the flow of this current: this causes the increase of series resistance. We also note that the series resistance increases with the junction recombination velocity. Indeed, the high frequencies do not promote good circulation of the holders. This will cause some parking and such holders resulting in an increase of the volume series resistance, surface, interface... conferring resistance to an increase in amplitude globally.

Taking different ranges recombination velocity values at the junction, we expand our study on other electrical parameter to known the capacitance.

I. PHASE OF THE SERIES RESISTANCE

The variation of the phase of the series resistance with the modulation frequency is shown in Fig. 8 [12].

![Figure 8 Phase of the series resistance based on the logarithm of modulation frequency for different values of the junction recombination velocity](image)

It is found that the variation of the phase of the series resistance is a function of the modulation frequency. Therefore, we see that the phase of the capacitance is negative and the phases’ effects outweigh the inductive. However, a slight variation of the phase occurs when the frequency is low of about $10^4$ rad / s, but beyond this value there is a rapid increase in the phase of the series resistance. When the modulation frequency increases, the response of the photocell is very low. It is observed that the applied junction recombination velocity slightly decreases the phase of the series resistance, which does not contribute to the good performance of the solar cell.

For junction recombination velocities are in the vicinity of the open-circuit, the module of series resistance which is small and almost constant. Then it increases significantly with increasing the junction recombination velocity in the vicinity of short-circuit. In the latter neighborhood, the cut-off frequency is slightly higher than the first.

J. CAPACITANCE

When the solar cell is illuminated, there is generation and diffusion of minority carrier through the Space Charge Region (SCR), which is accompanied by charge storage [14].

The capacity equation is given by the relation 16.

$$C = \frac{dQ}{dV_{ph}}$$

with

$$Q = q.\delta(x)_{x=0}$$

with

$$C = q \times \frac{\partial \delta(x)}{\partial V_{ph}}_{x=0}$$

We will see the variation of the capacitance of the solar cell information of the junction recombination velocity (Sf). In Fig 9, we present the profile of the solar cell of the capacitance according to the angular frequency for different vary of the junction recombination velocities.
The figure 10 has been shown to better monitor the module of the capacitance amplitude to the great values of the junction recombination velocity ($S_f$).

When the junction recombination velocity ($S_f$) goes to zero, the capacitance is maximum and remains practically constant until a $S_{foc}$, for the $S_f$ values above the $S_{foc}$, we note a considerable decrease in the capacitance of the solar cell that eventually cancel to large value of the junction recombination velocity ($S_f$). In fact, the capacitance characteristic of the carrier concentration level in the base of the solar cell. Then for the low junction recombination velocity ($S_f$). There is a little modularity carriers and therefore almost all of the carriers find themselves stoques in the base.

But $S_f$ is greater than the $S_{foc}$, we reach out to the energy; that is to say able to model energy of the carrier’s in a direction to participate in ordered photocurrent. While the base is seen empty its stock very quickly thus reducing the capacitance of the solar cell towards nothingness. We observes a decreases in capacitance solar cell with the angular frequency. Indeed, the pulse not promoting photogenerating carriers, it will induce a decrease in the capacitance of the solar cell [17].

The variation of the phase of the variation of the capacitance with the modulation frequency is shown in Figure 11 [12].

K. PHASE OF THE CAPACITANCE

The variation of the phase of the capacitance with the modulation frequency is shown in Figure 11 [12].
The phase of the Bode diagram of capacitance shows the existence of two levels. For \( \omega < 10^4 \) Hz, the phase of the capacitance is independent of the low values of the frequency. For \( 10^4 < \omega < 10^6 \) Hz, the phase of the capacitance decreases following negative values which confirms the presence of the capacitor.

For lower frequencies to the cut-off frequency (\( \omega_c \)), the modulus of the capacitance of the solar cell and its phase, short-circuit situation, remain almost constant with the angular frequency. We note that the amplitude ratio of the capacitance in short-circuit situation to the open circuit condition is of the order of \( 10^{-3} \); while the phase of the capacitance decreases in short-circuit situation. We get the same capacitance module-like phase and the logarithm of the angular frequency as in figure 12. We are seeing that Fig 12 decreased the amplitude of capacitance with angular frequency. With the law of Beer-Lambert, where the angular frequency increases, the absorption of incident light decreases and it corresponds to a low generation of minority carriers can be stored in the database.

**L. NYQUIST DIAGRAM OF THE JUNCTION RECOMBINATION VELOCITY AT THE ELECTRICAL PARAMETERS**

The figures 13 and 14 respectively show the Nyquist diagrams of the series resistance and shunt resistance.

We note that respectively for the two cases the existence of two characteristic points: For \( \omega \rightarrow 0 \), the imaginary part and the real part of the electrical parameter studied cancel and for \( \omega \rightarrow \infty \), the real and the imaginary of the series resistance (Fig12) increase, same characteristics are noticed on the shunt resistance (figure 13).

Following different junction recombination velocity, we represent the Nyquist diagram of the capacitance in figure 15 and figure 16. We get for all curves of semicircles center. For \( R_p \) good visibility (again called the parallel resistance of the diameter semicircle) and \( R_s \) (series resistance), figure 17 and figure 18 are shown.
We observe in these two cases three phenomena:

- For $\omega \to 0$, the imaginary part of the capacity is zero while the actual is different from zero and corresponds to the capacity $C_0$ in the dark or $R_s$ in the case of a resistive circuit.
- For $\omega = \omega_c$, the imaginary part of the capacity is a negative value when the real is positive and corresponds to a maximum.
- For $\omega \to \infty$, both the imaginary part that the real part of the capacity cancel.

This phenomenon allows us to determine the diameter of the semicircle namely $R_p$ [23,24]. From the Bode and Nyquist capability, we can derive the equivalent circuit that describes the electrical behavior of capacity (fig17). Where $C$ is the capacitance of the capacitor which describes the capacitive effect, the parallel resistance ($R_p$) and the series resistance ($R_s$).

IV. CONCLUSION

A theoretical study has been performed on the junction recombination velocity monofacial silicon solar cell and under monochromatic illumination modulation frequency. This study allowed us to remember the expressions of the global generation rate depending on the type of illumination and expressions of the diffusion coefficient according to some electrical parameters. Our study based on electrical parameters of silicon solar cell, characteristic of parasitic effects. We can say that the great values of the recombination velocity which reflect significant leaks minority charge carrier’s at the junction diminish the effects capacitive and contribute to improving the quality of our solar cell while the frequency drive it, it has a detrimental effect on the diffusion of minority charge carriers which affect the efficiency of the solar cell and consequently on the quality. The capacitance of the space charge region was studied using Bode and Nyquist diagrams. Using the junction recombination velocity concept permits us
to determine solar cell’s electric power for any operating point of the solar cell contrarily to others studies which used the maximal power point tracking (MPPT) control technic characterized by one operating point corresponding to the maximum output power delivered by solar cell.

kezicalik@itu.edu.tr; **coskun.firat@itu.edu.tr

Abstract— This study provides a feasibility analysis of the performance of a compact linear Fresnel reflector (CLFR) to be used in a renewable system for the energy demand in some cities in Turkey. The main idea of this work is to investigate whether it will be beneficial or not when CLFRs are used for energy production in Turkey. For this purpose, the optical performance of a CLFR system is investigated theoretically in six of the cities of different regions. The results obtained show that for residential and even for small size commercial usage of CLFR systems could satisfy a very huge amount of solar energy. When the energy need in different processes like heating, cooling, drying is considered, it is easily said that the collected solar energy by a CLFR system would be enough for energy need in many processes.

Keywords— Solar radiation in Turkey, concentrating solar energy, linear Fresnel reflectors, optical performance, renewable energy systems

I. INTRODUCTION

Today, the World is more dependent on energy than ever. Aside from the extraction and the combustion of fossil fuels having severe effect on human health, the decrease in reserves and the increase in energy prices make the renewable energy systems more popular [1]. Besides, increasing global emissions create a big concern [2]. Therefore, the use of renewable energy grows continually all over the world. For all that, the selection of the correct system for given location is still crucial. A detailed investigation of the system is a must for a considered particular location. Many similar works for different locations have been done in the literature [3-13]. In the referred works, different renewable energy systems have been considered for different locations in the world. Thus, the governments from all over the world put a target for renewable energy use in their own countries [14-29]. By having such targets many countries took big steps in renewable energy production. For instance, 114723 GWh of electricity in Germany came from renewable sources in the first nine months of 2015, which was almost double the amount produced from nuclear sources. Additionally, some electricity prices have decreased from the previous year [14]. Economic expansion, rising per capita income, positive demographic trends and the rapid pace of urbanization have been the main drivers of energy demand, which is estimated to increase by around 6 percent per annum until 2023 in Turkey. The current 70 GW installed electricity capacity is expected to reach 120 GW by 2023 to satisfy the increasing demand in the country [20]. Energy is used both as residential and commercial. It can be used for heating, cooling, drying, lighting and obtaining hot water, process steam, and electricity. For all of the purposes, energy can also be obtained through solar energy. The only concern would be the collected amount of the solar energy for these purposes.

This study provides a feasibility analysis of the optical performance of a compact linear Fresnel reflector (CLFR) to be used in a renewable system for the energy demand in some cities in Turkey. The main idea of this work is to investigate whether it will be beneficial or not when CLFRs are used for energy production in Turkey. For many domestic and even commercial but maybe not industrial applications, the solar concentration ratio of 5-15 would be enough to obtain the required energy. To fulfil the job in this paper, optical performance of a CLFR will be examined in detail.

II. SOLAR ENERGY POTENTIAL AND USAGE IN TURKEY

Turkey is located in a very advantageous geographical location with 7.2 hours/day of annual insolation duration and 3.6 kWh/m²·day of annual solar radiation [30]. Monthly solar energy potential of Turkey is given in Table I.

<table>

Also, solar energy potential according to the geographical regions in Turkey is given in Fig. 1.
Average annual total solar radiation map of Turkey is also given in Fig. 2. However it has been recognized that the existing meteorological data is lower than the actual solar energy data of Turkey. EIE (General Directorate of Renewable Energy) and DMI (Turkish State Meteorological Service) have been taking new measurements since 1992 to determine the more accurate solar energy data. Although the measurements have not been completed yet, the collected data indicates that the actual solar energy radiation values are 20-25% higher than the existing data [30].

Despite it seems the regions south-eastern Anatolia and Mediterranean have got the high solar energy potential in Turkey, in this study, the feasibility of using CLFR systems is evaluated for different provinces in different regions because of the changing insolation hours. For this purpose, it is desired to examine the applicability of a CLFR system in Istanbul city of Marmara region, Izmir city of Aegean region, Konya city of Central Anatolia region, Antalya city of Mediterranean region, Gaziantep city of South-eastern Anatolia and Van city of East Anatolia region. To introduce the solar energy potentials, the average monthly total solar energy (kWh/m²-month), and monthly sunshine duration hours (hours/month) are given in the following figures for the aforementioned cities in the selected regions. Since the solar radiation is not high enough in Black Sea region, this region is excluded in this study. Average monthly total solar energy potential for Izmir is given in the Fig. 3 as,
Energy demand in Turkey is mainly met by imported resources like gas and oil. The changes in the number of capita, energy demand, production and import are shown in Table II. Although Turkey has almost all kinds of energy resources, it is an energy importing country, since these resources are limited. More than half of the primary energy consumption in the country is met by imports and the share of imports continues to increase each year [37]. On the other hand, despite there is an annual potential of over 2600 hours sunshine in Turkey, benefit from solar energy was only about 420 ktoe (about 5 TWh as heat) as of 2007 [38].

</table>

It can also be easily said that the demand is tend to increase in the incoming decades. Therefore as a solution for this problem, renewable energy appears to be one of the most efficient and effective solutions for clean and sustainable energy development. Among all, solar power is one of the most promising and more predictable than other renewable sources and less vulnerable to changes in seasonal weather. Turkey has relatively rich solar potential. In spite of such a high potential, solar energy is not widely used, except for flat-plate solar collectors. They are only used for domestic hot water production, mostly in the sunny coastal regions. The electricity generation from the solar energy is realized by photovoltaics (PV) and solar collectors. Unfortunately, PVs have high installing costs; hence, an economical usage of them is not easily available today [39].

### III. OPTICAL CALCULATIONS FOR LINEAR FRENSEL REFLECTORS

A compact linear Fresnel reflector system shown in Fig. 9 consists of flat mirrors forming a parabola-like shape to reflect the incident solar rays onto a receiver tube which are placed on top of the mirror system.

Solar power on a collector-mirror is given as [33];

\[
P = I_b W L \sum_{i=0}^{N} \cos(\theta_i)
\]

Where \(I_b\) is direct normal irradiance (DNI) \(\text{W/m}^2\), \(L\) is the length of the mirror (m), \(W\) is the width of the mirror (m), \(N\) is the number of mirror in the system and \(\theta_i\) is the tilt angle of the \(i^{th}\) mirror. \(i=0\) refers the first mirror (if there is any, otherwise refers the central point of the mirrors) in the centre of the system. All of the geometrical parameters related to a CFLR system are given as in the Fig. 10.
The tilt angle of the \( i \)th mirror is defined as [33]:

\[
\theta_i = \frac{\alpha_T - \beta_i}{2}
\]  \hspace{1cm} (2)

where the transversal solar altitude angle \( \alpha_T \) and the angle \( \beta_i \) are defined as:

\[
\alpha_T = \arctan(\tan(\alpha_s)/\sin \gamma_s)
\]  \hspace{1cm} (3)

\[
\beta_i = \arctan(f/Q_i)
\]  \hspace{1cm} (4)

The angles \( \alpha_s \) and \( \gamma_s \) refer to the solar altitude and solar azimuth angles, \( f \) is the height of the absorber and \( Q_i \) is the distance of the \( i \)th mirror from the centre of the CLFR system. The Sun’s position in terms of the angles \( \alpha_s \) and \( \gamma_s \) is calculated through the following equations as [34, 35]:

\[
\cos \gamma_s = \frac{\sin \delta \cos \varphi - \cos \delta \sin \varphi \cos(\text{HRA})}{\cos \alpha_s}
\]  \hspace{1cm} (5a)

Eq.(5a) is valid when the Local Solar Time (LST) is smaller than 12 or hour angle (HRA) is negative, hence the azimuth angle for LST>12 or HRA>0 is calculated by:

\[
\gamma_s = 360 - \cos^{-1}\left(\frac{\sin \delta \cos \varphi - \cos \delta \sin \varphi \cos(\text{HRA})}{\cos \alpha_s}\right)
\]  \hspace{1cm} (5b)

\[
\sin \alpha_s = \sin \delta \sin \varphi + \cos \delta \cos \varphi \cos(\text{HRA})
\]  \hspace{1cm} (6)

where \( \delta \) is the declination angle of the Sun, \( \varphi \) is the latitude of the location of interest;

\[
\delta = 23.45^\circ \sin\left(\frac{360}{365}(d - 81)\right)
\]  \hspace{1cm} (7)

\[
\text{HRA} = 15^\circ \left(\text{LST} - 12\right)
\]  \hspace{1cm} (8)

In Eq.(7) \( d \) refers to the number of the day of the year and \( \text{LST} \) in Eq.(8) is an adjustment of local time (LT) given as:

\[
\text{LST} = \text{LT} + \frac{\text{TC}}{60}
\]  \hspace{1cm} (9)

\( \text{TC} \) in Eq.(9) stands for time correction factor (in minutes) which accounts for the variation of the \( \text{LST} \) within a given time zone due to the longitude variations within the time zone and also incorporates the Equation of Time (EoT) and they are given as:

\[
\text{TC} = 4(\text{longitude} - \text{LSTM}) + \text{EoT}
\]  \hspace{1cm} (10)

\[
\text{EoT} = 49.87 \sin (2B) - 7.53 \cos B - 1.5 \sin B
\]  \hspace{1cm} (11)

where,

\[
B = \frac{360}{365}(d - 81)
\]  \hspace{1cm} (12)

is resulted in degrees. And \( \text{LSTM} \) in Eq.(10) is the Local Standard Time Meridian (LSTM) which is a reference meridian used for a particular time zone and is similar to the Prime Meridian, which is used for Greenwich Mean Time (GMT) and it is calculated as;

\[
\text{LSTM} = 15^\circ \Delta T_{\text{GMT}}
\]  \hspace{1cm} (13)

where \( \Delta T_{\text{GMT}} \) is the difference of the LT from GMT in hours.

A CLFR mirror system might be in modules. There might be up to 15-20 modules in a collector area. Each of the module length and width of a commercial CLFR can be up to 100 m and 30 m respectively. And the width of a single mirror in a module can be 20 to 75 cm. In this study, three different size CFLRs are considered in the calculations. The number of the mirrors and the height of the receiver in the system are taken as 40 and 1 m respectively. These can be assumed either a standalone CLFR system or a module in a larger system. Their technical specifications are given in the Table III.

### TABLE III

**The Technical Specifications of the CLFR Modules**

<table>

</tbody>
</table>

As it can be shown in the Table IV that as the mirror size changes, the collected solar energy changes dramatically. Also, it can be noticed that although they are the cities in different locations from north to south and west to east, there are no big differences in collected energy in Turkey.

**IV. CONCLUSIONS**

Turkey is due to take place in the Sunbelt, despite having high solar energy potential and sunshine hours; this resource is used only in low temperature applications. Concentrating solar energy systems are very promising on making use of this abundant energy. Among them, the relatively low cost and high efficient CLFR systems might offer a very huge advantageous in solar energy use.

In this study, optical performance of CLFR systems in different size is examined for different cities in Turkey. Results show that for residential and even for small size commercial use of CLFR systems could satisfy a very huge amount of solar energy. When the energy need in different processes like heating, cooling, drying is considered, it is easily said that the collected solar energy by a CLFR system would be enough for energy need in many processes. This kind of feasibility studies can help to those who want to make investment in solar energy sector as well as those who want to study further in the subject.

Abstract: Energy harvesting from the surrounding environment has been a superior way of eliminating the burden of having to replace depleted batteries in wireless sensor networks (WSNs), thereby achieving a perpetual lifetime. However, the ambient energy is highly time-variable and depends on the environmental conditions, which raises the need to design new approaches for predicting future energy availability. This paper presents a performance evaluation and comparison of three recently-proposed solar energy prediction algorithms for WSNs. In order to provide an accurate performance of the algorithms, real-world measurements obtained from a solar panel were considered. Also, the performance characteristics of the algorithms in four seasons – winter, spring, summer and autumn – were demonstrated. To do this, a month in each season was selected for performance comparison, discussing the performance of the algorithms in each season.

Keywords: wireless sensor networks; energy harvesting; solar energy; EWMA.

I. INTRODUCTION

Wireless sensor networks (WSNs) are composed of a collection of sensor nodes designed to perform a common duty and which have the tasks of sensing, processing and communicating data, aiming to deliver it to a remotely-located central point [1]. The sensor nodes are often powered by limited-energy sources, typically small batteries. This makes energy efficiency a vital criterion in the development of WSNs, so the main emphasis has been placed on prolonging the lifetime of WSNs. A sensor node is equipped with four components as depicted in Fig. 1: (1) a sensing unit to detect environmental data such as temperature; (2) a micro-processor to process the data; (3) a radio for communication between the sensor nodes; and (4) an energy unit to supply energy to all the components. It is well-understood that data communication in a sensor node consumes the most energy. Therefore, communication between the sensor nodes has to be managed in an efficient manner. To control the transmission medium in a WSN effectively, medium access control (MAC) protocols are developed to reduce the energy consumption due to inefficient data communication (for example, by collision). There are huge numbers of MAC protocols specifically proposed for WSNs which minimize energy wastage as well as enhancing the channel performance (for example, throughput, delay and fairness) [2, 3]. However, such a WSN system will eventually fail to operate because of the limited energy supply.

In order to handle the inevitable energy depletion in WSNs, energy harvesting (EH) from the environment is an alternative technique to ensure an unlimited energy source. In this technique, each sensor node can harvest energy continuously from its surrounding environment through an EH device. The main purpose is to extract the environmental energy and convert it into electricity to power sensor nodes. The major sources of existing environmental energy for WSNs are solar, wind, vibration and thermal. In order to enable sensor nodes to benefit from EH technology, a new type of sensor node equipped with an EH unit has been developed to perpetuate the lifetime of WSNs [4]. Fig. 2 presents an example architecture of an EH sensor node with the sun as the energy source, a solar panel to produce energy from the sun, and a super-capacitor to store the harvested energy.
EH sensor nodes potentially provide a perpetual lifetime by exploiting the ambient energy. It should therefore be noted that the fundamentals of MAC protocols that will be developed for energy harvesting WSNs (EH-WSNs) will be re-considered to mitigate the uncertainty of amount of ambient energy over time. This is because ambient energy is highly dependent on environmental conditions and is time-variable. The ambient energy can be harvested using varying ratios at different time slots of a particular day. The main task of new MAC protocols is to maintain the performance of a network at an acceptable ratio with respect to the changing available rate of energy to be harvested. Currently, the design of MAC protocols for EH-WSNs is a fiercely-debated topic and an on-going research area. A number of MAC protocols proposed for EH-WSNs have been surveyed in detail in [5]. This survey explicitly highlights that existing MAC protocols should comfortably meet the energy neutral operation (ENO) condition in which the amount of energy generated must always be greater than the energy consumed within a particular time duration. The nodes which satisfy the ENO condition are assumed to operate perennially. In these protocols, a node is allowed to start transmission as long as it stores sufficient power in its battery.

Many of the current MAC protocols do not consider future energy availability as they only consider current residual energy level as discussed above. The future energy level, however, may change dramatically resulting in some nodes facing temporary energy shortages. This can cause significant problems, such as some important information might be transmitted very late or get lost. Therefore, future MAC protocols should arrange the transmission policies based on the energy generation ratio. Careful prediction of future energy levels opens a new perspective.

The aim of this paper is to study the solar energy prediction algorithms proposed for EH-WSNs, focusing particularly on the performance of the algorithms using real measurements. Solar energy was chosen for this study as it is the most appropriate energy source for EH-WSNs due to its high energy density. We selected three recent prediction algorithms: the exponentially-weighted moving average (EWMA) [6], the accurate solar energy allocation (ASEA) [7] and the weather-conditioned moving average (WCMA) [8]. These approaches had been previously tested in short-term scenarios (a few days) in which the actual performance of the approaches may not have been reflected. To avoid this, we obtained real measurements from [9] for the second month of each season in 2015. Also, the basic operations of the approaches will be described in detail in the following section. It is believed that this study will provide an insight into future research directions in the relevant area.

II. SOLAR ENERGY PREDICTION APPROACHES

A. Exponentially-Weighted Moving Average

The exponentially-weighted moving average (EWMA) is the main approach which has inspired the design of many prediction algorithms in the literature. The fundamental aim of EWMA is to benefit from the daily cycle in solar energy by adapting to seasonal variations. The 24-hour day is divided into slots of equal length, such as 24 one-hour slots. The energy in each slot is predicted based on an exponentially increasing/decreasing rule given by Eq. (1).

EWMA uses historical information of the energy generation pattern. For this purpose, the last amount of harvested energy (R) and estimated energy (E) by EWMA are summed with a weighting factor, \(0 < \alpha < 1\), arranging the importance of the R and E. A high value of \(\alpha\) corresponds to less importance of the last-harvested energy and vice versa.

\[
E(d, n) = \alpha E(d-1, n) + (1 - \alpha) R(d-1, n)
\]  

where \(d\) represents the present day and \(n\) is the slot identifier. One of the most important features of EWMA is its high adaptability for seasonal weather variations. The efficiency of EWMA in terms of time taken to adapt to such seasonal change depends on the duration of weather variation and an accurate choice of \(\alpha\). Fig. 3 presents an illustrative example for predicting energy using two different \(\alpha\) values. In this example, the energy estimation in slot 2 is performed in a case when the weather condition changes abruptly. The amount of harvested energy continues to be four times greater than the estimated energy. An \(\alpha\) value of 0.5 exhibits slower adaptability than an \(\alpha\) value of 0.3. This is because, as discussed above, smaller \(\alpha\) values take the latest real energy measurement into consideration more aggressively. After a specific time period, both \(\alpha\) values start to provide accurate overall predictions.

The major disadvantage of EWMA is its vulnerability to temporary changes. For example, the example presented below shows that the energy expectation on the day after \((T+6)\) day will certainly be a value close to 40. If, however, contrary to expectation, the harvested energy on this day is significantly higher/lower than the expected energy, EWMA produces highly inaccurate results. It is therefore crucial to consider the solar energy conditions on the current day.
is sample and the corresponding sample prediction equation. Also, the mean value of the values which are stored in a matrix, conditions.

Another algorithm which the current weather conditions into consideration.

Fig. 3 An example process of EWMA, α = 0.5 and α = 0.3.

B. Accurate Solar Energy Allocation

Accurate solar energy allocation (ASEA) attempts to allocate the harvested energy equally to each slot in a particular day for EH-WSNs regardless of the amount of generated energy in any slot. To do this, it modifies the EWMA to cope with the drawback of EWMA. The basic idea of ASEA is to look at the present conditions by adding a new parameter, \( \psi \), to Eq. (1). This parameter represents the ratio between the actual amount of energy harvested and the energy estimated by EWMA in the previous slot. The modified equation is therefore given as:

\[
\hat{E}(d, n) = E(d, n) \cdot \psi \quad \text{where} \quad \psi = \frac{R(d, n-1)}{E(d, n-1)} \tag{2}
\]

C. Weather-Conditioned Moving Average

The weather-conditioned moving average (WCMA) is another algorithm which takes the current weather conditions into consideration. WCMA collects past energy values which are stored in a matrix, \( E(i, j) \), where \( j \) is a sample on the \( i^{th} \) day. One of the main distinctive features of WCMA is that it incorporates previous samples into the prediction equation. Also, the mean value of the corresponding samples from previous days is calculated. Therefore, the prediction equation related to the previous sample and the mean value of the sample given by Eq. (3) is:

\[
E(d, n+1) = \alpha E(d, n) + (1 - \alpha) M(d, n+1)GAP \tag{3}
\]

where \( E(i,j) \) is the energy values taken from the \( E \) matrix and \( M(i,j) \) is the mean value of the sample. \( GAP \) is a new weighting factor introduced in order to reflect current weather conditions. The mean value of the sample is calculated as follows:

\[
M(d, n+1) = \frac{\sum_{i=1}^{D} E(i, n + 1)}{D} \tag{4}
\]

To compute the \( GAP \) value, a vector, \( V = [V_1, V_2, ..., V_K] \), is first defined. The elements of the \( V \) vector are the previous samples in the same day, each of which represents the ratio of the the harvested energy to the mean value. Hence, a value less than 1 means that the harvested energy is less than the mean:

\[
V_k = \frac{E(d, n-K+k)}{M(d, n-K+k)} \tag{5}
\]

Once the elements of the \( V \) vector are calculated, these values are weighted according to their distance from the actual sample. This is to give more importance to closer samples and less importance to far samples. To do this, a vector, \( P = [p_1, p_2, ..., p_K] \), is defined as follows:

\[
p_k = \frac{k}{K} \tag{6}
\]

The weighting factor, \( GAP \), is finally computed as:

\[
GAP = \frac{V \cdot P}{\sum P} \tag{7}
\]

The size of the \( E \) matrix is an important parameter to establish. Considering the limited memory in sensor nodes, the size should be carefully selected whilst meeting the memory constraint. Also, the value of \( K \) which is the number of past samples to weight should be carefully adjusted. It must be large enough to observe the current weather condition but also small enough not to consider some samples that do not have any impact on present conditions, such as night values.

In the original paper on WCMA, from an analysis of the choice of dimensions of the \( E \) vector, the value of \( K \) was calculated. The best values found to minimize the prediction error were \( D = four \) days, \( K = three \) samples. These values were used in all the experiments in this current study. Also, an \( \alpha \) value of 0.7 was the optimum value that gave the minimal error.
III. PERFORMANCE EVALUATION

The performances of the EWMA, ASEA and WCMA schemes were compared using real solar panel outputs in the second month of each season of 2015. The purpose of this was to demonstrate the behavior of the performance throughout the year. Fig. 4 presents the performance of the schemes in terms of prediction error ratio (PER). Each point in the curves represents the average of 30 days. Additionally, Fig. 4e depicts the prediction accuracy in January.

It is obvious that the weighting factor, α, had a significant effect on the prediction accuracy for all three schemes. EWMA and ASEA exhibited a similar performance as ASEA is an extension of EWMA. ASEA achieved a better performance than EWMA because ASEA reflects the latest current energy condition. The results tell us that high and low values of α in EWMA and ASEA provide highly inaccurate predictions, whereas medium values of $0.4 < \alpha < 0.9$, ensure more accurate predictions. In EWMA and ASEA, therefore, the estimated average energy (E) and real measured energy (R) (see Eq. (1)) should contribute closely to achieving accurate predictions. However, WCMA provided significantly high accurate predictions at low values of α. Eq. (3) clearly shows that low values of α mean a low contribution of energy in the previous slot. In other words, the mean of the energy in association with the current energy condition has more influence on the prediction. Hence, WCMA with small values of $\alpha$, $\alpha < 0.6$, predicts energy more accurately than EWMA and ASEA, but the high values of α make WCMA the worst scheme. As discussed above, EWMA would not be a good choice in frequently changing weather conditions. In January, the weather changes almost daily, as shown in Fig. 4e. The PER of EWMA is close to 0.6 (60%) at an α value of 0.7. When the weather does not change frequently, as in July, the PER reduces to 0.18. In all cases, ASEA has a similar curve to that of EWMA improving the PER. In WCMA, on the other hand, the contribution of energy in the previous slot of the same day does not actually seem to be relevant as the PER rises with the increasing influence of the previous slot’s energy value.

We conclude that WCMA is the best prediction algorithm as it benefits from the long-term current solar energy condition, provided that α has a small magnitude. EWMA can be considered as a baseline scheme which takes seasonal solar energy into consideration, resulting in high incorrect predictions with frequently changing solar conditions. ASEA considers only the latest solar energy condition which causes high inaccurate predictions in particular in times of temporary weather changes.

IV. CONCLUSIONS

Three popular solar energy prediction schemes have been studied in this paper. The performance of the schemes in terms of the prediction error using real solar panel outputs has been presented and compared. It has been shown that the level of ambient energy to be harvested is highly time-variable, so it is crucial to consider current weather conditions when predicting energy, particularly in changing diurnal weather conditions. Also, the weighting
factor, $\alpha$, in all three schemes plays an important role in enabling accurate prediction. The main conclusion of this study for high accurate energy prediction is to reconcile the past energy generation profile with the current energy pattern.

Methanol Combustion Simulation via CFD

Ali H. Abdulkarim

Kirkuk University Engineering Faculty, Department of Mechanical Engineering
Kirkuk-IRAQ
alihuseyin81@yahoo.com

Abstract— Methanol combustion can take place in various mediums ranging from internal combustion engines to burners and such. Consequently combustion efficiency and the dimensional system characteristics vary from system to system. Recent researches are going on to identify these aforementioned characteristics. Present paper is a part of such effort. A combustion domain representing the geometrical parameters of a burner was modelled and governing equations for combustion process were selected in a commercial CFD solver. Results constitute base for future work focusing on a similar burner performance. Static pressure distribution, mesh structure, temperature distribution, turbulence intensity, density distribution and velocity vectors are presented in both 2D planes and 3D domain. Results indicate the importance of combustion volume entrance design. There are dead regions adjacent to the combustion volume entrance. It is proposed that a new entrance region should be designed.

Keywords— CFD, Combustion, Fluid Dynamics, Methanol, Simulation

I. INTRODUCTION

Porous medium as an alternative to conventional burners attracts industrial and scientific communities. Their compact and complex inner structure leads to efficient burning of the fuels while its general geometry from outside can be adapted literally to any volume. Figure 1 is provided in order to give an idea for a porous medium burner.

Methanol combustion can take place in various mediums ranging from internal combustion engines to burners and such. Consequently combustion efficiency and the dimensional system characteristics vary from system to system. Recent researches are going on to identify these aforementioned characteristics.

There are remarkable studies in the literature about modeling porous combustion mediums and fuels such as methanol [1-3]. These studies focus on geometrical modelling of the medium, proper models for the flow and combustion and comparison of the obtained results with literature and experimental results.

As a preliminary evaluation tool, CFD was utilized in case of a cylindrical body representing a porous metal matrix burner. Methanol was simulated with air as an ideal gas. Boundary conditions were selected according to the real application operational parameters of the so called porous metal matrix burner. By this way, static pressure distribution, velocity profiles, density of the fluid, enthalpy, total pressure, turbulent kinetic energy and dynamic viscosity changes were presented versus radius of the examined body. Fluent was employed for the modelling and calculation software. A similar numerical work was conducted by Abdulkarim [4] and it can be referred for the results of a similar study.

II. ANALYSIS

Ansys Fluent was used for the computational analysis. Cartesian coordinates were used for the computational domain but curvilinear adapted mesh was utilized. This doesn’t lead to any complexities in the major fraction of the computational domain and the CFD code can handle this situation. Air was selected as the fluid and thermo physical properties were selected accordingly.

A fine mesh setting was applied to the cylindrical porous medium model geometry and the general view of the mesh structure is provided in Figure 2. k-ε turbulence model was utilized as a general and justified turbulence model for the examined geometry. Since internal boundaries are avoided for the present preliminary investigation, the utilization of the k-ε turbulence model was appropriate. The governing equations for this model are not provided here for the convenience of the space however as a well established and validated model, governing equations can be found easily in the literature.

Fig. 1 Combustion in a porous medium burner
III. RESULTS

Since the symmetry exists in the analysis, mainly axial change is presented and evaluated here. The graphics are presented on a 2D plane and in a 3D volume. The quantitative values can be extracted from the color scale which also includes and indicates numbers.

Due to the energy dissipation by the friction, static and total pressure values decrease in the flow direction. Pressure gradient in the axial direction occurs as the maximum pressure value exists at the entrance or in other words inlet of the medium. Quantitative results are presented for static pressure in Figure 3, Static Temperature in Figure 4, Contours of static temperature in Figure 5, Velocity vectors in Figure 6, Contours of velocity magnitude in Figure 7, turbulent kinetic energy distribution in Figure 8 and Density distribution in Figure 9 respectively.

As the fluid enters to the computational domain, a compression effect takes place and this leads to an increase at the initial part of the inlet. As the flow continues to the inlet neck, velocity increases and the static pressure is converted to kinetic energy and hence the value of the static pressure decreases here. When further continuing on the axial direction, static pressure recovers and has its final value.

3D domain in respect of the temperature quantitative results can be confusing since the wall has a dominant value comparing to the axis of the computational domain. The dominant temperature value at the boundaries is about 1300 K. Due to the dead points and relatively poor conduction at the corners, temperature value is about 940 K at the corners. Since the flame temperatures are much higher, these temperatures are expected at the boundaries. Considering the radiation, porous burner can actively transfer the heat via radiation. However the present work doesn’t contain boundaries for porous extensions, so the real application will lead lower temperatures at the outer boundaries.
When a 2D plane inserted in the 3D domain in order to inspect temperature distribution contours for the computational domain, one can see that the fluid temperature can reach approximately 1720 K at the axis of the medium. Since the present work doesn’t contain any solid boundaries at the center of the volume, this temperature can be regarded as the flame temperature. With the effect of the axial conduction and diffusion this maximum becomes lower as the field of interest advances more through dead points. We can see the effects of flow separation at close proximity of the adjacent edges perpendicular to the inlet. The lowest temperatures can be observed here because of the flow separation. However real world application will differ in this respect because of the axial conduction, i.e. reverse heat transfer.

Due to the conversion of the static pressure to the dynamic pressure, in other words to velocity, at the minimum diameter in the inlet, maximum velocity can be observed here in Figure 7. The maximum temperature seems to be around 24.1 m/s. At the first quarter of the volume the velocity decreases to 6.4 m/s and then gets a more moderate value around 2-4 m/s. We can see a dead point at the farthest point in axial direction.

Turbulence kinetic energy gives information of local fluctuations. A laminar and un-mixing flow would lead to a minimum turbulence kinetic energy pattern. Considering this information, Figure 8 indicates the locations of the shear layers. A relatively low turbulence kinetic energy, namely \(2.21 \text{ m}^2/\text{s}^2\) can be observed, so we can think that mixing process is not strong. However one should consider that real application won’t contain such a structure since there will be secondary boundaries due to the porous structure. Symmetry can also be seen for turbulence kinetic energy. At the inlet, a flow structure similar to the pipe flow can be observed due to the developing flow in the presence of close walls.
Density increases at the close proximity of the walls of the cylindrical body due to the compression in the presence of a solid obstacle. Considering the gas fluid, compression yields change in the density of the fluid. Also maximum enthalpy occurs near the outlet of the cylindrical body.

**IV. CONCLUSION**

The flow patterns and general flow conditions yielded a favorable situation in respect of a medium designed as a burner. Since the real application combustion volume will have several inner boundaries due to the porous structure, flow separations and irregularities will diminish and/or become smaller in scale.

Heat transfer will be superior with a porous inner structure by generally speaking. Since conduction, convection and radiation will exist, the burner can act a preferable device. Convection is expected to be the least effective mechanism in the porous volume comparing to the radiation and conduction. General geometry of the porous medium model is found to be favorable in respect of its operational flow conditions. Further work can be undertaken in order to achieve a more realistic geometry and numerical combustion can be included into the analysis.

An analytic assessment of ship energy efficiency in
maritime transportation engineering.

Emre Akyuz*
* Department of Maritime Management,
Bursa Technical University,
Osmangazi 16190, Bursa, Turkey.
emre.akyuz@btu.edu.tr; emreakyuz82@gmail.com

Abstract—Energy efficiency is one of the core topics in maritime
transportation industry as the ships consume a large amount of
energy due to nature of work. Environmental awareness is
another critical perspective to improve energy efficiency due to
greenhouse gas emission from the ships. Therefore, maritime
regulatory bodies adopted Ship Energy Efficiency Management
Plan (SEEMP) to provide necessary improvement of energy
efficiency on-board ship [1]. The aim of this paper is to assess
energy efficiency of ships analytically to enhance performance of
ships as well as minimize environmental pollution. In this
case, the paper adopts Buckley extension based analytic
hierarchy process (AHP) under fuzzy sets environment to
enhance the sensitivity. Besides its theoretical insight, the paper
has practical benefits to shipowner who can seek to improve the
energy efficiency aspects for not only ships but also company-
wide.

Keywords—Ship energy efficiency, fuzzy AHP, maritime
transportation, energy improvement.

I. INTRODUCTION

Although maritime transportation is a relatively efficient
mode of cargo carriage, ship consumes a large quantity of
energy when compared to other modes of transportation.
Particularly, greenhouse gas emission (GHG) largely pollute
environment due to the high sulphur content of fuel. The
International Maritime Organisation (IMO) was adopted a set
of rules such as Energy Efficiency Design Index (EEDI) and
Ship Energy Efficiency Management Plan (SEEMP) in order
to control aforementioned problem and improve ship
efficiency by better management. Each shipowner is
responsible to establish a SEEMP on the basis of ship fleet
operations, management and energy consumption. The
expectation from the shipowners or operators is to develop a
regular planning, implementation, monitoring and self-
evaluation of SEEMP. Figure 1 shows basic process of
SEEMP [2]. Accordingly, a good planning is needed to
establish SEEMP. Therefore, shipowner must review energy
consumption and procedures exercised on-board fleet ships. In
the second step, the plan, which has been developed by
reviewing current deficiencies, must be implemented. Then, a
short or long term monitoring must be performed to assess
performance. The final step is to conduct self-evaluation
whether how effective developed SEEMP is working. Hence,
the outcomes assist shipowners or operators to understand the
level of improvement about ship energy efficiency.

Since assessment of ship energy efficiency is of paramount
concern in maritime transportation, there have been limited
studies undertaken so far. Most of them give general
perspective and barriers with respect to the ship energy
efficiency. For instance, [3] discussed ship energy efficiency
management in a general perspective by proposing a total
solution approach. Another study was performed to compare
SEEMP to ISO 50001 and International Safety Management
(ISM) code [4]. The authors discussed gaps among the codes
and proposed recommendations to reduce CO2 emissions in
maritime transportation. Likewise, another study was
conducted to discuss barriers about energy efficiency in
maritime transportation industry [5]. The authors show that
the project management, communication, responsibilities and
resources are the key areas where most of barriers are placed.
Another study related to potential barriers to energy efficiency
in shipping was performed to deal with them [6]. A rational
framework provides the ability to cope with potential barriers
in energy efficiency management is proposed to improve
energy efficiency. Furthermore, a triangulated approach to
investigate the potential problem in ship energy efficiency was
introduced to improve implementation of energy efficiency in
maritime transportation industry [7]. The authors performed a
comprehensive survey with shipping company to obtain
energy efficiency data.

In the view of the ship energy efficiency, some scientific
researches have been performed, however those dedicated to
measure energy efficiency have remained limited. This paper
aims to evaluate the critical performance indicators associated with ship energy efficiency. To achieve this purpose, Buckley extended AHP under fuzzy environment is employed. Accordingly, this paper is organised as follows. This section presents a motivation behind the study and basic literature reviewing about analysis of ship energy efficiency. Section 2 defines the theoretical framework of Buckley extension based Fuzzy-AHP. Section 3 shows how proposed approach is applied to measure ship energy efficiency. The final section provides conclusion note and future studies.

II. METHODOLOGY

In this section, Buckley extension based Fuzzy-AHP method is expressed step by step to assess ship energy efficiency in maritime transportation engineering.

A. Buckley Extension Based Fuzzy-AHP

Analytic Hierarchy Process (AHP) is well-known multi-criteria decision-making (MCDM) tool to solve complicated decision problems. It was first introduced by Saaty [8]. The method suffers one major limitation: it does not cope with uncertainty and vagueness from the subjective perception and experience of humans in the decision-making process. To overcome this limitation, the method is extended with fuzzy logic, which presents interval judgements rather than fixed values [9]. Triangular fuzzy numbers (TFNs) are adopted to evaluate the vagueness of the linguistic evaluation quantifies the judgement value of linguistic expression. (l|m, m|u) or (l, m, u) is the illustration of TFN and stand for the smallest possible value, the most promising and the largest possible values [10]. In this context, equation (1) shows TFN accordingly.

$$
\mu\left(\frac{x}{\tilde{M}}\right) = \begin{cases} 
0, & x < l \\
\frac{(x-l)/(m-l)}{1}, & 1 \leq x \leq m \\
\frac{(u-x)/(u-m)}{m}, & m \leq x \leq u \\
0, & x > u 
\end{cases} \quad (1)
$$

Since there are wide range of fuzzy comparison matrices such as a fuzzy Logarithmic Least Squares Method (LLSM) [11], geometric mean method [12], a fuzzy Least Squares priority Method (LSM) [13], a fuzzy Preference Programming Method (PPM) [14] introduced in different domains, this paper takes benefit of Buckley’s Fuzzy-AHP algorithm to determine criteria weights. The main advantages of the method are to provide not only a unique solution to the reciprocal comparison matrix but also relatively simple calculation. The main steps of the Buckley extended Fuzzy-AHP method are expressed as follows [12].

Step 1. In this step, a pairwise comparison matrix (equation 2) in the hierarchical structure is established. Accordingly, linguistic terms that are provided in equation (3) nominated to construct pairwise comparison matrix.

$$
\tilde{M} = \left[ \begin{array}{cccc} 
1 & \tilde{a}_{12} & \cdots & \tilde{a}_{1n} \\
\tilde{a}_{21} & 1 & \cdots & \tilde{a}_{2n} \\
& \ddots & \ddots & \ddots \\
\tilde{a}_{nl} & \tilde{a}_{n2} & \cdots & 1 
\end{array} \right] = \left(1/\tilde{a}_{21} \begin{array}{cccc} 
1 \\
\vdots \\
\tilde{a}_{nl} \\
\tilde{a}_{n2} \\
1 
\end{array}\right) \quad (2)
$$

where,

$$
\tilde{a}_{ij} = \begin{cases} 
i, 3, 5, 7, 9 & \text{criterion } i \text{ has less importance to criterion } j \\
1, \tilde{i}^{-1}, \tilde{5}^{-1}, \tilde{7}^{-1}, \tilde{9}^{-1} & \text{criterion } i \text{ has relative importance to criterion } j 
\end{cases} \quad (3)
$$

Step 2. In this step, a consistency of data is acquired by using equation (4, 5 and 6). If the consistency ratio (CR) is found equal or smaller than 0.10, the expert judgement is considered as reasonable and consistent [15-16]. The CR is calculated to evaluate the consistency of the comparison matrix in classical AHP. However, the outcomes of fuzzy AHP are fuzzy numbers of linguistic judgments. Hence, it is necessary to perform a defuzzification technique. In this paper, the center of area defuzzification method is used because of its simplicity [17].

$$
Cl = \frac{\lambda_{\text{max}} \cdot n - m}{n-1} \quad (4)
$$

$$
\sum_{i=1}^{n} a_{ij} w_i = \lambda_{\text{max}} w_i \quad (5)
$$

$$
CR = \frac{Cl}{RI} \quad (6)
$$

Step 3. In this step, it is used a geometric mean method in order to identify the fuzzy geometric mean. Equation (7) shows notation accordingly.

$$
\tilde{r}_i = \left(\tilde{a}_{1i} \times \tilde{a}_{2i} \times \cdots \times \tilde{a}_{ni}\right)^{1/n} \quad (7)
$$

In the equation, $\tilde{a}_{ii}$ is a fuzzy comparison value of criteria.

Step 4. In this step, fuzzy weights of each criteria is determined by using equation (8) where $\tilde{w}_i$ denotes fuzzy weight of $i^{th}$ criteria and indicated by

$$
\tilde{w}_i = \tilde{r}_i \times \left(\tilde{r}_1 + \tilde{r}_2 + \cdots + \tilde{r}_n\right)^{-1} \quad (8)
$$
Step 5. In the final step, centre of area (COA) method is employed to ascertain the best non-fuzzy performance (crisp weight) of each criteria. In this context, equation (9) is used.

\[ BNPw_i = \frac{[(uw_i - lv_i) + (mw_i - lv_i)]}{3 + lw_i} \quad (9) \]

III. EVALUATION OF SHIP ENERGY EFFICIENCY

In this section, the fuzzy-AHP method is applied to evaluate energy efficiency of ships in maritime transportation to enhance ship performance.

A. Problem Definition

Energy efficiency management poses a major challenge for shipowner and operators since bunkering cost is one of the critical items in running cost of ship. Therefore, shipowners and operators monitor performance and improve their energy efficiency for ship fleets. There are a couple of parameters to initially evaluate improvement of energy efficiency. In the long term, energy efficiency improvement can be achieved through the integration of innovative technologies. Hence, it is essential to assess aforementioned parameters considering critical factors that affecting the energy efficiency of a ship’s operation.

B. Ship Energy Efficiency Assessment

In order to implement an effective SEEMP, critical parameters must be analysed and evaluated based on planning, implementation, monitoring and self-evaluation process. The ship fleetwide analysis is capable of providing useful performance indicators such as voyage planning, ship speed optimisation, ship handling, propeller cleaning, hull coating, etc. A sensitive comparison evaluation is required by shipowners or operators for performance assessment in effective manner. In this context, Table 1 shows critical performance indicators (CPI) to understand current energy efficiency and to make improvements through entire ship fleet.

In order to assess critical performance indicators for evaluating ship energy efficiency, a comprehensive survey was carried out with three marine experts who have been working for a prestigious shipping company. The marine experts profile includes marine engineers and superintended. The average experience in the field is about fourteen years. Each expert was asked to compare each CPI according to the Saaty’s 1-9 scale, which is provided in Table 2.

</tbody>
</table>

After aggregated three experts’ assessment, equations (1-9) are used to calculate priority weight of each critical performance indicator. In final step, defuzzification is performed by adopting equation (8) to get crisp value of each CPI. The consistency ratio (CR) can be found 0.1049 which is in acceptable limit. Hence, the marine expert judgements inserted in comparison matrices are found reasonable. Accordingly, Table VI illustrates defuzzified and normalised importance weights of CPIs.
In the view of importance weights of CPIs, hull design is one of the crucial indicators in maritime transportation industry from the point of ship energy efficiency since it may considerably affect effectiveness of ship types, sizes and routes. Hull design involves choosing proper proportions, decreasing resistance and evaluating the impact on resistance of sea waves and strong wind. Also, it is important to focus ship voyage planning and propeller cleaning to ensure necessary improvement trough ship energy efficiency.

IV. CONCLUSIONS

Ship energy efficiency is one of the core operational issues for shipowner and operators as it establishes a tool to improve the energy efficiency of ship in a cost-effective manner. Since a large amount of energy is consumed by ships, safety practitioners have been seeking an alternative solution to improve energy efficiency and minimize environmental pollution. This paper attempts to provide an analytic approach to evaluate ship energy efficiency by analysing critical performance indicators such as voyage planning, hull design, speed optimisation, hull coating, etc. A fuzzy –AHP method is employed to achieve this purpose.

In the view of sensitive analysis, hull design of the ship (CPI) become prominent as the most critical indicators in terms of ship energy efficiency since there is significant boom in the extent of ship’s hull form and propeller design. The outcomes of this paper are to encourage shipowner and operator focusing on options such as hull form optimisation and maintenance being prompted to enhance ship efficiency. The further study may be extended somehow to deal with resistance which is the major component of high energy consumption at ships.

Review of the Bismuth Telluride (Bi$_2$Te$_3$) Nanoparticle: Growth and Characterization

M.R.A. Bhuiyan, Hayati Mamur*

*Department of Electrical and Electronics Engineering, Cankiri Karatekin University, 18100, Cankiri TURKEY
hmamur@karatekin.edu.tr

Abstract— In this paper, a review of Bismuth Telluride (Bi$_2$Te$_3$) nanoparticle growth and its characterization at nanoscale are discussed through a theoretical and analytical process. Nanotechnology research has become challenging task for modern science and technology. Material of Bi$_2$Te$_3$ is basically known for thermoelectric generation. Now in nanotechnology, all devices are migrating to the level of nanometer scale, the significant amount of experiments are being progressed to keep it up with the rapidly growing research field of nanotechnology. For these reasons, the characterization of Bi$_2$Te$_3$ at nanoscale is investigated and its application as a thermoelectric generator (TEG), thermoelectric cooling (TEC) and other field of material technology is presented. Finally, it is concluded that Bi$_2$Te$_3$ nanoparticles have many future aspect and applications.

Keywords — Bismuth Telluride (Bi$_2$Te$_3$); Nanotechnology; Nanoparticle; Thermoelectric Generator

I. INTRODUCTION

This review paper presents an overview of the remarkable research progress on Bismuth Telluride (Bi$_2$Te$_3$) nanoparticle growth by solvothermal process. Bi$_2$Te$_3$ basically is a compound element of Bismuth (Bi) and Tellurium (Te). Bi physically behaves like a metal and when it is alloyed with Te then it behaves like an efficient thermoelectric type material which can be used for thermoelectric refrigeration, thermoelectric cooling (TEC) and other field of material science such as thermal sensor, thermoelectric generator (TEG) etc. [1-4].

Bi$_2$Te$_3$ and its alloys are most important semiconductor thermoelectric materials that used in state-of-the-art devices which temperature range between 200 and 400 K. The figure of merit, $ZT = (\alpha^2 \sigma / \kappa) T$, of the best Bi$_2$Te$_3$ based alloys is about unit [5], where $\alpha$ is the Seebeck coefficient, $\sigma$ and $\kappa$ the electric and thermal conductivity, respectively.

Many works have been done in recent years to improve the thermoelectric properties of Bi$_2$Te$_3$ based alloys. It was reported that the figure of merit of thermoelectric materials could be significantly improved if the materials were nanostructured [6]. In the present work, we discussed the review of the Bi$_2$Te$_3$ nanoparticle has been growth by solvothermal process [6-15].

II. FORMATION OF BISMUTH TELLURIDE

There are two approaches for any nanostructure formation and fabrication. First is the top-down and second is the bottom-up approach [16]. The top-down approach includes the successive splitting of the bulk to nanostructure materials. However, in the bottom-up approach, the process to construct nanoparticles is started from building up from the atomic or molecular scale to until the nanoparticle is constructed.

Nowadays, although the top-down approach has been becoming out-dated rapidly, the bottom-up approach has been becoming appreciable in industrial applications over a decade. The bottom-up approach produces significantly best option of realizing nanostructures with very low record of defects in it and also provides more homogeneous chemical compositions.

Analysis on the characterization and growth of Bi$_2$Te$_3$ has already utilized both the top-down and the bottom-up approaches in the last three decades. In the growth process, these methods are generally categorized into two methods, first the physical and second the chemical methods. In the growth of Bi$_2$Te$_3$, the physical methods basically involve evaporation, sputtering and spray pyrolysis techniques. In the chemical methods which involve electrochemical, chemical vapour, laser chemical vapour and electrolysis deposition, hydrothermal and solvothermal processes. The solvothermal process is the most common technique among the chemical methods.

III. LITERATURE REVIEW

Thermoelectric materials have attracted a great interest owing to their potential applications in TEGs, TECs and other field of material science.

A thermoelectric device is an energy conversion system that converts thermal energy to electrical energy. TEC occurs when the couple is put in a thermal gradient (i.e., the top is hotter than the bottom), in which case the device generates a current, thereby converting heat into electrical power by a phenomenon referred to as the Seebeck effect. Conversely, TEC occurs when current passes through the thermocouple, in which case the thermocouple cools on one side and heats on the other side by a phenomenon known as the Peltier effect.

Bi$_2$Te$_3$ is one of the best thermoelectric materials because they have the capability to convert waste heat energy into useful electric energy. In order to develop the solvothermal method, Bi$_2$Te$_3$ can be used to fabricate nanostructured form.

Recently, researchers have attempted to improve the efficiency of Bi$_2$Te$_3$ materials by creating the nanostructures where one or more dimensions are reduced, such as nanorod, nanowires, nanoplates, nanotubes, nanoflowers and nanosheets etc. [6, 8, 17-19]. The solvothermal method is found to be a simple way of preparing nanomaterials. In the preparation process, the size of crystal grain, formation of
phase and growth of morphology can be well controlled. This method does not need organometallic precursors. In this section, solvothermal methods with reference to Bi$_2$Te$_3$ nanoparticles are reviewed.

Yuan Deng et al. [15] reported a solvothermal reaction of Bismuth (III) chloride dihydrate BiCl$_3$·2H$_2$O, Tellurium powder Te, Potassium hydroxide KOH, Potassium borohydride KBH$_4$ with the solvent of N, N-dimethyl formamide (DMF) at temperature between 100 and 180°C to produce nanocrystalline Bi$_2$Te$_3$. They proposed the formation mechanism of Bi$_2$Te$_3$ nanoparticles could be a combination of two independent pathways. The first pathway, Te was reduced to Te$^{2-}$ and then Te$^{2-}$ reacts with Bi$^{3+}$. The second pathway was a direct combination of metal; Bismuth ions (Bi$^{3+}$) could be reduced to metal Bismuth readily by KBH$_4$ to form Bi$_2$Te$_3$ nanoparticles. The X-ray diffraction (XRD) pattern of the product revealed that the peaks in the patterns corresponded to the reflections of rhombohedral phase with cell constants a = 4.38 Å and c = 30.50 Å. Morphology and size of synthesized nanoparticles were depended on the reaction temperature and time. When reaction temperature was low and also time was short, the first pathway was the dominant formation process; and it was easy to form rod-like nanoparticles. When the reaction temperature increased or the time was prolonged, the second pathway could be occurred; the morphology of Bi$_2$Te$_3$ nanocrystals tends to be sphere shaped.

X.B. Zhao et al. [14] were prepared by solvothermal synthesis to produce Bi$_2$Te$_3$ nanoparticles and nanowires by using Bismuth (III) chloride BiCl$_3$ and Te as a precursor with ethylene diamine (EN), dimethyl formamide (DMF), pyridine, acetone, ethanol and distilled water respectively as the reaction medium. A sufficient amount of NaBH$_4$ was put into the solution as the reductant and NaOH used to control the pH-value of the solution. According to the XRD results, the major by-products were metallic Bi, Te and Bismoclite (BiOCl). This means that in addition to the expected reaction for Bi$^{3+}$ ions to combine with the reduced Te$^{2-}$ ions to form Bi$_2$Te$_3$ during solvothermal synthesis. Distilled water was the best solvent for the solvothermal synthesis of Bi$_2$Te$_3$. The product synthesized in distilled water contained a large portion of nanowires with a diameter less than 100 nm and length of about 10 μm.

Yongbin Xu et al. [13] reported about the solvothermal methods by using the material Bi$_2$Cl$_3$, Te, Sodium hydroxide NaOH, Sodium borohydride NaBH$_4$ and the solvent of hexadecyltri methyl ammonium bromide (CTAB) mixed with distilled water & ethanol. The experimental results showed that CTAB played a vital role to the formation of the plate-like morphology and controlled the growth rates of different crystalline faces. XRD pattern indicated a pure rhombohedral phase with lattice constants a = 4.435 Å and c = 30.056 Å and produced pure Bi$_2$Te$_3$. In other experimental results the authors demonstrated single crystalline nanoparticles of Bi$_2$Te$_3$ were produced with 70 to 200 nm diagonal and 30 nm thickness.

S. H. Kim et al. [12] produced a Bi$_2$Te$_3$ alloy nanotubes with 1–D structure by interfusion at the interface of Bi and Te. The author’s used the material Bismuth (III) oxide Bi$_2$O$_3$, Tellurium dioxide TeO$_2$ which dissolved in Hydrochloric acid HCl and employed as a solvent of Olic acid and Oleylamine at reaction temperature between 160 and 240°C in a nitrogen atmosphere. Moreover, the author’s synthesized the Te nanowire at a temperature of 200°C with an average diameter of 150 to 200 nm and length of 10 to 15 μm. The Te nanowire was developed into Bi$_2$Te$_3$ nanotubes conformed by TEM images. Additionally, they observed the Bi and Te crystals in the XRD patterns.

Y. Liang et al. [11] employed a simple solvothermal process by using Bi$_2$O$_3$, Te that were added to the polyvinylpyrrolodone (PVP) with ethylene glycol solution in order to prepare Bi$_2$Te$_3$ hexagonal nanoplates in the absence of NaOH. According to the author reports, the diffraction peaks in the XRD pattern could be indexed to Bi$_2$Te$_3$ rhombohedral lattice phase with the lattice constants a = 4.395 Å and c = 30.44 Å. Thus the XRD data indicated that Bi$_2$Te$_3$ nanoplates prepared this method was composed of Bi$_2$Te$_3$ rhombohedral lattice phase. Author’s showed the transmission electron microscope (TEM) image of a single hexagonal Bi$_2$Te$_3$ nanoplate used to make a detailed investigation of crystallinity and microstructure. Corresponding spot pattern of selected area diffraction (SAED) and high-resolution transmission electron microscope (HRTEM) lattice demonstrated the single crystalline nature of the nanoplate. The SAED pattern was obtained by aligning the electron beam perpendicular to the face of this plate. The hexagonally symmetric spot pattern indicated the single crystallinity and could be indexed based on a rhombohedral phase. An HRTEM image revealed the expected hexagonal lattice fringes with a lattice spacing of 0.223 nm, indicating that the as-prepared nanoplates were highly crystallized. The Raman spectrum showed that infrared (IR) active mode, which must be odd parity and is Raman forbidden for bulk crystal due to its inversion symmetry, was greatly activated and shown up clearly in Raman scattering spectrum.

H. He et al. [10] were prepared the Bi$_2$Te$_3$ nanosheets by the solvothermal method. The raw materials were Bi$_2$O$_3$, TeO$_2$, glycol, NaOH and PVPK-30. The samples were a hexagonal lattice with an average crystal size of 42 nm. Scanning electron microscope (SEM) revealed the samples excellent hexagonal nanosheets, which was in accordance with the results obtained by XRD. The diameter and thickness of the nanosheets could be estimated to be 400 to 600 and 40 to 50 nm, respectively.

On the other hand, the authors report indicated that the absorption spectrum which exist two absorption peaks around 362 nm (with energy of 3.43 eV) and 663 nm (with energy of 1.87 eV). The electron affinity of Te was 1.97 eV. Taking the chemically combined Te atoms in Bi$_2$Te$_3$ nanosheets into consideration, the value of the electron affinity might be changed. The absorption peak around 663 nm corresponds to the electron affinity of Te. In order to confirm the conclusion, the emission spectrum of the Bi$_2$Te$_3$ nanosheets was obtained. The theoretical value of the electron affinity (1.97 eV) was slightly different from the experimental value (1.87 eV).
Y. Zhang et al. [9] reported the hexagonal nanosheet of Bi$_2$Te$_3$ single crystals with uniform morphology through a high yield solvothermal route at low temperature. The author’s used the raw materials such as BiCl$_3$, Sodium telluride Na$_2$TeO$_3$, NaOH, and the kind of surfactants that PVP-K30, ethylen diamine tetra acetic acid (EDTA), CTAB, sodium dodecyl benzene sulfonates (SDBS), ethylene glycol (EG). The author’s obtained the nanosheets by solvothermal route display a pure rhombohedral phase of Bi$_2$Te$_3$. The calculated lattice constants were $a = 4.386$ Å and $c = 30.482$ Å. The experimental results clearly explained that high-yield hexagon nanosheets were obtained, which have a thickness of 40 to 60 nm and a distance of 400 to 600 nm between the opposite edges. These nanosheets exhibited a flat surface and sharp edges, which indicated an excellent crystallinity. Reaction time and temperature, concentration of NaOH, and kinds of surfactants played important roles in the growth of Bi$_2$Te$_3$ nanocrystals.

R. Jin et al. [8] synthesized a hierarchical flower-like Bi$_2$Te$_3$ through a facile solvothermal method. Author’s employed the Bismuth (III) nitrate pentahydrate Bi(NO$_3$)$_3$·5H$_2$O and Na$_2$TeO$_3$ which dissolved in the water and EG solution. Glucose, NaOH and hydrate hydrate N$_2$H$_4$·H$_2$O were added into the solution. The XRD pattern of the obtained products demonstrated a rhombohedral phase of Bi$_2$Te$_3$. No other crystalline impurities were detected, indicating the phase purity of the Bi$_2$Te$_3$ product. The SEM images displayed that the Bi$_2$Te$_3$ had a flower-like morphology with the width of 300 to 2000 nm. Closer observation demonstrated that the flowers were composed of smaller nanospheres with the average thickness of 30 nm. The concentration of glucose played a crucial role in the formation mechanism on structure and morphology. The results showed that the maximum ZT value of 0.6 could be achieved at 600 K.

Lei Yang et al. [7] inspected an N-type Bi$_2$Te$_3$ nanostructure by using a solvothermal method and enhanced thermoelectric performance. They were used the Bi$_2$O$_3$, TeO$_2$, NaOH, EG and PVP in order to produce the Bi$_2$Te$_3$ nanostructures. Author’s indexed exclusively the XRD as a rhombohedral phase with lattice parameters were $a = 4.386$ Å and $c = 30.478$ Å. The SEM images displayed that the Bi$_2$Te$_3$ had a hexagonal plate-like nanostructures. The lateral size distributions of these nanostructures were varied from 100 to several 100 of nanometres. Their typical thickness could be observed in the high magnification SEM, which was around 20 nm. These structural features reduced the overall thermal conductivity and in turn led to an enhanced ZT of 0.88 at 400 K.

W. Guo et al. [6] prepared the hierarchical Bi$_2$Te$_3$ nanoflowers assembled by 2-D thin nanosheets with defects by using a facile solvothermal method. They used the materials of Bi(NO$_3$)$_3$·5H$_2$O, Na$_2$TeO$_3$, PVP K30, EG, hydrazine monohydrate N$_2$H$_4$, formic acid, ethanol and acetone. The peaks in the XRD pattern were well indexed to the rhombohedral Bi$_2$Te$_3$. The low-magnification FE-SEM image shows that Bi$_2$Te$_3$ sample was composed of hierarchical nanoflowers assembled by curved and inter crossed nanosheets. The high magnification FE-SEM image further showed that of Bi$_2$Te$_3$ nanosheets had a diameter ranging from 500 to 600 nm and a thickness of about 16 nm. Authors were achieved the controllable self-assembly of nanoflowers consisted of 2-D thin nanosheets. The results showed that the maximum ZT value of 0.68 at 475 K.

The Bi$_2$Te$_3$ nanostructures have unique properties, which is summarized in the Table I. Table II shows the growth and characterization parameters of Bi$_2$Te$_3$ nanostructure:

Bi$_2$Te$_3$ is one of the best thermoelectric materials with a relatively high electrical conductivity and lower thermal conductivity. Already a lot of works has been done in Bi$_2$Te$_3$. Recent advances in theories and experiments have proved that defects can break the sub lattice symmetry and are thought to play a key role in the electronic scattering processes in the nanosheets. Thus, to enhance the transport and electronic properties of Bi$_2$Te$_3$ crystals, the ability to manipulate hierarchical Bi$_2$Te$_3$ nanostructures with defects is highly
desirable. In this communication, the controllable Bi$_2$Te$_3$ single crystal nanostructure to improve the thermoelectric performance, which governed by the dimensionless figure-of-merit ZT.

IV. CONCLUSION AND FUTURE RESEARCH

Eventually, the use of main materials of Bi(NO$_3$)$_3$·5H$_2$O and TeO$_2$ in solvothermal growth has been proposed in the review paper. Since it’s are ecological behaviour with low toxicity, low cost, stability in air, commercial availability and easy of handling properties. Many researchers use the KOH and other materials to prepare the solution. Here, in order to prepare the solution, Nitric Acid HNO$_3$ instead of these materials has also been recommended. TeO$_2$ powder has been dissolved in HNO$_3$. Thereafter Bi(NO$_3$)$_3$·5H$_2$O material is added at 80°C and dissolved accompanied by magnetic stirring and complete the other treatments to produce Bi$_2$Te$_3$ nanostructure. Possible chemical reaction under as follows:

\[
\text{TeO}_2 + 2\text{HNO}_3 \rightarrow \text{H}_2\text{TeO}_4 + \text{NO}_2
\]

\[
\text{Bi(NO}_3)_3\cdot5\text{H}_2\text{O} \rightarrow \text{BiONO}_3 + 2\text{HNO}_3 + 4\text{H}_2\text{O}
\]

\[
3\text{HTeO}_4^- + 9\text{H}^+ + 18\text{e}^- \rightarrow \text{Bi}_2\text{Te}_3^- + 6\text{H}_2\text{O}
\]

Further research is required to improve the Seebeck coefficient while still keeping the thermal conductivity low and electrical conductivity high.

DETERMINATION OF WIND ENERGY POTENTIAL OF CAMPUS AREA OF SIIRT UNIVERSITY

Nihat Bükür̈*, Mehmet Şahin+

*+, Department of Electrical and Electronics Engineering, Siirt University, 56100 Siirt, Turkey

(*nbugun@gmail.com, msahin@siirt.edu.tr)

Abstract- In this study, wind energy potential of Siirt University campus area is statistically examined by using the mean hourly wind speed data between 2014 and 2015 years which are measured by Vantage Pro2 device, located at the roof of the Engineering Faculty building with 6 m altitude. Weibull distribution function and Rayleigh distribution function are used as statistical approach to evaluate the wind data. Weibull distribution function is examined by using two different methods that are maximum likelihood estimation and Rayleigh method. The determination coefficient ($R^2$) and Root Mean Square Error (RMSE) values of these methods are compared. According the error analysis, it is indicated that the Rayleigh method gives better results. Wind speed and wind power density are calculated in pursuance of Weibull distribution parameters. The results are evaluated as monthly and annually. Hence, this preliminary study is made to determine the wind energy potential of Siirt University campus area.

Keywords-Weibull distribution, Rayleigh distribution, maximum likelihood estimation, wind speed, wind power density.

I. INTRODUCTION

Electrical energy requirement tends to increase depending on the rapidly advancing technology. Due to the limited amount of available fossil fuels used in electricity production and due to the fact that they will eventually run out, the ways to conserve electric energy and the use of renewable energy sources are constantly being studied on. One of those studies is harvesting wind energy to generate electric energy which has shown great development in recent years, especially in Europe. Turkey is a country with high potential regarding wind energy. In 2007, Wind Energy Potential Map of Turkey (REPA) was published [1]. In this map, wind energy potential of Turkey was provided in detail for each city. In scope of this study, wind energy potential of Siirt campus area was studied and evaluated using the Vantage Pro2 device located at the roof of Block C of Engineering and Architecture Faculty, measuring the average hourly wind speeds between years 2014 and 2015 for a total of 12 months from 6 meters of altitude. For the evaluation of wind data, Weibull and Rayleigh distribution functions were used as statistical approaches. These two distribution functions are widely used to determine the wind energy potential in many studies either in Turkey and other countries [2]. It is a known fact that wind data usually matches with Weibull distribution [2-4]. However, in some areas, wind data does not match with the two parameter Weibull distribution. But mostly, Weibull distribution is the method which is used to represent the wind distribution in many regions throughout the world. The reason for its use is because it fits perfectly with the wind distribution and also has a flexible distribution structure, also, its parameters can easily be determined and very few parameters are required. Its parameters can also easily be estimated for different altitudes, once one altitude parameters is determined [2].

Wind measurements are usually performed in the range of 10-30 meters, however, today's large and powerful wind turbines' hub height is much higher than this level. Thus, in order to deduct the value of wind speed in any particular altitude, for any spot which was measured for just one altitude, wind power profile law is being used. Weibull distribution function parameters have been analyzed using two different methods which are maximum likelihood estimation (MLE) and Rayleigh method. Both methods have been compared with coefficient of determination ($R^2$) and root mean square error (RMSE) analysis. Average speed and wind power density have been statistically determined depending on the Weibull distribution parameters.

II. WEIBULL DISTRIBUTION

Weibull distribution is used to calculate wind energy potential in many studies. Wind data is known to usually fit to this type of distribution. However, in some areas, wind data does not conform to the two-parameter Weibull distribution. Various methods have been developed in order to calculate the figure (k) and scale (c) parameters. The methods that we used for Siirt campus area are the maximum likelihood estimation (MLE) and Rayleigh method. Likelihood density function of two parameter Weibull distribution is expressed with eq.(1).

$$f(v) = \frac{k}{c} \left(\frac{v}{c}\right)^{k-1} e^{-\left(\frac{v}{c}\right)^k}$$  \hspace{1cm} (1)

Where the wind speed (m/s), k and c are dimensionless figure and scale parameters, respectively. The accumulation of Weibull
distribution (cumulative) likelihood density function is as in eq.(2) [5].

\[ F(v) = 1 - e^{-\frac{v}{c}} \]  

(2)

Weibull cumulative likelihood density function gives us the likelihood of the wind speed being actualized either smaller or equal to a specific v value. The average wind speed is calculated using the eq.(3) [5].

\[ V_{ort} = c \left( \frac{1}{k} + 1 \right) \]  

(3)

Weibull distribution is a function and this function has a peak spot. Finding this peak means finding the most probable speed, thus, finding the maximum wind speed. It is the (y) gamma function in eq.3 [2].

\[ V_{enolax} = c \left( \frac{k}{k} - 1 \right)^{\frac{1}{k}} \]  

(4)

The speed value which contributes the most to the energy flow is given in eq.(5) [2]

\[ V_{max} = c \left( \frac{k + 2}{k} \right)^{\frac{1}{k}} \]  

(5)

The average power density was shown in eq.(6) [3].

\[ P = \frac{1}{2} \rho c^3 \gamma (1 + \frac{3}{k}) \]  

(6)

Where, "\( \rho \)" is the air density value and in calculations it was taken as an average of 1.226 kg/m³ for Siirt campus area. Figure parameter (k) is a parameter indicating the frequency of the wind. If the wind speed does not show much fluctuation in an area, and if the wind is blowing with an approximate constant speed (low or high), it k parameter is greater. Scale parameter (c) indicates the relative cumulative wind speed frequency. In simple words, c parameter changes depending on the average speed. If the average speed is higher, c parameter is also higher [3]. Wind speed measurements are usually made in between an altitude range of 10 to 30 meters. However, nowadays, the hubs of wind turbines are much higher than this level. Therefore, in order to deduct the wind speed value of any particular altitude of any location, wind power profile law is being used together with the measured wind speed data of that location [6]. Speed values for different altitude are measured using eq.(7).

\[ \left( \frac{V_2}{V_1} \right) = \left( \frac{h_2}{h_1} \right) \]  

(7)

In eq.(7), \( V_1 \) represents the measured wind speed, \( V_2 \) represents the desired wind speed, \( h_1 \) represents the altitude that the \( V_1 \) speed was measured, \( h_2 \) represents the altitude that \( V_2 \) speed is demanded to be determined, \( \alpha \) represents the Hellman coefficient and is dependent on the specifications of the location of the wind speed measurement is made.

\[ \left( \frac{P_2}{P_1} \right) = \left( \frac{h_2}{h_1} \right)^{3\alpha} \]  

(8)

If the power level in the reference altitude can be found using eq.(8), the power density in the desired altitude can be calculated also. In the equation, \( h_1 \) is the reference altitude, and if the power density in this altitude is \( P_1 \) and the power density in the desired altitude (\( h_2 \)) is represented with \( P_2 \).

III. MAXIMUM LIKELIHOOD ESTIMATION

Maximum likelihood estimation is one of the methods to find the k and c values which are the figure and scale parameters of Weibull distribution. In maximum likelihood estimation, wind data shall be organized as \( V_1, V_2, V_3, \ldots, \ldots, V_n \) which will form a set with \( n \) number of elements. The likelihood of any data to be \( V=V_i \) is proportional with \( f(V; k, c) \). Similarly, the likelihood of \( V=V_1, \ldots, V=V_n \) occurrence of all the data can also be expressed. These events are independent from each other. Thus, the likelihood of the occurring of events can be defined as a likelihood function as in eq.(9) [7].

\[ L = \prod_{i=1}^{n} f(V_i; k, c) \]  

(9)

The scale parameter can be obtained using eq.(10).

\[ c = \left( \frac{\sum_{i=1}^{n} V_i^k}{n} \right)^{\frac{1}{k}} \]  

(10)

Figure parameter can be calculated using eq.(11).

\[ k = \left( \frac{\sum_{i=1}^{n} V_i^k \ln(V_i)}{\sum_{i=1}^{n} (V_i)^k} - \frac{\sum_{i=1}^{n} \ln(V_i)}{n} \right)^{-1} \]  

(11)

The likelihood function can be used to find the value that will make the highest likelihood function, for the k and c parameters calculated using above given equations. Here, the equation for \( V_i=0 \) which is used for k figure parameter can not be solved. Therefore, the value of 0 should be removed from the dataset [2].
IV. RAYLEIGH DISTRIBUTION

The change and distribution of the wind in a specific period is very important for energy production evaluations. Turbine designers need such information like wind distribution and change in order to make improvements on turbines and to reduce the costs to a minimum. If in any location, the only known data is the average wind speed \( \langle V \rangle \); using Rayleigh distribution function, it should be possible to find the percentage of any specific wind speed \( V \) blowing time (hr). The wind speed values derived from such calculations are a distribution of likelihood density. When this distribution is schematically depicted, the region which is below this distribution is equal to 1. Because the likelihood of the wind blowing in any speed including zero is equal to 100%. Rayleigh density function is as it was shown in eq.(12) [2, 5-10].

\[
f_r(\nu) = \left( \frac{\nu}{\nu_m} \right) \exp \left[ -\left( \frac{\nu}{\nu_m} \right)^2 \right] \quad (12)
\]

Rayleigh cumulative distribution function can be represented as in eq.(13)

\[
F_r(\nu) = 1 - \exp \left[ -\left( \frac{\nu}{\nu_m} \right)^2 \right] \quad (13)
\]

The biggest advantage of Rayleigh distribution is that the distribution can be determined with just using the average wind speed. In Rayleigh distribution, calculations are done considering that the \( k \) scale parameter equals to 2. Because the calculations are made over a single parameter, it is a simpler method compared to Weibull distribution. Its validity in wind studies have been shown in many references [2-5].

V. ERROR ANALYSIS

Error analysis shall be done in order to find out which of the figure and scale parameters calculated using Weibull distribution, MLE and Rayleigh are the most suitable ones for the real data. The methods used in this study have been analyzed using two different error analysis methods. The first of these is \( R^2 \) (determining coefficient) and it can be expressed as in eq.(14) [2, 8, 9].

\[
R^2 = 1 - \frac{\sum_{i=1}^{n}(y_i - x_i)^2}{\sum_{i=1}^{n}(y_i - \bar{y})^2} \quad (14)
\]

The other error analysis method is root mean square error (RMSE), and it has been represented in eq.(15).

\[
RMSE = \sqrt{\frac{1}{n} \sum_{i=1}^{n}(y_i - x_i)^2} \quad (15)
\]

Where, \( n \) is the number of observations, \( y \) are real values, \( x \) are values calculated using Weibull distribution and average real values. The fact that \( R^2 \) value is the largest and RMSE value is the smallest shows that this distribution function is the best one [2, 8, 9].

VI. RESULTS AND DISCUSSION

In the estimation of the parameters of Weibull distribution and Rayleigh function, hourly wind speed data measured in 6 meters of altitude for 12 months between 2014 and 2015 in Siirt campus area was used. Then the results for 40 meters of altitude were calculated using Hellmann coefficient.

Table 1 shows the analysis of hourly wind data in Siirt campus. Calculations were performed with hourly measurements made at an altitude of 6 meters. Then, using Helmann coefficient, wind power density was calculated for the altitude of 40 meters. As seen in table 1, the highest average
speed and power density in Siirt Campus took place in June. But these two data distributions are not sufficient for energy investments, it is necessary to examine the distributions of other data as well. When we examine the seasonal data, we can see that the highest average speed and power density happens to be in summer and late spring months. Fig.1 shows the power density values calculated in the years 2014-2015 for Siirt Campus area.

![Power density graph](image)

Fig.1. Power densities calculated using MLE for years in between 2014-2015

Depending on the altitude, wind speed and its power density varies. Parameter values in different altitudes were deducted from the revised data obtained for the altitude of 6 meters and by adapting it to 40 meters of altitude.

Table 2 shows the analysis according to Rayleigh distribution of the hourly wind speed data for Siirt campus area for years 2014-2015. According to the calculations, the highest power density was recorded in June and the lowest was recorded in December.
Fig. 2 shows the power density data calculated using Rayleigh distribution for Siirt campus area for years 2014-2015. As can be seen in the figure, the highest power density was recorded in June and the lowest was recorded in December. The coefficient of determination ($R^2$) is valued either 0 or 1, as the measurement of the power of estimation of any model. The closer the coefficient of determination to 1, the higher the power of estimation of the model used. The smaller the RMSE value gets, the better that particular distribution function becomes.

The data obtained from Weibull and Rayleigh distributions for Siirt campus area for 2014-2015 was presented in Table 3. When the table is examined, it can be seen that a statistical comparison of Weibull and Rayleigh distributions was made according to $R^2$ and RMSE criteria. If these comparisons are examined, it can be seen that the use of Rayleigh distribution is more suitable for that particular region. This can also be seen in Fig. 3. If the figure is examined, it can be seen that the highest coefficient of determination was obtained using Rayleigh distribution.

Fig.3. The comparison of Weibull and Rayleigh distributions according to $R^2$ criteria for Siirt campus area in between years 2014 and 2015

VII. CONCLUSIONS

For the determination of the wind potential of any region for energy purposes, its wind speed distribution should be known first. Depending on the wind speed distribution data, wind power density is calculated and after the required economic and environmental analysis, it can be understood if the wind farming would be beneficial for that particular area or not. In this study, Weibull parameters used to determine the distribution of speed have been determined using two different distribution methods, maximum likelihood estimation (MLE) and Rayleigh distribution method. As a result of the error analysis made in Siirt campus region, and also considering the $R^2$ and RMSE factors, it was seen that Rayleigh distribution gave better results. The data was obtained for 6 meters of altitude by using the device Vantage Pro2 device, located at the roof of the Engineering Faculty building, and using the Hellmann coefficient, the possible wind data for the altitude of 40 meters was calculated. Generally speaking, when evaluated for its wind potential throughout 2014-2015, for a period of 12 months, it has been understood that late Spring and Summer months had the highest potential of power density, and the lowest power density was observed in months of Winter and Fall. For any location to be eligible to have a wind farm, its power density should be over 50 W/m². In our measurements, we have come to the conclusion that in order to have a wind farm in this location, the wind turbine rotors should be situated above 40 meters of altitude.

Abstract—Palladium–metal (Cobalt, Zinc, Vannadium, Manganese) bimetallic nanocatalysts were synthesized by polyol method using ethylene glycol (EG) as the solvent and performed reduction by using NaBH4 at room temperature. Glassy carbon (GC) electrodes are modified with the Pd based catalysts. The electrocatalytic properties of the PdM/CNT are examined for methanol, ethanol and ethylene glycol oxidation with cyclic voltammetry (CV) and chronoamperometry (CA). The electrocatalytic activity of PdCo/CNT is four, eight and ten times higher in methanol (MeOH), ethanol (EtOH) and ethylene glycol (EG), respectively compared to other catalyst modified electrodes (PdZn/CNT, PdV/CNT and PdMn/CNT).

Keywords—Palladium based catalysts, methanol oxidation, ethanol oxidation, ethylene glycol oxidation, cyclic voltammetry, chronoamperometry.

I. INTRODUCTION

Direct Oxidation Fuel Cells (DOFCs) are attracting widespread interest over the past few years due to their low pollution for the environment, easy transportation and handling. The fuel cells that operate directly using liquid fuels have focused attention on the electrochemical oxidation of alcohols and other small organic molecules such as methanol, ethanol, propanol, ethylene glycol, etc [1]. Methanol is the most studied liquid fuel even its high toxicity and high flammability. However C2-fuels such as ethanol and ethylene glycol are alternative to methanol due to their electro-oxidation at low temperatures and high energy density. DOFCs are promising power sources for portable electronic devices and electric vehicles. However, there are some problems such as slow reaction kinetics, catalyst poisoning and fuel crossover. Therefore, the study on catalyst material and preparation method to increase the activity and stability of the catalysts is important. The major reason to decrease catalytic activity is that the catalyst is affected by chemisorbed carbonaceous intermediates. It is well known that Pt and Pt-based alloys are promising catalysts used in direct oxidation fuel cells, but Pt has some limitations such as its limited abundance, high cost and low CO tolerance. However, Pd is more abundant, less expensive and stable in alkaline solutions than Pt. Moreover, Pd has better CO tolerance comparing to Pt catalysts. These properties have led to consider Pd based nanomaterials as effective catalysts for direct liquid fuel cells [2]. A number of studies have been devoted to Pd-based catalysts for the electrooxidation of alcohols in alkaline medium [3]-[5].

In the present study, the catalytic activities of PdM (M: Co, Zn, V, Mn) catalysts for different liquid fuels (MeOH, EtOH and EG) have been compared. The electrocatalytic activities of the catalysts are characterized with electrochemical methods such as cyclic voltammetry (CV) and chronoamperometry (CA) methods.

II. EXPERIMENTAL

A. Preparation of Catalysts
Carbon nanotube supported PdM catalysts were prepared by polyol method in ethylene glycol. In brief, certain amount of aqueous metal salts (Cobalt, Zinc, Vannadium, Manganese) solution was prepared. Then, appropriate amount of ethylene glycol and carbon nanotube support were added into the solution prepared. The pH of the solution was fixed at 10 by the addition of KOH solution and carbon nanotube support was dispersed in this solution. Certain amount of NaBH4 was added to above solution and stirred at room temperature under stirring.

B. Electrochemical Measurements
All the electrochemical measurements were conducted using CH Instruments 6043d potentiostat. The electrochemical experiments were carried out in an N2-purged NaOH solution and a standard three-electrode electrochemical cell. A Pt foil electrode and an Ag/AgCl served as the counter and reference electrode, respectively. Prior to each experiment GC electrode surface was polished with slurry of 0.05 mm alumina powder until a mirror-like surface obtained. Then the electrode was washed thoroughly with acetone and distilled water.

All electrochemical measurements were carried out in 1 M KOH. The alcohol concentrations are 1 M. The alcohols examined in the present study were MeOH, EtOH and EG. The CV technique was carried out by scanning of the potential between -1.0 and 0.4 V with the scan rate of 50 mV s⁻¹. Chronoamperometry experiments were performed at -0.35 V, at room temperature. All potentials in this article have been reported versus normal hydrogen electrode (NHE).

III. RESULTS AND DISCUSSION
The electrochemical characterization of PdM/CNT electrocatalysts was evaluated by cyclic voltammetry in the 1.0 M KOH solution at 25 °C. The cyclic voltammograms were recorded at 50 mV s⁻¹. The cyclic voltammetric behaviors of PtM catalysts were compared with each other. and presented in Fig. 1. The hydrogen adsorption/desorption peaks (in the −0.1 and 0.8 V region) and palladium oxide reduction peak (at −0.05 V) was seen in the figure. Higher
current value of hydrogen adsorption desorption peaks were obtained for PdCo/CNT catalyst.

Cyclic voltammetry (CV) is the most important electrochemical technique for acquiring information about catalysts activity toward alcohol oxidation. The CV provides basic information on the kinetics and thermodynamics of the electro-oxidation reaction. Some of these informations are established in terms of the (a) onset potential ($E_{\text{onset}}$), (the more negative the value the easier the electrocatalysis); (b) peak potential separation ($E_p$), (the lower the value the more efficient the catalyst) [6]; (c) forward peak current ($I_f$) maximum current of catalyst and (d) the ratio of forward to reverse peak current ($I_f/I_r$), (the higher the value the more tolerant to poisoning the catalyst) [7]. The CV data as depicted in Table I clearly show that the PtCo/CNT is a better catalyst for alcohol oxidation reaction than the other synthesized Pd based catalysts. The onset potential at the PtCo/CNT is more negative, while the current is about four, eight and ten times higher in methanol (MeOH), ethanol (EtOH) and ethylene glycol (EG), respectively than the other Pd based catalysts.

A good fuel cell catalyst should have high current at low overpotentials, and retain such current at long period of time. The stability of current generated by the electrocatalyst was tested by chronoamperometric experiments. Fig. 3 compares the chronoamperometric curves of PdCo/CNT, PdZn/CNT, PdV/CNT and PdMn/CNT in KOH solutions of the three alcohols (methanol, ethanol and ethylene glycol). The chronoamperometric curves exhibit fast decrease at the initial period due to the accumulation of intermediate species at the surface of catalysts. As it was obtained from the CV measurements, PdCo/CNT catalyst shows a higher initial current and a higher current at the longer time. This confirms that PdCo/CNT, catalyst has higher electrocatalytic activity, higher resistance to CO, and better long term stability compared to the other three catalysts.

IV. CONCLUSIONS

PdM nanocatalysts have been successfully prepared by polyol method with NaBH₄ reduction. Electrochemical study of alcohol electrooxidation reaction on Pd based catalysts was investigated by different electrochemical techniques. Cyclic voltametric and chronoamperometric measurements demonstrate that PdCo/CNT catalyst has higher catalytic activity than the other Pd based electrocatalyst for alcohol electro-oxidation in alkaline solution. The synthesized PdCo/CNT catalyst promises great potential as a kind of novel anode electrocatalyst with high electrochemical activity for application in DOFCs.

Abstract—In this study, hydroxy (HHO) dry cell with different plate combination performances in terms of current and temperature were experimentally investigated and modeled with Rule-Based Mamdani-Type Fuzzy (RBMTF) modeling technique. Input parameters plate number and time; output parameters current, temperature were described by RBMTF if-then rules. The dimensions of the plates were 9x9 cm², 10x10 cm² and 11x11 cm². Current and temperature were measured for the different plate combination. Tap water was used in the experiments and the system was set to 5 minutes. For each combination, new cells were prepared. Experimental data which obtained for current and temperature according to combination and time were used in the training step. Numerical parameters of input and output variables were fuzzificated as linguistic variables: very very low (L₁), very low (L₂), low (L₃), negative medium (L₄), medium (L₅), positive medium (L₆), high (L₇), very high (L₈) and very very high (L₉) linguistic classes. With the linguistic variables used, rules were obtained for this system. The comparison between experimental data and RBMTF is done by using statistical methods like the coefficient of multiple determinations (R²). The actual values and RBMTF results indicated that RBMTF can be successfully used in HHO dry cell.

Keywords—HHO Dry Cell, Plate Combination, Rule-based Mamdani-type fuzzy modelling

I. INTRODUCTION

Hydrocarbon fuel is one of the sources of energy used for electrical power generation, heating and transportation in the world. But they have negative side effects like polluting emissions, large scale oil spill, etc. Due to its widespread dependence and difficulties in getting other alternatives the use of hydrocarbon fuel could not be eliminated. To mitigate the above problems and to reduce the use of hydrocarbon fuel, hydrogen gas can be supplemented. Hydrogen gas to air intake of a combustion process will improve flame speed, lean burn ability and flame quenching distance. But scarcity and production cost makes it more difficult to implement. Hydrogen rich gas produced from electrolysis of water called the Brown’s Gas or Oxyhydrogen (HHO) could solve the potential difficulties [1].

In 1918 Charles Frazer, a North American inventor, patented the first water electrolysis machine act as a hydrogen booster for internal combustion engines. Yull Brown, a Bulgarian born Australian inventor patented and attempted to popularize Browns Gas as a cutting gas and fuel additive during the 1970’s and 80’s [2]. HHO is an enriched mixture of hydrogen and oxygen bonded together molecularly and magnetically. HHO Gas is produced in a common-ducted electrolyser & then sent to the intake manifold to introduce into combustion chamber of the engine. HHO gases will combust in the combustion chamber when brought to its auto-ignition or self-ignition temperature [3]. This Energy’s performance must be increased which is predicted to be more important in the future. One of the methods to determine the effects of the parameters on performance is fuzzy logic method.

In the existing literature, there have been many investigations on application of fuzzy logic. Some of briefly mentioned below. İşıktaş et al. [4] studied about fuzzy logic modelling of performance HHO dry cell with different type membership functions. They noted that RBMTF which has a triangular membership function has a more better performance than other membership functions for determine performance of HHO dry cell. Ata and Dincer [5-9] studied about rule-based Mamdani-type fuzzy (RBMTF) modelling of performance proton exchange membrane fuel cell with carbon nanotube. They noted that RBMTF can be successfully used for the specification PEM performances with coating carbon nanotube. Özek et al. [10] studied modelling of air conditioning system by fuzzy logic approach, because one of the main problems in control systems is the difficulty to form the mathematical model associated with the control mechanism. They realized that the fuzzy logic without using mathematical model of control system can create control mechanism only with the help of linguistic variables. Kim et al. [11] examined an electrical modelling of the fuel cell generation system. They used fuzzy logic controller to overcome inherent disadvantages such as uncontrollable large overshoot and large current ripple. They noted that fuzzy
controller is very effective in output control and desired operating point operation, which in turn offers high system stability and performance. Tong et al. [12] studied about 1 kW PEM fuel cell unit and developed the models of stack voltage, cathode flow, anode flow. They proposed that the power demand of the external load can be provided by the fuel cell stack under the control of a real-time simplified variable universe fuzzy controller. Tiryaki et al. [13] studied about dishwasher which is frequently used in daily life is modelled and simulated by using fuzzy logic. They concluded that if an appropriate hardware support and appropriate sensors are provided for the dishwasher, with the aim of the fuzzy logic model the washing process may be done without human intervention according to the inputs such as quantity of the dishes, type of the dishes by the machine.

In this experimental study, three different plate combinations compared in terms of HHO dry cell performance. Also in this study, Rule-based Mamdani-type fuzzy modeling used to evaluate performance of HHO dry cells with different plate combination. Performance parameters are plate numbers, time, current and temperature. Study includes fuzzification of input variables, representation of fuzzy set with 9 linguistic variables, formation of rule basis and a comparison between output values obtained by experiments and by calculation based on generated rules and RBMTF technique.

II. MATERIALS AND METHODS

Fuzzy logic is a superset of Boolean-conventional logic that has been expanded to handle the concept of partial truth and truth values between “completely true” and “completely false”. Fuzzy theory should be seen as a methodology to generalize any specific theory from crisp to continuous. Fuzzy modelling opens the possibility for straightforward translation of statements in natural language-verbal formulation of the observed problem-into a fuzzy system. Its functioning is based on mathematical tools [14].

Fuzzy inference system consists of a fuzzification interface, a rule base, a database, a decision-making unit, and finally a defuzzification interface. The function of each block is as follows. A rule base containing a number of fuzzy IF–THEN rules, a database which defines the membership functions of the fuzzy sets used in the fuzzy rules, a decision-making unit which performs the inference operations on the rules, a fuzzification interface which transforms the crisp inputs into degrees of match with linguistic values and a defuzzification interface which transforms the fuzzy results of the inference into a crisp output. Mamdani's method is the most commonly used in fuzzy inference system, due to its simple structure of 'min-max' operations. Mamdani's method can be used is widely used in fields which require specialized knowledge and is a fuzzy logic method that can be applied to any solution of all kind of problem [15].

The knowledge base of RBMTF is a collection of fuzzy IF-THEN rules. The term fuzzy logic denotes a modelling approach, where functional dependencies between the input and output variables are described by means of a set of IF-THEN rules following the reasoning with the operators AND, OR and NOT in general linguistic usage. RBMTF is a type of fuzzy relational model where each rule is represented by an IF–THEN relationship. [16].

The aim of this experimental study is to compare different plate combination for HHO dry cell performance and to model fuzzy logic method. With the aid of experimental data, HHO dry cell performances at different plate combination in terms of current and temperature were modeled with Rule-Based Mamdani-Type Fuzzy (RBMTF) modeling technique. RBMTF was designed using MATLAB fuzzy logic toolbox. In the developed RBMTF system, output parameter current and temperature was determined using inlet parameters plate numbers and time. Hereafter the rules, which are used to detect the behavior of the fuzzy logic controller and the relationship between system’s input and output, are determined. As a result of these rules, every value obtained from the experimental study is also determined by fuzzy logic too.

III. RESULTS AND DISCUSSION

In this experimental study which is used to detect HHO dry cell performance; the effect of the plate number and time on current and temperature is investigated. Experimental system was set to 5 minutes. Current and temperature values are obtained on every plate from 60th second to 300th second by 60 second intermittently in the experimental study. The aim of this study with the aid of experimental data, HHO dry cell performances in terms of current and temperature were modeled with fuzzy logic modeling technique. In the developed RBMTF system, output parameters A and T were determined using inlet parameters plate number and t.

Figs. 1-2 shows respectively comparison of experimental data for 9x9 cm², 10x10 cm² and 11x11 cm² plate dimensions for current and temperature.

Fig. 1 Comparison of experimental data for the variation of time with plate number of current values for different plate dimension
These figures present that:
- 11x11 cm$^2$ and 10x10 cm$^2$ has more better performance than 9x9 cm$^2$.
- In the case of each plate temperature increases by the course of time and the current value decreases by the increasing plate number.
- According to the experiments, high temperature has been found 29 °C, 32 °C and 33 °C and current density has been found 0.02 A/cm$^2$, 0.023 A/cm$^2$ and 0.024 A/cm$^2$ for 9x9 cm$^2$, 10x10 cm$^2$ and 11x11 cm$^2$ respectively (Figs 1-2).

Figs. 3-8 shows respectively comparison of experimental data with RBMTF for the variation of time with combination of current and temperature values for 9x9 cm$^2$, 10x10 cm$^2$ and 11x11 cm$^2$ plate dimensions (plate number = 1-10; t = 60-300 s). From a comparison of the experimental results with the results of the fuzzy logic study, one can see that the results are quite compatible (Figs. 3-8).
Figs. 3-8 present that:

- For 9x9 cm², the maximum current value is 1.07 A at 9-7 combination and 300 s. For 10x10 cm², the maximum current value is 1.2 A at 11-9 combination and 300 s. For 11x11 cm², the maximum current value is 1.25 A at 11-9 combination and 300 s.
- For 9x9 cm², the minimum current value is 0.1 A at 9-1 combination and 60 s. For 10x10 cm², the minimum current value is 0.11 A at 11-1
combination and 60 s. For 11x11 cm², the minimum current value is 0.13 A at 11-1 combination and 60 s.
- For 9x9 cm², the maximum temperature value is 29 °C at 9-7 combination and 300 s. For 10x10 cm², the maximum temperature value is 32 °C at 11-9 combination and 300 s. For 11x11 cm², the maximum temperature value is 33 °C at 11-9 combination and 300 s.
- For 9x9 cm², the minimum temperature value is 22 °C at 9-1 combination and 60 s. For 10x10 cm², the maximum temperature value is 23 °C at 11-4 combination and 300 s. For 11x11 cm², the maximum temperature value is 23 °C at 11-4 combination and 300 s.

The comparison between experimental data and fuzzy logic is done using statistical methods such as the coefficient of multiple determination (R²) are defined as follows, where n is the number of data patterns, yp,m indicates the predicted, tm,m is the actual value of one data point m, and t̄m,m is the mean value of all actual data points [17]. When Table I is observed, it is found that actual values and the values from fuzzy technique are very close to each other.

\[ R^2 = 1 - \frac{\sum_{m=1}^{n} (t_{m,m} - y_{p,m})^2}{\sum_{m=1}^{n} (t_{m,m} - \bar{t}_{m,m})^2} \]

IV. CONCLUSIONS

In this study, HHO dry cell performances at different plate combinations in terms of current and temperature were experimentally investigated. For HHO dry cell, 11x11 cm² and 10x10 cm² has better performance than 9x9 cm². With the aid of experimental data, HHO dry cell performances at different plate combination in terms of current and temperature were modeled fuzzy logic technique. In the developed RBMFTF system, output parameters A, T was determined using inlet parameters plate number and t. Every value obtained from the experimental study is also determined by fuzzy logic too. The comparison between fuzzy logic and experimental data is done using statistical methods. R² is calculated for the current value 98.49% at 9x9 cm², 98.6% at 10x10 cm² and 98.23% at 11x11 cm². R² is calculated for the temperature value 97.2% at 9x9 cm², 97.8% at 10x10 cm² and 97.5% at 11x11 cm². The actual values and RBMFT results indicated that RBMFT can be successfully used for the specification HHO dry cell performances at different plate combination.

Abstract—Development of technology and industry has been causing a remarkable energy demand all around the world. In order to meet this huge energy demand, conventional energy sources are being used a lot and this issue brings along a serious environmental pollution. Especially, last decades many countries have signed the agreements to prevent environmental pollution. In conjunction with these events, renewable energy sources have become important. In this context, most of countries have been increasing the incentives to the clean energy systems. Also, Turkey has been increasing the incentives to renewable energy investments; therefore renewable energy usage is increasing day by day. In 2015, Turkey’s total installed capacity has reached 72146.7 MW and 42.7% of this amount is met by renewable energy sources. In Turkey most commonly used renewable energy sources are hydroelectric energy, wind energy, solar energy and geothermal energy respectively. In 2013, installed wind energy capacity of Turkey was 2759.6 MW and this capacity reached 4503.2 MW in 2015. It can be deduced from this data, wind power investment in Turkey has been expanding dramatically. In this study, a wind power plant (WPP) feasibility study for Gemlik region in Bursa Province is released by using 5 number of Vestas V90 commercial wind turbines. Also, climatology data obtained from Turkish State Meteorological Service are used for this study and by applying these data to the Windsim software; annual energy production (AEP) and capacity factor of the WPP are calculated. The study shows that, establishment of a WPP which has 30.6 GWh/y AEP and 34.9% capacity factor is feasible.

Keywords—Gemlik, Renewable Energy, Wind Energy, Windsim, Wind Power Plant.

I. INTRODUCTION

Energy demand has been increasing all around the world day by day due to the fact that technology and industry have been growing rapidly. As a result, significant environmental pollution issues and problems have been emerging. In recent years, most of agreements have being signed by many countries in order to prevent environmental pollution such as Kyoto Protocol [1]. The main objective of the Kyoto Protocol is that controlling greenhouse gases emission and struggling for reducing hazardous effects of these gases [2]. In parallel with these agreements, clean energy technologies, sustainability and energy efficiency has become important subject matters. Therefore, the developing countries have been increasing incentives and investments to the clean energy technologies. In addition to that, Turkey as a developing country, has been noticed the importance of the renewable energy technologies and it has been raising the investments to this field [3]. The population of Turkey is about 74 million inhabitants and it is estimated that 75.5% of this remarkable population lives in urban centers [4]. Also, this important population is increasing in conjunction with the technological improvement and as natural consequence of this situation; Turkey’s energy demand is increasing each passing day and it causes huge energy demand in the country. Turkey is a foreign dependent country because domestic fossil reserves are limited and inadequate. In order to decrease foreign dependency, Turkey needs to benefit from renewable energy sources such as wind, solar, hydropower, biodiesel etc. [5]. Wind energy as a renewable energy source has shown a great development across the world since it is clean, sustainable and efficient energy source. In this context, thanks to Turkey’s geographical position Turkey is a rich country in terms of wind energy. According to Turkish Wind Energy Association (TWEA) installed wind energy capacity has reached 4718 MW by the year of 2015 [6]. As shown in Fig.1, amount of wind power plant and naturally wind energy production has been increasing each passing year [7]. According to Turkey’s development plan, Turkey wants to increase the share of renewable energy source usage to at least 30% [8].

Fig. 1 Cumulative wind energy production by years in Turkey [7]

In this study, wind power potential of Bursa Province in Turkey is evaluated. A WPP feasibility study is revealed for Gemlik region in Bursa Province and total energy production of the designed WPP is calculated. The main objective of this study is providing inputs to researchers and encouraging the investors for harvesting wind potential of the region.
II. MATERIALS AND METHODS

The amount of wind power potential is depend on following factors; structure of terrain, wind speed and the distance to the energy transmission lines (ETL). In the first part of this study, wind power potential in Turkey is evaluated. Secondly, Gemlik region in Bursa Province is selected for a wind power plant investment and the wind power potential of the region is evaluated by considering related parameters. In this context, Turkey wind energy potential atlas created by Turkish Electric Affairs Etude Administration is used. Finally, roughness formation and distance to energy transmission lines and transformer stations are analyzed in order to determine whether wind power plant investment is feasible or not.

A. Assessment of Wind Power Potential in Turkey

Thanks to its geographical position, Turkey has a significant wind power potential. The leading regions in terms of wind power potential investment are Marmara and Aegean region in Turkey. According to TWEA report published in 2016, %49.94 of total number of WPP is in Marmara region and 24.82% of this amount is in Aegean region [7]. The wind atlases given by Fig.2 and Fig.3 were used to estimate the wind power potential for 50 meter and 100 meter elevation respectively. According to wind atlases, average wind speed at 50 meter elevation is approximately 6.5-7.0 m/s throughout the country and this value is nearly 7.5 m/s for 100 meter elevation. In Marmara region this parameter changes between 7.0 and 7.5 m/s at 50 meter elevation and this value is pretty sufficient for the WPP investments.

The WPP which have 5 MW capacity or more can be installed in the fields where have 7.5 m/s or more wind speed at 50 meter above ground level [12]. When considered from this aspect, Marmara and Aegean regions are the pretty suitable region for WPP investments.

B. Assessment of Wind Power Potential in Bursa Province

Bursa Province is located between 40 degrees longitude, 28-30 degrees latitude and located in North-western Anatolia, within the Marmara Region. It is the fourth most populous city in Turkey and it is one of the most industrialized metropolitan cities [13].

Wind power potential of Bursa Province was analyzed by using Wind atlases created by Turkish Electric Affairs Etude Administration. As illustrated in Fig. 6 and Fig. 7, average wind speed at 50 meter elevation is 7.0-7.5 m/s in Bursa Province. In addition to that, average wind capacity factor is 30%-35% for the city.
According to Fig. 6 and Fig. 7, coastal areas of Bursa Province have notable wind speed and wind capacity factor. Especially, Gemlik region where located in coastal area of Bursa Province has average 7.0-7.5 m/s wind speed and nearly 35% capacity factor at 50 meter elevation. In the light of these informations, it can be said that Gemlik region is a suitable field for a WPP investment.

III. WIND POWER PLANT FEASIBILITY STUDY

In this section firstly, Windsim software is introduced. Secondly, wind farm layout design is realised by considering roughness formation and distance to ETL and transformer stations in Gemlik region. Finally, annual energy production and capacity factor of the designed wind farm are calculated.

A. Windsim Software

Windsim is one of the popular wind farm design tools which developed by a Norway company named Windsim AS [15]. The software is based on the Reynolds Averaged Navier-Stokes equations of the Atmospheric Boundary Layer and by solving these equations; the correlation is provided [16]. The calculation steps of Windsim software is shown in Fig. 8. Three inputs; terrain data, roughness map and meteorological data are defined to the software as inputs. Then, solutions are obtained by using computational fluid dynamics (CFD) method.

B. Wind Farm Layout Design

Wind farm site selection is carried out by considering roughness formation and distance to ETL in Gemlik region. For this purpose, the roughness map of Bursa Province was used as shown in Fig. 9. According to Fig. 9, most part of Bursa Province containing Gemlik region is feasible for the WPP investments.

Energy transmission lines and transformer stations in Bursa Province is given in Fig. 10. As shown in Fig. 10, there is a transformer station which is rather close to Gemlik region and it is vital parameter for an economical WPP investment due to the fact that it will reduce the initial investment cost.

After analyzing of the roughness formation and distance to ETL and transformer stations in Gemlik region, a wind farm site selection for WPP investment was realised. As shown in Fig. 11, hillside of Gemlik region was chosen for a WPP feasibility study.
5 Vestas V90 commercial wind turbines were installed in the selected region for numerical analysis. The locations of the installed wind turbines are given in Fig. 12.

Wind turbine layout design was carried out by considering wake affect which decrease the energy efficiency of the wind turbines. Turbine layout was performed by considering wind turbine layout proposal as shown in Fig. 13 in order to decrease wake effect.

In addition to the wake affect, energy analysis of the designed wind farm was implemented by considering the air density change with elevation. Energy analysis results of the WPP were obtained as given in Table I. According to Table I, annual energy production (AEP) and capacity factor of the designed WPP were calculated as 30.6 GWh/y and 34.9% respectively. Also, wake loss of the wind farm is 2.301% and it is a satisfactory value for the energy efficiency.

### TABLE I

### IV. CONCLUSIONS

Turkey’s economy has been growing very fast, and this important growth causes a huge energy demand in the country. Turkey as a developing country has noticed the important of the energy to provide the continuity of the production and combat with the other countries. That is why Turkey has been increasing the incentives and the investments towards the renewable energy systems. Wind energy as a renewable energy sources has a vital importance for Turkey’s future since Turkey has a remarkable wind power potential thanks to its geographical position. If the country benefit efficiently from this remarkable source, it will be able to reach the energy management objectives and goals.

In this study, a WPP feasibility study for Gemlik region in Bursa was realised. According to feasibility study, investment of a WPP which has 30.6 GWh/y AEP and 34.9% capacity factor is feasible by 5 number of commercial Vestas V90 wind turbine. However, cost analysis of the designed WPP was not considered in this study. Also, only one analysis was performed to estimate the economical aspect of the WPP. If the cost analysis is done and the numbers of analyses are increased, more reliable results can be obtained.

### V. ACKNOWLEDGEMENT

The authors would like to thank Turkish State Meteorological Service for their support given to this work.

Thermodynamic analysis of the Organic Rankine Cycle and the effect of refrigerant selection on cycle performance

Omer Kaynakli*, Ali Husnu Bademlioglu*, Nurettin Yamankaradeniz*, Recep Yamankaradeniz*

*Department of Mechanical Engineering, Engineering Faculty, Uludag University, Bursa, Turkey

Abstract - The Organic Rankine cycle is a power-generation system for lower temperature ranges in which organic fluids with hydrocarbon components are used instead of water. Organic Rankine Cycles, which are suitable for heat recovery applications at low temperatures, can be used for generating electric energy from various waste heat sources. In this study, a thermodynamic analysis is conducted on an example Organic Rankine Cycle that is used to generate electric energy from a geothermal source. The working fluid to be used in the cycle was selected as R134a, R236fa, R245fa and R600a, which are commonly used. For these selected organic fluids, the required cycle performance to generate 1 MW of energy from the turbine was analyzed according to the geothermal source temperature (90-140°C), and the thermal efficiency of the cycle was calculated. The obtained results are presented comparatively with the help of the graphs. R245fa was defined to be more appropriate for the cycle as a refrigerant at constant work conditions.

Keywords - Organic Rankine Cycle, refrigerant, thermodynamic analysis, cycle performance, thermal efficiency

I. INTRODUCTION

Steam power plants are cycles that use water as refrigerant. Thermodynamic model of these power plants is the Rankine cycle. Rankine cycle transforms thermal energy into work. Water is commonly used in the cycle as a refrigerant and it is preferred in medium and big-size power plants for the generation of electric power.

Whereas the water has significant properties such as being safe, environment-friendly and it can enable high heat transfer, it also has certain disadvantages. Some of these disadvantages are that; it is highly corrosive and it has a rather high freezing temperature. Tchanche et al. [1] investigated the physical and chemical properties, the advantages and disadvantages of water and organic fluids.

In recent years, higher-molecular mass hydrocarbon compound fluids have been used in Rankine cycle instead of water. With the use of these fluids, the systems have been referred to as the Organic Rankine cycle and they have been included in the power generation processes that are most common in thermal, solar and geo-thermal power etc. applications in factories [2]-[4].

Yamamoto et al. [10] showed that; in Rankine cycle, the utilization of the fluid R123 instead of water could provide a higher performance value. Lui et al. [11] investigated the impact of the critical temperature of organic fluids on performance. Teng et al. [12] classified the organic dry type fluids.

R245fa, which is one of the isentropic fluids, have become popular recently and there are numerous theoretical and experimental studies on it [13]-[14]. Cihan [15] modeled a system in which the organic Rankine cycle that operates with low-temperature waste heat is combined with the traditional vapor-compression refrigeration cycle. He used R600, R600a and R601 as fluid.

Pulyaev et al. [16] conducted the thermodynamic analysis of the generation of electricity through the organic Rankine cycle by making use of the waste heat that comes out during the transfer of the natural gas to the turbine once it has been pressurized in the combined cycle plant. Ozden and Paul [17] investigated the Sarayköy Geothermal Power Plant which generates electricity through the organic Rankine cycle.

TABLE I
This paper discusses the thermodynamic analysis of a sample Organic Rankine cycle that generates electric power through a geothermal resource. The fluids to be used in the cycle were determined as R134a, R236fa, R245fa and R600a. For these organic fluids, the cycle performance required to obtain 1 MW work from the turbine was analyzed based on the temperature of the geo-thermal resource (90-140°C) and the thermal efficiency was measured. R245fa was defined to be more appropriate for the cycle as a refrigerant at constant work conditions.

II. MATERIAL AND METHOD

A. Organic Rankine Cycle

Organic Rankine cycles function with the same principle as Rankine cycles in terms of thermodynamics. The only difference between Organic Rankine cycles and Rankine Cycles is the fact that; the fluid is an organic fluid that evaporates in lower temperatures compared to water. The cycle consists of a pump, evaporator, turbine and condenser. The turbines used in Organic Rankine cycles only need a single step expansion and thus, they are more practical and economical compared to the conventional steam turbines.

The schematic diagram of the organic Rankine cycle used to generate electric power from various thermal sources (such as bio-mass, geo-thermal, exhaust gases etc.) is given in Fig. 1. The Fig. 2 presents the T-s diagram of the cycle.

Fig.1 Schematic diagram of the Organic Rankine cycle

Fig. 2 T-s diagram of the Organic Rankine cycle

An Organic Rankine cycle technology that is based on the system that generates electricity from heat uses the heat of the hot source in order to evaporate the organic fluid inside the evaporator. The pressurized vapor is then delivered to the turbines. The fluid that is in vapor state at high temperature and pressure expands isentropically in the turbine, it rotates the turbine shaft attached to the electric generator and produces work. The pressure and temperature of the vapor are reduced during this process and they take their last states to enter the condenser. The vapor that comes out of the turbine is mostly a saturated liquid-vapor combination that is highly dry. Then the vapor gives heat to a lake, river or to the atmosphere in a condenser which is a great heat exchanger, indeed and gets condensed at constant pressure.

The vapor that comes out of the condenser as a saturated liquid enters into the pump and here, it is isentropically compressed up to the evaporator operating pressure. Due to the slight reduction observed in the specific volume of the fluid, the temperature of the fluid increases slightly. The organic fluid that comes out of the pump enters into the evaporator as a compressed liquid and it completes the cycle.

B. Thermodynamic Analysis of the Organic Rankine Cycle

For the thermodynamic analysis of the Organic Rankine cycle, the first law equations were used to estimate the performance of each element in the cycle and to detect the thermal efficiency of the cycle [18]-[20].

1) Turbine: As isentropic expansion occurs in the turbine between 1 and 2s,

\[ Q_{12s} = 0 \quad , \quad s_1 = s_2 \]  

If the first law of thermodynamics is applied on the turbine,

\[ Q_{12s} - W_{T12s} = h_{2s} - h_1 = \dot{m} (h_{2s} - h_1) \]  

Necessary arrangements are made to calculate the isentropic turbine work through the following equation:

\[ W_{T12s} = \dot{m} (h_1 - h_{2s}) \]  

The actual turbine work and the actual enthalpy value at the turbine exhaust from 1 to 2 is calculated through the following equation:

\[ \eta_{T, isen} = \frac{W_{T12}}{W_{T12s}} = \frac{(h_1 - h_2)}{(h_1 - h_{2s})} \]  

In this equation; \( W_{T12} \) means the isentropic turbine work, \( W_{T12s} \) means the actual turbine work and \( \eta_{T, isen} \) means the isentropic efficiency of the turbine.

2) Condenser: Between 2 and 3, the heat is emitted from the condenser at constant pressure and there is no work exchange during this time.

\[ W_{23} = 0 \]  

\[ Q_{con} = Q_{23} = \dot{m} (h_2 - h_3) \]  

The heat emitted at the condenser is delivered to the cooling water at thermal power plants. Thus; the amount of cooling water required for the condensing process is calculated through the following equation:

\[ Q_{con} = \dot{m}_w c_w (T_{in} - T_{out}) \]
In this equation; \( m \) means the amount of the cooling water, \( c \) means the specific heat of the cooling water, \( T_{in} \) and \( T_{out} \) mean the inlet and outlet temperatures of the cooling water.

3) Pump: Between 3 and 4s, isentropic compression occurs in the pump. The fluid used in the pump is deemed as an incompressible fluid (\( v_3 = v_4s = \text{constant} \)) and the specific work (the work required to compress unit mass of working fluid) of the pump is calculated through the following equation:

\[
-w_{P34s} = \int v \, dP = v_3 (P_4 - P_3) = h_{4s} - h_3
\]

As in this expression the specific volume of the fluid and the inlet-outlet pressures of the pump are known, the specific work of the pump is easily found. Also by making use of the equation (8), the specific pump work is found and the enthalpy of the fluid at the outlet of the pump is calculated through the following equation:

\[
h_{4s} = v_3 (P_4 - P_3) + h_3
\]

The actual pump work between 3 and 4 and the enthalpy value at the outlet of the pump is calculated through the following equation:

\[
\eta_{P,isen} = \frac{\dot{W}_{P34s}}{\dot{W}_{P34}} = \frac{(h_{4s} - h_3)/(h_4 - h_3)}{(h_{3s} - h_3)/(h_4 - h_3)}
\]

In this equation; \( \dot{W}_{P34s} \) is the isentropic pump work, \( \dot{W}_{P34} \) is the actual pump work and \( \eta_{P,isen} \) is the isentropic efficiency of the pump.

4) Evaporator: Between 4 and 1, the hot source is used to deliver heat to the organic fluid at constant pressure. The amount of heat delivered to the evaporator is calculated through the following equation:

\[
\dot{Q}_{vap} = \dot{m} (h_1 - h_4)
\]

The amount of heat delivered to the evaporator from the hot source is calculated through the following equation:

\[
\dot{Q}_{vap} = \rho_{\text{water}} V_{\text{water}} C_{\text{water}} \Delta T
\]

Here; \( \Delta T \) is the temperature difference between the hot source and its surrounding.

5) Thermal Efficiency of the Cycle: When performing the thermal calculations of the elements that make up the cycle, the thermal efficiency of the cycle is calculated through the following equation:

\[
\eta_{\text{thermal}} = \frac{\dot{W}_{\text{net}}}{\dot{Q}_{\text{vap}}} = (\dot{W}_{T12} - |\dot{W}_{P34}))/\dot{Q}_{\text{vap}}
\]

III. RESULTS AND DISCUSSION

The design parameters and working conditions to be used for the thermodynamic analysis of the system elements are presented in Table II.

<table>
<thead>
<tr>
<th>Parameters</th>
<th>Values</th>

</tr>
</tbody>
</table>

In the thermodynamic analysis that was made using the parameters given in Table II, the turbine inlet temperature was defined based on the temperature of the geothermal resource and was taken as 5°C lower than the temperature of the geothermal resource. As for the turbine inlet pressure, saturation pressure was taken as 10°C lower than the temperature of the geothermal resource.

Based on the temperature of the geothermal resource, variation of flow rate of refrigerant that is required to obtain 1 MW turbine work is given in Fig. 3 for constant working conditions. As seen in Fig. 3, the flow rates of each four refrigerants decrease based on the increasing temperature of the geothermal resource. R236fa is the fluid with the highest flow rate required for 1 MW turbine work whereas R600a is the fluid with the lowest flow rate.

Based on the temperature of geothermal resource, variation of amount of heat supplied to the evaporator that is required to obtain 1 MW turbine work is given in Fig. 4 for constant working conditions. As seen in Fig. 4, for each of the four refrigerants, the amount of heat supplied to the evaporator from the geothermal resource decreases depending on the increase observed in the temperature of the geothermal resource.

When R245fa and R600a are used in the cycle as refrigerants, the amounts of heat delivered to evaporator depending on the temperature of the geothermal resource are very close to each other and the amount of heat delivered to the evaporator is lower compared to the other two refrigerants. The amount of heat delivered to the evaporator from the geothermal resource is higher when R236fa is used within an approximate range of 95-120°C geothermal resource temperature and when R134a is used outside this range (Fig. 4).
Based on the temperature of the geothermal resource, variation of flow rate of geothermal resource that is required to obtain 1 MW turbine work for different refrigerants. As the pump’s specific heats remains constant at critical pressure, the required pump work decreases depending on the increasing geothermal resource temperature.

Based on the temperature of geothermal resource, variation of amount of heat required to be exhausted from the condenser to obtain 1 MW turbine work is given in Fig. 7 for constant working conditions. For each of the four refrigerants, the amount of heat required to be exhausted from the condenser decreases depending on the geothermal resource temperature. When R245fa and R600a are used as fluids, the amount of heat required to be exhausted from the condenser is higher when R236fa is used within an approximate range of 95-120°C geothermal resource temperature and when R134a is used outside this range (Fig. 7).

For different refrigerants, variation of thermal efficiency of the organic Rankine Cycle that provides the performance required to obtain 1 MW turbine work is given Fig. 8 based on the temperature of geothermal resource. For each of the four refrigerants, the thermal efficiency of the cycle increases
These refrigerants are lower compared to other refrigerants. Hence, the amount of heat exhausted from the condenser are very close to each other and these are lower compared to other refrigerants. R236fa is the fluid with the highest flow rate. R245fa should be preferred as the refrigerant as the thermal efficiency of the cycle would be higher. Normally at constant working conditions when the temperature of the geothermal resource increases the thermal efficiency of the cycle increases as well.

The flow rates of the refrigerant to be used in the cycle show that; the refrigerant with the lowest flow rate that is required to obtain 1 MW turbine work is R600a whereas R236fa is the fluid with the highest flow rate. When R245fa and R600a are preferred as refrigerants, the amounts of heat exhausted from the condenser are very close to each other and these are lower compared to other refrigerants. Hence; the amount of cooling water required for the condensing process is expected to be lower with respect to these refrigerants.

### IV. CONCLUSIONS

There are numerous factors that influence the performance of Organic Rankine cycles. Selection of the refrigerant to be used in the cycle is one of the most significant of these factors. In this analysis performed for the specific conditions, R245fa should be preferred as the refrigerant as the thermal efficiency of the cycle would be higher. Normally at constant working conditions when the temperature of the geothermal resource increases the thermal efficiency of the cycle increases as well.

The flow rates of the refrigerant to be used in the cycle show that; the refrigerant with the lowest flow rate that is required to obtain 1 MW turbine work is R600a whereas R236fa is the fluid with the highest flow rate. When R245fa and R600a are preferred as refrigerants, the amounts of heat exhausted from the condenser are very close to each other and these are lower compared to other refrigerants. Hence; the amount of cooling water required for the condensing process is expected to be lower with respect to these refrigerants.

Abstract - Many industrial processes deal with reducing production costs and energy consumptions. Additionally, increase in energy demand is becoming a highly challenging issue in past decades. Therefore, strategies on significant energy savings in industries are required. Moreover, a great focus on climate change is needed for greenhouse gas emissions.

Seydişehir ETİ Aluminium Plant (SEAP) is a highly energy consumer plant in the regional area. This is mainly due to the current technology used. The alumina refinery commenced mass production by 1973 and the smelter unit started to work in 1974 utilizing Söderberg cell technology (SCT). Previously in SEAP, alumina was manually added to each pot in large quantities. This was labour intensive and harmful to thermal balance and current efficiency. Additionally, it caused more specific energy consumptions and environmental emissions.

Within the modernization of smelter unit, SEAP changed SCT to Pre-baked technology and began to use an "Environmentally-friendly" system. In the process, the pot does not encounter large variations in alumina concentration. This caused a 26.5% reduction in specific energy consumption and decrease in PFC emissions. Furthermore, expansion in production amount, increase in amperage and improved current efficiency were obtained. Another on-going modernization operation in SEAP is the installation of a stationary calciner with high thermal efficiency to replace the conventional rotary kiln. This is expected to bring about 26.1% reduction in specific energy consumption. Moreover, SEAP is planning to change its direct heating technique with live steam injection in the digestion process to decrease the evaporation energy consumption by about 13%.

This study mainly shows the effects of these improvements on energy savings and current efficiencies. Energy and exergy analyses of digestion, evaporation and calcination units in SEAP were also discussed. Recommendations within the study enable the process more efficient, profitable, productive and feasible while having lower energy consumptions.

Keywords - Alumina calcination/electrolysis, bauxite digestion, energy and exergy analysis, Pre-baked technology, Söderberg technology.

Introduction

The Hall-Héroult process is a high temperature process takes place in the smelter unit that has a distinguished mutually dependent relation between the mass and thermal balance. These two effects bring a significant dependence of the system performance on the thermal balance. A well-computed thermal balance provides proper melting of charged materials, keeps the ledge in a desired level, avoids the sludge formation and this will result in better process efficiency [1].

As the operating conditions have been tightened in the past decades due to the requirement for optimization of current efficiency and reducing energy consumption, it becomes more important to keep the thermal balance as stable as at a desired level from operational and control point of view [1].

Bayer process is also highly energy consumer process used for the alumina production that has a remarkable importance on energy efficiency from both an economic standpoint, with the drive to continually reduce operating costs and also from an environmental perspective, with the greater focus on climate change due to greenhouse gas emissions [2].

Seydişehir ETI Aluminium Plant (SEAP) alumina refinery commenced mass production by 1973 and the smelter unit started to work in 1974 with 248 reduction cells in four potlines utilizing Söderberg cell technology (SCT). In the previous years of SEAP, alumina was manually added to each pot in large quantities. This was labour intensive and harmful to thermal balance and current efficiency. Additionally, it caused more specific energy consumptions and environmental emissions.

After a Greenfield investment for the smelter unit modernization, SEAP took the opportunity to convert SCT to Pre-baked technology and began to use an "Environmentally-friendly” system. In the process, the Pre-baked system consists of 94 reduction cells with 300 kA pot capacity and it does not encounter large variations in alumina concentration. This caused a 26.5% reduction in specific energy consumption and decrease in PFC emissions. Furthermore, expansion in production amount, increase in amperage and improved current efficiency were obtained. Another on-going modernization operation in SEAP is the installation of a stationary calciner with high thermal efficiency to replace the conventional rotary kiln. This is expected to bring about 26.1% reduction in specific energy consumption. Moreover, SEAP is planning to change its direct heating technique with live steam injection in the digestion process to decrease the evaporation energy consumption by about 13%.
This study aims to show energy and exergy analysis of the SEAP both Hall-Héroult process and Bayer process take into account SCT and Pre-baked system, boiler house, digestion, evaporation and calcination processes with the following potential improvements:

i. With the conversion of the SCT to Pre-baked system, there is a gain about 10 GJ per tonne of Aluminium metal in terms of electricity usage.

ii. An almost assured energy improvement can be achieved by replacing conventional rotary kiln with stationary calciner with high thermal efficiency, for an energy efficiency gain of 1.5 GJ per tonne of alumina (Al₂O₃).

iii. The indirect digestion heating process should be applied for the SEAP Bayer digestion system to save energy and increase the efficiency. Direct steam injection to the digesters (autoclaves) adds unnecessary dilution that has to be removed by additional evaporation, resulting in capital and operating cost impacts, and production losses. This will enable sending live steam condensate from digestion process back to the boiler house as boiler feed water and the decrease in evaporation discharge liquor caustic concentration range due to the elimination of additional bauxite slurry dilution in digestion.

Basically the analyses of heat flow diagrams of complex chemical processes consider only the first law of thermodynamics. The size of the energy input from an external source is accepted as an absolute measure of a process. A sum of entropy increments of all the heat transfers and assumed to not produce any useful work. As far as only the first law of thermodynamics is taken into consideration, the heat flow diagram heat efficiency is used as the criterion of thermodynamic perfection [3].

The First Law of Thermodynamics is conventionally used to analyse energy consumption and determine the plant performance. However, it comes up short to judge the quality of energy therefore it is required to conduct a overall exergy analysis. Exergy analysis, as a result of the Second Law of Thermodynamics, can measure the quality of energy in a process industry, and has been carried out for various industries [4]. The exergy is a property that determines the useful work potential of a given amount of energy in a specific state [5]. In a wider sense, one can say that exergy is the capacity to do work.

According to the Second Law of Thermodynamics, any heat process is characterized by growth of system entropy. The incremental system entropy can serve as an absolute criterion of thermodynamic perfection in the analysed heat process. A sum of entropy increments of all the heat-using elements defines a supply of energy from an external source, for example, a thermal power station [3].

The thermodynamic analysis of a system can be conducted according to the so-called exergy method [3].

Exergy analysis of a system and its stages includes calculation of exergy losses at any process steps, shares of external exergy losses, and exergy efficiency. Put another way, it is the analysis of size and quality of secondary power resources and expediency of their utilization [3].

I. EXERGY ANALYSIS METHODOLOGY ON A CHEMICAL PROCESS

The exergy of a non-isolated system is the maximum work that can be extracted from this system during a process that brings the system into thermodynamic equilibrium with its environment. By choosing as a surrounding medium for all systems the environment of our planet, exergy, which is measured in energy units, can become a universal measure of the quality of matter and energy. In general, exergy can be defined as the resource consumed by dissipative structures to produce structure/information and remain in states far from thermodynamic equilibrium with their environment or the resource consumed by decaying structures as they proceed to thermodynamic equilibrium with their environment [6].

For matter that is not fuel, the standard chemical exergy (eᵢₒ) can be calculated from its theoretical reaction of formation at the environmental standard state (Tₒ, Pₒ)

\[ aA + xX + yY \rightarrow AaXxYy \]  

(1)

according to relationship

\[ e^0_i, AaXxYy = \Delta G^0_i, AaXxYy (T_o) + \sum v_i e^0_i \]  

(2)

where \( \Delta G^0_i, AaXxYy (T_o) \) is chemical free energy of formation of the substance, \( v_i \) is the stoichiometric coefficient, and \( e^0_i \) is the standard chemical energies of element \( i \) [6].

The standard chemical exergy of elements is related to reference substances found more commonly in the environment and are given in literature [6].

The chemical exergy of solution containing \( n \) chemical species at the environmental state (\( Tₒ, Pₒ \)) is

\[ e_x = \sum n_i e^0_{x,i} = \sum n_i e^0_{x,i} + RT_o \sum n_i ln(y_{x,i})x_i \]  

(3)

The thermomechanical exergy of matter \( e_{p,T} \) which is the exergy of matter due only to its differences in pressure and temperature from the environment, is

\[ e_{p,T} = h - h_o - T_o(s - s_o) = \Delta h - T_o \Delta S \]  

(4)

where \( h, s \) are the specific enthalpy and entropy of matter at \( T, P \) and at \( Tₒ, Pₒ \) [4].

Finally the total exergy of a solution at conditions \( T, P \) different from the environmental state is

\[ e = e_x + e_{p,T} \]  

(5)
Moreover, chemical exergy allows the definition of a thermodynamic efficiency coefficient for any process, based on a simple exergy balance,

$$E_{\text{in}}^{\text{tot}} = E_{\text{out}}^{\text{tot}} + D^{\text{tot}}$$  \hspace{1cm} (6)

where $E_{\text{in}}^{\text{tot}}$, $E_{\text{out}}^{\text{tot}}$ are the total exergy flows entering and exiting the system (a steady state process is assumed), and $D^{\text{tot}}$ is the total exergy losses or exergy consumption or waste heat due to irreversible processes inside the system (internal losses) and between the system and the environment (external losses). According to the Guy-Stolola equation and the Second Law of Thermodynamics

$$D^{\text{tot}} = T_0 \Delta S^{\text{tot}} \geq 0$$  \hspace{1cm} (7)

where $\Delta S^{\text{tot}}$ is the total increase in entropy in both system and environment [4].

By dividing the exergy outflow $E_{\text{out}}^{\text{tot}}$ into products and wastes (e.g., chemical wastes) according to equation

$$E_{\text{out}}^{\text{tot}} = E_{\text{product}}^{\text{tot}} + E_{\text{waste}}^{\text{tot}}$$  \hspace{1cm} (8)

The efficiency of the processes can be defined as

$$\eta_{\text{ex}} = \frac{E_{\text{product}}^{\text{tot}}}{E_{\text{in}}^{\text{tot}}} \quad 0 \leq \eta_{\text{ex}} \leq 1$$  \hspace{1cm} (9)

II. OVERALL EXERGY ANALYSIS OF THE SEAP

In the context of the thermodynamic laws, SEAP both Bayer process and Hall- Héroult process exergy analysis is performed by calculating the chemical exergy values for all the compounds that are used in the process. The Bayer process in total is characterized by very low exergy efficiency as large amounts of exergy are spent solely to achieve the chemical extraction of alumina from the bauxite and the precipitation of alumina as aluminium hydroxide [7]. To understand the reasons for this exergetic inefficiency, a closer look in the process is required. First of all there is an internal inefficiency in the chemical process itself, as in process of boehmite digestion, liquefication, gibbsite precipitation and evaporation, as well as alumina calcination [6]. Similarly, Hall-Héroult process is also one of the great energy consumer which is mainly electricity power, in the process the electrolytic bath is a molten solution of cryolite and alumina.

The SEAP Bayer process is essentially a cyclic process designed to extract the alumina from the boehmite bauxite ore through caustic leaching under high temperature conditions and controlled precipitation, according to the simplified reaction scheme:

$$2\text{Al}_{2}\text{O}_{3} \cdot \text{H}_{2}\text{O} \_{\text{bauxite}} + 2\text{NaOH} \_{\text{aq}} \rightarrow 2\text{NaAlO}_{2} \_{\text{aq}} + 4\text{H}_{2}\text{O} \_{\text{l}} \rightarrow \text{Al}_{2}\text{O}_{3} \cdot 3\text{H}_{2}\text{O} \_{\text{s}} + 2\text{NaOH} \_{\text{aq}}$$

Also the Hall-Héroult process is the electrolytic process to produce molten aluminium. In this process, alumina (Al$_2$O$_3$) is dissolved in a molten cryolite (Na$_3$AlF$_6$) bath at around 960 °C where it is reduced to produce liquid aluminium metal and oxygen ions. The liquid aluminium metal is slightly denser than the electrolyte and is continuously deposited at the bottom of the cell while the oxygen reacts with the carbon anode to form CO$_2$. The simplified overall cell reaction is [8]:

$$2\text{Al}_{2}\text{O}_{3} \_{\text{solution}} + 3\text{C} \rightarrow 4\text{Al} \_{\text{l}} + 3\text{CO}_2 \_{\text{g}}$$

The calculated previous and current overall mass and exergy analysis of the SEAP for 1 tonne liquid aluminium produced is given in below tables and figures.

</table>

In the SEAP Bayer process, alumina is extracted from boehmitic bauxite with a sodium hydroxide solution, under a pressure of 4 MPa and at elevated temperature (250 °C), in autoclaves (digestion stage). The produced slurry contains dissolved sodium aluminate and a solid residue (red mud), which is removed in thickeners (clarification stage). The aluminate solution is then seeded with gibbsite (aluminium tri hydroxide) at 60 °C to accelerate the precipitation of gibbsite (precipitation step).

Finally the precipitated aluminium hydroxide is removed from the solution and is calcined at 1000 °C to produce powdered, smelter and commercial grade metallurgical alumina (calcination step).
In the Hall-Héroult process, aluminium is produced by the electrolytic reduction of metallurgical grade alumina, which is dissolved in a molten bath consisting mainly of cryolite (Na$_3$AlF$_6$), at a temperature of about 960°C. Consumable carbon anodes and a potential of voltage are employed in the reduction cell to produce molten aluminium.

evaporating liquor will be significantly decreased. The current situation and expected future conditions are shown in Fig. 3. In the SEAP Bayer Process the evaporation area uses steam at 6.5 bar pressure and a temperature of 190 °C, supplied from the boiler house.

![Image](40x562 to 292x719)

**Fig. 3** Evaporation discharge liquor caustic concentration vs. specific steam consumption

The SEAP calcination area can be somewhat quantified, with existing rotary kiln technology achieving typically 3.5 – 4.5 GJ/tAl₂O₃, while the more modern stationary calciner achieve 2.8 GJ/tAl₂O₃. That is why SEAP has already determined the need for investment on a new type stationary calciner to replace the high energy consuming rotary kilns. The comparison of energy consumption of rotary kiln and stationary calciner technology is given below [9, 10]:

</table>

The newly built SEAP Pre-baked system consume 1300 kWh (DC) electricity, 0.41 t carbon anodes per tonne of liquid aluminium metal, compared with the previous Söderberg system which used to consume 1600 kWh (DC) electricity, 0.55 t carbon anodes per tonne of liquid aluminium metal, nearly 19 % reduction in electricity consumption and about 27 % decrease in carbon anode usage. Also the benefits of reasonable thermal balance should be beard in mind.

**IV. CONCLUSIONS**

The exergy analysis preformed in this study clearly indicates that radical changes are needed both in digestion and calcination processes, in order to achieve major benefits supported with the latest technological opportunities in the energy and exergy efficiency of the industry. In this study energy intensive areas in the SEAP Bayer process and the increment of energy efficiencies with possible improvements for each process step is showed. The contribution of the proposed improvements on energy efficiency for both digestion and calcination processes were evaluated and the total benefits in terms of exergetic efficiencies were determined.

Within the modernization of smelter unit caused a 26.5% reduction in specific energy consumption. This has facilitated expansion in production amount, increase in amperage, improved current efficiency and reduction in specific energy consumption and decrease in PFC emissions [11]. Therefore, the cell does not encounter big changes in alumina concentration which extremely help improving performances.

Currently total energy consumption of SEAP Bayer process is around 14.6 GJ/t Al₂O₃, which is slightly higher compared to other boehmitic bauxite processing alumina refineries. The roadmap for SEAP is to perform major changes in the calcination and digestion units. For this reason, SEAP has initiated the replacement of existing rotary kilns with stationary calciner to bring down energy consumption of its calcination process from 3.8 to 2.8 GJ/t Al₂O₃, which also means nearly a 26 % reduction in specific energy consumption.

In the near future, SEAP will change its direct heating technique with live steam injection in the digestion process to indirect heating system to decrease evaporation energy consumption by about 1.4 GJ/t Al₂O₃, and increase the productivity of boiler house by using less live steam for heating of boiler feed water.

The total gain for SEAP in terms of energy savings will be about 2.5 GJ/t Al₂O₃ and exergy efficiency of the process will be improved nearly 17 %. With its own capability, SEAP produces 1 GJ energy for about 8 US$, therefore the total savings will be around 20 US$/t Al₂O₃ with the 15.4 % internal rate of return (IRR) according to financial analysis. Considering the 2.5 GJ/t Al₂O₃ decrease in total energy consumption in the Bayer process, SEAP will improve its energy efficiency ranking among the alumina production plants in the world at 12 GJ/t Al₂O₃.

Abstract— In this study, investigated effect on performance, emission and combustion characteristics of fuel obtained with adding bioethanol to safflower oil biodiesel – diesel fuel blends in a diesel engine which has single cylinder, direct injection and water cooling. The prepared test fuels are coded as diesel fuel (DF), BD10 (90% diesel fuel + 3% biodiesel), BDE5 (85% diesel fuel + 10% biodiesel + 5% bioethanol) and BDE10 (80% diesel fuel + 10% biodiesel + 10% bioethanol). Engine tests were performed different engine speeds (1000 min−1 – 3000 min−1, ranges of 200 min−1) at full throttle condition. As the results, observed that engine performance values were effect as negative from biodiesel and bioethanol. HC emission is decreased by adding biodiesel to diesel fuel, and it’s increased some with adding bioethanol. The observed that reduced to smoke emission of using biodiesel, and it’s decreased rather with using bioethanol. NO emission values increased due to biodiesel are decreased by adding bioethanol.

Keywords— Safflower oil, engine performance, exhaust emissions, biodiesel, bioethanol.

I. INTRODUCTION

Biodiesel is a promising substitute for mineral diesel as it is renewable, non-toxic, easily biodegradable and contains physicochemical properties that are very close to that fossil fuel. Therefore, biodiesel has been widely proposed as a substitute for mineral diesel fuel, presenting good results in terms of flammability and lower environmental impacts of exhaust emissions in compression ignition engines [1].

Alcohols have been widely used in compression ignition engines as alternative fuels. Although alcohols are cheaper than standard diesel fuel, there are challenges with respect to utilization of alcohols in diesel engines and blending these fuels with diesel [2]. Because of its high octane number, ethanol (CH₃CH₂OH) is a good spark-ignition engine fuel, but it is true that it has been considered (rather vividly) and experimented also as alternative fuel in diesel engines, as reported in recent review paper [3]. It is a biomass based renewable fuel, which can be produced by alcoholic fermentation of sugar from various vegetable materials or agricultural residues [4].

Labeckas et al. worked effects on combustion, performance and emissions of ethanol–diesel–biodiesel blends. According to results, maximum heat release rate (MHRR), maximum combustion pressure (MCP), NOx, CO emissions and smoke opacity increased with used of blend fuels [5]. Kim et al. investigated effect on exhaust emissions of biodiesel and bioethanol blended diesel fuel on a CRDI engine. Test results showed that biodiesel increased CO and NOx emissions although it decreased THC, smoke and PM emissions. Also CO, THC and NOx emissions were increased, and smoke and PM emissions were decreased by addition bioethanol [6]. Fang et al. tested effects of ethanol-diesel-biodiesel blends on combustion and emissions in premixed low temperature combustion. According to results of their study, blend fuels decreased NOx, smoke emission but, it increased CO and HC emissions. However, MCP and MHRR values increased with used of biofuels [7]. Tse et al. investigated effects on the combustion characteristics and particulate emissions from a diesel engine fueled with diesel-biodiesel-ethanol blends. According to test results, biodiesel and bioethanol increased MCP and MHRR, and they decreased PM emissions [8].

II. MATERIAL AND METHODS

A. Test Fuels

Biodiesel used in tests was produced from safflower seed oil with transesterification method. Also, bioethanol was produced from sugar beet of Cumra Sugar Integrated Plant. The prepared test fuels are coded as diesel fuel (DF), BD10 (90% diesel fuel + 3% biodiesel), BDE5 (85% diesel fuel + 10% biodiesel + 5% bioethanol) and BDE10 (80% diesel fuel + 10% biodiesel + 10% bioethanol). The properties of test fuels are given in Table 1.

C. Experimental Method

Engine tests were performed at different engine speeds (1000 rpm – 3000 rpm, ranges of 200 rpm) at full throttle condition. In-cylinder pressure values of a minimum of 50 engine cycles at a precision of 1° crank angle (CA) were recorded by a computer using the data-logger.

III. TEST RESULTS

A. Engine Performance

Figure 1 show that changes depending on the engine speed of specifically fuel consumption (SFC) and thermal efficiency values. The SFC values with used of biodiesel were increased 5.7% on average compared to DF, and they were further increased down to 23% on average by used of bioethanol. Both biodiesel and bioethanol decreased thermal efficiency values as down to approximately 14.87% on average.

Figure 2a and 2b show that cylinder pressure and heat release rate resulting at 1400 rpm engine speed obtained at maximum torque. The MCP values of blend fuels were higher than that DF. Especially, bioethanol increased MCP values. Both biodiesel and bioethanol, same way, increased the MHRR values.

B. Combustion Characteristics

Oxygen content in both biodiesel and bioethanol increased combustion rate of fuel. Therefore, blend fuels burned faster than DF, and in this case MCP and MHRR increased. This result were compatible with studies of Alptekin et al. [12], Su et al. [13] and Anbarasu et al. [14].

C. Exhaust Emissions

Figure 3, 4 and 5 show that changes of exhaust emissions. Biodiesel increased NO emissions although it decreased HC and smoke opacity emissions. Biodiesel increased NO emissions as 15.67% on average, decreased HC and smoke opacity values as 22.98% and 3.93% on average respectively, due to its oxygen content. Besides, while bioethanol increased HC emissions as up to 82.14 on average, it decreased NO emissions and smoke opacity values as down to 47.55% and 13.14% on average respectively, due to high combustion rate and low combustion temperature. Yilmaz et al. [2], Rounce et al. [15] and Mofijur et al. [16] also presented similar results in their studies.
The results of this study can explain:

- The use of biodiesel–diesel blends decreased the HC and smoke opacity emissions but increased NO emissions, as the oxygen content of the fuel increased.
- The use of bioethanol increased the HC but decreased NO emissions and smoke opacity.

As results, biodiesel and bioethanol may use in diesel engines by biodiesel and bioethanol mixed with diesel fuel.

Abstract— Last decades with rapidly penetration of distributed energy resources to the power system, the interest on microgrid is growing. Microgrid appears with the development of distributed generations and distributed energy resources, such as PV, wind, microturbines, fuel cell, combined heat and power, etc. A microgrid combines distributed energy resources, storage devices (flywheels, energy capacitors and batteries) and flexible loads, and connected to the power grid via switches. Microgrids as a key component of the smart grid are intended to improve energy efficiency, a reliability of power system and decrease carbon dioxide emissions. Uzbekistan has a huge potential of renewable energy resources, especially in solar energy. In this paper are introduced the concept and operation of microgrid, as well as considered the problems and development perspectives of microgrid in Uzbekistan.

Keywords— microgrid, smart grid, distributed energy resources, distribution generation, Uzbekistan

I. INTRODUCTION

The energy sector is a key infrastructure element of the economy of Uzbekistan. An operation and development of this infrastructure largely determines the living conditions of the population and the country's economic development. The population’s growth and economic development of Uzbekistan as well as in many countries require an increase in demand for electrical energy. On the other hand, meeting the need for electric energy society in the future should be, given the limitations of non-renewable resources, while providing energy stability and significantly reducing the negative impact on the environment. Power systems operation becomes more labor-consuming, which ultimately will require the widespread introduction of intelligence in the interest of safety, economy and efficiency, thereby creating the preconditions for the emergence of "Smart Grid" concept. These problems have led to a new concept of Smart Grid. According to the European Technology Platform of Smart Grids [1], a smart grid (SG) is an electricity network that meets future requirements for energy-efficient and economical operation of the power system through the coordinated management and using modern two-way communications between the elements of electrical networks, power plants, accumulating devices and consumers. Microgrid (MG) is a basic element of SG and as a key component of the smart grid are intended to improve energy efficiency, the reliability of power system and decrease carbon dioxide emissions. The term microgrid refers to the concept of single electrical power subsystems associated with a small number of distributed energy resources (DERs), both renewable and/or conventional sources, including photovoltaic, wind power, hydro, internal combustion engine, gas turbine, and microturbine together with a cluster of loads [2]. Last decades with rapidly penetration of DER to the power system, the interest on MG is growing.

II. MICROGRID DEFINITION AND CONCEPT

The pioneers of MG the Consortium for Electric Reliability Technology Solutions (CERTS) and the European Commission Project Micro-Grid gave the following definitions to MG:

According to the CERTS [3], “Microgrid is the cluster of loads and microsources operating as a single controlled entity and providing both power and heat energy. The microgrids are power electronically interfaced as they enhance the power reliability and quality of the power supply”. A vision of MG by CERTS is illustrated in fig.1.

According to the EU research projects [4], [5]: “Microgrids comprise LV distribution systems with distributed energy resources (DER) (microturbines, fuel cells, PV, etc.) together with storage devices (flywheels, energy capacitors and batteries) and flexible loads”. A vision of MG by EU research projects is illustrated in fig.2.

The main components of MG are:
• distributed generation (DG) sources such as photovoltaic panels, small wind turbines, fuel cells, diesel and gas microturbines etc.;
• distributed energy storage devices such as batteries, supercapacitors, flywheels etc.;
• critical and non-critical loads.
In general, literature analyses [8], [9] identified that microgrid architectures divided into three categories: AC, DC, and hybrid microgrids.

MG can be operated:
1) in stand-alone or islanded mode, if MG operates autonomously;
2) in grid-connected mode, if MG connected to the main grid.

In stand-alone mode, microsources provide loads with necessary power energy and MG never connects to the main grid.

In grid-connected mode, MG remains connected to the main grid either totally or partially and extra power generated in MG can be exchanged with the main grid providing auxiliary services.

MG consists of a group of radial feeders (A, B and C), which could be part of a distribution system architecture and a collection of loads (figure 3). The radial system is connected to the distribution system by a point of common coupling (PCC) via a static switch. The PCC is on the primary side of the transformer and separates main grid from MG. Each feeder has a circuit breaker and microsource controller [6].

Fig. 3 Schematic diagram of the microgrid.

IV. BENEFITS AND ADVANTAGES OF MICROGRIDS

There are several technical benefits of MG:
- the lack of vulnerability of large networks
- power blackouts reduction
- energy loss reduction
- improved voltage quality via coordinated reactive power control and constrained active power dispatch
- relief of congested networks and devices, for example during peak loading through selective scheduling of microsource outputs.

The economic benefits of MG consist:
• higher energy efficiency
• reduced transmission and distribution costs
• minimization of fuel cost
• the small scale of individual investments reduces capital exposure and risk, by closely matching capacity increases to growth in demand.
• the low capital cost potentially enables low-cost entry into a competitive market.

The environmental benefits of MG include:
• reduced emissions of greenhouse gases
• reduced emissions of criteria pollutants.

Researchers note that MG offers a number of important advantages [6], [14], [15]:
• The ability of MG, during a utility grid disturbance, to separate and isolate itself from the utility seamlessly with little or no disruption to the loads within the MG;
• In peak load periods it prevents utility grid failure by reducing the load on the grid;
• Significant environmental benefits made possible by the use of low or zero emission generators;
• The use of both electricity and heat permitted by the close proximity of the generator to the user, thereby increasing the overall energy efficiency;
• MG can act to mitigate the electricity costs to its users by generating some or all of its electricity needs;
• Enhancing the quality of power which is delivered to sensitive loads.

V. DEVELOPMENT ISSUES OF MICROGRID IN UZBEKISTAN

Currently, the majority of energy consumed in Uzbekistan is produced by thermal power plants. At the same time, the main share in the structure of energy consumption belongs to the oil and gas resources. Uzbekistan has substantial proven reserves of organic fuel and a robust hydroelectric potential. It accounts for more than 40% of the entire Central Asia’s natural gas and some 20% of Central Asia’s oil. The proven reserves of condensate oil exceed 350 million tons, of a natural gas reach around 2,000 billion cubic meters, and coal almost 2,0 billion tons. Uzbekistan is among the top ten largest producers of natural gas in the world. Hydrocarbons are the main sources of electricity in Uzbekistan (figure 4).

Experts of the center for economic research believe that country’s proven reserves of hydrocarbons are enough to keep its economy running steadily for the next 20-30 years.

The installed capacity of power plants in Uzbekistan exceeds 12.5 million KW including 10 thermal power plants with a capacity of 11.0 million KW and 29 hydraulic electric stations with capacity of 1.4 million KWh (figure 5) [16].

According to the information of Uzbekistan’s Ministry of Economy, implementation of measures to promote renewable energy resources in the basic sectors of the economy will lead to savings of 250.1 million KWh electric energy, of natural gas – 3 million of cubic meter and heat energy – 20.1 GCal.

The most important factor driving the development of distributed energy in the world as well as in Uzbekistan is the diversification of energy balance by increasing the share of local and alternative energy sources (biomass, renewable energy, etc.), which entails more rational use of strategic resources - hydrocarbons. Therefore, one of the most important areas of energy policy at the present stage is the transition from traditional, centralized model of unified energy system of Uzbekistan with a predominance of large generation sources to a variety of types and forms of harmonious combination of DG in Uzbekistan regions.

Undoubtedly, the development of MG in Uzbekistan requires state support measures aimed at stimulating the expansion of its use. There is required to develop a regulatory
framework providing the development of MG; to create an appropriate methodological basis; to amend the legislation providing customs and tax incentives for the development of MG such as reduction of import duties on equipment, preferential taxation of production.

According to today’s experience and publications, MGs can find its application in Uzbekistan in the major MG market segments such as (i) institutional and campus MGs, (ii) commercial and industrial MGs, (iii) military MGs, (iv) community and utility MGs, (v) island and remote “off-grid” MGs. MG helps the transition from a centralized system using large sources of electricity generation, the use of different types of DER, the most appropriate to natural conditions and features of specific customers.

In the last years some work on the development of renewable energy is carried out in the republic. As part of the regulations and Decrees of the President of the Republic of Uzbekistan from March 1, 2013 # BP-4512 “On measures for further development of alternative energy sources” and # RP-1929 “On creation of the International Solar Energy Institute” Solar Energy Institute established.

The solar PV station with capacity of 130 kW was start of operation on December 7, 2015, in Pap district of Namangan region.

A mobile stand-alone solar power plant with capacity of 1.2 MW has been put into operation in Bukhara region at the beginning of 2016. The station is designed for the continuous provision of energy production facilities and the construction of infrastructure projects Kandym deposits of the Russian company “Lukoil”, staying away from the central power supply networks.

In addition, the works on involving in the fuel and energy balance of renewable energy sources are carried out by Joint Stock Company “Uzbekenergo”. In the medium term, planned construction of solar photovoltaic power plants with a capacity of 100 MW in Samarkand, Namangan and Surkhandarya regions.

VI. CONCLUSIONS

The MG as a basic element of smart grids has an important role to increase the grid efficiency, reliability, and to satisfy the environmental issues. This paper presents the architecture, operation and control of MG.

Uzbekistan has a huge potential for using renewable energy sources and the issues of developing the concept of a microgrid in Uzbekistan have been examined.

The evaluations of gross and technical potentials of renewable energy sources in Uzbekistan give the following conclusions:

- the availability of some types of renewable energy is almost all over the country is required for radical revision of using strategy of national energy resources, both in the near and in the long-term perspective;
- the implementation of MG will be bringing above mentioned technical, economic and social benefits to the economy of Uzbekistan;
- large-scale use of renewable energy sources by switching to a decentralized energy supply would solve a number of problems to improve the energy supply facilities in rural areas, especially in remote inaccessible areas.

Abstract— Blade Element Momentum (BEM) theory is generally used technique for calculation of aerodynamic performance of such turbine application. To obtain close results with blade element momentum theory, aerodynamic data of airfoil has to be as correct as possible. Nowadays, Computational Fluid Dynamics (CFD) is used for optimization and design of turbine application. Lift coefficient, drag coefficient and Lift coefficient over drag coefficient are tried to optimize by XFOIL code results, are compatible with each other until stall angle. Also, lift coefficient over drag coefficient was tried to optimize by changing the airfoil geometry.

Keywords— Xfoil, Computational Fluid Dynamics (CFD), Transition SST k-omega model, low reynold number

I. INTRODUCTION

Airfoil is such an aerodynamic shape and it generates aerodynamic forces. The air passes above and below the wing. Due to the momentum conversation, the speed of air particles on wing’s upper surface increases and also the pressure on the wing’s upper surface decreases due to the energy conversation. Because of that the high air pressure moves toward low air pressure. Air pushes the wing so that the force known as lift force is generated [1].

The point at front of the airfoil is defined as the leading edge. Similarly, the point at behind of airfoil is defined as the trailing edge. The chord length is the characteristic dimension of airfoil section [1].

It is possible to predict aerodynamic performance airfoil by using experimental, Computational Fluid Dynamics (CFD) and a user friendly program such as 2d panel code XFOIL that combines a conformal-mapping method for the design of airfoils with prescribed pressure distributions, a panel method for the analysis of the potential flow about given airfoils, and an integral boundary-layer method [3]. Although experimental and Computational Fluid Dynamics (CFD) methods are more expensive and require longer time than panel method, XFOIL results have less accuracy than experimental and CFD methods due to some assumption.

In this paper, the aerodynamic performance of low Reynolds airfoil SG6040 which is designed exclusively for horizontal wind turbines with small blades [4] is predicted by using XFOIL and ANSYS-FLUENT at two different Reynolds number (Re = 3x10^5, 4x10^6). Firstly, the 2D model of airfoil is generated by using airfoil coordinates. After that, aerodynamic performance of the airfoil is obtained by XFOIL software under General Public License. Domain construction and grid generation for calculating the 2D airfoil performance is described in CFD analysis. Then, the aerodynamic performance is calculated by using CFD methods (in Fluent commercial software). Finally, lift coefficient to angle of attack and drag coefficient to angle of attack of the airfoil obtained by the CFD results, are compared with XFOIL results and also literature.

II. XFOIL AND CFD ANALYSIS

A. SG6040 Airfoil

The low Reynold SG6040 airfoil, investigated in this study, has a maximum thickness of % 16, a camber of 2.5 %. The profile is shown in Fig. 2. This airfoil was designed exclusively for wind turbines with small blades (1-5 kW) [5].

Fig. 1. Basic geometry of airfoil [2]
B. XFOIL

The XFOIL [3] code combines a potential flow panel method and an integral boundary layer formulation for the analysis of the flow around airfoils. The code was developed to rapidly predict the airfoil performance at low Reynolds numbers and its convergence is achieved through the iteration between the outer and inner flow solutions on the boundary layer displacement thickness.

For calculating the airfoil performance in XFOIL coordinates of SG6040 airfoil was loaded to XFOIL. After loading airfoil coordinates, the number of point was defined as 250 point, and also number of iteration was defined as 100 iteration. Then, Reynolds number of the flow was set up as 3x10^5 and 4x10^5. The results were drawn as graph of the lift, drag coefficient versus angle of attack and also pressure distribution around the airfoil can be acquired.

C. CFD Analysis

CFD analysis for aerodynamic performance of SG6043 were carried out by using ANSY-FLUENT. The FLUENT code solves the RANS equations using finite volume discretization. Steady state solver, SIMPLE pressure based solver and Green-Gauss cell based discretization were used in the analysis. Also, second order scheme was used for the momentum and turbulence equations discretization. When applying the CFD analysis to airfoil at low Reynolds numbers, it is difficult to solve boundary layer elements with common turbulence methods. Because of that, more error has been obtained in calculation of drag force. To obtain more correct prediction of drag force, transition turbulence models are more suitable. With SST k-ω turbulence transition model, the results were acquired. The convergence of the numerical solution was controlled by monitoring numerical error of the solution.

O-ring type domain structure was chosen. The external domain is a circle which has a diameter of 25 m. It was defined as a boundary condition of “Velocity Inlet”. The airfoil bottom and top surfaces were defined as “Wall” boundary conditions. The domain which is defined as air which has a density ($\rho$) of 1.225 kg/m$^3$ and dynamic viscosity ($\mu$) of 1.7894e-05 Pa s.

Circular domain was placed 12.5 times of the chord length away from the airfoil. The computational domain and mesh structure were shown in Fig. 3.

Different sizes of grids were used to ensure grid independency of the analysis results. This is achieved by obtaining solution with increasing number of grids nodes until a stage is reached where the solution exhibits negligible change with further increase in the number of nodes.

The convergence rate is monitored during the iteration process by means of the residuals of the dependent variables of the governing differential equation. Convergence is also checked using the relative differences between two successive iterations for each of the integrated force coefficients. In order to resolve the boundary layer, 42 layers in the boundary were introduced and first layer was located 0.005 mm from the wall. Hence, the first grid point of the wall in the normal direction was placed at a distance less than $y^+ = 1$ from the wall. The $y^+$ ($\rho U y / \mu$) is defined as the non-dimensional wall distance for wall-bounded flow in a turbulent boundary layer analysis. To consider the viscous sub layer in the turbulent boundary layer, the value of the $y+$ has to be less than 10 [6, 7]. The detail of the mesh around the airfoil is shown in Fig. 4.

In Fig. 5 and Fig. 6, the comparison of the aerodynamic coefficients of SG6040 in CFD, XFOIL and experimental results [4] at different Reynolds number are shown.
Fig. 5. Comparison of lift coefficient (a) and drag coefficient (b) between CFD, XFOIL and experiment at 3x10^5 Reynolds number.

Fig. 6. Comparison of lift coefficient (a) and drag coefficient (b) between CFD, XFOIL and experiment at 4x10^5 Reynolds number.
For the 0.27 of angle of attack degree at $3 \times 10^5$ Reynolds number and 0.23 of angle of attack degree at $4 \times 10^5$ Reynolds number, the contours of static pressure on SG6040 were obtained. As expected, the pressure on lower surface of airfoil is higher than upper surface, also negative pressure value was obtained on the lower surface.

Hence, the value of coefficient of lift and drag increases with increasing the angle of attack as expected.

III. CONCLUSION

Flow performance characteristics of SG6040 has been computationally investigated at Reynolds number $3 \times 10^5$ and $4 \times 10^5$. The commercial code Fluent with SST k-ω transition and general public license XFOIL, was used for numerical analysis.

The comparison between the experimental literature studies, CFD analysis and XFOIL analysis was analyzed. That the results of XFOIL analyses show as good as agreement with CFD analyses and experiment results, was observed. Although, SST k-ω transition model shows promising results to predict accurate aerodynamic coefficients such as lift ($C_L$) and drag ($C_D$) values, it is clear that XFOIL analysis tool can be used easily to predict aerodynamic performance of airfoils at low Reynolds number for the conceptual design in engineering.

Abstract—The software QBlade under General Public License is used for analysis and design of wind turbines. QBlade uses the Blade Element Momentum (BEM) method for the simulation of wind turbines and it is integrated with the XFOIL airfoil design and analysis. It is possible to predict wind turbine performance with it. Nowadays, Computational Fluid Dynamics (CFD) is used for optimization and design of turbine application. In this study, Horizontal wind turbine with a rotor diameter of 2 m, was designed and objected to performance analysis by QBlade and Ansys-Fluent. The graphic of the power coefficient vs. tip speed ratio (TSR) was obtained for each result. When the results are compared, the good agreement has been seen.

Keywords—QBlade, Computational Fluid Dynamics (CFD), Horizontal wind turbine, Blade Element Momentum (BEM), Wind Energy

I. INTRODUCTION

The importance of the renewable energy sources gradually increases with climate change. One of the renewable energy sources is the wind. Nowadays, the numbers of the green energy systems are increasing day by day and also, the small-scaled wind turbine are designed for the purpose of using at the greenhouse.

Generally, two types of wind turbine are used. One is horizontal wind turbine and another is vertical wind turbine.

Also, the countries’ economic growth is shown parallelism with the amount of the generated energy. In order to resume economic growth, the amount of the generated energy should be increased.

The energy sources based on fossil fuel increases carbon dioxide emission, therefore, studies on alternative energy source like wind and sun are continued.

Fig. 1 (a) is shown that, the amount of the generated energy from wind energy is approximately 432.88 GW until December 2015. Fig. 1 (b) is shown that new wind energy power system having capacity of 63.467 GW was installed in 2015 [1].

Wind turbine can be classified as large, medium, small and small-scaled. Large wind turbines have 50-100 m rotor diameter and they generate energy between 1 to 3 MW. Medium wind turbines have 20-50 m rotor diameter and they generate energy between 100kw to 1 MW. Small wind turbines have 20-50 m rotor diameter and they generate energy between 25kw to 100 kW. Small-scaled wind turbines can be separated three different types as micro, mini and household. Micro-scale wind turbines have 0.5-1.25 m rotor diameter and they generate energy between 0.004 kW to 0.25 kW. Mini-scale wind turbines have 1.25-3 m rotor diameter and they generate energy between 0.25 kW to 1.4 kW. Household wind turbines have 3-10 m rotor diameter and they generate energy between 1.4 kW to 16 kW [1].

It is possible to predict aerodynamic performance of wind turbine by using experimental, Computational Fluid Dynamics (CFD) and Blade Element Momentum (BEM) methods. Experimental and Computational Fluid Dynamics (CFD) methods are more expensive and require longer time than Blade Element Momentum (BEM) method. But, BEM method has less accuracy than experimental and CFD methods due to some assumption.

In this paper, for the horizontal wind turbine with a rotor diameter of 2 m, the aerodynamic performance is predicted by using QBlade and Ansys-Fluent. Firstly, the turbine is designed and aerodynamic performance is obtained by the software QBlade under General Public License. After that, the 3D model of turbine is generated by using CATIA. Domain construction and grid generation for calculating the 3D wind turbine performance is described. Then, the aerodynamic performance is calculated by using CFD methods (Fluent commercial

Fig. 1 (a) Cumulative capacity of wind turbines in 2015 around the world (b) New installed wind turbine capacity in 2015
software). Finally, power curve and torque curve of the turbine obtained by the 3D CFD results, are compared with Qblade results.

II. QBLADE AND CFD ANALYSES

A. Blade Element Momentum Method

Blade element momentum (BEM) theory is widely used in aerodynamic performance predictions and design applications for wind turbines. This theory combines both momentum theory and blade element theory methods. Momentum theory is useful to predict for ideal efficiency and flow velocity. Forces acting on the rotor to produce the motion of the fluid is determined by the mean of momentum theory. Momentum theory does not depend on the blade geometry. However, blade element theory depends on the blade geometry and it determines the forces acting on the blade after the motion of fluid. If these two theories are combined BEM theory, known as strip theory, is obtained and BEM theory defines the relation of rotor performance to rotor geometry. It is necessary to make assumption for the blade element theory and momentum theory.

For momentum theory:

a) Blade operate without frictional drag
b) A slipstream that is well defined separates the flow passing through the rotor disc from that outside disc
c) The static pressure in and out of the slipstream far ahead of and behind the rotor are equal to the undisturbed free-stream static pressure
d) Thrust loading is uniform over the rotor disc
e) No rotation is imparted to the flow by the disc

For blade element theory:

a) There is no interference between successive blade elements along the blade
b) Forces acting on the blade element are solely due to the lift and drag characteristics of the sectional profile of a blade element [2].

The tangential and normal force coefficients in wind turbines can be calculated as the following:

\[ C_T = C_L \sin \phi - C_D \cos \phi \]  
\[ C_N = C_L \cos \phi + C_D \sin \phi \]  

BEM theory equations can be solved as iteratively. There are two iterative variables that are axial and radial induction factors, in BEM theory. These variables can be defined as follows [3].

\[ a' = \frac{1}{4 \sin \frac{\phi}{2} \cos \frac{\phi}{2} \left( \sigma C_T \right)} - 1 \]  

where, \( \phi \) is the inflow angle, \( C_T \) and \( C_N \) is the tangential and normal force coefficient respectively, \( \sigma \) is the solidity which is defined as the ratio of the planform area of the blades to the swept area [4]. It can be expressed as follows:

\[ \sigma = \frac{cB}{2\pi r} \]  

where, \( c \) is the chord length, \( B \) is the number of blades and \( r \) is the disk radius.

Fig. 2 shows the velocity component in the rotor plane. If the axial and radial induction factors are firstly guessed, the inflow angle \( \phi \), can be computed. Then, the angle of attack \( \alpha \), that is the between the chord line of the airfoil and the relative wind speed, can be obtained by using the following equation:

\[ \theta = \theta_p + \beta \]  
\[ \alpha = \phi - \theta \]  

where \( \beta \) is a twist angle of the blade, \( \theta_p \) is a pitch angle of the blade, \( \theta \) is the combination of the twist angle \( \beta \) and the pitch angle \( \theta_p \). After the calculation of the angle of attack, the lift and drag coefficient of the airfoil can be obtained from the lift and drag curves of the airfoil. By using these force coefficients, new induction factors can be calculated and compared to the initial induction factors. When the maximum value of the \( \Delta a \) and \( \Delta a' \) is below the convergence criterion \( e \), it means that the iteration converge. Then, the next element can be calculated.

The flow diagram, which is used to solve iteratively for Axial Induction Factor and the Radial Induction Factor solution of BEM theory is shown in Fig 3.
For an ideal wind turbine blade design, firstly it was decided to design a 2 m blade diameter turbine. SG6043 airfoil type which is designed exclusively for wind turbines with small blades [6] was selected. Tip speed ratio, \( \lambda \), was chosen 5. For SG6043 airfoil, the lift coefficient at the angle of attack 4.5\(^\circ\), where the \( C_L/C_D \) ratio has maximum rate, was acquired as 1.22 from XfIrf software. Blade section was divided 9 parts. Then from the formulas inflow angle, chord length and twist angle were calculated for each section.

The rotor blades parameter and the design parameter of wind turbine are listed in Table 1 and Table 2, respectively.

The SG6043 airfoil, has a maximum thickness of 10%, a camber of 5.5% and a leading edge radius of 1.7%. The profile is shown in Fig. 4. Also blade model of turbine is shown in Fig 5.

**B. Blade Shape Design for Optimum Rotor with Wake Rotation**

When an ideal rotor is design, the effect of wake rotation is taken into design. The blade shape optimization for ideal rotor includes wake rotation except drag \( (C_D = 0) \) and tip losses \( (F = 1) \). The power coefficient depends on the angle of the inflow angle, \( \varphi \). The power coefficient can be obtained from the following equation:

\[
C_p = \left( \frac{8}{\pi^2} \right) \int_{\varphi_b}^{\lambda} \sin^2 \varphi \left( \cos \varphi - \lambda_r \sin \varphi \right) \left( \sin \varphi + \lambda_r \cos \varphi \right) \left[ 1 - \left( C_d/C_l \right) \cot \varphi \right] \left( \lambda_r \right)^2 d\lambda_r
\]  

(8)

Taking the partial derivative of the part of the integral for \( C_p \) and the derivative is set to equal zero.

\[
\frac{\partial}{\partial \varphi} \left( \sin^2 \varphi \left( \cos \varphi - \lambda_r \sin \varphi \right) \left( \sin \varphi + \lambda_r \cos \varphi \right) \right) = 0
\]  

(9)

The local tip speed ratio, inflow angle, chord length of the blade section can be calculated as the follows:

\[
\lambda_r = \sin \varphi (2 \cos \varphi - 1)/[(1 - \cos \varphi)(2 \cos \varphi + 1)]
\]  

(10)

\[
\varphi = (2/3) \tan^{-1}(1/\lambda_r)
\]  

(11)

where \( \lambda_r \) is the local tip speed ratio, \( c \) is the chord length of the blade section, \( B \) is the number of the blade, \( C_L \) is lift coefficient at the angle of the attack, \( \alpha \) which the angle is at the highest value of the ratio of the lift-drag coefficient.
C. **Qblade Analysis**

Qblade analyses were conducted on the turbine blade in the range of the tip speed ratio, \( \lambda \) from 2.5 to 6.5. In the analyses design velocity of 12 m/s was kept to be constant while the rotation of the rotor was varied with respect to \( \lambda \). As results, the power coefficient and torque values vs. various tip speed ratio graphics were obtained (Fig. 6, Fig. 7).

D. **CFD Analysis**

Numerical simulations for aerodynamic performance of wind turbine were carried out by using Anys-Fluent, which is commercial software for CFD analysis based on the finite volume method. In CFD analysis, SST k-\( \omega \) turbulence module with curvature correction for Reynolds-average Navier-Stokes (RANS) equation was used. Also, second-order upwind discretization in space was used. The convergence rate was monitored during the iteration process by means of the residuals of the dependent variables of the governing differential equations.

Wind turbine module shown in Fig. 8 was obtained using CATIA, commercial software for 3D CAD design.

The external domain, which is a rectangular parallelepiped of width 6 m, length 15 m, height 6 m, is shown in Fig. 9. Domain entrance was defined as “Velocity Inlet” and exit was defined as “Pressure Outlet” boundary conditions. The outer domain's walls were defined as “Symmetry” boundary condition. A cylindrical domain which is connected to external domain was also created around the blades. Moving Reference Model (MRF) was used for this cylinder domain to give blade rotation.
The unstructured grid was applied on the turbine rotating disk area and external flow domain surrounding the turbine. The conformal grid was used on the interface between the rectangular external flow domain and cylindrical rotating disk domain. Different size of grids was used to obtain grid independency of the analysis results. This is achieved by obtaining solutions with increasing number of grid nodes until a stage is reached where the solution exhibits negligible change with further increase in the number of nodes. The grid structure is shown in Fig. 10.

In order to resolve the boundary layer, 25 layers in the boundary were introduced and first layer was located 0.015 mm from the wall. Hence, the first grid point off the wall in the normal direction was placed at a distance less than y⁺=3 from the wall. The y⁺ (ρUf y/μ) is defined as the non-dimensional wall distance for wall-bounded flow in a turbulent boundary layer analysis. To consider the viscous sublayer in the turbulent boundary layer, the value of the y⁺ has to be less than 10 [7, 8].

After the CFD analysis, obtained distribution of the y plus on the blades is shown in Fig 11.

Based on 12 m/s of design wind speed, horizontal axis wind turbine performance analyses were performed by using Ansys-Fluent software. As results, the power coefficient and torque values vs. various tip speed ratio graphics were obtained (Fig. 12, Fig. 13).

### III. CONCLUSION

This study was considered the performance characteristics of the wind turbine, which has SG6043 airfoil. The commercial code Fluent with SST k-ω and the general public license QBlade, which uses BEM theory to predict aerodynamic
coefficients, were used respectively. The following conclusions were drawn:

Xflr5 software was used to obtain the values of the angle where $C_L/C_D$ ratio has maximum and max. $C_L$ at this angle of attack. These values were obtained as 4.50 and 1.22 respectively. Maximum torque value was obtained as 29.937 Nm in Qblade and 25.204 Nm in Fluent at the tip speed ratio of 3.5. Maximum power coefficient value was obtained as 0.457 in Qblade and 0.424 in Fluent at the tip speed ratio 5.5.

The efficiency of the system first increases and reaching to maximum value and then decreases with increasing the tip speed ratio.

There are reasonable agreements between Qblade and Fluent analyses. At high tip speed ratio value, the results get closer in Qblade and Fluent solutions (Fig. 14, Fig. 15).

Abstract—Wind speed modelling plays a critical role in wind related engineering studies. Frequency distribution of wind speed can be displayed different distributions such as Gamma, lognormal, Rayleigh and Weibull. Weibull distribution is used to model of many regions of the world wind speed in recent year. In this paper, wind speed potential analysis realized using Inverse Weibull Distribution (IWD) for Bilecik, Turkey. Maximum likelihood method for parameter estimation used for wind speed modelling analysis. All analysis is carried out by Matrix Laboratory (MATLAB) programming language. Monthly and yearly wind speeds are modeled by Inverse Weibull distribution. Accuracy of the modelling is evaluated in terms of Root Mean Square Error (RMSE)

Keywords—Wind Speed, Modelling, Weibull Distribution, Renewable Energy, Inverse Weibull Distribution.

I. INTRODUCTION

In modern societies, one of the most important indicators of the economic growth is energy. Energy demand increases continuously due to the rapid population growth and industrialization. This demand cannot be satisfied with the available limited resources. Thus, it is gaining much more importance to benefit from the renewable energy resources in a more effective manner.

One of the renewable energy resources is wind energy. Actually wind energy which is the oldest source has been used since BC 2800 by humankind. Until recent year this energy has been used for water pumping and power generation in rural areas. Today it is used as an alternative source of energy production. Wind energy systems operate depend on wind regime, wind shaft position and size of power generation system [1,2]

The potential of wind energy of a certain region can be determined before a wind conversion system is installed. The determination of wind energy potential depends on accurately modeling wind speed. Statistical properties of the wind speed are important to predict the output energy of a wind conversion system [2]. There are several distribution functions for wind speed and power density analysis in literature. The log-normal distribution [3-6], the inverse Gaussian distribution [7], the wake by [8,9], three-parameter log normal [10], the gamma distribution [11,12], two-parameter gamma distribution [13], hybrid distributions [14-16], the three parameter generalized gamma distribution [17-18], and similar distribution functions were used about energy and other research areas.

Two-parameter Weibull density function [19] is commonly used in wind resource assessment to describe wind speed as a stochastic quantity. There are many different methods for estimating the shape (k) and scale (c) parameters of Weibull wind speed distribution function [19-23].

Alternative distribution which is Inverse Weibull Distribution (IWD) for modelling wind speed data is proposed by Akgül et al [24]. IWD is used for Bursa and Sakarya seasonal wind speed data by them. In this paper, monthly and yearly modeling of wind speed realized using Inverse Weibull distribution and Two Parameter Weibull distribution for Bilecik, Turkey. Maximum likelihood method used for modeling of wind speed. This paper is structured as follows: IWD and Two-parameter Weibull distribution methods are explained by Section 2. Section 3 contains parameter estimation method for IWD. Comparative modeling results are presented in Section 4. Finally, conclusion is given in Section 5.

II. INVERSE WEIBULL DISTRIBUTION

There are different methods for determining the wind speed distributions. In the literature, the two parameters Weibull distribution is often used in the statistical analysis of data. The Weibull distribution function is given by Equation (1).

\[
f_w(v) = \frac{k}{c} \left( \frac{v}{c} \right)^{k-1} e^{-\left( \frac{v}{c} \right)^k}
\]

Where \(f_w(v)\) is the frequency or probability of occurrence of wind speed \(v\), \(c\) is the Weibull scale parameter with unit equals to the wind speed unit and \(k\) is the unitless Weibull shape parameter. The higher value of \(c\) indicates that the wind speed is higher, while the value of \(k\) shows the wind stability.

The cumulative Weibull distribution function \(F_w(v)\) gives the probability of the wind speed exceeding the value \(v\). It is expressed by Equation (2):

\[
F_w(v) = 1 - e^{-\left( \frac{v}{c} \right)^k}
\]

The probability density function and cumulative density function of Inverse Weibull Distribution are given below [24]

\[
f_{IW}(v) = \frac{k}{c} \left( \frac{c}{v} \right)^{k-1} e^{-\left( \frac{c}{v} \right)^k}
\]

\[
F_{IW}(v) = 1 - e^{-\left( \frac{c}{v} \right)^k}
\]
and 
\[ F_W(v) = e^{-\frac{v}{k}} \]  
\( (4) \)

Different scale \((k)\) and shape \((c)\) parameter estimation methods which are Maximum Likelihood Method (MLM), Modified Maximum Likelihood Method (MMLM), Moment Method (MM), Power Density Method (PDM), Graphical Method (GM) and empirical methods are used in literature.

III. MAXIMUM LIKELIHOOD METHOD FOR IWD

The likelihood function for two parameter Weibull distribution is given by
\[ L(k, c) = \prod_{i=1}^{n} f(v_i; \theta) \]
\( (5) \)
\[ L(k, c) = \prod_{i=1}^{n} k c^{-1} v_i^{c-1} \exp(-c^{-1} v_i^c) \]
\( (6) \)

Taking the natural logarithm of likelihood function
\[ \ln L(c, k) = n \ln k - nk \ln c - (k+1) \sum_{i=1}^{n} \ln v_i - c \sum_{i=1}^{n} x_i^{c-1} \]
\( (7) \)

By taking the derivatives of left side the equation with respect to these parameters and equating them zero, the following likelihood equations are obtained
\[ \frac{\partial \ln L(k,c)}{\partial k} = \frac{n}{k} + n c - c \sum_{i=1}^{n} \ln v_i - c \sum_{i=1}^{n} x_i^{c-1} = 0 \]
\( (8) \)
\[ \frac{\partial \ln L(k,c)}{\partial c} = n k - k c^{-1} \sum_{i=1}^{n} v_i^{c-1} = 0 \]
\( (9) \)

These equations are solved Newton-Raphson iterative method by using Matlab (MATrix LABoratory) software in this paper.

IV. WIND SPEED POTENTIAL ANALYSIS

Future and available wind potential is very important to build wind energy conversion system. For this reason estimation parameter results of distribution are studied monthly. Optimum model can be chosen according to performance criteria. The actual data sets collected hourly basis in Bilecik, Turkey, are taken from the Turkish State Meteorological Service. The IW and the Weibull distributions are used to model these data sets.

Fig. 1. Location of selected station and Bilecik province on the map of Turkey

Bilecik is located at N 39° 39’ and E 30° 40’ at the height of 850 m in Turkey as shown in Figure 1.

The maximum likelihood method was used for determining Inverse Weibull and Weibull parameters.

Some descriptive statistics including maximum, mean, standard deviation, skewness and kurtosis of the used wind speed data for selected station is presented Table 1. The coefficient of Kurtosis is very high for Bilecik. It gives the degree of width of peak of a distribution.

In this paper, estimation of monthly and annual parameters for Bilecik region are implemented in Table 2 by using hourly wind speed data for 2014 year.

Hourly wind speed recorded by Turkish State Meteorological Service at 10 m height for the period of one years from January 2014 to December 2014.

It can be seen from the Figure 2 that Weibull and Inverse Weibull probability distribution function and cumulative distribution function of sample data .April 2014, are shown

Fig.2. Probability density and cumulative probability density function for sample month for Weibull and Inverse Weibull distribution
Performance criteria of analysis is shown Root Mean Square Error (RMSE) by Equation (10).

\[
RMSE = \sqrt{\frac{1}{n} \sum_{i=1}^{n} (y_i - x_i)^2}
\] (10)

Where, \(y_i\) is the actual wind speed probability value, \(x_i\) is the probability value calculated from Weibull distribution and \(n\) is the number of observations.

Table 2 shows monthly wind speed data modeling results which consist of Weibull and Inverse weibull distributions and error values. Error values presented for probability density functions (pdf).

IWD results for some months are better than Weibull distribution. Especially, left side of the probability density function is good fit to IWD. In other words, good results are observed for low wind speed data in IWD (Figure 3).

Fig.3. Comparison of low wind speed data

**V. CONCLUSIONS**

The potential of wind energy of a certain region can be determined before a wind conversion system is installed. The determination of wind energy potential depends on accurately modeling wind speed. Statistical properties of the wind speed are important to predict the output energy of a wind conversion system. There are several distribution functions for wind speed and power density analysis in literature.

In this paper Inverse Weibull Distribution which is proposed for wind speed data by Akgül et al. and Two-parameter Weibull Distrubition function are used for actual hourly wind speed data for Bilecik, Turkey. Although Akgül et al. modelled for seasonal wind speed data, monthly analysis are used for IWD in this paper.

IWD results are better than Weibull distribution function for low wind speed data modelling. These analysis are preliminary research for wind speed data.

In future studies, we will apply this method for seasonal analysis which has lots of years and different parameter estimation methods.
ACKNOWLEDGMENT

We are thankful to Turkish State Meteorological Service, for the support in the accomplishment of the present study.

Abstract— Learning Systems (LS) such as machine learning, statistical pattern recognition and neural networks are computer programs that can learn from sample data and develop a prediction model that makes prediction for new cases. The most important think related with a prediction model is to achieve results as closer as to real situation while making predictions. This is important because being closer to real results help to reduce the costs of feasibility studies in system installation. The performance of Learning Systems has been raised in latest years such as it sometimes exceeds the performance of humans. That’s why the applications of Learning Systems have been increased in many areas. This paper reviews the present applications of Learning Systems in energy system modeling and prediction especially in renewable energy systems such as wind and solar. The aim of this paper is to create a vision for researchers by gathering the present applications and outline their merits and limits and the prediction of their future performance on specific applications.

Keywords— Energy efficiency, Source installation, Estimation, Artificial intelligence

I. INTRODUCTION

Learning Systems (LS) are research areas of computer science that are used to extract information from large data stores [1, 2]. It includes concepts such as machine learning, statistical pattern recognition and neural networks. In everyday life in many areas such as education, health, telecommunication, transportation, marketing, meteorology, earth sciences and etc. a large quantity of data have been collected. Due to the growth in these data, extracting valuable information from large data stores has become an engineering discipline. This valuable information than is used for developing prediction models that can learn from sample data and develop a prediction model that makes prediction for new cases [3-5]. The objective of this paper is to gather and argue the studies that are related to Learning System techniques in modeling and prediction for renewable energy systems. The following of the paper is organized as follows: In the second part the learning system is explained briefly. While wind energy applications of learning system are given in the third part, solar energy applications are given in the fourth part. Finally conclusion is given.

II. LEARNING SYSTEMS

Learning systems are the computer programs that can learn from the sample data and can predict for the future [1, 2]. While there are many learning system methods and applications in the literature, this paper is focused on the presentation of some of the learning system applications on energy system modeling and prediction. Since energy sources are not abundant predictions for appropriate and satisfactory use of these energy sources are essential. Some of the most common methods of learning systems, used in the field of energy system modeling and prediction, are linear regression, artificial neural networks (ANN), support vector machine (SVM), decision trees and etc. [6]. In the literature many studies can be found related to the solar irradiation, wind speed, production of energy from wind and solar and reducing the operating costs with the realization of economic dispatch [7]. In design of wind farms, solar plants and power generators, wind and solar characteristics such as distribution of wind speeds and solar irradiation of the location have to be known. As this information is not always available Learning System algorithms are used to predict this information according to the historical data.

Learning System algorithms are the samples of supervised classification algorithms. A supervised classification algorithm uses a database which includes attributes and the class information. The sample of a database, which is given in Table1, has \( m \) data that each one has \( n \) attributes, called as predictors, and class information, called as target.

A supervised classification includes two steps which are the training and the testing steps. First of all the database is split into two parts according to some criterion. First part of the database, training set, is used in the training step and the second part, test set is used in the testing step. In the training step, a model is constructed by using the training set of which the class information is known.
TABLE I
A SAMPLE DATABASE

</tr>
</tbody>
</table>

Than using the test set the performance of the constructed classification model is evaluated. Once the model is constructed, a sample data with its known attributes and unknown class information can be classified into a class. In the following part some of the popular Learning System algorithms that are used in renewable energy systems are explained briefly.

A. Linear Regression

Linear regression model is a very popular mathematical classification model that is used for making predictions, and has many applications in various fields including sciences such as social sciences and physical sciences [8]. In the regression analysis it is used a database that is based on observed data over a period of time. In this database attributes would be the predictors and the class information would be the target (Table1). As this is a supervised classification model, it has a training step in which the database, which’s target values are known is used and a regression model is constructed. Than the model is tested using the part of the database that is not used for the training process. At the end, once the model is constructed it can be used to predict the target value of a case which’s target value is unknown.

Basically a linear regression model explains the relationship between the predictor and the target with a straight line. In some applications there is only one predictor but in some applications it could be more than one predictor, multivariate linear regression analysis [8]. The single predictor linear regression model can be expressed as in Eq.1 and the 2-Dimensional graphical representation is given in Fig.1.

\[ y = ax + b + \epsilon \]  

(1)

In Eq.1 the regression parameters a and b are the angle between a data point and the regression line, and the point where x crosses the y axis (x=0) respectively [9].

In multivariate linear regression analysis the regression equation has a form as given in Eq.2.

\[ y = b + ax_1 + cx_2 + \cdots + ex_{n-1} + \epsilon \]  

(2)

B. Artificial Neural Networks (ANN)

Artificial Neural Networks is a supervised learning algorithm which bases the working principle of human brain. It learns from data samples, and then develops a model which can learn from these data samples and can make predictions for the future. It consists of basically two layers that are called the input layer and the output layer. Each layer has different numbers of neurons which are associated with the neurons in the other layer with a weight. Working principle of an ANN is given in Fig 2. The output of the network is the application of the sum of the weighted inputs to an activation function.

There are some advantages of ANN compared to the conventional algorithms such as the speed, the simplicity, the capacity of the network to learn from examples and the realistic results due to the use of actual data for the training step of the network [10].

C. SVM

Support Vector Machine (SVM) is a tool for solving pattern recognition problems and it is based on the concept of finding the decision planes that define decision boundaries, and can separate a set of objects belonging to different classes (Fig.3.) In Fig 3.a a schematic example of a linear classifier can be seen. But however in most real classification problems, data points, belong to different classes, cannot be distinguished from each other linearly (Fig.3.b). Classification tasks given in Fig.3.b, are known as hyper plane classifiers and SVMs are particularly suited to handle such tasks. In other words with hyper plane classifiers, the data can be mapped into a
higher dimensional feature space, and an optimal separating hyper plane can be constructed in this new space [11-13] (Fig.4).

Fig. 3 A schematic example of a) A linear classifier, b) A nonlinear classifier [14]

![Input space Feature space](image)

Fig. 4 The basic of a SVM classifier [14]

SVM algorithm can cope with high dimensional data well although when the training samples are relatively small [15]. In the literature SVM algorithm is used for medium and long term wind speed predictions [16-18], and a few studies can be found in which SVM is used for short-term wind speed prediction [19].

III. WIND ENERGY APPLICATIONS

Wind speed predictions are performed for three different time scales such as short, medium and long terms. While the time intervals in short term are about 10 sec or 10 min [20-22] they become hourly predictions for medium term [23-25] and involve days for long term predictions [26-28]. Each time scale is indicative of different things. For example short term wind speed prediction is important to control of wind turbines, medium term supports unit commitment planning and the long term is used in determining generation mix and scheduled maintenance of power systems [29]. Wind speed prediction methods can be grouped into four categories such as statistical, physical-based, data mining and hybrid methods [30]. When the wind characteristics are examined, it can be seen that it has both linear and nonlinear characteristics that can be analyzed with the learning systems such as data mining methods that can model both the linearity and the nonlinearity of wind speed [30].

The frequently used data mining algorithms in wind speed prediction are tree-based regression algorithms [31-34], k-nearest neighbor [35], support vector machine (SVM) [36-37], Artificial Neural Networks [38-40] and ensemble data mining algorithms [41]. Among these prediction models prominent ones are developed from ANN and SVM algorithms [30]. The ANN wind speed prediction model is applied for short [20, 42-44] and the long term predictions [42]. The data mining models may suffer from the limited data in terms of accuracy [45]. The long term approaches of ANN model can be seen as monthly in [46] and as monthly and daily in [47]. ANN model has some advantages according to the conventional algorithms such that the speed, the simplicity and the capacity of the network to learn from examples. [48].

In [23] ANN is used for wind speed prediction that is the mean monthly wind speeds prediction in Cyprus where any data is not available. In [49] it is proposed multivariate time series models to predict the power ramp rates of a wind farm of 100 turbines for a time horizon of 10-60 min. In the study, the power changes are predicted at 10 min intervals and five data mining algorithms are used to build the model. These are multilayer perceptron algorithm (MLP), the support vector machine (SVM) regression, the random forest, the classification and regression (C&R) tree and pace regression algorithm. According to the results of the study, the SVM regression algorithm outperforms the rest of the four algorithms. In [19] a least-squares SVM (LS_SVM) approach is applied for wind speed prediction. In the paper it is presented a systematic study on fine tuning of LS_SVM model parameters for one-step ahead wind speed forecasting. In the study they applied three different SVM kernels that are linear, Gaussian and polynomial kernels. Training sample size, SVM order, kernel parameters and regularization parameter are used as the SVM parameters. According to the obtained results LS-SVM performance is closely related to the dynamic characteristics of wind speed, performance of the model is closely related to the parameters comparable results are obtained for the three of the kernels under optimal combination of parameters after fine tuning and finally when the training sample size or SVM order is small the linear kernel gives the worse performance. In [50] they integrated data mining and evolutionary computations to monitor wind farm power output. In the study five different data mining algorithms are compared. These algorithms are multi layer perceptron (MLP), REP tree, M5P tree, bagging tree and the k-nearest neighbor (k-NN) algorithm. According to the results the best prediction results are obtained from the k-NN model combined with the principal component analysis approach. In order to obtain good performance from this model, the conditions of the wind farm has to be normal otherwise its performance is poor. In [51] they used learning systems algorithms to analyze time series models for predicting the power of a wind farm for 10-min and hour-long intervals. As in [50] the model is built using the same five data mining algorithms. The results showed that SVM regression algorithm gives the best predictions of wind power and wind speed at 10-min intervals up to 1 h into the future. The MLP gives the best predictions over hour-long intervals up to 4 h ahead. As it is reported in the study wind speed predictions are poor.

IV. SOLAR ENERGY APPLICATIONS

In the literature in various fields of renewable energy systems it can be found many modeling and prediction applications of ANN. In [52] two different application of ANN can be seen. The two of these applications are for to determine the collector optical efficiency which is a very
important parameter as it is used to determine the overall effectiveness of solar concentrating collectors. In the first application to determine the collector optical efficiency ANN is used for the estimation of collector intercept factor and in the second one it is used to estimate the radiation profile on the receiver of collector.

In [48] an extended version of the study given in [52] can be found. In [48] ANN is also used for solar water heating systems besides the modeling of a solar steam generator. According to the results ANN can be successfully used in the estimation of the system energy extraction and the stored water temperature rise [53].

In [10] a study is performed that gives an overview using Artificial Intelligence (AI) techniques for sizing photovoltaic (PV) systems. The Artificial techniques included in the paper are Artificial Neural Networks (ANN), fuzzy logic, genetic algorithm, wavelet and the hybrid systems that are fuzzy neural networks, genetic algorithms and neural networks, wavelet and neural networks, genetic algorithms and fuzzy logic. In the paper included applications of AI techniques are as follows: Neural networks for sizing stand-alone PV systems; genetic algorithms for sizing hybrid PV system; genetic algorithms for sizing grid-connected PV-system; genetic algorithms for sizing hydrogen PV system; neural networks, neuro-fuzzy and genetic algorithm for sizing stand-alone PV systems and neuro-fuzzy and wavelet for sizing PV systems. According to the overview in [10] the use of AI techniques for sizing PV systems has the advantage that it provides good optimization, especially in isolated areas, where the weather data are not always available. In [54] they argue the solar forecasting methodologies and also the solar resource and power output of solar plants applications. As learning system algorithms, they examine the ANN and k-NN algorithms. In [55] they performed a prediction model for solar power generation from weather forecasts using linear least squares and SVM using multiple kernel functions. According to the results they showed that SVM-based models are 27% more accurate than existing forecast-based models.

V. CONCLUSIONS
The Learning Systems (LS) are computer programs which learn from sample data and develop a prediction model makes prediction for new cases. The performance and accordingly the application of Learning Systems have been raised in the last years. This paper reviews some of the present applications of Learning Systems in energy system modeling and prediction especially in renewable energy systems such as wind and solar. As the learning systems linear regression, ANN and SVM are considered. It is aimed with this study to create a vision for researchers by gathering the present applications and outline their merits and limits and the prediction of their future performance on specific applications.

Numerical simulation of a single PEM fuel cell with double-serpentine flow channel

Elif Eker Kahveci*, İmdat Taymaz*

*Faculty of Engineering, Mechanical Eng. Dept., Sakarya University, Sakarya, Turkey
tt@eeker.taymaz@sakarya.edu.tr

Abstract—In this study, a 3-dimensional, single-phase model has been established to investigate the performance of proton exchange membrane (PEM) fuel cells with double-channel serpentine flow fields. The single PEM fuel cell has a 13x73 mm² active layer. The complete set of conservation equations, mass, momentum, energy, species and charge were taken into account and solved using the commercial computational fluid dynamics (CFD) software ANSYS Fluent® 16.2 with Gambit® (2.4.6) as a pre-processor. Two flow patterns including co-flow and counter flow were considered for all flows in the cell. The model was used to investigate the performance of fuel cell by determining the current density, oxygen and hydrogen mass fraction distributions. The simulation results were illustrated polarization curves including I–V and I–P curves. As a result the co-flow model is more accurate and has higher current density than the co-flow model. It is also noted that the optimal oxygen consumption of the channels was achieved at 0.6 V value obtained the maximum current and power density to improve the performance of fuel cell. Also the performance of the PEM fuel cell can be improved by increasing the reactant gases humidification. But increasing the humidity of the cathode at low cell voltage will lead to decrease performance.

Keywords—PEM fuel cell, current density, humidification, performance

I. INTRODUCTION

Fuel cell is an electrochemical device that continuously changes the chemical energy of a fuel (hydrogen) and oxidant (oxygen or air) directly to electrical energy and heat, without combustion. The proton exchange membrane fuel cell (PEMFC) is considered to be a promising power source, especially for transportation and stationary cogeneration applications due to its high efficiency, low operating temperature, high power density, low emission and low noise.

In reference [1], it was studied time-dependent measurements of pressure drop in different flow fields on the cathode of a PEM fuel cell with different operating conditions. Their results showed that the interdigitated flow channel has the biggest pressure drop among the other flow field channel configurations.

Other working groups observed that channel geometry and surface property both have appreciable effects on the volume of accumulated water. Also it was resulted that the water droplets were larger and dispersed individually in the direction of flow in the rectangular channels with serpentine flow fields. And the channels with triangular geometry retained less water than rectangular channels of the same cross-sectional area, and the water was mostly trapped in the two corners adjacent togas the diffusion media. [2]

Based on the work of [3] it was solved for three different flow channel geometries: 4-step serpentine, parallel and pin-type high temperature polyelectrolyte membrane fuel cell (HTPEMFC) by using Computational Fluid Dynamics (CFD). Their results showed that serpentine and pin-type flow channels were found to perform very similarly. Also better fuel cell performance was predicted while temperature grows as it could be expected.

In their work, Cheng et al. presented in [4] that following results: Increasing the relative humidity enhances the membrane ion conductivity, which favours the current density output. On the other hand, reducing the mass fraction of oxygen gas at entrance plane with high relative humidity diminishes the fuel cell performance as the relative humidity of the cathode gas increases. At low current densities, an increase of relative humidity causes the water vapour concentration in the catalyst layer to reach the saturation level, reducing the occurrence of ohmic polarization.

Various operating factors, such as mole fractions of species, pressure distribution, overpotential, and inlet relative humidity, affect the performance of proton exchange membrane fuel cells (PEMFCS) [5]. Specifically, the land ratio of the gas channel and rib is an important parameter affecting PEMFC performance because current density distribution is influenced by this geometrical characteristic. Yang et al. investigated geometrical shape and relative humidity in their study. A three-dimensional numerical PEMFC model was developed to illustrate the current density distribution as the determining factor for PEMFC performance.

In reference [6], the effects of operation conditions on the performance of a polymer electrolyte membrane fuel cell with 25cm² active area were investigated experimentally. It was found that the performance of fuel cell performance can be enhanced by increasing the RH and temperature of the inlet gases and the operating temperature.

Takalloo et al. in reference [7] investigated the impact of alteration in humidification and inlet flow rates on performance improvements for PEMFC both experimentally and numerically. One of their results is that anode side needs
more humidity for preventing the membrane from drought and the cathode side needs less humidity because of producing water and avoiding from flooding.

In this study, it was investigated a 3-D, isothermal, single-phase, steady-state model with double serpentine flow channel configuration of a PEM fuel cell by using ANSYS-Fluent based on computational fluid dynamic technique.

II. NUMERICAL MODELLING

In this study, the model presented is a three-dimensional, isothermal, single-phase, steady-state model that resolves coupled transport processes in membrane, catalyst layers, gas diffusion layers and reactant flow channels of a PEM fuel cell (Fig.1). The number of elements in the computational domain field is 30439 elements. General geometrical property of the PEM fuel cells components are given at Table I.

A. Description of Model

The geometric model is created in Gambit 2.4.6. ANSYS-Fluent 16.2 PEMFC module is used in this research to compile the appropriate user-defined functions for a PEMFC. In this model, the numerical domain is a single-cell geometry domain. Pure hydrogen and air are used as reactant gases in the model. The inlet flow velocity was controlled by stoichiometry numbers of 2 at the anode and 2 at the cathode. The operating pressure was 200 kPa absolute at the exit of the cell. The active surface area is 13x73 mm², with double-serpentine flow field configuration. The channels are 1 mm in width and 1 mm in depth. The width of the rib is 1 mm. (Fig. 2)

B. Theoretical Formulation

Basic equations used during fuel cell operation are as follows:

Conservation of mass equation:
\[ \nabla (\rho \mathbf{u}) = S_m \] (1)

The source terms are;
\[ S_m = S_{H_2} + S_{W_{el}} + S_{w_{lp}} + S_{aw_{w_{e}}} \] (2)
\[ S_m = S_{O_2} + S_{w_{el}} + S_{w_{lp}} + S_{c_{w_{e}}} \] (3)

\[ S_{H_2} = - \frac{M_{H_2} A_{cel}}{2F} \] (4)
\[ S_{O_2} = - \frac{M_{O_2} A_{cel}}{4F} \] (5)

Momentum transport equation:
\[ \nabla (\rho \mathbf{u} \mathbf{u}) = -\nabla P + \nabla \cdot (\mu \nabla \mathbf{u}) + S_{p,i} \] (6)

Here \( \beta \) is the permeability, \( S_{p,i} \) is the sink source term for porous media in x, y and z-directions;
\[ S_{p,i} = - \left( \sum_{j=1}^{3} \frac{1}{E_j} \mu u_j \right) \] (7)

Species transport equation:
\[ \nabla (\rho m_i \mathbf{u}) = \nabla (J_m) + S_z \] (8)
Here \( n \) denotes for \( H_2, O_2 \) water vapor and liquid water. The source terms are the same as those of the conservation of mass equation. The diffusion mass flux (\( J \)) of species \( n \) in \( x \)-direction is:

\[
J_{x,n} = -\rho D_{x,n} \frac{\partial m_{x,n}}{\partial x}
\]  

(9)

Energy equation:

\[
\nabla (\rho u h) = \nabla (k \nabla T) + S_h
\]  

(10)

The source term \( S_h \) can be obtained by energy losses and heat source by phase change. The heat source from the electrochemical reaction:

\[
S_{he} = h_{ran} \left[ \frac{I_{cell}}{2F} \right] - IV_{cell}A_{cv}
\]  

(11)

The local current density of the cell is calculated from the open circuit voltage (\( V_{oc} \)) and the losses:

\[
I = \frac{\eta}{t} \left(V_{oc} - V_{cell} - \eta\right)
\]  

(12)

where \( t \) is the membrane thickness and \( \sigma_m \) is the membrane conductivity and defined as:

\[
\sigma_m = \left( 0.51 \frac{m_{m, dry}}{m_{m, dry}} C_{wa} - 0.326 \right) \exp \left( 1268 \left( \frac{1}{T_0} - \frac{1}{T} \right) \right)
\]  

(13)

C. Computational Method

The solution strategy was based on the SIMPLE algorithm. Momentum equations were solved for the velocity followed by solving the equation of continuity, which updates the pressure and the flow rate. A HP-PC-Intel® Xeon® CPU E5-2650v2@2.6 GHz, 2.6 GHz, 64 GB was used to solve the set of equations. The computational time for solving the set of equations was about 3 min.

Boundary conditions are set as follows: constant mass flow rate at the channel inlet (mass flow inlet type) and constant pressure condition at the channel outlet (pressure outlet type). The membrane-GDL interface was defined as a wall. The anode voltage was grounded (\( V = 0 \)) and the cathode voltage was adjusted 0.9V, 0.8V, 0.7V, 0.6V, 0.5V, 0.4V respectively less than the open-circuit potential (0.95 V). The current density values which correspond to each voltage value in the simulation results were noted. Both anode and cathode terminals were assigned wall boundaries. Hydrogen and air velocities are evaluated from the chemical stoichiometric ratio, operational pressure and temperature by the following equations:

\[
u_{a,in} = \frac{I_{ref}}{n_e F A_{MEA}} \frac{1}{X_{H_2,in}} \frac{R T_{in,cell}}{P_{a,in}} \frac{1}{A_{ch}}
\]

\[
u_{c,in} = \frac{I_{ref}}{n_e F A_{MEA}} \frac{1}{X_{O_2,in}} \frac{R T_{in,cell}}{P_{c,in}} \frac{1}{A_{ch}}
\]

(14)

(15)

Where \( I_{ref} \) is the reference current density, \( F \) is the Faraday constant, \( n_e \) is number of electrons transferred which equals 2 for the anode flow side and 4 for the cathode side.

Both the anode and cathode side exit boundary conditions are selected as pressure outlet, inlet conditions are selected as mass flow inlet type conditions. The operational temperature is 343 K for the anode and cathode side. Physical and electrochemical properties of the PEM fuel cells are given at Table II.

III. RESULTS AND DISCUSSIONS

A. Effects of Direction of The Reactant Gases on Current Density

Fig. 3 Contours of current density distribution (A/m²) in the middle of model at x-y plane, 0.6 V (a) counter flow, (b) co-flow

Fig. 3(a) and 3(b) shows the counters of current density distribution at x-y plane in the middle of the model for co-
flow and counter flow channels at the value of 0.6 V. It can be seen from the Fig. 3 that the counter flow channel model has better current density distribution than co-flow channel model. The reason of obtaining higher local current density in counter flow channels is that inlets and outlets providing for an increasing mass transfer.

![Graph 1](image1.png)

Fig. 4 I–V and I–P curves of the model with co-flow and counter flow at 100% relative humidity

In Fig. 4, 5 and 6 compare the highest and lowest performance polarization and power density curves respectively of different humidification conditions for both co-flow and counter flow channels. Similar to the performance curves presented in Fig. 4, 5 and 6 for the double serpentine pem fuel cell, varying the relative humidity, counter flow channel model has better performance results than co-flow channel model.

![Graph 2](image2.png)

Fig. 5 I–V and I–P curves of the model with co-flow and counter flow at 50% relative humidity

Fig. 5 displays polarization curves that produced similar performance results (within a voltage value of 0.6V) for 50% relative humidity both types of channels.

![Graph 3](image3.png)

Fig. 6 I–V and I–P curves of the model with co-flow and counter flow at 10% relative humidity

As shown in Fig. 6, decreasing the relative humidity of anode has a similar effect as higher performance of counter flow for the 100% anode humidification value, and is most notable at low cell voltage value, particularly after 0.5 V. Although maximum power density was approximately reached at 0.4V cell voltage value with this relative humidity condition.

Fig. 4 shows that it was reached at 0.6V and 100% relative humidity. As a result of them, decreasing the relative humidity from 100% to 10% has caused serious decline of 66.6 percent of cell performance.

### B. Effect of Humidity of Reactant Gases

1) **Anode Humidification**: In order to reach good cell performance, there must be water balance between anode and cathode. When hydrogen at the anode inlet is fully humidified, the humidity of the membrane can be well maintained. However if hydrogen is insufficiently humidified, membrane dehydration could occur on the anode side. The problem of water deficiency on the anode side of the membrane can be solved by humidification of hydrogen flow at anode side. For each of the gas humidification configurations for the double-serpentine PEMFC model, it was investigated the water accumulation in the membrane operated with constant operating conditions. In Fig. 7 it is shown that I–V and I–P curves cathode RH= 10% and anode RH =10%, 50%, 100% respectively. According to the simulated results in Fig.7, as anode relative humidity increase, the overall water uptake in the system increases. This increase enhances the cell performance. Maximum power density was reached at 0.7 V, 0.9258 A/cm² with the value of 0.6481W/cm².
Contours of current density distribution (A/m²) in the middle of model with different relative humidity at x-y plane, 0.6V is shown at the Fig. 8. From Fig. 8(a), Fig. 8(b) and Fig. 8(c), it can be seen that the current density increases while the relative humidity of hydrogen increases.

2) Cathode Humidification: The membrane is sufficiently hydrated by taking in water available from the fully humidified hydrogen. In Fig. 10 it is shown that I–V and I–P curves anode RH = 100% and cathode RH = 10%, 50%, 100% respectively. However, it is clearly seen from the figure that the current density is increased by the decreasing cathode relative humidity at low cell voltage. But, the cell performance increases with increasing relative humidity of oxygen at low current densities and high cell voltage. According to the results obtained below; cathode humidification was found not to be as important as the anode humidification.

C. Effect of Cell Voltage on Oxygen Concentration

It can be seen in Fig. 11 the molar concentration of O₂ at cathode channel increases with increasing the cell voltage. But Fig. 11 displays clearly that a reduction between input and output of the cell at the low voltage value has occurred while it is not seen a significant change of the gas concentration at high voltage.
maximum current and power density

As mentioned above, the reason for this decrease is that diffusing the oxygen from channel through the GDL in order to occur the electrochemical reaction. As shown in the Fig. 11(b), it is also noted that the optimal oxygen consumption of the channels was achieved at 0.6 voltage value obtained the maximum current and power density to improve the performance of fuel cell.

IV. CONCLUSIONS

A three-dimensional computational fluid dynamics model of a PEM fuel cell with double serpentine flow channels was developed to investigate the effects of flow direction, cell voltage and reactant gases humidification on performance. Using a single-phase, steady-state, three-dimensional model of PEM fuel cell, the following conclusion was obtained; the humidity in the reactant gases is an important factor to consider for improving the cell performance. As the relative humidity of anode side increases, both the chemical reaction and mass transfer of hydrogen are enhanced due to the increase of water content in the membrane, which leads to a better cell performance. It was observed that excessive humidification of the cathode caused to decrease the performance. By using low humidification condition of cathode side, the oxygen concentration in the reactants increases and the water vapour concentration on the cathode side decreases, this reduces cathode flooding and improves the cell performance. Because of that providing for an increasing mass transfer between inlet and outlet, optimum power density value was reached at counter flow channel PEM fuel cell. The maximum power density for the highest performing was 0.6481 W/cm² and occurred at 100%/10% anode/cathode humidification with counter flow channel.

Monthly Optimization of a New Hybrid Renewable Energy System Considering Energy and Agricultural Efficiency

Selmin ENER RUSEN*, Buket BEZGIN CARBAS*, Abdurrahman ULKER

Department of Energy Systems Engineering, Karamanoğlu Mehmetbey University, Karaman, Turkey.

selmin.enerrusen@gmail.com, bcarbas@kmu.edu.tr

Abstract—Clean and cheap energy in agriculture play a key role in improving agricultural productivity, environmental sustainability, and economic performance. This paper presents the result of the monthly optimization analysis for enhancing energy efficiency and conservation in a new hybrid system based on solar and wind energy potentials by reason of its climatic and regional factors. Using the data for one year, a preliminary study has been carried out for the selected station which produced important information for an extended work. The monthly optimization analysis results have been determined by using earth observation data of solar and wind which are registered in this region. According to the wind and solar data, the optimum month was found as July considering energy and agricultural efficiency. Results can be used either to increase the performance of the new hybrid system or to analyze long-term agricultural and energy studies with more efficiently.

Keywords—Hybrid Renewable Energy System, Optimal Energy Production.

I. INTRODUCTION

Energy is one of the biggest requirements for humanity since the first ages. In the modern age, energy has been indispensable for us in houses, agricultural regions, industrial regions, public utilities and outdoors with different needs. Most of these energy demands are met from fossil sources [1-3]. Fossil sources have been decreasing and for that reason more pollution has occurred day by day. Therefore, new energy sources are necessary to meet the energy needs [4, 5]. It is known that the renewable energy resources like as sun, wind, hydro, biomass and geothermal should be evaluated for the future of our world in view of the environmental effects such as global warming, climate change, and carbon emission. They come to mind first between clean energy resources, the sun has the biggest energy potential among them. Researchers are under way of progress in by forming this huge potential for the benefit of humanity like solar PV technology [6-8]. Wind energy is also other one of the most promising renewable power generation technologies nearly as large as solar energy potentials and also it is, used widely as a cheap source of energy for local energy requirements in all over the world. The capacity of modern wind turbines generated in recent years is quite high [9,10].

It is difficult to provide uninterrupted power with the solar and the wind renewable energy sources alone because these kinds of systems are dependent on the weather conditions. The design of hybrid systems is the necessary in order to ensure uninterrupted energy from these systems [11]. Since different renewable energy sources can implement to each other, multi-source hybrid alternative energy systems provide higher quality and quality power to people than a system based on a single resource. The thought of taking advantage of the hybrid renewable energy systems come the first and foremost when taken together with the environmental and economic impacts in today's conditions [12-14].

In the hybrid system studies, system components are usually installed to detached and large areas. In this case, it causes to gradually decrease in agricultural lands and limits the application of renewable energy systems. With this study, a new hybrid renewable energy system was designed. All system components are collected on a greenhouse enable to using agricultural land. In addition, optimum energy production was determined according to working performance of the system on a monthly basis.

II. MATERIAL AND METHOD

This study focuses on, environment-friendly energy deposition, an effective usage of agricultural land and obtaining maximum energy per unit area. All components of this new system are illustrated in Figure 1.

![Fig. 1 Schematic representation of New Hybrid Systems](image-url)
A. System Components

1) Photovoltaic System (PV): Photovoltaic solar panels generate electricity energy from solar radiation directly [15]. In this study, Si-poly module was selected according to the reasonable price and performance properties that are the important factor for selection of panel [16]. Totally 450 panels, which are specified during the design of panels connected in series. These panels are located on the greenhouse which has 20x50 m² area. Monthly output power performances of the selected photovoltaic system are given in Figure 2.

2) Wind Turbine System (WT): Wind turbines firstly convert the kinetic energy of the wind to the mechanical energy and then electrical energy [17]. The selected wind turbine has 34 m rotor diameter, its stepping area of horizontal axis 904 m and it has maximum 250 kW output power [18]. In addition, the wind turbine was selected according to wind data of Karaman province and horizontal axis wind turbine that works at least %45 efficiency [10]. Monthly output power performances of selected wind turbine are given in Figure 3.

3) Pumped Hydroelectric Power Station System (PHS): Pumped hydroelectric power station system is a clean energy deposition method which has an upper-bottom reservoir and mechanical parts. It enables to deposition of energy on water, and works without any chemicals. There are lots of studies about pumped hydroelectric systems [19-23]. With this new system design, it is aimed to store excess energy via PHS system for use when there is no power production is provided. This PHS system with 92 kW total instantaneous powers was designed. Pelton turbine was selected according to capacity and physical properties of the system.

4) Light Transmission System: In the designed hybrid system, photovoltaic panels were located on the top of the greenhouse that is application area of the system. But they block the light transmission in the greenhouse. An efficient light transmission system which is located on shading distance of photovoltaic panels light transmission in the greenhouse is provided when the plants need at certain times. In this way, sufficient light transmission in the greenhouse is provided. The light transmission system is given in Figure 4.
5) **Plant-House**: Greenhouses protect of plants and provide increasing of their yield and quality by keeping the indoor temperature in appropriate circumstances. The existing agricultural fields will be brought to the more efficient state thanks to greenhouse without being affected by seasonal differences. These systems have been used for a long time in the world and in our country. In this proposed new system a greenhouse with 20x50 m² area was selected.

### III. RESEARCH RESULTS AND COST ANALYSIS

In this study, electric production for new designed hybrid renewable energy system was calculated. Annual solar radiation, wind and temperature data for Karaman was used for calculations. The maximum electric production was observed in July by data on a monthly base. In addition cost analysis of the new designed system is detailed in Table 1. As a result of the installation of the system and calculation of the total investment payback period was calculated as 4.09 years.

In this study, a new hybrid renewable energy system was designed for the nature-friendly electric production without harming to agricultural lands. The performance of the designed system has been examined separately for each month of the year using one-year data of Karaman. The best electric production performance for this system has been determined in July. In addition, the total payback period was calculated as 4.09 years. According to research results, it is predicted that this new system is practicable for Karaman due to its geographical and climatic features. As a result, the proposed new system will support the expansion of the use of renewable energy systems that will be built in the future, because it provides high output power and high performance from the field of agricultural production, as well as being nature-friendly.

### IV. CONCLUSIONS

The authors would like to thank Turkish State Meteorological Service (TSMS), for providing us with measured data and Authors would like to express their gratitude to Karamanoglu Mehmetbey University for financial support.

Laminar Natural Convection in Triangular Enclosures

Emin Fuad Kent
Mechanical Engineering Faculty
Istanbul Technical University
Gümüşsuyu, Istanbul, Turkey
kente@itu.edu.tr

Abstract— Natural convection in non-rectangular enclosures is numerically analyzed in this study. Streamlines and isotherms are presented for different triangular enclosures with different boundary conditions and Rayleigh numbers.

Keywords— Natural convection, laminar flow, Nusselt number, Rayleigh number, triangular enclosure.

I. INTRODUCTION

One of the first studies about natural convection in rectangular enclosures was a solely experimental study made by Flack et al. [1] in 1979. After this, in 1982 Akinsete and Coleman [2] analysed natural convection of air in a two dimensional laminar right triangular enclosure using numerical methods. Steady state solutions are made for the conditions in which the aspect ratio (A.R.) is between 0.0625 and 1, and Grashof number varies in a range of 800 to 64000. Poulikakos ve Bejan [3] analysed right triangular enclosures in which the upper wall is cold and the lower wall is hot. The conditions that the aspect ratio is closing up to zero are analysed with Rayleigh number varying from $10^3$ to $10^5$.

Lam et al. [4] analysed the natural convection in right triangular, trapezoidal and rectangular enclosures by experimental and numerical methods. In all the cases, bottom wall is hot and side walls are adiabatic. Aspect ratio is kept constant at 4 and the horizontal angle is changed between $0^\circ$ and $25^\circ$.

Tabbarrok and Lin [5] analyzed natural convection in various geometries by finite element method. Square and quarter circle are among the examined geometries. The results that have been found with different Rayleigh numbers are similar with the previous researches.

Karyakin et al. [6] studied laminar natural convection inside isosceles triangular enclosures. Salmun [7,8] used air and water in right triangular geometries. The calculations are made for different Rayleigh number values between $10^2$ and $10^3$ and aspect ratios between 0.1 and 1.

Asan and Namli [9] studied the natural convection during the winter time heating of an attic space. They used finite volume method and analysed cases where Rayleigh numbers vary between 0.25 and 1. Multi-cellular structure is obtained in every enclosure when Rayleigh number equals to $10^5$. As aspect ratio decreases multi-cellular streamlines are observed at lower Rayleigh numbers.

II. MATHEMATICAL MODEL

For a steady state heat transfer with constant thermal and physical properties, laminar and steady incompressible flow with no viscous dissipation, the partial differential equations take the following vectorial forms.

Continuity,

$$\nabla \cdot V = 0$$  \hspace{1cm} (1)

Momentum,

$$\rho (\nabla \cdot V) V = \eta \nabla^2 V - \nabla p - \rho g$$  \hspace{1cm} (2)

Energy,

$$\nabla \cdot (\rho c_p V T) = k (\nabla V) T$$  \hspace{1cm} (3)

Two-dimensional form of these partial different equations in Cartesian coordinates can be written in primitive variable formulation as follows.

Continuity,

$$\frac{\partial u}{\partial x} + \frac{\partial v}{\partial y} = 0$$  \hspace{1cm} (4)

x-momentum,

$$\frac{\partial (\rho u u)}{\partial x} + \frac{\partial (\rho v u)}{\partial y} = \eta \left( \frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} \right) - \frac{\partial p}{\partial x}$$  \hspace{1cm} (5)

y-momentum, with the Boussinesq approximation for the buoyancy term,

$$\frac{\partial (\rho v v)}{\partial x} + \frac{\partial (\rho v v)}{\partial y} = \eta \left( \frac{\partial^2 v}{\partial x^2} + \frac{\partial^2 v}{\partial y^2} \right) - \frac{\partial p}{\partial y} + \rho g \beta (T - T_{\text{ref}})$$  \hspace{1cm} (6)

energy,

$$\frac{\partial (\rho u T)}{\partial x} + \frac{\partial (\rho v T)}{\partial y} = k \left( \frac{\partial^2 T}{\partial x^2} + \frac{\partial^2 T}{\partial y^2} \right)$$  \hspace{1cm} (7)

Rayleigh number,
III. PHYSICAL MODEL

The triangular grid structure is given in Fig. 1. In this work, natural convection of air with Prandtl number of 0.72 is analysed. The change of the streamlines and isotherms at different Rayleigh numbers ranging from $10^3$ to $10^5$ are obtained numerically and presented as graphics.

IV. NUMERICAL MODEL

Navier Stokes governing equations which are discretized with finite volume method are solved by Fluent 6.0.12 commercial software [12] by using SIMPLE and Upwind Difference methods. Iterations are continued until the convergence is obtained in a 60x60 grid structure.

Before starting to solve the problem, trial calculations are made in 30x30, 45x45 and 60x60 grid structures in order to prove that the problem is grid independent. Solution method is applied to these grid structures and then the calculated Nusselt numbers, maximum values of stream functions and the coordinates of these stream function values in the enclosure are compared. All the comparisons have shown that the change of these values are under 1% between 45x45 and 60x60 grid structures. So the problem is accepted to be grid independent and calculations are made by using 60x60 grid structure in order to get more precise results.

In Case-I, hypotenuse is cold, vertical wall is hot and horizontal wall is adiabatic. Streamlines and isotherms of this case are shown in Fig. 2. As the Rayleigh number is raised, isotherms start to get non-uniform shapes.

![Streamlines and isotherms inside the right triangular enclosure with the Case I boundary conditions for Rayleigh numbers 10^3,10^4 and 10^5, respectively](image)

Fig. 2  Streamlines and isotherms inside the right triangular enclosure with the Case I boundary conditions for Rayleigh numbers 10^3,10^4 and 10^5, respectively.

For Case II, when Rayleigh number is $10^3$, there is a conductive heat transfer inside the triangle and isotherms have an absolute symmetry. But when Rayleigh number is raised to $10^5$, heat transfer turns out to be convective as isotherms get non-uniform shapes. The results are given in Fig. 3.

For Case III, streamlines and isotherms for the case with A.R.=1 is shown in Fig. 4. Stream function values increase from the side to the inner part of the triangle and gets its maximum value in the central cell. If we compare this case with Case II, we can see that the triangle that we analyzed in Case III has lower stream function values when Rayleigh number is equal to $10^3$ and $10^4$. But when Rayleigh number is raised to $10^5$, maximum stream function value in Case III becomes higher than Case II. This shows that convection effect on the heat transfer in Case III is more than Case II.

For A.R.=0.5, streamlines and isotherms are shown in Fig. 5. Multicellular streamlines are also obtained in the present study when Rayleigh number is raised to $10^3$ and aspect ratio is below 1. While Rayleigh number is $10^5$, streamlines are very similar to those in the right triangular enclosure with A.R.=1. But, when Rayleigh number is raised to $10^3$, streamlines transform into a three cells structure.

$$Ra_c = \frac{g \beta \Delta T h^3 \rho^2 c_p}{k \eta}$$ (8)
For Case IV, streamlines and isotherms are shown in Fig. 6. While Rayleigh number is $10^3$, isotherms seem to be symmetrical and uniform. But, with the increase of Rayleigh number, isotherms get a non-uniform structure.

**IV. CONCLUSIONS**

In this study, steady state laminar natural convection in right triangular enclosures is analyzed. Finite volume method is used to discretize the Navier Stokes equations. SIMPLE
algorithm and upwind difference methods are applied to the governing equations. In order to investigate the effects of aspect ratio on the streamline patterns and isotherms, calculations are made on two different triangular enclosures.

Design and Thermal Analysis of Free Piston Linear Generator Using In Range Extended Electric Vehicles

Ramazan ŞENER*

*Mechanical Engineering, Marmara University, Turkey
ramazan.sener@marun.edu.tr

Abstract—Today, battery electric vehicles (BEV) have zero emission (tank to wheel) and very high efficiency. However, the most important obstacle of BEV is insufficient range. This disadvantage can be eliminated in term of range extender systems. Range extender system like generator can charge battery when required. Free Piston Linear Generator (FPLG), Wankel engine, Piston Internal Combustion Engine, Gas Turbine Engine and Fuel Cell Engine can be used as range extender unit.

In this study, opposed-piston free-piston linear generator which can be used in low weight electric vehicles, which has spark ignition, 153 cm3 volume, and gasoline direct fuel injection was designed via SOLIDWORKS® software. Thermal analysis of the engine were performed by means of ANSYS® software using temperature in the literature.

Finally, the engine design is determined to suit thermal operating conditions. It is find out that this system can be used as a range extender unit.

Keywords—Finite Element Method, Thermal Analysis, Free Piston Linear Generator, Computer Aided Design.

I. INTRODUCTION

Energy sources of conventional Internal Combustion Engines (ICE), oil reserves, are gradually in decreasing. Also, adverse effects of conventional ICE on the environment have led to many car manufacturers to product electric car. The inefficiency in ICE’s with low speed and, despite inefficient work with the reason of stop-start urban traffic, energy with regenerative braking, the electric car back in the storage and low speed is an advantage with less energy consumption. While the conventional ICE cars have low efficiency in both too low and too high engine speed and in start-stop city traffic, the electric cars have regenerative braking and consume less energy in low speed.

ICEs have different efficiencies a torques with different speeds, so it cannot operate with maximum efficiency, continuously. Unlike ICE, electric motors can give maximum torque in a wide speed ranges and can work with maximum efficiency in a wide torque ranges.

The forthcoming of electric vehicles are promising, because electric vehicles have no emission during operation. However, current battery technology is not at the desired level owing to short range and long charging times, which is the biggest obstacle in the development of battery electric vehicles. Although Electric cars for daily use are sufficient, they are still not suitable for long-distance travel. For this reason, to solve this problem, in the place of adding some battery unit to electrical car, which causes both an extra weight to car and extra costs, it can be added a range extender unit. Range extender unit has fuel station in anywhere and it can be charge to car’s battery while driving. In this way, car which is both can charge from mains and, if needed, FPLG can charge the batteries using gasoline, diesel or LPG. Vehicle will be made suitable for long trips [1, 3]. Furthermore, range extender can be made portable.

Many engines can be used as range extender unit such as internal combustion engines, gas turbine engines, wankel engines, and fuelcell engines etc. However, free piston linear engine may be smaller volume, lighter, and also high efficiency. Because these engines do not have the crank-rod mechanism although it works like a conventional internal combustion engines. Linear motion of pistons directly converted to electrical energy by means of the linear alternator instead of converting circular motion. Hence efficiency does not loss and weight and volume do not increase due to auxiliary units (Fig.1).

Free piston linear engine and generator have been designed and produced as prototype since the mid-twentieth century. Especially, companies such as Pempek Systems (Australia), Volvo, DLR (Germany), Micron AG (Switzerland) and Toyota have made free-piston linear generator design [4]. Table 1 shows the basic characteristics of the FPLG [2].

![Illustration of the part of the free-piston linear generator](image-url)
The REXEL study estimates the weight of a free piston linear generator with a central combustion unit at 55.9 kg. This weight involves the power electronics needed to run the FPLG. The power density for this prototype is 350 W/kg and the volumetric power density of FPLG is 470 W/l. Former experimental studies showed that the combustion unit could easily achieve an efficiency of 36% and efficiency of engine is about 36% and cost is approximate 2100 € per unit. Yet cost can be reduced to 1500 € per unit using mass production. FPLG with modular size and low weight is a good alternative for range extender units for electric vehicles. Vehicle can extend its range up to a 300 kilometers with adding just about 100 kg (including tank etc.) [1, 2].

II. MODELING OF ENGINE

Computer-aided design (CAD) is the use of computer systems to aid in the creation, modification, analysis, or optimization of a design. CAD is used to increase the productivity of the designer, to improve the quality of design, to improve communications through documentation and to create a database for manufacturing [5].

Free piston linear engine for range extended electric vehicles was designed using CAD software (SOLIDWORKS®) in order to analyze thermal using finite element method. The basic technical characteristics of the engine which was analyzed are given in Table 2.

The literature (Fig. 2) [1, 6].

Table 2

<table>
<thead>

</tbody>
</table>

Piston, cylinder, wrist pin and rod were redesigned based on the design in the literature (Fig. 2) [1, 6].

Temperature in cylinder change between 100oC and 2500oC and Pressure in cylinder change between 0.8 and 70 bar [18]. So, Cylinder to withstand these conditions are usually made of ductile cast iron grade or steel.

In our design, GGG40 material is selected benefiting from literature, due to damping capacity, good wear and temperature resistance, good machinability, and inexpensive to produce. For cooling, fins were added to cylinder.

By reason of moving at different speed and direction in cylinder, piston should be made of the lightweight material in order to decrease inertia force. Piston of gasoline engines are usually made of AISi including 12% silicon. As ratio of silicon in AISi go up, thermal expansion, wear rate and machinability go down [18]. In our design, AISi12CuNi is selected. Piston are designed as D-cup.

By virtue of free-piston linear engine, only axial forces come to rod. Thus, it is exposed to less load than conventional engines. AISI 4140 is selected for rod material. Rod has unusual shape, because engine designed has not crankshaft.

As FPLG has not crankshaft, rod does not angular movements. So rod pin fix rod and piston. Moreover rod pin, rod and piston can be monolithic. However, it is designed conventionally.

Piston, rod, rod pin and cylinder are designed according to the desired properties benefiting from the literature. Alternator is drawn as represent. Then, parts designed are assembled (Fig. 3 and 4).
III. THERMAL ANALYSIS OF ENGINE PARTS

A. Mathematical Formulation

The temperature $T(x, y, z, t)$ as a function of coordinate parameters and time satisfies a parabolic differential equations. It can be expressed as follows called heat equation,

$$\frac{k_x}{x^2} \frac{\partial^2 T}{\partial x^2} + \frac{k_y}{y^2} \frac{\partial^2 T}{\partial y^2} + \frac{k_z}{z^2} \frac{\partial^2 T}{\partial z^2} + Q = \rho c_p \frac{\partial T}{\partial t}$$

where $Q(x, y, z, t)$ is the source or sink rate of heat in a domain (W/m²), $c_p$ is the specific heat at constant pressure (kJ/kg°C) and $k$ is the thermal conductivity (W/m°C). The essential boundary condition on the boundary and the natural boundary condition can be defined, respectively, as

$$T(x, y, z, t) = T_i(x, y, z, t)$$

$$k_n \frac{\partial T}{\partial n} + q_p + h(T - T_o) + \sigma \epsilon (T^4 - T_o^4) = 0$$

where $k_n$ is the thermal conductivity normal to the surface, $q_p (x, y, z, t)$ is a prescribed flux (W/m²), $h$ is the heat transfer coefficient for convection (W/m²C), $\sigma$ is Stefan–Boltzmann constant (W/m²C⁴), $\epsilon$ is the emissivity and $T^{\infty}$ is the ambient temperature for convection and/or radiation. Boundary condition becomes nonlinear when radiation is included or the convective heat transfer coefficient is temperature dependent. Besides the boundary conditions, the initial condition must be specified for a heat transfer analysis:

$$T(x, y, z, 0) = T_{in}(x, y, z)$$

B. Finite Element Formulation

The domain is broken into a set of discrete volumes or finite elements that are generally unstructured; in 2D, they are usually triangles or quadrilaterals, while in 3D tetrahedral or hexahedra are most often used. The distinguishing feature of finite element method (FEM) is that the equations are multiplied by a weight function before they are integrated over the entire domain [7, 19].

This approximation is then substituted into the weighted integral of the conservation law and the equations to be solved are derived by requiring the derivative of the integral with respect to each nodal value to be zero; this corresponds to selecting the best solution within the set of allowed functions. The result is a set of non-linear algebraic equations [7].

The basis of the finite element method is a piecewise polynomial approximation for the temperature field within each element:

$$T = \sum_{i=1}^{n} N_i T_i$$

where $N_i$ are basis functions dependent only on the type of the element and its size and shape, and “$n$” represents the node number that each element has. Physically, $T_i(t)$ are nodal values of the temperature at time $t$, and mathematically, they are undetermined coefficients. Basically, by using different techniques, Eq. (1) can be reduced to

$$CT + KT = F$$

in which ($K$) is an effective conductivity (stiffness matrix) and ($F$) is an effective load (residual vector). For steady-state analysis, effective load becomes zero. By solving the system, the temperature distribution on the domain is determined [8, 9].

C. Thermal Analysis using Finite Element Method

Numerical analysis was performed to evaluate the temperature gradients in FPLG. The finite element mesh of the FPLG model using ANSYS® is shown in Fig. 5. In the thermal analysis, 209,721 elements are used. 378,597 nodes are also used in thermal analysis.

In this research, thermal boundary conditions were determined by examining the similar works in literature. The temperature values in the cylinder were taken to be average of ICE [9-14].

![Figure 5. Finite element mesh of FPLG designed](image)

Properties of FPLG materials used in thermal analysis are shown in Table 4 [15-17].

Thermal boundary conditions are shown in Fig. 6 and Table 5. Piston thermal boundary conditions consist of the combustion side thermal boundary condition (A), upper ring land (B), lower ring land (C), skirt surface thermal boundary condition (D), outside of cylinder thermal boundary condition (E), surface of rod and rod pin thermal boundary condition (F), inside of cylinder thermal boundary condition (G) and surface of combustion chamber thermal boundary condition (H) [9-14].

The resulting temperature distributions given in Fig. 7 and the resulting heat flux distribution are illustrated in Fig. 8. Temperature distribution in the top and side surface of piston is demonstrated Fig. 9 and Fig. 10, respectively.

Fig. 14 was shown that the surface temperature of the piston decreases from the center to the edge of the piston. The temperature at the center was found as 223°C, it decreased by ~10% and reached to 207°C at the edge of the piston. It indicates that the temperature distribution of the piston surface tends to decrease from the center to the edge of the piston. This situation is valid for the spark ignition engines at real working condition.

IV. RESULTS AND DISCUSSION

In order to evaluate the temperature gradients of the FPLG parts, numerical analyses were carried out. Minimum-maximum temperatures and heat fluxes values of piston and cylinder that is found in thermal analyses are shown in Table 6. Maximum temperature of combustion chamber is 231.56°C in the top surface of piston. Maximum heat flux of combustion chamber is 1.09*10⁶ W/m² and minimum heat flux of combustion chamber is 4.76*10⁴ W/m².

V. CONCLUSIONS

Although electric vehicle has advantages such as high efficiency, no emission and much quieter; it is limited by range and take about 4-6 hours to get fully charged. Range extender can eliminate these obstacles. Free piston linear generator in range extender units attract the attention with compact size, relatively simplicity and efficiency.

In this study, cylinder, piston, rod and rod pin of FPLG using in electric vehicles were designed. After defining all boundary and initials conditions in a finite element environment a thermal solution of the FPLG is achieved. According to findings of the analysis, the temperature occurred in engine is acceptable. Hence, it is clearly seen for results of analysis that, if manufactured, engine parts designed can work properly.

Abstract—In this study, effect of diesel, ethanol and EN blends as fuel in a diesel engine were examined with regard to performance parameters such as brake power, fuel consumption, specific fuel consumption and exhaust emissions such as NOx, CO, CO2. The blends prepared by mixing 10% of ethanol, diesel and EN in different proportions as volume were symbolized as E10 (%10 ethanol and % 90 diesel), E10E2 (%10 ethanol, %2 EN and % 88 diesel), E10E4 (%10 ethanol, %2 EN and % 84 diesel), E10E6 (%10 ethanol, %6 EN and % 84 diesel). The results obtained for these blends were compared with the results for diesel.

Keywords—Alternative fuel, diesel, ethanol, engine performance, exhaust emissions

I. INTRODUCTION

Diesel engines are internal combustion engines in which fuel is injected on pressurized hot air within the cylinder by compression in order to obtain the heat required for ignition. In these engines, combustion occurs, where the ignition conditions is optimum, with self-ignition of fuel-air mixture at the end of a certain ignition delay period following the injection of fuel. The longer ignition delay period leads to uncontrolled combustion of the fuel-air mixture causing an increased amount of fuel air mixture taken into the cylinder. This phenomenon which occurs with the sudden pressure increase causing the engine to work harder and noisy is known as diesel knock. There are many parameters that affect the ignition delay period and diesel knock. These are ambient temperature, ambient pressure, which are two main factors, operational factors such as engine speed, intake air temperature and pressure, engine load, oxygen concentration, and structural factors such as compression ratio, engine cooling conditions, injection quality and fuel factors [1]. When evaluated in terms of fuel, the most important parameter is the cetane number which is a measure of fuel ability to self-ignition. When it is desired to increase the fuel's ignition ability, cetane improver additives are needed to prevent diesel knock and shorten the ignition delay period. These additives shorten the ignition delay period between injection fuel and combustion where the various physical and chemical reactions occur such as atomization, evaporation, mixing with air [2].

The most commonly used cetane improver additive is 2-ethylhexyl nitrate (commonly used as abbreviations of EHN, 2EHN or EN), which improve combustion characteristics and lower burning point by shortening ignition delay [3]. Some researches related with most commonly used cetane improver EN (2 ethylhexyl nitrate) are summarized below. Zhang, et al. have been used a single-cylinder heavy-duty diesel engine fueled with D40 (40% DMF (2,5-dimethylfuran) by volume) with 2% 2-ethylhexyl nitrate addition. Results have showed that ignition delay has been shortened with EHN addition and maximum pressure increase rate has been decreased linearly with the proportion EHN. With high EGR rate, while EHN addition increases NOx emissions, it greatly decreases THC emissions. Based on their results, it has also been stated that EHN addition to D40 has solve trade-off problem between combustion noise and soot emissions for low cetane number oxygenated fuels [3]. Ickes, et al. have investigated the effect of a direct injection, diesel engine LTC operating mode fueled with diesel fuel doped with 2-EHN. It has been detected that adding 2-EHN to the fuel increase NOx emissions for premixed LTC [4]. İleri and Koçar examined the effect of adding antioxidants, butylated hydroxyanisole (BHA), butylated hydroxytoluene (BHT), tert-butylhydroquinone (TBHQ) and 2-ethylhexyl nitrate to B20 biodiesel/diesel blend. It has been observed in their study that addition antioxidants decrease brake specific fuel consumption. EHN is the best in reducing the NOx emissions (4.63%) but each antioxidant led to an increase in CO emission [5]. Li, et al. has examined the effect of three different cetane improvers (2-ethylhexyl nitrate, cyclohexyl nitrate and 2-methoxyethyl ether) with the ratio of 0.3% each one added to the B90M10 methanol/biodiesel blend. It has been confirmed that each cetane improver increase HC and CO concentrations while it reduce NOx concentration and...
smoke. Furthermore no matter they have added to blend, it has not observed any effect on brake thermal efficiency and exhaust temperature [6]. Atmanli has examined the effect of EHN addition at 500, 1000 and 2000 ppm concentration to (70% diesel, 20% hazelnut oil, 10% n-butanol or 10% 1-pentanol by vol.) DnBH and DPnH micro emulsions on fuel properties and engine characteristics. Tests have been carried out for 5 different engine loads (0%, 30%, 60%, 90% and 100%) at 2200 rpm constant engine speed. It has been obtained that EHN addition has no significant effect on density, kinematic viscosity, cloud point, cold filter plugging point (CFPP) or flash point but it has increased cetane numbers approximately 13.12%, 12.26%. It has also confirmed that EHN addition has cause significant reductions in brake specific fuel consumption and (NOx) emissions while it has cause to increase in (CO) emissions [7]. Ileri investigated the effect of 2-ethylhexyl nitrate on engine performance and exhaust emissions of a diesel engine fueled with diesel/sunflower oil/n-butanol (D70S20P10) or 1-pentanol blends (D70S20B10). Results of this study are as follows: Adding EHN to micro emulsion blends has little effect on brake power and brake mean effective pressure while it produce lower NOx, higher CO emission. As EHN concentration increase, brake specific fuel consumption reduces [8]. Relekar et al. have conducted an experimental study to determine the best percentage of additives which ensure maximum efficiency and minimum emissions. For this purpose, experiments have been performed with five samples obtained by blending three different additives. As a result, it has been expressed that best percentages are 70%, 15%, 15% for Dimethyl Carbonate, Ethyl Acetate, and 2Ethylhexyl Nitrate as fuel additive [9].

As mentioned above, there are many studies related to EN in the literature. These are focused on reducing NOx emissions and increasing the cetane number. In this study, the effects of EN (2 ethylhexyl nitrate) addition to ethanol and diesel blends in different ratios (2%, 4%, 6% by vol.) on diesel engine performance and exhaust emissions has been investigated. Performance parameters investigated in this study are brake power, fuel consumption and specific fuel consumption, exhaust emissions are CO, CO₂ and NOx emissions. The results were compared with E10 and the reference diesel fuel.

II. MATERIAL AND METHODS

The experiments were performed on a four-cylinder, water-cooled diesel engine. Other specifications of the engine are given in Table 1.

Diesel procured from gas station and ethanol procured from Konya Sugar Refinery were used for tests and they were performed at five different engine speeds (800, 1100, 1400, 1700, 2000 rpm) using diesel fuel, E10 (%10 ethanol and %90 diesel), E10EN2 (%10 ethanol, %2 EN and %88 diesel), E10EN4 (%10 ethanol, %4 EN and %86 diesel) and E10EN6 (%10 bioethanol, %6 EN and %84 diesel). Fuel properties used during the tests are given in Table 2.

### III. RESULTS AND DISCUSSION

#### A. Engine Performance

The variation of brake power with engine speed for each test fuel is shown in Fig. 1. Maximum torque has been obtained at 1100 rpm while 1700 rpm is maximum power speed for all fuels. Maximum brake power has the output value of 27.7, 26.8, 27.1, 26.0 and 24.6 for diesel, E10, E10EN2, E10EN4 and E10EN6 at 1700 rpm respectively. For all engine speed, higher power values have been obtained for diesel fuel and average decreases in power compared to diesel fuel are approximately 4.88%, 6.24%, 14.34%, 10.52%. The reasons for reducing engine power are lower cetane number and calorific value when ethanol is used. When these results have been evaluated, maximum average brake power value of E10 is higher than E10EN2, E10EN4 and E10EN6. Although EN addition to fuel improves combustion by increasing the cetane number, it also leads to reduction of performance and power along with lower heating value.
Variation of fuel consumption depending on engine speed for each fuel has been depicted in Fig. 2. The brake specific fuel consumption curve with engine speed for each test fuel is given in Fig. 3. For almost all fuel, it could be observed that raise in engine speed leads to increasing fuel consumption. Highest fuel consumption has been obtained in case the test engine operates with E10, except for 2000 rpm. When taken diesel fuel as a reference, increase in average fuel consumption is 2.06%, 1.00%, 1.85%, 2.46% for E10, E10EN2, E10EN4 and E10EN6 respectively. It can be explained by lower calorific value of diesel being higher than ethanol. When examining specific fuel consumption curve, the average specific fuel consumption is more than approximately 6.5% for E10, 19.2% for E10EN2, 63.1% for E10EN4 and 41.2% for E10EN6 compared to diesel. Namely, the amount of fuel required to generate the same work is less than for the engine fueled with diesel. This situation results from combined effect of lower heating value and density.

B. Exhaust Emissions

The variation of CO emissions, obtained by using diesel, E10, E10EN2, E10EN4 and E10EN6 as fuel in the test engine, with respect to engine speed is given in Fig. 4. As seen, CO emission values obtained for diesel fuel are higher for all engine speeds. Because of the high oxygen-content of ethanol, it is an expected result that CO emissions are lower for fuels containing ethanol within itself. CO emissions have shown a downward trend as engine speed generally increases for all fuel. Maximum CO emission at all engine speed is obtained when operating with diesel. Average decrease of CO emission is %7.93, %20.54, %19.34, %9.01 for E10, E10EN2, E10EN4, E10EN6 respectively.

Fig. 5 shows the variation of CO₂ emission depending on engine speed and fuel. Minimum value of CO₂ emission has been obtained at 2000 rpm while CO₂ emission has the maximum value at 1100 rpm, where engine torque has the
respectively. The average NOx concentration has a positive effect on NOx emission in engine speed. When each rpm is evaluated within its own, EN fuel has the maximum value of brake power compared with other fuels.

As it is seen in Fig. 6., NOx emissions reduces while engine speed increases. The maximum values of NOx emission has been obtained at 800 rpm while NOx emission has the lower value at 2000 rpm, maximum engine speed, for all fuels. When considering fuels, it can be seen that fuel which cause maximum NOx emission is diesel fuel for all engine speed. When each rpm is evaluated within its own, EN concentration has a positive effect on NOx emission in association with the increase in rpm. The average NOx emissions are 882 ppm, 742 ppm, 615 ppm, 748 ppm for diesel, E10, E10EN2, E10EN4 and E10EN6 respectively.

As the results are listed below:
- When assessed in terms of performance, diesel fuel has the maximum value of brake power compared with other fuels.
- The highest values of NOx, CO, CO\(_2\) emissions have also been obtained for diesel fuel.
- By the addition of EN, cetane number has increased approximately 5.45%, 5.17%, and 4.91% for E10EN2, E10EN4 and E10EN6 respectively compared to the E10.
- EN addition of 4% is a critical point with respect to brake power. Because brake power have increased with the increasing EN content in fuel from 2% to 4%. After E10EN4, the behavior of brake power with increasing EN content has changed in the opposite direction.
- E10 has the maximum average brake power value than E10EN2, E10EN4 and E10EN6. The reason is that EN addition to fuel improves combustion so this situation leads to reduction of performance and power.

### IV. CONCLUSIONS

In this study, it has been investigated the use of diesel and ethanol blends doped with EN (2 ethylhexyl nitrate), which is the best known cetane improver, in a diesel engine. Test fuels have been shown as E10, E10EN2, E10EN4 and E10EN6. The tests have been conducted at five different engine speed (800, 1100, 1400, 1700, 2000 rpm) for each fuel. The brake power, fuel consumption, specific fuel consumption as performance parameters and CO, CO\(_2\), and NOx as exhaust emissions have been analyzed and all the results have been compared with diesel fuel.

Optimal Tilt Angle for Obtaining Maximum Energy in Photovoltaic System for Siirt Province, Turkey

Asim Balbay, Resul Santas, Muhammet Camci
Mechanical Engineering, Siirt University, Siirt, Turkey
{asimbabay, resulsaritas, muhcamci}@gmail.com

Abstract— Renewable energy sources such as wind, sunlight, waves, hydroelectricity and thermal heat etc. are considered as alternative energy sources that can be replaced with energy derived from other energy sources. In particular, Photovoltaic(PV) systems has recently attracted more attention for generating electricity or power to supply energy requirement. Turkey, especially south parts of it, has relatively more solar energy capacity than Europe and west countries. It is very critical measurement that tilt angle between incident sunlight and photovoltaic system plays great changes on producing the power. Thus, we here present an experimental study that reports optimal angle for obtaining maximum energy in photovoltaic system for Siirt Province. In addition to the angle, solar irradiance, air moisture level, panel and ambient temperature, current and voltage were also measured. PV performance for a single module was assessed using PV module efficiency, which is defined as ratio of DC energy output from the PV module. Also, other parameters determining power production were studied: solar radiation level for measuring current from PV and temperature of PV for measuring output voltage.

Keywords—PV module, Optimal tilt angle, Solar irradiance, Siirt, Solar power

I. INTRODUCTION

Solar energy recently became a very popular energy source to supply required energy. Thus, interest in using PV systems launched to increase due to its great offers such as environmental benefits, cost effective, and renewable source. Maximum power generation in PV systems depends on atmospheric conditions for example temperature and solar radiation etc. [1]. Thereby, maximum power point tracker (MPPT) technique is needed and then introduced to obtain maximum power from sunlight. Enslin et al [2] introduced a highly efficient maximum power point tracker (MPPT) integrated into PV system and shows that MPPT provides with 25% more energy compared to conventional system. On the other hand, some investigators, in the literature, showed optimal tilt angle for photovoltaic system for maximum power generation in the case of certain cities. Such as, Kacira et al [3] found that optimal angle to place PV system varies through the year and reported the angle as 13° in June while it is 61° in December in the city of Sanliurfa. Hussein et al [4] presented a theoretical study that determines the performance of mono-crystalline silicon type PV modules at different angles and showed that maximum power is obtained while PV system facing south with a tilt angle between 20° and 30°. Also Ibrahim [5] introduced a theoretical approach to calculate optimal angle four times throughout a year, and he stated that according to results, average optimal tilt angle is found to be 14° for summer season while it is 48° for winter in Cyprus. Tang et al [6] investigated optimal angle with using a mathematical model for various months of year in China and their results indicate that in winter seasons, optimum tilt angle is calculated to be (ʎ+18°) in all cities except Chengdu Plain, Chongqing and Guizhou where optimal tilt angle is approximately (ʎ+10°), where ʎ is local latitude. Yakup et al [7] presented an analytical method to determine also optimal tilt angle and to obtain total global solar radiation in Brunei Darussalam and they concluded that annually averaged optimal tilt angle is obtained to be 3.3° for a south facing solar collector.

Theoretical techniques were indicated to obtain optimal tilt angle while collectors are facing through equator based on beam radiation [8,9]. El-Sayed [10] illustrated a mathematical approach to obtain optimal tilt angle taking account of solar reflectivity, latitude effect, number of glass covers and clearing index. Ahmad et al [11] stated a theoretical examination on determining of tilt angle of solar flat-plate collectors at ten different places in the world and they concluded that annually optimal tilt angle is calculated to be nearly equal to latitude of the location. Moreover, Liu et al [12] presented a theory that determines mean daily global radiation which is expressed as following:

\[ H_B = (H - H_d)R_b \]  \hspace{1cm} (1)
Where $H$ and $H_d$ are mean daily global and diffuse radiation for each month and $R_b$ is the ratio of daily averaged beam radiation on tilted surface [11].

$$ R_b = \frac{\cos(\theta - \beta) \cos \alpha \sin w + w_1 (\sin \theta - \beta) \sin \alpha}{\cos \theta \cos \alpha \sin w + w_1 \sin \theta \sin \alpha} \tag{2} $$

Where $\theta$ is latitude, $\alpha$ is the angle of declination, ‘min’ stands for smaller value of two terms in bracket, and $w_1$ is given as [11];

$$ w_1 = \min[\cos^{-1}(-\tan \theta \tan \alpha), \cos^{-1}(-\tan(\theta - \beta) \tan \alpha)] \tag{3} $$

In this paper, we present an experimental technique that identifies optimal tilt angle of PV system facing to south for Siirt Province to obtain maximum energy in summer season. In addition to the angle, solar irradiance, air moisture level, panel and ambient temperature, current and voltage were also measured. PV performance for a single module was assessed using PV module efficiency, which is defined as ratio of DC energy output from the PV module. Also, other parameters determining power production were studied: solar radiation level for measuring current from PV and temperature of PV for measuring output voltage.

II. MATERIAL AND METHODS

**Experimental Setup**

An experimental apparatus, with PV module that allows us to change at the different angles was designed and fabricated in order to determine the change in power of the PV module under the different angles. The pictorial view of the experimental set up is presented in Fig. 1. The set up consist of PV modules (40W and 80 W), multimeter, pyranometer, datalogger and humidity & temperature sensors. The specifications of the pyranometer used in this study are listed in Table 1. The pyranometer is properly suited for the solar irradiative flux in horizontal or tilted configurations.

Fig. 2 shows the schematic picture of a PV module at different angles which was drawn in a CAD program. As it can be seen from the figure, PV system, which exists of 40 W, placed to face south was tilted from $0^\circ$ to $50^\circ$ to observe the obtained solar energy from sunlight in Siirt Province. Siirt is located at $37^\circ$ 56 N and 41 57 E and 895 m above sea level in the Southern East of the Anatolia. The averaged data have taken between 21st May 2016 and 15th June 2016. Measurement time started at 8:00 am and ended at 5:00 pm. While PV system was tilted for each event, current and voltage values were measured. After determining optimal angle, PV system which exists of 80 W, was used and placed at optimal angle to obtain total solar radiation curve throughout a day. In addition to these values, solar irradiance, air irradiance, air moisture level, panel and ambient temperatures were also measured in this study.

A circuit based on the simulation model for a PV cell for assessing the I-V characteristic curves of PV module with respect to changes on environmental parameters (temperature and irradiance). P-V characteristics are presented in Fig. 3 by varying irradiance from 200 W/m² to 1000 W/m² under constant temperature. The operating point of a PV under constant irradiance and temperature is the intersection point of the I-V characteristics and the load characteristics. Also, I-V characteristics are presented in Fig. 4 by varying temperature from 0 °C to 75 °C under constant irradiance. They are implemented under a Matlab/
Simulink environment; the most used software by researchers and engineers.

III. RESULTS AND DISCUSSION

Fig. 5 demonstrates experimental results of different tilt angles for 40 W PV module system and solar radiation. Experiments run for 9 hours starting at 8:00 am and ending at 5:00 pm. Based on the results, maximum power, which is approximately 40 W during noon time, occurs when the PV system is tilted between 10° and 20°. However, as the tilt angle increased from 20° to 50°, the power launches to drop as shown in the figure. Minimum obtained power in noon time is found to be about 33 W. Also, solar radiation is also measured throughout the day and maximum radiation is found to be approximately 930 W/m² in noon time. Fig. 6 shows experimental results of 80 W PV module system at 15° tilt angle that maximum power is obtained. As it can be seen from the figure, solar irradiance, air moisture level, panel surface and ambient temperatures are measured. According to the results, air ambient and panel surface temperatures are calculated to be approximately 35 °C and 57 °C relatively.

Moreover, measured maximum current and voltage values for 80 W PV module are found to be about 20 V and 5 A relatively. On the other hand, moisture ratio decreases starting from 50 % down to about 15 % during the day.

IV. CONCLUSION

It is very critical to identify optimal tilt angle for PV system to capture maximum power. Thus, we here present an experimental study that reports optimal angle for obtaining maximum energy in photovoltaic system for Siirt Province. Our experimental results show that optimal tilt angle for Siirt Province is 15 ° that maximum power occurs. In addition to the angle, solar irradiance, air moisture level, panel and ambient temperature, current and voltage were also measured and reported in this study. PV performance for a single module was assessed using PV module efficiency, which is defined as ratio of DC energy output from the PV module. Also, other parameters determining...
power production were studied: solar radiation level for measuring current from PV and temperature of PV for measuring output voltage.

Computational Investigation of Turbulent Flow in Pipes

Tahir Karasu

Department of Mechanical Engineering, Eskişehir Osmangazi University, Meşelik, 26480 Eskişehir, Türkiye
tkarasu@ogu.edu.tr

Abstract — This original research work presents the results of an extensive study of computational solution of steady, incompressible and axisymmetric developing turbulent flow in circular-sectioned pipes at three different Reynolds numbers. Employing the finite-volume method, a computer program based on the SIMPLE (Semi-Implicit Method for Pressure Linked Equations) algorithm has been developed. Computer solution of the conservation equations of mass and momentum, together with the standard k-ε turbulence model, are obtained using an iterative numerical solution technique. Near the solid boundary, wall-functions are employed. Computational predictions for radial profiles of axial velocity, turbulence kinetic energy, turbulence kinetic energy dissipation rate, effective viscosity, centre-line velocity variation, wall-shear stress and friction coefficient distributions along axisymmetric pipe flow geometry are presented and compared with experimental data. The results of computational investigation are generally in good agreement with experimental measurements.

Keywords — Flow in pipes; k-ε turbulence model; Computations

I. INTRODUCTION

Developing turbulent flow in pipes of circular cross-section is one of the basic flow studies. This flow is basically a transition from a boundary layer-type flow at the entrance to a fully developed flow downstream. The free stream in the inlet region is completely surrounded by the boundary layer, which by diffusion of momentum through laminar and turbulent mechanisms grows in thickness as the distance from the pipe inlet increases. The growing boundary layer accelerates the free stream which eventually loses its identity as the boundary layer merges with it. Following the disappearance of the free stream, further changes occur in the velocity distribution and turbulence structure until the flow attains a fully developed state. Turbulent pipe flow has wide application in the field of engineering. The ability to compute the detailed nature of the behaviour of developing turbulent flow in pipes would lead to the improved design of engineering equipment. In practice, turbulent pipe flow is mostly encountered in: transportation of various liquids and gases in long pipes, heat exchangers, coolant passages of electrical generators, combustion chamber systems and air conditioning and heating systems. Considerable experimental and theoretical works on turbulent flow in pipes have been reported in the literature. Among the most interesting ones are the works of [1]-[26]. In the present computational investigation, the experimental measurements of [7], [8], and [25] have been used for comparison with the numerical computations. The main objective of this investigation is to obtain numerical predictions of steady, incompressible, developing turbulent flow in pipes using the standard k-ε turbulence model [27] with a wall-functions boundary condition, and to compare the results of numerical computations with available experimental measurements in the literature for validation.

II. MATHEMATICAL AND PHYSICAL MODEL

A. Governing Equations and Turbulence Model

With reference to Figure 1, the partial differential equations governing steady, incompressible turbulent flow in cylindrical-polar coordinates are written in the following time-averaged, two-dimensional form, with axial and radial coordinates x and r, respectively, as follows:

$$\frac{\partial}{\partial x}(\rho u) + \frac{1}{r} \frac{\partial}{\partial r}(r \rho v) = -\frac{\partial}{\partial x}\left( r \phi \right) - \frac{1}{r} \frac{\partial}{\partial r}\left( r \phi \right) + S_\phi$$  \(1\)

This represents a transport equation for a general variable \(\phi\). The flow is assumed to remain in radial planes. The variables \(u\) and \(v\) are axial and radial velocity components, \(\rho\) is the fluid density and \(\Gamma_\phi\) is the transport coefficient. The final term, \(S_\phi\), is the source term. The variables, \(\phi\), necessary in this computational investigation are \(u, v, k\) and \(\varepsilon\). Here, \(k\) and \(\varepsilon\) stand for the kinetic energy of turbulence and its dissipation rate, respectively. The turbulence model employed in the present study is the k-ε model of [27]. If \(\phi\) is set equal to unity and \(\Gamma_\phi\) and \(S_\phi\) to zero, \(1\) also represents the equation of continuity. Pressure is derived from the pressure correction equation [28]. The transport equations, coefficients and the source terms are summarised in Table I.

![Fig. 1 Coordinate system and geometry of the pipe flow](image-url)
The finite volume forms of the partial differential equations coupled with the boundary conditions are solved iteratively using a line-by-line solution procedure in conjunction with a tridiagonal matrix form.

D. Computational Details

The numerical computations were performed on an Intel(R) Core(TM) i5-2400 CPU @ 3.10GHz 3.40GHz personal computer. The computational grid distributions for all of the pipe-flow cases studied are depicted in Figures 2, 13 and 23. All the computational grids employed were non-uniformly distributed with finer spacings in the regions of large spatial gradients, i.e., the near-wall region and inlet region of the pipe. Staggered control volumes were used for axial and radial velocity components. All other quantities of interest were calculated at the grid points. The line-by-line method was employed to obtain converged solutions iteratively. Under-relaxation factors were used to promote numerical stability with values of 0.6,0.6,0.8,0.8,0.5 and 0.5 for \( u, v, k, \varepsilon, P \) and \( \mu_e \), respectively. The convergence criterion adopted in the present computations was that the summation of the absolute values of the mass residual in the entire computational domain be less than a prescribed value of \( 10^{-8} \). Grid tests were performed with different grid sizes to obtain an optimum grid-independent solution for each flow case studied. All the computations presented in this study are grid-independent. Table II summarises details of the computational requirements for the flow cases investigated. In this table, \( Re \) is the Reynolds number and \( N \) is the number of iterations performed to obtain a converged solution.

</tbody>
</table>

**Note:** 1. \( \mu_t = C_\mu \rho k^2/\varepsilon \).

2. Turbulence model constants are assigned the following values [27]:
   \( C_\mu = 0.09, C_1 = 1.44, C_2 = 1.92, \sigma_k = 1.0, \sigma_\varepsilon = 1.3 \)

3. \( G = \mu \left\{ 2 \left[ \left( \frac{\partial u}{\partial x} \right)^2 + \left( \frac{\partial v}{\partial x} \right)^2 + \left( \frac{v}{r} \right)^2 \right] + \left( \frac{\partial u}{\partial r} + \frac{\partial v}{\partial x} \right) \right\} \)

### B. Boundary Conditions

With reference to Figure 1, the boundary conditions for turbulent flow in the pipes studied are given below. At the inlet to the pipe, a uniform axial velocity corresponding to the experimental condition is specified, while the radial velocity is assumed zero. Empirical relationships are employed to assign uniform entrance values to turbulence quantities \( k \) and \( \varepsilon \); that is, \( k=(0.001-0.002) u_b^2 \) and \( \varepsilon=(C_\mu k^{1/2} / 0.02R) \), where \( u_b \) is the bulk velocity and \( R \) is the radius of the pipe.

The pipe section was chosen to be sufficiently long so that fully developed conditions could be assumed to prevail at the outlet; that is, all axial derivatives were assumed to vanish and the radial velocity was assumed zero. At the pipe axis, symmetry is assumed: \( \frac{\partial \phi}{\partial r} = v = 0 \), where \( \phi \) can be any of \( u, k \) or \( \varepsilon \). At the pipe wall, velocity components \( u, v \) and turbulence quantities \( k \) and \( \varepsilon \) are set to zero. The values of \( k \) and \( \varepsilon \) at the near-wall grid points are calculated using the wall-functions of [27]. Initial field values throughout the computational domain were specified properly so as not to cause numerical divergence.

### C. Numerical Solution Procedure

In this computational investigation, employing the conventional finite-volume approach, a computer program based on the SIMPLE algorithm of [28] has been developed. The partial differential equations (1) are discretised by a control-volume-based finite-difference method with a hybrid scheme. The finite-volume forms of the partial differential equations coupled with the boundary conditions are solved iteratively using a line-by-line solution procedure in conjunction with a tridiagonal matrix form.

### III. PRESENTATION AND DISCUSSION OF RESULTS

Computations were carried out for developing turbulent flow in circular-sectioned pipes at three different Reynolds numbers, and the results of computations were compared with the experimental data of [7], [8], and [25]. With air used as the working fluid in the pipe, the experimental measurements of [8] are first selected as the comparison basis for this computational study. The Reynolds number based on the pipe diameter and bulk velocity is \( Re=1.78 \times 10^5 \) (\( Re= \frac{u_b d}{\nu} \), where \( u_b \) is the bulk velocity). For this flow situation, the calculation domain is extended to an axial distance of 128.57 diameters downstream of the inlet section of the pipe. The
computational grid distribution for the axisymmetric pipe flow of [8] is depicted in Figure 2. Figures 3 and 4 show the computational radial profiles of axial velocity in dimensionless form $u/u_c$, and radial distance $r/R$, at axial stations ranging from $x/d=1$ to 128.57, together with experimental measurements of [8]. From these figures, it is seen that the computational axial velocity profile develops along the pipe and shows excellent agreement with experimental measurements at the last cross-section $x/d=128.57$. In Figure 5, the predicted axial variation of centre-line velocity is presented in terms of $u_c/u_b$ and axial distance $x/d$. Here, the centre-line velocity ($u_c$) is normalised with the bulk velocity ($u_b$), and the axial distance is normalised with respect to pipe diameter ($d$). As can be seen from the figure, the predicted axial variation of centre-line velocity increases first until it attains its maximum value and then decreases slightly to its fully-developed value downstream after which it remains constant. In Figure 6, the predicted axial distribution of dimensionless turbulence kinetic energy $k^{0.5}/u_b$ along the symmetry axis of the pipe is shown. As seen from the figure, the turbulence kinetic energy decreases until it attains its minimum value at about $x/d=19$, and thereafter increases sharply along the pipe axis until it reaches its maximum value at about $x/d=48$, and then after showing a little bit decrease it attains its fully-developed value, after which it remains constant along the pipe axis. In Figure 7, the predicted radial profiles of turbulence kinetic energy are plotted in dimensionless form of $k/u_b^2$ and radial distance $r/R$ at the same downstream locations as in Figure 3.

As can be seen from the figure, the predicted radial distribution of turbulence kinetic energy increases over the cross-section as the flow develops along the pipe. Figure 8, on the other hand, shows the predicted radial distribution of turbulence kinetic energy for pipe flow of [8] at $x/d=128.57$. Here, the turbulence kinetic energy is made dimensionless with respect to friction velocity $u^2_\tau$.

Figures 9 and 10 reveal the computational radial profiles of turbulence kinetic energy dissipation rate and effective viscosity, respectively, across the pipe at the same downstream positions as in Figures 3 and 7. Here, the predicted profiles are normalised with respect to maximum values of turbulence kinetic energy dissipation rate $\epsilon_{\text{max}}$ and effective viscosity $\mu_{\text{emax}}$ in the flow field, respectively. These figures show how the calculated turbulence kinetic energy dissipation rate and effective viscosity profiles develop along the pipe.

Fig. 2 Computational grid distribution for pipe flow of [8]

Fig. 3 Comparison of predicted radial profiles of axial velocity along the pipe with experimental data of [8]
Fig. 4 Comparison of predicted radial profile of axial velocity with experimental data of [8] at x/d=128.57

Fig. 5 Predicted axial variation of dimensionless centre-line velocity along the pipe axis of [8]

Fig. 6 Predicted axial distribution of dimensionless turbulence kinetic energy along the pipe axis of [8]

Figure 11 displays the computed variation of the wall-shear stress along the pipe wall, in terms of the ratio $\tau_w / \tau_{wd}$, plotted against nondimensional distance $x/d$ from the inlet of the pipe. The wall-shear stress has been made dimensionless with respect to its fully-developed value, $\tau_{wd}$. For this flow situation, as can be seen from the figure, the fully-developed value of the wall-shear stress is reached at about $x/d=85$. Beyond this location, it remains practically constant. Finally, the computed distribution of the friction coefficient ($C_f = 2 \tau_w / \rho U_b^2$) along the pipe wall, as a function of downstream distance $x/d$, is plotted in Figure 12. As seen from the figure, the friction coefficient exhibits the same trend as the wall-shear stress shown in Figure 11.

Fig. 7 Predicted radial profiles of dimensionless turbulence kinetic energy for pipe flow of [8]
Fig. 8 Predicted radial distribution of turbulence kinetic energy for pipe flow of [8] at x/d = 128.57

Fig. 9 Predicted radial profiles of normalised turbulence kinetic energy dissipation rate for pipe flow of [8]

Fig. 10 Predicted radial profiles of normalised effective viscosity for pipe flow of [8]
The predicted radial profiles of axial velocity along the pipe in dimensionless form \( u/u_c \), and radial distance \( r/R \), at axial locations ranging from \( x/d = 0.6 \) to 96.15 are plotted in Figures 14 and 15, and compared with the experimental data of [25]. As seen from the figures, the predicted axial velocity profile develops along the pipe, and at cross-section \( x/d = 87 \) the agreement obtained between the predictions and experimental data is very good. Figure 16, on the other hand, displays the predicted axial variation of dimensionless centre-line velocity \( (u_c) \) along the pipe axis, normalised to bulk velocity \( (u_b) \) and plotted as a function of downstream distance normalised to pipe diameter \( (d) \). As can be seen from the figure, the predicted axial variation of centre-line velocity increases until it reaches its maximum value and then decreases slightly to its fully-developed value after which it remains constant. In Figure 17, the predicted axial distribution of dimensionless turbulence kinetic energy \( k^{0.5}/u_b \) along the symmetry axis of the pipe is revealed. As seen from the figure, the turbulence kinetic energy decreases until it attains its minimum value at about \( x/d = 20 \), and thereafter increases sharply along the pipe axis until it reaches its maximum value at about \( x/d = 45 \), and then after showing a little bit decrease it attains its fully-developed value, after which it remains constant along the pipe axis. In Figure 18, the predicted radial profiles of turbulence kinetic energy are displayed in normalised form of \( k/u_b^{2} \) and radial distance \( r/R \) at the same downstream stations as in Figure 14. As can be seen from the figure, the computed radial distribution of turbulence kinetic energy increases over the cross-section as the flow develops along the pipe, except near the wall region at which it decreases slightly with increasing axial distance. Figures 19 and 20 give the predicted radial profiles of turbulence kinetic energy dissipation rate and effective viscosity, respectively, across the pipe at the same downstream locations as in Figures 14 and 18. These figures indicate how the predicted turbulence kinetic energy dissipation rate and effective viscosity profiles develop along the pipe flow configuration of [25]. In Figure 21, the predicted variation of the wall-shear stress in nondimensional form of \( \tau_w/\tau_{wd} \) along the pipe wall is given as a function of downstream distance normalised to pipe diameter. For this flow case, as can be seen from the figure, the fully-developed value of the wall-shear stress \( \tau_{wd} \) is attained at about \( x/d = 73 \). Beyond this location, it remains practically constant. Finally, the computed distribution of the friction coefficient \( (C_f = 2 \tau_w/\rho U_b^2) \) along the pipe wall, as a function of downstream distance \( x/d \), is plotted in Figure 22. As seen from the figure, the friction coefficient exhibits the same trend as the wall-shear stress shown in Figure 21.
Fig. 14 Comparison of predicted radial profiles of axial velocity along the pipe with experimental data of [25]

Fig. 15 Comparison of predicted radial profile of axial velocity with experimental data of [25] at x/d=87

Fig. 16 Predicted axial variation of dimensionless centre-line velocity along the pipe axis of [25]

Fig. 17 Predicted axial distribution of dimensionless turbulence kinetic energy along the pipe axis of [25]
Fig. 18 Predicted radial profiles of normalised turbulence kinetic energy for pipe flow of [25]

Fig. 19 Predicted radial profiles of normalised turbulence kinetic energy dissipation rate for pipe flow of [25]

Fig. 20 Predicted radial profiles of normalised effective viscosity for pipe flow of [25]
The third flow configuration is for the pipe flow experiment of [7] with air used as the working fluid. The Reynolds number of the pipe flow is $Re=1\times10^5$ ($Re=\frac{u_b d}{\nu}$, where $u_b$ is the bulk velocity). For this flow situation, the computational domain is extended to an axial distance of 240.7 diameters downstream from the inlet plane of the pipe. The computational grid distribution for the pipe flow of [7] is indicated in Figure 23. The computed radial profiles of axial velocity along the pipe in dimensionless form $u/u_c$, and radial distance $r/R$, at axial positions ranging from $x/d=3$ to 240.7 are depicted in Figures 24 and 25, and compared with the experimental measurements of [7]. As seen from the figures, the computed axial velocity profile develops along the pipe, and at cross-section $x/d=240.7$ the agreement obtained between the predictions and experimental data is excellent.

IV. CONCLUDING REMARKS

The main concluding remarks from the computational study of the present investigation can be summarised as follows. Developing turbulent flow in pipes of circular cross-section at three different Reynolds numbers has been computed numerically employing the standard k-ε turbulence model. Using the finite-volume method, a computer program based on the SIMPLE algorithm of [28] has been developed. The performance of the standard k-ε turbulence model has been investigated for developing turbulent pipe flow. The computed radial profiles of axial velocity, turbulence kinetic energy, turbulence kinetic energy dissipation rate, effective viscosity, axial variation of centre-line velocity, wall-shear stress and friction coefficient distributions along the pipe are presented and, wherever available, compared with experimental measurements reported in the literature. The results of computational investigation are generally in good accord with the experimental measurements.

Abstract— Autonomous underwater vehicles (AUVs) or unmanned air vehicles (UAVs) as a part of defence systems are evaluated for underwater or atmospheric conditions, respectively. In these operation conditions, these vehicles are expected to have some critical properties such as energetic performance, longer range, less deflection from the target. These expectations are generally related with less resistance or drag. Due to these aforementioned issues, drag coefficient carries importance in the design of a defence vehicle. In the application, drag coefficient for a model can be measured with force measurement systems in water or wind tunnels. With this approach, drag coefficients of torpedo-like geometries have been obtained by force measurement system integrated to an open wind tunnel in Fluid Mechanics Laboratory of Aksaray University. Different models have been investigated for Reynolds numbers range of Re = 6.6 x 10^4 and Re = 33.1 x 10^4. The elliptical cross-sectional one has only been investigated at several attack angles varying from α = 0˚ to α = 30˚. The effects of torpedoes having various leading edge types with changing length/diameter (L/D) ratios and trailing edges of the elliptical cross-sectional one with different numbers of appendages on drag coefficients have been considered. When the wind speeds increase, drag coefficients decrease owing to shrinking wake region size. In addition, while attack angles rise, drag coefficients also increase because of flow separation around leading edge. Various leading edge types just like elliptical cross-sectional one, circular cross-sectional one and swaged headed one have been examined; the lowest drag coefficient has been found to be an elliptical cross-sectional one whereas the highest one was yielded for the swaged headed one. Furthermore, the more appendages added to trailing sections of torpedo-like geometries, the higher drag coefficients have been obtained. Moreover, inverse relationship between L/D ratios and drag coefficients has been observed.

Keywords— Defence vehicles, drag coefficient, Reynolds number, torpedo, wind tunnel

I. INTRODUCTION

Examination the deeps of seas and abyssal ocean zones for the development of defence systems, improves the motivation of scientists and engineers to keep on their researches and studies. It is known that oceans and seas cover the two thirds of our world, but oceans and seas have not drawn enough interest when analogized with land and atmosphere. Another point to be emphasized is that underwater research vehicles or underwater defence vehicles are exposed to huge forces than land and air vehicles. When their manoeuvre capabilities are considered, investigation of the hydrodynamic characteristics for these aforementioned vehicles is very crucial for engineering community. In this content, torpedo and torpedo-like geometries are described in the classification of unmanned (autonomous) underwater vehicles. In this study, drag coefficients of torpedo-like geometries have been determined with respect to the experimental results obtained from the force measurement system in an open wind tunnel. In this perspective, many studies related with the hydrodynamic characteristics of these underwater vehicles were presented before. Feldkamp (1987) has examined the drag, energetic cost and efficiency associated with the locomotion of a sea lion. In the experiments, four sea lions have been investigated in terms of drag coefficient. They have obtained the results for frontal areas as follow C_D = 0.07 at Re = 2.03 x 10^4; C_D = 0.069 at Re = 2.13 x 10^4 and C_D = 0.046 at Re = 2.87 x 10^4 [1]. Beheshi et al. (2009) have studied on the flow physics around an airship in a water tunnel and have carried out experiments to determine the aerodynamic characteristics of these aircrafts in the range of Re = 1.09 x 10^4 and Re = 7.05 x 10^4. They have measured the drag on a small scaled model of the airship to identify a laminar-to-turbulent boundary layer transition. It has been observed that the body with appendages resulted in 30% higher drag compared to the bare hull [2]. Husaini et al. (2009) have simulated the cooperative AUV motion by using CFD to study on drag variation in terms of distance between two AUVs and position arrangement. They have stated that the drag of the follower AUV in position arrangement is always lower than leading drag [3]. Abrebeekooh and Rad (2011) have obtained the drag force acting on a tubular frustum designed eligible for underwater conditions. All experiments have been completed in the range of Reynolds numbers between 10^7 and 7 x 10^7. These experimental results have been confronted with numerical results of k-ε turbulence model. The geometry has been reversed to obtain results for different L/D ratios. In other words both at upstream and downstream, the tubular frustum has been placed with respect to its small diameter. By this way, different flow directions have been attained. In case of the small diameter of the tubular
International Conference on Advanced Technology & Sciences (ICAT’16) September 01-03, 2016 Konya-Turkey

frustum at upstream, less drag force has been observed owing to low pressure [4]. Mirzaei et al. (2012) have investigated the drag of different aircraft aft bodies both experimentally and numerically. Experiments have been carried out in a wind tunnel and numerical analyses have been done by using CFD code. They have found that changing the passenger aircraft aft body to the basic cargo aft body led to a 28% increase in the drag coefficient [5]. Pan et al. (2012) have utilized the numerical simulations to determine the hydrodynamic coefficients of a SUBOFF submarine model. Steady and unsteady Reynolds Averaged Navier-Stokes (RANS) simulations have been carried out for the flow analyses. Dynamic mesh method has been adopted to examine the manoeuvre capabilities. The computational results have been verified by comparison with experimental data and therefore this method has been recommended by authors [6]. Okawa et al. (2013) have measured the drag exerted on different archery arrows in a wind tunnel for various attack angles. In the experimental study, Reynolds numbers range from 9 × 10^5 and 2.4 × 10^6. They have stated that drag coefficient decreased due to increase in Reynolds number. On the other hand, when the angle attack increases drag coefficient also rises [7]. Saeidinezhad et al. (2015) have presented a study on experimental investigation of hydrodynamic characteristics of a submersible vehicle model. A wind tunnel with smoke flow visualization technique has been used to test the submarine model with all its appendages at length based Re = 6.6 × 10^6 for different pitch angles between α = -10° and α = 27°. Drag coefficients have been examined with respect to Reynolds numbers of Re = 4.7 × 10^6 and Re = 8 × 10^6. A perpetual increment in both drag and lift coefficients has been observed due to raise in pitch angles. Flow separation near to nose tip has been monitored as non-axisymmetric nose shape existed [8]. Fureby et al. (2016) have studied a generic conventional submarine at yaw angle of 10°. Wind tunnel with PIV has been utilized as an experimental setup and LES turbulence model has been used for the numerical study [9]. Skarolek and Karabelas (2016) have investigated the flow over an aircraft wing by LES turbulence model at Re = 2.5 × 10^6 while the angles of attack varying from 4° to 12°. The results indicated that maximum drag decreased by approximately 40 at low attack angles [10]. The aim of this study is to determine the drag coefficients of different torpedo-like geometries positioned in an open wind tunnel for several cases at various Reynolds numbers, experimentally.

II. MATERIAL AND METHOD

In this study, drag coefficients of different torpedo-like geometries having various length/diameter (L/D) ratios have been determined experimentally. Here, the diameter of the torpedo-like geometry is D = 40 mm for the elliptical cross-sectional and circular cross-sectional ones while the diameter of the swage headed one is D = 45 mm. While the diameter of the geometry is constant, the length/diameter ratios are L/D = 5 to L/D = 8.125. Only several angles of attack changing from α = 0° to α = 30° have been considered for the elliptical cross-sectional one. Furthermore, the elliptical cross-sectional one has been examined by adding appendages to its trailing edge. All torpedo-like geometries used in the experiments have been shown in Fig. 1. However, these geometries have been indicated with the length/diameter ratio of L/D = 5. Other L/D ratios (such as L/D = 6.125, 6.875 and 8.125) have been attained by adding attachment part into the middle of the torpedo-like geometries.

Fig. 1 Torpedo-like geometries used for the experiments performed in the open wind tunnel

The experimental results have been obtained from the force measurement system in an open wind tunnel in Fluid Mechanics Laboratory of Aksaray University for Reynolds numbers ranging from Re = 6.6 × 10^4 to Re = 33.1 × 10^4.

A. Experimental Setup

An open wind tunnel with a force measurement system has been used in the facilities of Fluid Mechanics Laboratory at Aksaray University in Aksaray/Turkey as indicated in Fig. 2. The wind tunnel is the classic experiment system for aerodynamic flow experiments. The open wind tunnel has been manufactured by German brand called as G.U.N.T. Hamburg Gerätebau GmbH. Technical drawing of the system has been shown in Fig. 3.
The dimensions of the open wind tunnel which is G.U.N.T. Hamburg HM 170 are 2860 mm x 860 mm x 1700 mm and these are length, width and height of the wind tunnel, respectively. Fan motor power is 2.25 kW and the wind tunnel is able to reach up to 2800 rpm with variable frequency control. With respect to catalogue data, fan head is given as 500 Pa and 2.5 m/s of maximum air flow is provided. A body is positioned in a measurement section having cross-sectional area of 292 x 292 mm² through the approximate length of 420 mm. In the force measurement part of the wind tunnel, the diameter of the model holder is 4 mm and its length to centre of the model is defined as 225 mm. The measurement range of the system is up to 10 N with the resolution of 0.1 N in terms of both forces of drag and lift [11].

The wind tunnel consists of (1) inlet contour, (2) flow straightener, (3) nozzle, (4) measurement section, (5) model, (6) force sensor, (7) display and control unit, (8) diffuser, (9) switch cabinet, (10) inclined tube manometer and (11) axial fan as seen in Fig. 4 [11].

The model being studied remains at rest while the flow medium is set in motion, and thus the desired flow around the model is generated. It is an "Eiffel" type open wind tunnel used to demonstrate and measure the aerodynamic properties of various models. For this purpose, air is drawn from the environment and accelerated.

The air flows around a model, in a measurement section. The air is then decelerated in a diffuser and pumped back by a fan. The carefully designed nozzle contour and a flow straightener ensure a uniform velocity distribution with little turbulence in the closed measurement section. The flow cross-section of the measurement section is square. The built-in axial fan with outlet guide vane system and a variable-speed drive is characterised by an energy-efficient operation at high efficiency. Air velocities up to 28 m/s can be reached in this open wind tunnel. This type of wind tunnel is only suitable for relatively low air velocities in the range of 0 < Mach number of Ma < 0.2. Turbulence intensity of the wind tunnel is estimated as 3%. The system is equipped with an electronic two-component force sensor. Lift and drag forces are detected and displayed digitally. The air velocity in the measurement section is displayed on the inclined tube manometer. The tube manometers are utilized for measurement of the pressure in drag bodies [11].

All experiments have been carried out in this wind tunnel for different free-stream air speeds which are $U_\infty = 5$ m/s, 7.5 m/s, 10 m/s, 12.5 m/s, 15 m/s, 17.5 m/s, 20 m/s, 22.5 m/s and 25 m/s corresponding Reynolds numbers of $Re = 6.6 \times 10^4$, 9.9 $\times 10^4$, 13.2 $\times 10^4$, 16.6 $\times 10^4$, 19.9 $\times 10^4$, 23.2 $\times 10^4$, 26.5 $\times 10^4$, 29.8 $\times 10^4$ and 33.1 $\times 10^4$, respectively. Attack angles are $\alpha = 0^\circ$, 4°, 8°, 12°, 15° and 30° and these values have only been considered for the elliptical cross-sectional torpedo-like geometry. The effects of torpedo-like geometries having various leading edge types with changing length/diameter (L/D) ratios on drag coefficients have been examined while different leading edge types are elliptical cross-sectional one, circular cross-sectional one and swaged headed one. The length/diameter ratios (L/D) have been given as L/D = 5, 6.125, 6.875 and 8.125, respectively. Moreover, the elliptical cross-sectional one has been investigated by adding three and four appendages to its trailing edge.

The force measurement system of the wind tunnel presents the drag force acting on the model. For this reason, drag coefficients ($C_D$) of different torpedo-like geometries in this study have been calculated by using Eq. (1):
\[ C_D = \frac{2F_D}{\rho AV_{\infty}^2} \] (1)

Here, \( F_D \) stands for the drag force acting on the model. As the model holder has been used in the experiments for the stability of the model, drag force has taken place on the model holder. Drag force value \( (F_{DH}) \) of the model holder has been subtracted from the total measured value of the drag force \( (F_D) \) to calculate the actual drag force value \( (F_D) \) acting on the torpedo-like geometry as seen in Fig. 5 [11].

![Fig. 5 Error caused by model holder [11]](image)

In Eq. (1), \( \rho \) is the density of air and it has been taken as \( \rho = 1.205 \text{ kg/m}^3 \) at 20 \( ^\circ \text{C} \) temperature and 1 atm pressure. By the way, \( A \) is the frontal reference area of the torpedo-like geometry. In the experiments, it alters with respect to the diameter of the torpedo-like model used and also appendages added. The areas of the torpedo-like geometries have been given in Table I.

In Eq. (1), \( V_{\infty} \) symbolizes the free-stream velocity which is called as \( U_v = 5 \text{ m/s}, 7.5 \text{ m/s}, 10 \text{ m/s}, 12.5 \text{ m/s}, 15 \text{ m/s}, 17.5 \text{ m/s}, 20 \text{ m/s}, 22.5 \text{ m/s} \) and \( 25 \text{ m/s} \). Drag coefficient results obtained with respect to the Eq. (1) have been given in the following comparison graphics for different cases considered.

![Fig. 6 Angle of attack effect on drag coefficients of an elliptical cross-sectional torpedo-like geometry for different Reynolds numbers](image)

TABLE I

| REFERENCE FRONTAL AREAS OF THE TORPEDO-LIKE GEOMETRIES |

In Fig. 6, drag coefficients of elliptical cross-sectional torpedo-like geometries with different angles of attack have been presented at various Reynolds numbers. Attack angles of \( \alpha = 0^\circ, 4^\circ, 8^\circ, 12^\circ, 15^\circ \) have been considered for \( Re = 6.6 \times 10^4, 9.9 \times 10^4, 13.2 \times 10^4, 16.6 \times 10^4, 19.9 \times 10^4, 23.2 \times 10^4, 26.5 \times 10^4, 29.8 \times 10^4 \) and \( 33.1 \times 10^4 \). According to the given comparison graphic, maximum drag coefficients at whole cases have been obtained for the free-stream air speed of 5 m/s corresponding \( Re = 6.6 \times 10^4 \). At \( Re = 6.6 \times 10^4 \), \( C_D = 1.0995 \) is at attack angle of \( \alpha = 0^\circ \); \( C_D = 1.1571 \) is at attack angle of \( \alpha = 4^\circ \); \( C_D = 1.4008 \) is at attack angle of \( \alpha = 8^\circ \); \( C_D = 1.4922 \) is at attack angle of \( \alpha = 12^\circ \); \( C_D = 1.7671 \) is at attack angle of \( \alpha = 15^\circ \) and \( C_D = 2.2215 \) is at attack angle of \( \alpha = 30^\circ \). When the free-stream air speeds (also corresponding Reynolds numbers) acting on the torpedo-like geometry increase, less drag coefficient values have been attained. It has been found that \( C_D = 1.0995 \) for \( Re = 6.6 \times 10^4 \); \( C_D = 0.5303 \) for \( Re = 9.9 \times 10^4 \); \( C_D = 0.3903 \) for \( Re = 13.2 \times 10^4 \); \( C_D = 0.2704 \) for \( Re = 16.6 \times 10^4 \); \( C_D = 0.1892 \) for \( Re = 19.9 \times 10^4 \); \( C_D = 0.1640 \) for \( Re = 23.2 \times 10^4 \); \( C_D = 0.1594 \) for \( Re = 26.5 \times 10^4 \); \( C_D = 0.1553 \) for \( Re = 29.8 \times 10^4 \) and \( C_D = 0.1538 \) for \( Re = 33.1 \times 10^4 \) for the attack angle of \( \alpha = 0^\circ \). Another result is that while the attack angles of the torpedo-like geometry rise, there are increment obtained in drag coefficients related with increasing frontal reference areas. At the value of \( Re = 33.1 \times 10^4 \) calculated for \( U_v = 25 \text{ m/s} \), it has been obtained that \( C_D = 0.1538 \) for \( \alpha = 0^\circ \), \( C_D = 0.1574 \) for \( \alpha = 4^\circ \), \( C_D = 0.1881 \) for \( \alpha = 8^\circ \), \( C_D = 0.2280 \) for \( \alpha = 12^\circ \), \( C_D = 0.4873 \) for \( \alpha = 15^\circ \) and \( C_D = 0.7380 \) for \( \alpha = 30^\circ \).
Fig. 7 indicates drag coefficients of various leading edge types with length/diameter (L/D) ratio of L/D = 5. Here, different leading edge types are elliptical cross-sectional one, circular cross-sectional one and swaged headed one. The effects of torpedo-like geometries having various leading edge types have been examined for $Re = 6.6 \times 10^4$, $9.9 \times 10^4$, $13.2 \times 10^4$, $16.6 \times 10^4$, $19.9 \times 10^4$, $23.2 \times 10^4$, $26.5 \times 10^4$, $29.8 \times 10^4$ and $33.1 \times 10^4$. With respect to the given graphic, maximum drag coefficients for all cases have been detected for the free-stream air speed of 5 m/s corresponding $Re = 6.6 \times 10^4$. At $Re = 6.6 \times 10^4$, $C_D = 1.1624$ is for the circular cross-sectional one; $C_D = 1.0995$ is for the elliptical cross-sectional one and $C_D = 1.0262$ is for the swaged headed one. While the free-stream air speeds (also corresponding Reynolds numbers) acting on the torpedo-like geometry rise, drag coefficients decrease. At $Re = 33.1 \times 10^4$, $C_D = 0.1580$ is for the circular cross-sectional one; $C_D = 0.1538$ is for the elliptical cross-sectional one and $C_D = 0.1502$ is for the swaged headed one. It has been found that $C_D = 1.1624$ for $Re = 6.6 \times 10^4$; $C_D = 0.6216$ for $Re = 9.9 \times 10^4$; $C_D = 0.4255$ for $Re = 13.2 \times 10^4$; $C_D = 0.3056$ for $Re = 16.6 \times 10^4$; $C_D = 0.2129$ for $Re = 19.9 \times 10^4$; $C_D = 0.1943$ for $Re = 23.2 \times 10^4$; $C_D = 0.1784$ for $Re = 26.5 \times 10^4$; $C_D = 0.1647$ for $Re = 29.8 \times 10^4$ and $C_D = 0.1580$ for $Re = 33.1 \times 10^4$ for the circular cross-sectional one. Furthermore, it has been obtained that $C_D = 1.0995$ for $Re = 6.6 \times 10^4$; $C_D = 0.5303$ for $Re = 9.9 \times 10^4$; $C_D = 0.3903$ for $Re = 13.2 \times 10^4$; $C_D = 0.2704$ for $Re = 16.6 \times 10^4$; $C_D = 0.1892$ for $Re = 19.9 \times 10^4$; $C_D = 0.1640$ for $Re = 23.2 \times 10^4$; $C_D = 0.1594$ for $Re = 26.5 \times 10^4$; $C_D = 0.1553$ for $Re = 29.8 \times 10^4$ and $C_D = 0.1538$ for $Re = 33.1 \times 10^4$ for the elliptical cross-sectional one. Moreover, it has been observed that $C_D = 1.0262$ for $Re = 6.6 \times 10^4$; $C_D = 0.4495$ for $Re = 9.9 \times 10^4$; $C_D = 0.3295$ for $Re = 13.2 \times 10^4$; $C_D = 0.2585$ for $Re = 16.6 \times 10^4$; $C_D = 0.1779$ for $Re = 19.9 \times 10^4$; $C_D = 0.1629$ for $Re = 23.2 \times 10^4$; $C_D = 0.1562$ for $Re = 26.5 \times 10^4$; $C_D = 0.1522$ for $Re = 29.8 \times 10^4$ and $C_D = 0.1502$ for $Re = 33.1 \times 10^4$ for the swaged headed one. As a result of passive flow control, the lowest drag coefficient has been found to be the swaged headed one whereas the highest one was yielded for the circular cross-sectional one.

Drag coefficients of the elliptical cross-sectional ones with different numbers of appendages on trailing edges have been shown in Fig. 8 for the length/diameter (L/D) ratio of L/D = 5. Here, it has been considered with or without appendages. In the presence of appendages, three or four appendages have been added to the trailing edges of the geometry. These aforementioned cases have been examined for $Re = 6.6 \times 10^4$, $9.9 \times 10^4$, $13.2 \times 10^4$, $16.6 \times 10^4$, $19.9 \times 10^4$, $23.2 \times 10^4$, $26.5 \times 10^4$, $29.8 \times 10^4$ and $33.1 \times 10^4$. In the graphic, maximum drag coefficients have been observed for the free-stream air speed of 5 m/s corresponding $Re = 6.6 \times 10^4$. For $Re = 6.6 \times 10^4$, $C_D = 1.4288$ is for the elliptical cross-sectional one with four appendages; $C_D = 1.3216$ is for the elliptical cross-sectional one with three appendages and $C_D = 1.0995$ is for the elliptical cross-sectional one without any appendages. After the free-stream air speeds (also corresponding Reynolds numbers) acting on the torpedo-like geometry increase, the decrease in drag coefficients has been observed. It has been interpreted that $C_D = 1.4288$ for $Re = 6.6 \times 10^4$; $C_D = 0.8413$ for $Re = 9.9 \times 10^4$; $C_D = 0.5050$ for $Re = 13.2 \times 10^4$; $C_D = 0.3688$ for $Re = 16.6 \times 10^4$; $C_D = 0.2532$ for $Re = 19.9 \times 10^4$; $C_D = 0.2245$ for $Re = 23.2 \times 10^4$; $C_D = 0.2066$ for $Re = 26.5 \times 10^4$; $C_D = 0.1805$ for $Re = 29.8 \times 10^4$ and $C_D = 0.1745$ for $Re = 33.1 \times 10^4$ for the elliptical cross-sectional one with four appendages. In addition, it has been obtained as $C_D = 1.3216$ for $Re = 6.6 \times 10^4$; $C_D = 0.7803$ for $Re = 9.9 \times 10^4$; $C_D = 0.4564$ for $Re = 13.2 \times 10^4$; $C_D = 0.3400$ for $Re = 16.6 \times 10^4$; $C_D = 0.2456$ for $Re = 19.9 \times 10^4$; $C_D = 0.2170$ for $Re = 23.2 \times 10^4$; $C_D = 0.1993$ for $Re = 26.5 \times 10^4$; $C_D = 0.11756$ for $Re = 29.8 \times 10^4$ and $C_D = 0.1701$ for $Re = 33.1 \times 10^4$ for the elliptical cross-sectional one with three appendages. What’s more, it has been found that $C_D = 1.0995$ for $Re = 6.6 \times 10^4$; $C_D = 0.5303$ for $Re = 9.9 \times 10^4$; $C_D = 0.3903$ for $Re = 13.2 \times 10^4$; $C_D = 0.1779$ for $Re = 19.9 \times 10^4$; $C_D = 0.1629$ for $Re = 23.2 \times 10^4$; $C_D = 0.1562$ for $Re = 26.5 \times 10^4$; $C_D = 0.1522$ for $Re = 29.8 \times 10^4$ and $C_D = 0.1502$ for $Re = 33.1 \times 10^4$ for the elliptical cross-sectional one with two appendages. The more appendages added to trailing sections of torpedo-like geometries, the higher drag coefficients have been obtained because of increase in frontal reference areas.
In Fig. 9, drag coefficients of elliptical cross-sectional torpedo-like geometries with the length/diameter (L/D) ratios have been given at various Reynolds numbers. Different elliptical torpedo-like geometries having length/diameter (L/D) ratios of L/D = 5, 6.125, 6.875 and 8.125 have been considered for $Re = 6.6 \times 10^4$, $9.9 \times 10^4$, $13.2 \times 10^4$, $16.6 \times 10^4$, $19.9 \times 10^4$, $23.2 \times 10^4$, $26.5 \times 10^4$, $29.8 \times 10^4$ and $33.1 \times 10^4$. With respect to the given graphic, maximum drag coefficients at all cases have been obtained for the free-stream air speed of 5 m/s corresponding $Re = 6.6 \times 10^4$. At $Re = 6.6 \times 10^4$, $C_D = 0.7083$ is for length/diameter (L/D) ratio of L/D = 5; $C_D = 0.9286$ is for length/diameter (L/D) ratio of L/D = 6.125; $C_D = 0.7976$ is for length/diameter (L/D) ratio of L/D = 6.875 and $C_D = 0.7083$ is for length/diameter (L/D) ratio of L/D = 8.125, respectively. While the free-stream air speeds (also corresponding Reynolds numbers) acting on the torpedo-like geometry rise, decrease in drag coefficient values has been observed. Minimum values of drag coefficients have been seen for the circular cross-sectional torpedo-like geometry with the length/diameter ratio of L/D = 8.125 as $C_D = 0.1552$ for $Re = 8.125 \times 10^4$. In Fig. 10, different circular cross-sectional torpedo-like geometries having length/diameter (L/D) ratios of L/D = 5, 6.125, 6.875 and 8.125 have been considered for $Re = 6.6 \times 10^4$, $9.9 \times 10^4$, $13.2 \times 10^4$, $16.6 \times 10^4$, $19.9 \times 10^4$, $23.2 \times 10^4$, $26.5 \times 10^4$, $29.8 \times 10^4$ and $33.1 \times 10^4$. With respect to Fig. 10, maximum drag coefficients for entire situations have been attained for the free-stream air speed of 5 m/s corresponding $Re = 6.6 \times 10^4$. At $Re = 6.6 \times 10^4$, $C_D = 1.1624$ is for length/diameter (L/D) ratio of L/D = 5; $C_D = 1.0360$ is for length/diameter (L/D) ratio of L/D = 6.125; $C_D = 0.8737$ is for length/diameter (L/D) ratio of L/D = 6.875 and $C_D = 0.8034$ is for length/diameter (L/D) ratio of L/D = 8.125, respectively. While the free-stream air speeds (also corresponding Reynolds numbers) acting on the torpedo-like geometry increase, decrease in drag coefficient values has been obtained. Minimum values of drag coefficients have been seen for the circular cross-sectional torpedo-like geometry with the length/diameter ratio of L/D = 8.125 as $C_D = 0.1527$ for $Re = 33.1 \times 10^4$. Additionally, when the length/diameter ratios increase, drag coefficients decrease for the elliptical cross-sectional ones. At the value of $Re = 33.1 \times 10^4$ calculated for $U_\infty = 25$ m/s, it has been obtained that $C_D = 0.1527$ for length/diameter (L/D) ratio of L/D = 8.125 for the elliptical cross-sectional ones. In addition, when the length/diameter ratios increase, drag coefficients decrease as in the Fig. 8 for the elliptical cross-sectional ones. At the value of $Re = 33.1 \times 10^4$ calculated for $U_\infty = 25$ m/s, it has been obtained that $C_D = 0.1538$ for length/diameter (L/D) ratio of L/D = 5; $C_D = 0.1521$ for length/diameter (L/D) ratio of L/D = 6.125; $C_D = 0.1509$ for length/diameter (L/D) ratio of L/D = 6.875 and $C_D = 0.1501$ for length/diameter (L/D) ratio of L/D = 8.125 for the elliptical cross-sectional ones.
At \( \text{Re} = 6.6 \times 10^4 \) as in Fig. 10, \( C_D = 1.0262 \) is for length/diameter (L/D) ratio of \( L/D = 5 \); \( C_D = 0.9000 \) is for length/diameter (L/D) ratio of \( L/D = 6.125 \); \( C_D = 0.7798 \) is for length/diameter (L/D) ratio of \( L/D = 6.875 \) and \( C_D = 0.6754 \) is for length/diameter (L/D) ratio of \( L/D = 8.125 \), respectively. While the free-stream air speeds (also corresponding Reynolds numbers) acting on the torpedo-like geometry rise, decrease in drag coefficient values has been observed. Minimum values of drag coefficients have been obtained for the swaged headed torpedo-like geometry with the length/diameter ratio of \( L/D = 8.125 \) as \( C_D = 0.6754 \) for \( \text{Re} = 6.6 \times 10^4 \); \( C_D = 0.3689 \) for \( \text{Re} = 9.9 \times 10^4 \); \( C_D = 0.2489 \) for \( \text{Re} = 13.2 \times 10^4 \); \( C_D = 0.2296 \) for \( \text{Re} = 16.6 \times 10^4 \); \( C_D = 0.1710 \) for \( \text{Re} = 19.9 \times 10^4 \); \( C_D = 0.1568 \) for \( \text{Re} = 23.2 \times 10^4 \); \( C_D = 0.1515 \) for \( \text{Re} = 26.5 \times 10^4 \); \( C_D = 0.1491 \) for \( \text{Re} = 29.8 \times 10^4 \) and \( C_D = 0.1461 \) for \( \text{Re} = 33.1 \times 10^4 \). In addition, when the length/diameter ratios increase, drag coefficients decrease as in the Fig. 10 for the swaged headed ones. At the value of \( \text{Re} = 33.1 \times 10^4 \) calculated for \( U_o = 25 \text{ m/s} \), it has been obtained that \( C_D = 0.1502 \) for length/diameter (L/D) ratio of \( L/D = 5 \); \( C_D = 0.1500 \) for length/diameter (L/D) ratio of \( L/D = 6.125 \); \( C_D = 0.1475 \) for length/diameter (L/D) ratio of \( L/D = 6.875 \) and \( C_D = 0.1461 \) for length/diameter (L/D) ratio of \( L/D = 8.125 \) for the swaged headed torpedo-like geometries.

IV. CONCLUSIONS

In this study, drag coefficients of torpedo-like geometries have been obtained by force measurement system integrated to an open wind tunnel. Different torpedo-like models have been investigated in the range of \( \text{Re} = 6.6 \times 10^4 \) and \( \text{Re} = 33.1 \times 10^4 \). The elliptical cross-sectional one has only been examined at various attack angles varying from \( \alpha = 0^\circ \) to \( \alpha = 30^\circ \). The effects of torpedoes having various leading edge types with changing length/diameter (L/D) ratios and trailing edges of the elliptical cross-sectional one with different numbers of appendages on drag coefficients have been considered. For all cases, maximum drag coefficient values have been obtained for the free-stream air speed of 5 m/s corresponding \( \text{Re} = 6.6 \times 10^4 \) and the free-stream air speeds (also corresponding Reynolds numbers) acting on the torpedo-like geometry increase, less drag coefficient values have been attained. Another result is that while the attack angles of the torpedo-like geometry increase, there are increment obtained in drag coefficients related with increasing frontal reference areas. As a result of passive flow control, the lowest drag coefficient has been found to be the swaged headed one whereas the highest one was yielded for the circular cross-sectional one. Another deduction is that, the more appendages added to trailing sections of torpedo-like geometries, the more drag coefficients have been obtained because of increase in frontal reference areas. In addition, when the length/diameter ratios (L/D) increase, decrease in drag coefficients has been observed.

ACKNOWLEDGEMENT

The authors would like to acknowledge the funding of Academic Staff Training Program (OYP) for Project No. of 2015-OYP-007 and Scientific and Technological Research Council of Turkey (TUBITAK) under Contract No. 214M318.

Abstract— Hydraulic turbines are turbomachines that transforms the hydraulic energy into mechanical energy. Francis turbines are the most common hydraulic turbine type in use. A francis turbine consists of several components such as spiral case, stay vanes, guide vanes, runner and draft tube. Design and performance analysis of these turbines requires much time. During the recent years, Computational Fluid Dynamics (CFD) has been frequently used to examine turbomachinery performance since CFD is more effective in terms of time and economy. In this study, a francis turbine is designed with respect to head and discharge values which are significant parameters for preliminary design. Performance analyses have been carried out with commercial CFD codes by changing guide vane positions. For each position of guide vanes, turbine efficiency and velocity and pressure distributions are obtained. In conclusion, the optimum guide vane position is determined for the maximum turbine performance.

Keywords—Francis Turbine, Guide Vanes, Performance Analysis, Computational Fluid Dynamics (CFD)

I. INTRODUCTION

In recent years, hydraulic energy becomes one of the significant renewable energy type due to its high potential and efficient transformation into electrical energy. The structures which transforms hydraulic energy into electrical energy are called hydroelectric power plants. The process of transformation is provided by two steps. First, hydraulic energy transforms into mechanical energy by way of a hydraulic turbine. Then a rotating shaft, which rotates simultaneously with turbine runner, drives a generator to transform the mechanical energy into electrical energy. Although there are a lot of turbine types used for transforming energy, Francis turbines are the most common type in use due to their efficient working principle.

Francis turbine is a reaction turbine. That means there should be a pressure drop between inlet and outlet of the turbine because both kinetic and potential energy of water are used. Francis turbines are generally used in mid-range head and discharge values. Head and discharge values are significant because the performance of turbine depends on these values. So the selection of turbine types is carried out via these parameters. The types of turbine depending on head and discharge values are given in Figure 1.

Fig. 1 Variation of turbine types depending on head and discharge values[5]

A francis turbine comprises of several components. These components are named as spiral case, stay vanes, guide vanes, runner and draft tube. These components play important roles while turbine is working. Spiral case is the structure which
surrounds the whole turbine components. This component has several sections which decrease towards its outlet section. Spiral case distributes the inflow that comes from penstock through the stay vanes on equal pressure values in its each section. Stay vanes are the fixed blades which are responsible of regulating the flow towards to guide vanes. Guide vanes are the configurable blades that control the flow rate value which enters the runner. As performance of the turbine depends on flow rate value, it can be said that guide vanes directly effects the performance of a Francis turbine. Turbine runner is the main component where the transformation of hydraulic energy into mechanical energy occurs. Turbine blades rotate with the water motion that moves out of guide vanes. As transformation of energy provided, water which rotates the runner and gives it to the stream. Water gains pressure due to increasing cross sectional area of draft tube but it never has its former pressure in spiral case inlet. In Figure 2, components of a Francis turbines are shown.

There has been a certain number of studies about Francis turbines in literature. Schweiger [1] examined the dimensionless parameters, geometrical quantities and specific speed of a Francis turbine. Siervo and Leva [2] manifested diagrams and equations about the design of the spiral case, runner and draft tube. Nilsson and Davidson [3] studied the relation between velocity and pressure in a Francis turbine runner by changing trailing edge angle of runner blades. Caillot et al. [4] investigated the design of guide vanes in order to send the water in desired angle and flow rate to the runner.

In this study, the effect of guide vanes positions on turbine efficiency is examined by means of commercial CFD codes. Different guide vane angles are used in several performance analyses and the optimum guide vane position is determined according to the best efficiency value.

II. DESIGN METHODOLOGY

Designing a Francis turbine is a complicated process so it should be done step by step. Five stages are specified: inputs, preliminary design, geometry design, CFD analyses and final design. Thus, a design methodology is established. The stages of design methodology are given in Figure 3.

Head and discharge values are the most significant parameters in designing process. All the preliminary design parameters depend on these two values. Therefore, head and discharge values must be determined in first stage. In this study an actual turbine’s values are used as head and discharge.

After specifying head and discharge values, preliminary design stage starts. In this stage, experimental curves and theoretical data in literature are used for determining main dimensions of components. There’s an order to design components’ main dimensions. First of all, dimensions of runner should be determined based upon it is the inner component between others. Another reason is runner has the smallest diameter and other components’ dimensions are specified by runner diameter. Runner diameter and heights are determined from theoretical data. After runner’s dimensions are determined, guide vanes’ dimensions can be specified. Guide vanes surround the runner, so its diameter should be larger than runners. According to the studies in literature, it’s generally taken as 1.16 times larger than runner’s diameter [5].

\[
D_{\text{guide vanes}} = 1.16D_{\text{runner}} \tag{1}
\]

The number of guide vanes and maximum guide vane angle at full load are determined based on a parameter, named velocity coefficient(Ω). The number of guide vanes are determined from an experimental diagram in literature by way of velocity coefficient. Maximum guide vane angle is determined from
equation (2). Calculation of velocity coefficient is shown in equation (3), (4) and (5).

\[
\alpha = 4(-4\Omega^2 + 13\Omega + 1) \\
\Omega = \omega \sqrt{Q} \\
\omega' = \omega / \sqrt{2gH} \\
Q' = Q / \sqrt{2gH}
\]

Stay vane diameter is selected based on guide vane diameter. Leading edge angle of stay vanes is specified as same as guide vane’s due to flow regulation. After selecting stay vanes diameter, spiral case -the outermost component- parameters are determined. Specification of spiral case parameters is done based on technical data and experimental curves as the same in runner. Spiral case sections are designed based on MATLAB codes [6]. Finally, draft tube parameters are designed. The inlet diameter of draft tube is determined based on runner’s outlet diameter. Other parameters of draft tube are designated by theoretical data in literature as runner and spiral case.

As preliminary design finished, geometry of turbine is created computationally in ANSYS Design Modeler and ANSYS BladeGen. First of all, blade profiles of runner, guide vanes and stay vanes are generated in ANSYS BladeGen module. NACA profiles are used in generating these profiles. These blade profiles are turned into solid geometries and then flow domains of runner, guide vanes and stay vanes are generated. Flow domains of spiral case and draft tube are generated in ANSYS Design Modeler. The whole components are unified at last. The computational design of Francis turbine’s flow domain is shown in Figure 4.

After completing the geometry design, computational fluid dynamics (CFD) analyses are carried out. If the efficiency of turbine is low, based on analyses, guide vane angle is changed and carried the analysis out again until the best efficiency point obtained. When the best efficiency point obtained, it is decided that guide vane angle of this point is the optimum guide vane position. More details of CFD analyses will be given in Chapter III.

### III. COMPUTATIONAL FLUID DYNAMICS

Computational Fluid Dynamics (CFD) codes are common tools in use to predict turbomachinery performance in recent years. In this study, a commercial CFD code, ANSYS v.15 is used to examine turbine performance and flow characteristics. There are some dependents that effect the CFD codes such as boundary conditions, discretization schemes, advection schemes, turbulence models. Some different approaches are used based on the dependents used in analyses.

#### A. Mesh Generation

The flow domains of Francis turbine are meshed in ANSYS ICEM CFD. All components are meshed separately. Tetrahedral and hexahedral elements are used while generating grids.

Face and body sizing are used while meshing the components. By applying proximity and curvature size function, an automatic refinement on grids is carried out for more detailed grids. Despite all components are meshed separately, the mesh domains are assembled for solution. In Figure 5, assembled mesh domain of Francis turbine is shown.

![Grids of Francis Turbine](image)

The grid-dependency is controlled in different types of mesh structures and element numbers and it is obtained that the model is independent from grid. Details of grids and element numbers are given in Table 1 for each components grid structure.

B. Boundary Conditions

Boundary conditions are specified as mass flow inlet and static pressure outlet for this study. Inlet boundary condition is defined on spiral case inlet as 4160 kg/s and outlet boundary condition is defined on draft tube outlet as 1 atm. Besides, the reference pressure is defined as 0 atm.

C. Schemes, Models and Approaches

In this study, ANSYS CFX 15.0 is used as commercial Reynolds-Averaged Navier-Stokes codes for modelling turbulent flow. These codes use finite volume method as discretization scheme.

While modelling flow, RNG k-ε is used as turbulence model due to its reliability. As an advection scheme, high resolution is used in solution. The convergence criteria is defined as 10^-5 for the momentum and mass residuals.

Despite the components are designed separately, they are assembled for solution in CFX solver. Thus, some interface approaches are needed to be used. Multiple Reference Frame (MRF) is used to unite interface surface grids. Within the scope of MRF, Frozen Rotor approach is used for interfaces between “runner and guide vanes” and “runner and draft tube”. For the interfaces between “spiral case and stay vanes” and “stay vanes and guide vanes”, General Grid Interface (GGI) approach is used.

IV. RESULTS

After completing CFD analyses, pressure and velocity distributions of each component are obtained. Besides, efficiency values are calculated based on torque values which are obtained from analyses.

Analyses carried out in five different angles. As a result, largest efficiency value, %94, is obtained on the guide vane angle 22. Figure 6 shows the efficiency curve on different guide vane angles.

Pressure and velocity distributions for the most efficient point are given in following figures. In Figure 7, pressure distribution on the mid-plane of spiral case is shown.

Vectors show that water flows regularly on each section of spiral case. Pressure is gradually decreasing towards the stay vanes. Therefore, water velocity increases. As can be seen on pressure contours, pressure distribution is uniform for each section.

Pressure and velocity distribution of guide vanes are shown in Figure 8 and Figure 9.

In Figure 8, it is shown that water flows regularly among the guide vanes. Velocity contours indicate that flow velocity is increasing against the runner. Besides, water flows in right direction according to vectors.

It is clearly seen on Figure 9 that the stagnation point is obtained on the symmetry point of guide vane leading edge. That proves the angle of guide vanes are selected correctly and the flow between components are fixed.
Water enters turbine runner with high velocity after leaving guide vanes axis. Since the water particles hit the runner blades with high velocity, runner blades rotate more efficiently. Thus, hydraulic energy turns into mechanical energy by means of the rotation of shaft which is synchronized with runner rotation. After transforming hydraulic energy into mechanical energy, the water which rotates runner should be carried from runner area.

Draft tube steps in there. Tail water flows into draft tube and moves on inside it. Water has a rotational motion early on in draft tube, but as long as the sections enlarge, flow becomes tranquil and regular. The pressure between inlet and outlet of the draft tube are different because of the increasing cross-sectional area. While flow loses its speed, pressure rises. At the outlet section of draft tube, water stands at atmospheric pressure. In Figure 10, pressure distribution of the mid-plane on draft tube is given.

As can be seen on Figure 10, pressure increases gradually towards the outlet of draft tube. Some high pressure contours occur on inclined wall of draft tube but these are considered as elbow.

All in all, obtained pressure and velocity distributions are approved as appropriate. The final design’s efficiency value is %94.

V. CONCLUSION

In this study, a Francis turbine is designed based on the experimental curves and theoretical data on literature. Computational design of this turbine is actualized on ANSYS Design Modeler and ANSYS BladeGen. Computational grid structures of turbine flow domains are created on ANSYS ICEM CFD. Based on this design, the effects of guide vane positions are investigated in different guide vane angles.

Five different CFD analyses in different guide vane angles are carried out. An efficiency curve is composed based on this analyses. 22 guide vane angle is the point which corresponds the best efficiency point on efficiency curve. For each position of guide vanes, turbine efficiency and velocity and pressure distributions are obtained. As it is mentioned in Chapter IV, pressure and velocity contours prove that flow between components are fixed. Contours are examined and decided as appropriate flow characteristic.

In conclusion, the optimum guide vane position is determined for the maximum turbine performance.

Abstract— Wind energy is being used to generate electricity in many countries all over the world and still the contribution of wind energy to electricity supply increases every day. Researchers work on innovative solutions to increase the efficiency and decrease the cost of wind turbine components, especially those of blades. Various blade designs for different operation conditions are presented in the literature and sweep-twist blades are new type of blades introduced recently. This paper focuses on the numerical investigation of a sweep-twist wind turbine blade using ANSYS-Fluent. NREL Phase VI wind turbine blade is used as the baseline blade and the sweep-twist blade is designed by adding 5% sweep-twist to the tip. Power output and thrust forces are calculated using the simulation results for both original and sweep blades. In addition, results are compared to the experimental data of original NREL Phase VI blade.

Keywords— Wind, Blade, Sweep-twist, CFD

I. INTRODUCTION

Each passing day the need for the use of clean energy sources rises since power production from fossil fuels damage our planet continuously. Within this scope, many developed and developing countries have set some goals to generate some part of energy consumption from renewable energy sources. For instance, the ministry of energy of Turkey has decelerated the strategic plan for 2015-2019 an increase in installed renewable energy capacity by nearly twice compared to the value of 2013 [1]. Hence, wind energy – recognized as an efficient renewable energy source – has taken the role of being one of the leading alternative sources. In past few decades, huge improvements have taken place in wind power technology especially on the design of blades which influences the efficiency directly. Within this scope, many experts who are interested in aerodynamics contributed the literature with some studies about various blade designs. Sweep-twist wind turbine blades were firstly introduced by Sandia National Laboratories of U.S. Energy Department. After completing the research, they presented a final report (2010) where they introduced analysis results of Sweep Twist Adaptive Rotor (STAR) blades [2]. In the report, they stated that the STAR technology provided significantly greater energy capture – about 10-12% compared to baseline Z48 turbines - without higher operating loads on the turbine. The results are also presented by Ashwill et al. (2010) in a conference [3]. Sing and Ahmed performed a study about design and performance testing of a small wind turbine rotor for low wind speed applications. A new airfoil was designed and the performance of a 2-bladed rotor for low Re application fitted to an Air-X marine 400 W wind turbine was tested at a wind speed range of 3-6 m/s. Authors stated that the new 2-bladed rotor produced more electrical power at the same freestream velocity in comparison with the baseline 3-bladed rotor [4]. Wang and Zhan (2013) investigated the performance of a micro-wind turbine using CFD and concluded that the performance of the wind rotor with semi-circular blades is comparable to that of the semi-cylindrical wind rotor, and is slightly lower than that of the helically twisted wind rotor [5]. Bai et al. (2013) designed a 10 kW horizontal axis wind turbine blade and performed aerodynamic investigation using numerical simulation of it. It has been reported that CFD is a good method compared to the improved BEM theory method on the aerodynamic investigation of HAWT blades [6]. Koc et al. (2015) studied the hydrodynamic performance of a twin-blade hydrofoil numerically and experimentally in three dimensions for tip speed ratios ranging between 1.5 and 5.5. Authors reported that the optimum tip speed ratio of 3.5 for twin blade turbine is too low comparing the optimum tip speed ratio of 5.0 for the slat hydrofoil or standard hydrofoil turbine applications and added that the wind and hydrokinetic turbines with the twin blade hydrofoil can operate in lower wind and current speeds [7]. A detailed review of aerodynamic developments on small horizontal axis wind turbine blades is presented by Kartikeyan [8]. In the present study, numerical investigation of the aerodynamics around a sweep-twist wind turbine blade using ANSYS-Fluent is performed. NREL Phase VI wind turbine blade is used as a baseline blade and the sweep-twist blade is designed by adding an offset as much as 5% of the blade diameter to the tip of the blade. Results are compared with the original blade.

II. NREL VI AND SWEEP-TWIST BLADES

NREL Phase IV wind turbine blade is selected as a baseline blade. It has S809 airfoil sections from root to tip and a pitch angle of 3 degrees. The description of the NREL Phase VI blade is given in Table 1 and chord and twist variations along the blade are given in Table 2 [9]. In this study, some sections
including the ones which have radial distance between 0.660 and 1.257 and the one with 3.185 radial distance are excluded since the sections are very close to the previous section.

The 3-D drawings of the blades are given in Fig. 1. To draw the sweep-twisted blade, all the same properties as NREL Phase IV blade are used except a tip offset which is 5% of the blade diameter (0.25 m) is given beginning from the middle of the blade. The sections from the beginning of the sweep – located at the 2.562 m radial distance- until the tip of the blade are interpolated. Dimensions of the original and sweep-twisted blades are given in Figure 2.

![Fig. 1 3-D drawings of the NREL PHASE VI (up) and sweep-twisted blade (down)](image_url)

![Fig. 2 Dimensions of the original and sweep-twisted blade](image_url)

### III. NUMERICAL SIMULATION

In this study, 3-D air flow around the wind turbine blade is simulated with ANSYS Fluent 16. The dimensions of the flow field are 12 R in the stream-wise direction extruded from a circle having 3 R dimension where R is the radius of the blade. The domain of flow field including boundary conditions is given in Fig. 3.

![Flow field and boundary conditions](image_url)
Meshing of the fluid domain is performed using ANSYS meshing. The thickness of the first cell to the wall was kept at $2 \times 10^{-5}$ m to obtain proper $y^+$ value for the used turbulence models. In order to increase the mesh quality, sharp trailing edge of the blades is rounded. Mesh construction and a sliced section of the mesh around the blade and rotor hub can be seen in Fig. 4. Mesh independence study is performed for various models containing different number of elements and a model containing 9.8 million elements is used.

**k-\(\varepsilon\) Turbulence Model**

One of the turbulence models used for tests is \(k-\varepsilon\) Realizable turbulence model. The \(k-\varepsilon\) model is a two-equation turbulence model consists of turbulence kinetic energy and turbulence dissipation rate equations given below.

\[
\begin{align*}
\frac{\partial k}{\partial t} + \frac{\partial (\rho u_j k)}{\partial x_j} &= P_k - \rho \varepsilon + L_k \quad \text{(1)} \\
\frac{\partial \varepsilon}{\partial t} + \frac{\partial (\rho u_j \varepsilon)}{\partial x_j} &= \frac{\varepsilon}{k} \left( \frac{\mu_t}{\sigma_\varepsilon} \frac{\partial k}{\partial x_j} + \frac{\varepsilon}{k} \frac{\partial^2 k}{\partial x_j^2} + \frac{1}{3} \frac{\partial u_j}{\partial x_j} \right) + \frac{\varepsilon^2}{k} + C_{1\varepsilon} \frac{k}{
\end{align*}
\]

where $P_k$ is turbulent production and viscosity are defined by the Eq. 3 and Eq. 4, respectively.

\[
P_k = \tau_{ij} \frac{\partial u_i}{\partial x_j}
\]

\[
\mu_t = \rho_f \mu_t \frac{k^2}{\varepsilon} \quad \text{(4)}
\]

**k-\(\omega\) SST turbulence model**

This turbulence model combines both \(k-\varepsilon\) and \(k-\omega\) models. The original \(k-\varepsilon\) turbulence model has the problem of over predicting the shear stress that might delay or prevent the separation where inverse pressure gradients are possessed, and the original \(k-\omega\) model is very sensitive to free stream values that are specified outside the shear layer [11]. The original \(k-\omega\) model is defined by the Equations 5 and 6 [11,12].

\[
\begin{align*}
\frac{\partial (\rho k)}{\partial t} + \frac{\partial (\rho u_j k)}{\partial x_j} &= P - \beta \mu \omega + \frac{\partial}{\partial x_j} \left( \mu + \frac{\rho \mu}{\sigma_\omega} \frac{\partial k}{\partial x_j} \right) \quad \text{(5)} \\
\frac{\partial (\rho \omega)}{\partial t} + \frac{\partial (\rho u_j \omega)}{\partial x_j} &= \frac{\varepsilon}{k} \left( \frac{\mu + \sigma_\omega \rho k}{\omega} \frac{\partial \omega}{\partial x_j} \right) + \frac{C_3 \rho}{\omega} \frac{\partial \omega}{\partial x_j} \frac{\partial \omega}{\partial x_j} \quad \text{(6)}
\end{align*}
\]

**IV. VALIDATION OF THE SOLVER**

The solver is validated against experimental data of NREL Phase VI. The mechanical power of numerical and experimental tests is presented in Fig. 5. The mechanical power is simply calculated by multiplying rotation speed, $\Omega$ (rad/s) by torque, $T$ (Nm) obtained from FLUENT as given in Eq. 7. As seen from the Fig. 5, experimental and numerical power outputs are in general agreement. However, after 10 m/s CFD predictions cannot predict the stall very accurately. Thrust force measurements and CFD predictions are in very good agreement as it can be seen from the Fig. 6. Also, pressure distributions for 5 m/s case at 47% and 80% span are in agreement with experimental data as shown in Fig. 7.
This study compared the original NREL Phase VI blade with a sweep-twisted model of it. Power results are compared in Fig. 8 for the sweep-twist and original blade. It is observed that wind turbine blades sweep-twisted to the leading edge side of the blade generate lower power than the original blade. In addition, it is obtained that the $k - \omega$ SST turbulence model predicts lower power output than the $k - \varepsilon$ Realizable. In Fig. 9, the thrust force for sweep-twist and original blade are compared and results show that the sweep-twisted blade has lower thrust force (more than 10%) at each wind speed except 20 and 25 m/s. The pressure distributions for 5 m/s case at 47% and 80% span are compared in Fig. 10. It is clear that the pressure distribution on the original blade is able to generate more power than the sweep-twist blade.
V. CONCLUSIONS

In this paper, mechanical power outputs and thrust forces of original NREL VI and a sweep-twist wind turbine blade are compared. Both k - ω SST and k - ε Realizable turbulence models predicted the thrust force very close to experimental measurements. In addition, CFD predictions of mechanical power output are found to be overall in agreement with experimental data, however, after the wind speed of 10 m/s when the stall occurs, CFD predictions were not very successful. Generally, the k - ω SST turbulence model predicted lower power output than k - ε Realizable for both original NREL Phase VI and sweep-twisted blade. Results of comparison of original and sweep-twist blades show that sweep-twisting the blade against the direction of rotation causes to decrease in both power output and thrust force. So, the load on the wind turbine tower may be lower if sweep-twist wind turbine blades that are twisted in the leading edge direction and that have same rotor diameters are used. This means that sweep-twist wind turbines blades with larger rotor diameters may be used on same towers that carry original wind turbine rotors.

Abstract — Gaining information about the location of a person or an object has become an important issue in the field of built environment as well as industries such as logistics, transportation, manufacturing and healthcare. Location-based services such as on-road navigation, transportation tracking and route monitoring are the motives for a need towards outdoor location detection. In indoor built environments, the importance of localization arises from its value for construction industry in a various range of applications. Detection of building occupancy for automation systems, tracking personnel and equipment for effective management of facilities, providing assets location in construction sites and supporting building emergency response operations are all within the scope of indoor localization. This research aims to validate the need for indoor localization in buildings and to provide a review of indoor localization use cases in the built environment together with the currently available technologies.

Keywords — Indoor localization, building occupancy detection, asset tracking on construction sites, facility maintenance and operations, building emergency response operations

I. INTRODUCTION

Access to location information in outdoors is possible via Global Positioning System (GPS), which is adapted for both military and civil use cases and available to public since early 1980s. Yet, GPS could not be utilized in indoor environments due to the fact that satellite signals are not strong enough to penetrate through the walls [1]. In order to establish a reliable location detection solution in indoor spaces, numerous wireless technologies including radio frequency identification (RFID), wireless local area network (WLAN), ultra-wide band (UWB), and Bluetooth have been studied. However, a convenient and universally accepted solution for sensing locations still does not exist due to the trade-offs between various performance/cost/usability metrics of the currently available technologies. As the performance of indoor localization technologies improve along with the ongoing researches, their utilization in the built environment for various purposes has become an essential issue.

Indoor localization can be defined as the process of identifying the semantic position (such as a room number) of a person or an object in an indoor environment. Location detection in indoors is of great value for architecture, engineering and construction industry. Localization technologies can be used in buildings for various purposes including building occupancy detection, automated asset tracking in construction sites, supporting facility maintenance and operations, and guiding people in building emergency response operations. This paper aims to investigate the need for indoor localization technologies in the built environment and provide a review of localization use cases in buildings.

II. USE CASES OF INDOOR LOCALIZATION IN BUILT ENVIRONMENTS

In this section of the paper, a review of indoor localization use cases will be presented.

A. Building Occupancy Detection

Reducing CO2 emissions by 20% over 1990 values, and increasing renewable energy use by 20% by the year 2020 were put as future objectives for ‘20-20-20 targets’ by the European Commission [2]. Since buildings use 40% of total energy in the world, nearly-zero energy buildings should be the only choice for built environments in the future. Benezeth, et al. [3] listed three solutions for economizing energy consumption, which are utilizing renewable energy sources, providing passive solutions like insulation, and managing the active energy consumption in buildings. It is indicated that reliable building occupancy information is a prerequisite for the third solution. However, a massive part of the large building stock in today’s world are usually operated by energy-wise inefficient building management systems that function based on fixed schedules and do not take crucial factors like presence of people as an input for their operations. Presence and behaviours of people influence the demands for facility operations and increase the energy consumption in buildings [4]. For example, a space’s ventilation and cooling load that represent the amount of fresh air to be supplied to that particular space to maintain good air quality and thermal comfort is affected by the number of occupants in that space zone. Consequently, developing solutions for operating facility services like heating, cooling, air conditioning, and lighting in an occupancy-based demand driven manner has been the topic for many researches in the recent years.

In the current approach of the industry, demand-driven facility services are operated through relying on assumption models and pre-defined occupancy profiles. There are various occupancy assumption models such as the model proposed by
the American Society of Heating, Refrigerating, and Air-Conditioning Engineers (ASHRAE) which includes the definition of several occupancy profiles for office building day types [5].

Yet, considering the excessive uncertainty in the nature of occupancy and unpredictable variations over numerous time-scales, it can be deduced that fixed occupancy profiles for buildings are not reliable and real-time monitoring is necessary to gain instant occupancy information. Erickson, et al. [6] emphasize the inefficiency of relying on maximum occupancy assumptions in their paper and explain the situation in office buildings as:

In general, the approach used is to assume that all rooms are occupied during working hours and not being used during the night. However, it is obvious that this does not maximize energy savings. Rooms are often left empty during part of the day or perhaps are only used semi regularly, e.g. conference rooms. It would be more efficient to only condition rooms during the times that are actually occupied. Using an L-HVAC system, various environmental aspects of room can be controlled for energy savings. Thus, knowledge of occupancy is crucial in order to maximize efficiency of a system (p. 19).

In order to understand the influence of dynamic occupancy information on energy usage, Dong and Andrews [7] simulate energy consumption of an office zone with both static occupancy profiles and dynamic occupancy data. Their research shows that, sensing occupancy in real-time could remarkably reduce the energy consumption to a level of 30%. The definition of occupancy information is made by Li, et al. [8] as “the number and identities of occupants in a thermal zone and the resulting activities from occupant being present” (p.89). Considering the fact that one of the main requirements for an economical energy consumption management in buildings is reliable occupancy information, real-time occupancy detection, i.e. instant localization of people in indoor spaces, may be recognized as an effective solution for operating demand driven facility services.

Particularly in dynamic environments, having real-time occupancy information, including the number of occupants and their locations in the building, as Li, et al. [8] claim, may be very useful both in building energy management and applications areas including security, safety and emergency response. The research of Lo and Novoselac [9] showed that a reduction of 30% in cooling energy consumption is possible with the utilization of occupancy control in an open plan office, through considering occupied and unoccupied zones separately in providing facility services. Furthermore, as Erickson, et al. [10] affirm, the energy consumed for air conditioning annually in an office building can be reduced by 42% through sensing the location of people in the buildings while keeping the comfort standards optimum for occupants.

B. Asset Tracking on Construction Sites

As construction materials and equipment account for almost two-thirds of the total cost in a typical construction project, management of assets on the construction site is a critical task for a successful project completion within a constrained budget and targeted project duration [11]. Although the cost of construction projects may be reduced with a comprehensive asset management strategy on site, currently, building materials, equipment, and workers are located and tracked manually within the large project sites. Due to the complex nature of project management and uncontrollable size of built environments, locating and getting spatial information about building materials manually is a difficult task. As the scale of projects gets larger and buildings become more complex, it becomes even harder to track information related with asset locations and manage supply chain manually. Therefore, providing a real-time localization solution and integrating automation in material management becomes a necessity in construction projects. Bisio, et al. [12] revealed that having location information of building components enhance a considerable efficiency in labour, on account of the fact that workers waste almost one third of their time on searching the positions of the desired resources [11]. Besides, Caron, et al. [1] imply that progress state of projects on the site can be monitored in real-time through localization of construction assets.

Considering the fact that countless number of materials and components go through various stages according to project schedule until the completion of on-site installation in a construction project, there exist a direct relationship between asset management procedure and project performance. The results of ineffective asset management on construction sites such as lost materials, late detection of additional material needs, material deliveries in incorrect sequences and deficiencies in supply chain lead to a reduction of 40% in construction productivity [13]. The primary purpose of asset management is clarified by Song, et al. [14] as to track the availability of construction materials and to provide accurate location information when they are needed by the operation crew. Since manual processes of recording data about the availability and locations of construction components depends on the observations and reporting skills of on-site personnel which is both time-consuming and error prone, there is a huge potential in utilizing identification and localization solutions in construction asset management.
Finding the location of a material, a component or a tool is one of the most essential phases of asset management. Song, et al. [15] state that popularity in the prefabricated components usage in the last fifteen years has made tracking and locating the construction components on the field even more critical for project management. Ergen, et al. [16] indicate that there is a dense circulation process for prefabricated materials within the construction sites from material delivery to installation. Moreover, since most of the components are uniquely produced according to the precise architectural design decisions, each prefabricated asset is required to be identified, located and tracked separately. Due to the just-in-time delivery requirement of prefabricated precast concrete, for example, Ergen, et al. [16] developed their research on integrating a localization solution with the purpose of gaining the position information of precast concrete components quickly and accurately when requested and minimizing human input in the recorded asset data. Similarly, Song, et al. [14] point out that automated localization and tracking solutions are of utmost importance since lots of unique components of piping activity in construction projects go through a number of phases including fabrication, delivery, storage, and installation.

In addition to advantages of localization of assets on construction sites, locating on-site personnel in an accurate and precise manner is also critical for various tasks of project management including workers’ productivity estimation, activity sequence analysis, early detection of travel path conflicts, and providing construction work safety.

C. Facility Maintenance and Operations

Activities related with operation and maintenance, which form the fundamental part of facility management for ensuring the continuity in efficient building functionality, constitute almost 85% of the total lifecycle cost of buildings [17]. The definition of facility maintenance is made by Cotts, et al. [18] as:

The work necessary to maintain the original anticipated useful life of a fixed asset. It is the upkeep of property and equipment. Maintenance includes periodic or occasional inspection, adjustment, lubrication, cleaning (non-janitorial), painting, replacement of parts, minor repairs, and other actions to prolong service and prevent unscheduled breakdown, but it does not prolong the life of the property or equipment or add to its value (p. 408).

Maintenance of a facility indicates the works that are to be realized by the facility management services for both keeping the living and working built environments comfortable for inhabitants and administrating the performance of equipment and assets of the facilities. Two main category of maintenance activities are sorted by Thomas [19] as:

- **Demand Work**: where the client calls in for service, where breakdowns in equipment require repairs and emergency events that affect the facilities department.
- **Preventive Maintenance Work**: where a scheduled program of work maintains the investment in the physical assets for a corporation. These assets may be equipment assets or facility assets (p. 457).

Considering its huge percentage in the lifecycle cost of buildings, there are many researches that have been conducted for optimization of facility maintenance where the primary subject of most studies are related to the utilization of computational support for asset management in built environments. In order to ensure an efficient asset management and facility maintenance optimality, indoor localization systems that provide accurate and precise location information of any intended assets or objects in buildings should be integrated into facility management services.

</table>

Lee and Akin [20] listed the core maintenance activities under two categories and demonstrated the time spent for each activity depending on their observations. According to the outcomes of their research, the main inefficiency in the facility maintenance is caused by localization of equipment, which takes approximately 10% of the total maintenance time. It is possible to make an optimization in facility maintenance and save a remarkable amount of time through utilizing accurate localization solutions.

Throughout the activities for providing maintenance in a facility, finding the location of a problematic asset for a demanded work or identification of an equipment for preventive maintenance is always a prerequisite. It is not significant whether the intended asset or equipment is in line of sight or hidden behind a wall or an object, manual visual search is a highly time consuming action on site for facility management service personnel. Lee and Akin [20] indicate that maintenance activities take more time than they should, due to the difficulty in localization of building equipment. It is even harder to locate a building asset or an equipment in more complex and larger buildings and wasting time by searching manually for finding the accurate location may result in more damage in emergencies. In the time of urgent maintenance requirements in buildings, Primary reason for failure in preventing damage is the lack of ability to locate an out of repair component instantly.

For instance, Ergen, et al. [21] point out that fire valves that are placed in different points in a building, some of which are in non-line of sight and unobservable due to some obstructions, should be checked twice a year by facility management services.
personnel according to the fire regulations. However, it is not easy for workers to notice each separate fire valve in a building and locating a fire valve takes five to ten minutes for an experienced worker; whereas an inexperienced worker spends thirty to sixty minutes for each one. Even an experienced worker may have difficulties in finding a target location in a complex facility layout. What Ergen, et al. [21] emphasize is that facility management services workers might not be willing to perform this time consuming and troublesome maintenance task properly and verification of a complete maintenance for desired assets is very hard. Consequently, it cannot be assumed as reliable to put a check mark on a prescheduled maintenance activity in the current approach. Ergen, et al. [21] clarify that indoor localization has a crucial significance for optimization of facility management activities, and sticking a sensor tag which would give a unique identification code to each fire valve and make the localization of all desired assets possible can be the solution for overcoming this inefficient workflow on site.

There is a significant potential in location sensing solutions for minimizing the time spent for asset searching in facilities and ensuring a more effective maintenance. The information about the locations of building assets is needed at different stages of building lifecycle and indoor localization is a timesaving requirement for the maintenance of facilities. In his article, Wing [22] affirms that the position of water and gas pipes that are either buried under floors or pass through the walls can be determined with localization systems. In their research, Lee and Akin [20] demonstrate that it is possible for facility maintenance activities to be performed in a 12% more time-efficient manner through supporting on-site personnel with instant assets-related and location information.

Apart from tracking the locations of assets such as fire valves, pipes or other building assets, indoor localization can also be beneficial for finding the position of hand tools and equipment in a facility. Goodrum, et al. [23] state that since availability of tools in a facility has an impact on the productivity of maintenance personnel, it is important to develop some strategies for equipment management. What Goodrum, et al. [23] believe is that, contrary to frequent approach of having excessive number of tools in a building for ensuring productivity of workers, which may be described as waste of resources in return, having sufficient number of tools and improving their management on site through indoor localization systems is the right strategy.

D. Building Emergency Response Operations

Emergencies in buildings such as structural collapse, flooding and especially fire can turn into fatal disasters for occupants in the buildings and first responders. Li, et al. [24] state that real-time localization of people can be remarkably beneficial in minimizing severe injuries and enhancing success rate in first-time response in building emergency operations. A recent study composed of interviews with first responder professionals by Li, et al. [25] showed that the location of people were considered as one of the most important information piece that is required in times of fire emergency incidents. Throughout the study, a number of information items were given to responders and a pre-determined procedure was followed in order to reach a classification between all information items. A simplified part of the result drawn was shown in Table 2.

Table 2: Importance of Indoor Localization (Adapted from Li, et al. [25])

<table>
<thead>
<tr>
<th>Stage</th>
<th>Importance</th>
<th>Information Items</th>
</tr>
</thead>
<tbody>
<tr>

<td></td>
<td></td>
</tr>
</tbody>
</table>

According to Li, et al. [26], at an emergency scene, detecting presence and position of occupants is not efficient at all with the current process, in which visual inspections are done from a distance to the site, depending on the observations and estimations of incident commanders. It is pointed out that it would be easier to guide the emergency response team only if real-time location information was accessible for monitoring. The inefficiency of current process and need for localization in building emergency response operations is explained by Li, et al. [27] as:

First responders are the first line of defence when building fire emergencies happen, and one of their foremost important tasks is to search and rescue the people trapped in buildings. First responders usually have little knowledge about the location of trapped building occupants, preventing informed decision-making with regard to search route planning and task force allocation. Instead, first responders have to perform a complete search of indoor spaces where people may be trapped. Such search is mostly blind and not efficient, increasing the chances of fatalities and injuries of trapped occupants (p. 78).

Considering the current situation, Li, et al. [27] implied that utilization of a real-time location detection system could reduce the time spent for rescuing the trapped people in an incident and prevent possible fatal outcomes. As they are subjected to lots of dangers in emergencies due to the difficulty in being oriented in complicated, unfamiliar built environments, the real-time location information of the operation units is also critical [26]. Although the professionalism and skills of incident commanders are important factors in a good emergency management based on available collected information, a successful coordination and decision-making is only possible with real-time location monitoring of on-site units for ensuring their safety and guiding them with the correct routes within the disaster sites. Li, et al. [24] suggested that, those first responder units that are disoriented in dangerous spaces can be noticed and alerted by incident commander through real-time monitoring, and they can be directed to trapped people with navigational directives. In addition, it is asserted in the paper.
that potential dangers can be better detected and prevented by first response units themselves if they are provided with access to their real-time positions accurately on the field.

III. OVERVIEW OF WIRELESS BASED APPROACHES FOR INDOOR LOCALIZATION

Despite the popularity of Global Positioning System (GPS) for locating people and positioning objects in outdoor environments, the system does not work for indoors properly due to attenuation of electromagnetic waves by the walls and obstacles due to obstruction of line of sight between the satellites and receivers. Since radio waves have the capability of penetrating walls, obstacles, and human body, radio frequency based technologies are suitable for indoor localization with their wide coverage area and less hardware necessity.

One of the most popular methods studied for detecting occupancy is RFID based models. What separate RFID from the other sensor technologies is its benefits such as its tags features of having unique identity numbers and light, portable designs, its effectiveness in non-line of sight and longer detection range compared to infrared, ultrasound, and WLAN technologies [28]. Despite the capability of RFID sensor based detection systems to provide comprehensive fine-grained occupancy information for demand driven applications in buildings, it has some limitations such as the multipath effect for signal propagation, changing environments’ negative effects on RSSI, and unwillingness of occupants to wear RFID tags.

In WLAN based location detection models, position of every Wi-Fi compatible mobile device can be determined using existing Wi-Fi infrastructure with the aid of a positioning server. In this application line of sight is not required between access points and the target units [29]. Moreover, the coverage area of a WLAN based localization system is expandable since it can bear additional access points, and any mobile target can be tracked unless it goes out of the covered range. Despite its potential for gaining occupancy information, WLAN based systems have their shortcomings and limitations, such as the negative effects of possible changes (i.e. moving furniture) in the environments on Received Signal Strength (RSS), high initial deployment cost, variations in Wi-Fi signal strength by time and possible interferences with other appliances [30].

Ultra-wideband technology is based on data transmission technique through sending and receiving ultra-short radio pulses. UWB systems have the capability of high accuracy indoor localization with low power consumption even in non-line-of-sight conditions. Since signals transmitted from UWB tags use a wider radio spectrum than the other RF-based tools, it is not affected by the interference of other signals in the environment and it has resistance to multipath effects. In addition, large bandwidth of UWB provides high resolution in both time and location for positioning and tracking, and it is suitable for utilizing positioning techniques including time of arrival and time difference of arrival [30]. There are several studies in the literature for developing an applicable UWB based localization and tracking system, yet there are no widely accepted solutions. Although UWB based location detection models have the highest accuracy and precision (with a location error of 15 cm) among all other indoor localization solutions, a comprehensive receiver-transmitter infrastructure is required and the necessary initial deployment is so expensive that it is not in wide-scale use [30].

Bluetooth is a wireless standard for wireless personal area networks, which has zero dBm maximum power output. Classic Bluetooth was released as a unification tool for computers and other devices, and the main purposes of usage were connecting headsets and cell phones, and enabling file transfer between devices and printers. However, the latest version of Bluetooth, namely Bluetooth Low Energy has a potential to be used in indoor localization. Low cost, high security, low power, small size and unique ID identification for each Bluetooth tag can be listed as the main advantages [29]. In addition, since an embedded Bluetooth module do exist in almost every mobile device in today’s world, this technology can be used as a location detection tool without any extra infrastructure. Even though some researchers investigate the applicability of BLE technology for indoor localization, a comprehensive analysis and technological assessment of this technology do not exist in the literature.

IV. CONCLUDING REMARKS

Indoor localization technologies have become a need in the built environments. Building occupancy detection, automated asset tracking in construction sites, supporting facility maintenance and operations, and guiding people in building emergency response operations are demonstrated as the main use cases at the present time. Apart from reviewed cases, localization can also be utilized for route guiding for people in unfamiliar facilities like airports, convention centres, shopping malls, and hospitals. As the performance metrics of localization technologies are constantly improving with the current studies, there will probably be more utilization areas in buildings, which are not applicable now.

Despite the extensive need for a reliable indoor localization system in the built environment, no current approach was identified to be an extensive solution. Once a globally accepted comprehensive solution is provided for localization in indoors, the wasted energy and resources in both buildings and construction sites can be reduced dramatically. As a results, the goal for having a more sustainable and intelligent built environment can be achieved in the future.

Abstract—The regulation of temperature, pressure, humidity and oxygen intensity of an aircraft cabin is crucial for the flight conditions of a commercial aircraft. Lack of oxygen, lower temperature and pressure induce some health problems for passengers on board. For this reason, hot and pressurized air supplied from aircraft engine compressor section is conditioned in the air-conditioning packages to present comfortable ambience inside of the aircraft cabin as well as cooling of electric components. In this study, an air-conditioning system of Airbus A330 as a commercial aircraft has been investigated at the altitude of 11000 m for 289 people on board under the flight conditions. At this altitude for the aircraft cruising with 871 km/h (Ma = 0.82), cooling loads of cockpit (crew station), passenger cabin and other appliances needed cooling in the aircraft have been calculated. The parameters affecting the cooling load are mainly temperature, pressure and air intensity of aircraft inside and atmospheric outside. In the calculation of the cooling loads, generated heat and heat loss have been considered. For the generated heat value, heat generation by passengers, cabin crew, illumination systems, other equipment and solar radiation have been assumedly calculated. The heat loss from the aircraft fuselage at 20 °C cabin to the outside of the aircraft at -56.5 °C has been found. Heat transfer to meet the fresh air need inside the aircraft has been taken into account. Finally, the obtained cooling loads are 7.4 kW for the maximum value and 5.1 kW for the minimum value at these aforementioned conditions. The maximum and minimum values have been obtained for the daytime and the night time depending on solar radiation, respectively. In the upcoming study, energy analysis is going to be combined with the exergy analysis and the appropriate air-conditioning system for the optimum energy consumption will be evaluated.

Keywords—Air-conditioning, aircraft, altitude, cooling load, energy analysis

I. INTRODUCTION

Air craft cabin temperature and pressure are very important to be conditioned as the passenger aircrafts cruise at high altitudes and at also various conditions. Due to lower pressure and temperature at higher altitudes, air-conditioning system of aircrafts play an important role for both human health and comfort conditions. For this reason, pressurized and hot air of aircraft engine is evaluated to provide high class air ambient inside of the aircraft cabin. Another case is pressurization of the aircraft cabin and it is very crucial to maintain the optimum pressure level at lower altitudes as the cabin has to be impermeable under any circumstances. With this way, high oxygen density can be supplied to the aircraft cabin through the pressurized air as this a significant step to ensure the air-conditioning for passenger health. In present study, an air-conditioning system of Airbus A330-300 RR Trent 700 as a commercial aircraft has been considered for 289 people on board. It is assumed to be cruised at the altitude of 11000 m (correspondingly 36100 ft) with the speed of 871 km/h. Various studies in the literature could be encountered about the air-conditioning of an aircraft cabin. Hocking (2002) has studied on trends in cabin air quality of commercial aircraft in terms of industry and passenger perspectives. It has been presented that improving the aircraft cabin air quality and the partial pressure of oxygen can be provided for minimal cost [1]. Cakir et al. (2003) have presented a study about air-conditioning system in commercial aircrafts and comfort. They have explained the importance of air-conditioning system as it is not easy to provide comfortable and fast trips at high altitudes [2]. Arslan et al. (2009) have investigated the air-conditioning system of an aircraft and its effect to inner air quality. In their study, Boeing 737-800 has been used and they have stated that the filters, sensors, indicators and the control and maintenance of the equipment are substantial for the air-conditioning system of the aircraft [3]. Dumas et al. (2014) have defined a design methodology for the global thermodynamic performance of an airship cabin for high altitude. A fundamental cabin sizing and energetic performance of cabin thermal insulation have been provided [4]. Chen et al. (2015) have studied on hot air distribution of ship cabin air-conditioning. They have pointed out that the ship cabin air-conditioning formed suitable air distribution for characteristics of variable air volume, big air volume and high air velocity [5]. Oliveira et al. (2015) have evaluated the passive aircraft cooling systems for variable thermal conditions. The fuselage condenser performance has been tested for the temperature range between -30 °C and 50 °C. They have determined that heat removal capacity of the fuselage was more dominant in terms of forced convection acting on all condensers [6]. Yang et al. (2015) have researched on the numerical simulation of aircraft cabin smoke as it is a threat for the flight safety severely. They have analyzed the flow regularity of smoke in the aircraft cabin and also the influence of ventilation on cabin smoke diffusion. It is certain that high level of ventilation could decrease the smoke.
and temperature distributions, effectively [7]. Yao et al. (2015) have examined the flow characteristics and turbulence simulation for an aircraft cabin environment. They have utilized BV2FAM simulation and have theoretically showed that topological structure of flow fields in the cabin was unstable [8]. Zhu et al. (2015) have considered the air distribution with natural convection effect of passengers in an air cabin mockup by using PIV experimental setup. They have observed the interaction between natural convection from the passengers and forced convection from the supply air diffusers. They have measured the air flow jet in a 7-row cabin mockup and have concluded that air jet decay rate was slower with increment of natural convection [9]. Čavka et al. (2016) have dealt with energy efficiency in aircraft cabin environment in the context of safety and design. They have emphasized that cabin air temperature, cabin noise, cabin evacuation time and accident rate were the certain parameters for the consideration of aforementioned issues [10]. The aim of this study is energy analysis for an air-conditioning system of a commercial aircraft in case of Airbus A330.

II. COMPOSITION OF ATMOSPHERE

The mixture of gases that make up the atmosphere of the earth is commonly called air. It is composed principally of 78% nitrogen and 21% oxygen and the remaining 1% is made up of various gases in smaller quantities as shown in Fig. 1. Some of these are important to human life, such as carbon dioxide, water vapor, and ozone. Fig. indicates the respective percentage of the quantity of each gas in its relation to the total mixture [11].

![Fig. 1 The percentage of the various gases that comprise the atmosphere [11]](image)

As altitude increases, the total quantity of all the atmospheric gases reduces rapidly. However, the relative proportions of nitrogen and oxygen remain unchanged up to about 50 miles above the surface of the earth. The percentage of carbon dioxide is also fairly stable. The amounts of water vapor and ozone vary [11].

Nitrogen is an inert gas that is not used directly by man for life processes; however, many compounds containing nitrogen are essential to all living matter [11].

The small quantity of carbon dioxide in the atmosphere is utilized by plants during photosynthesis. Thus, the food supply for all animals, including man, depends on it. Carbon dioxide also helps control breathing in man and other animals [11].

The amount of water vapor in the atmosphere is variable but, even under humid conditions at sea level, it rarely exceeds 5%. Water also occurs in the atmosphere as ice crystals. All forms of water in the atmosphere absorb far more energy from the sun than do the other gases. Water plays an important role in the formation of weather [11].

Ozone is a form of oxygen. It contains three oxygen atoms per molecule, rather than the usual two. Most of the ozone of atmosphere is formed by the interaction of oxygen and the rays of sun near the top of the stratosphere in an area called the ozone layer. This is important to living organisms because ozone filters out most of the sun’s harmful ultraviolet (UV) radiation. Ozone is also produced by electrical discharges, such as lightning strikes. It has a faint odor, somewhat like that of weak chlorine, that may be detected after a thunderstorm. Auroras and cosmic rays may also produce ozone. Ozone is of great consequence to living creatures on earth and to the circulation of the upper atmosphere [11].

III. FLIGHT CONDITIONS

Aircrafts are able to cruise at various flight and climate conditions, successfully. At these conditions, the regulation of temperature, pressure, humidity and oxygen intensity of an aircraft cabin is crucial for a commercial aircraft as many passengers are on board. These parameters tend to change with respect to the cruise altitude as in Table I. It indicates that there is a decrease in temperature while rise in altitudes is observed. Particularly, this decrease is seen for the pressure for increasing altitudes. As mentioned before, the total quantity of all the atmospheric gases goes down swiftly because of increase in altitude values.

Heat sources for a passenger are solar radiation, the heat of air supplied by air-conditioning system and the heat released by other passengers. Moreover, inner air temperature is conditioned with the help of air-conditioning system in the aircraft cabin. Inner air temperature is adjustable in range of 18.5 °C and 29.5 °C with respect to the human health and comfort conditions [2]. However, cabin temperature is under effect of static and dynamic situations. Another heat source except the air-conditioning system is due to the passengers. At rest, a person generates heat between 80 - 100 W in terms of...
static situation [2]. On the other hand, dynamic situation includes the motion of passengers on board or power-up, take-off and landing of the aircraft. When relative humidity value is investigated, the maximum altitude for the flight of an aircraft presents nearly same humidity value with the driest region of the world. It is obvious that these conditions can cause illnesses and diseases in terms of human health. Therefore, air-conditioning system of an aircraft cabin is significant for previously stated situations. In addition, less oxygen level is seen at higher altitudes. Especially, lack of oxygen for human health is observed and felt after the altitude of 3000 m [2]. This situation affects negatively the respiratory system of a person. For this reason, it is needed to serve ambient quality equivalent to the sea level conditions and it is named as cabin altitude. In air-conditioning system for aviation applications, there are two alternatives to reduce the cabin altitude. Firstly, it can be done by providing sufficient oxygen level or second way is to increase the air pressure. In aviation, global cabin altitude for a commercial aircraft is 8000 ft (2438 m) and it is limit value for a person to breathe on his/her own without any appliances [2].

IV. AIR-CONDITIONING SYSTEM

There are two types of air conditioning systems commonly used on aircraft. Air cycle air conditioning is used on most turbine-powered aircraft. It makes use of engine bleed air or APU pneumatic air during the conditioning process. Vapor cycle air conditioning systems are often used on reciprocating aircraft. This type system is similar to that found in homes and automobiles. It is known that some turbine-powered aircraft also use vapor cycle air conditioning [11]. Air-conditioning system of a commercial aircraft aims following cases such as heating, cooling, equipment cooling, mission cooling, pressurization, distribution and temperature control as indicated in Fig. 2.

![Air Conditioning System Diagram](image1)

As in Fig. 3, the hot compressed air is cooled, conditioned and delivered to the fuselage compartments and then discharged overboard through two outflow valves. Fresh air can also be supplied to the distribution system through two low-pressure ground connections. A ram air inlet supplies emergency air to fuselage if there is a complete failure of the air generation system during flight. A mixing manifold mixes fresh air with cabin air. The cabin air that enters the underfloor area is drawn through recirculation filters by fans. The recirculation fans then blow the air through check valves to the mixing manifold. The flight deck is supplied by fresh air only [13].

Hot bleed air is tapped downstream of the pack valves. The air flows through two hot air valves which control the pressure...
of the hot trim air going into two hot air manifolds. To control the temperature in the different upper deck zones, the quantity of trim air added is controlled through the cockpit and cabin temperature control system [13]. By the way, component locations of an air-conditioning system in the aircraft have been shown in Fig. 4.

Hot air is delivered to air supply ducts through the related zone trim air valves. The trim air valves are controlled through the temperature requirements of each zone and duplicated for cabin zone flexibility. The trim air system has several features to ensure that no substantial comfort degradation occurs in case of trim air valve or hot air valve failure; a hot cross-bleed valve is installed between the hot air manifolds and will open to maintain trim air supply to all rise ducts in the event of hot air failure (blocked open). Moreover, in the event of trim air failure (blocked open) and/or duct overheat, as the shut-off valve is normally closed and there are two riser ducts per cabin zone, only half of each zone will lose its trim air supply. The flight deck is permanently supplied by a constant restricted trim air flow in addition to the normal controlled trim air supply [13].

Fig. 4 Component locations of an air-conditioning system in the aircraft [11]

Heat is an expression of energy, typically measured by temperature. The higher the temperature of a substance, the more energy it contains. Heat always flows from hot to cold. These terms express the relative amount of energy present in two substances. They do not measure the absolute amount of heat present. Without a difference in energy levels, there is no transfer of heat energy [11].

Adding heat to a substance does not always raise its temperature. When a substance changes state, such as when liquid changes into a vapor, heat energy is absorbed. This is called latent heat. When a vapor condenses into a liquid, this heat energy is given off. The temperature of a substance remains constant during its change of state. All energy absorbed or given off, the latent heat is used for the change process. Once the change of state is complete, heat added to a substance raises the temperature of the substance. After a substance changes state into a vapor, the rise in temperature of the vapor caused by the addition of still more heat is called superheat [11].

The temperature at which a substance changes from a liquid into a vapor when heat is added is known as its boiling point. This is the same temperature at which a vapor condenses into a liquid when heat is removed. The boiling point of any substance varies directly with pressure. When pressure on a liquid is increased, its boiling point increases, and when pressure on a liquid is decreased, its boiling point also decreases. Vapor pressure is the pressure of the vapor that exists above a liquid that is in an enclosed container at any given temperature. The vapor pressure developed by various substances is unique to each substance [11].

A. Air Cycle Air-Conditioning

Air cycle air-conditioning prepares engine bleed air to pressurize the aircraft cabin as seen in Fig 5. The temperature and quantity of the air must be controlled to maintain a comfortable cabin environment at all altitudes and on the ground. The air cycle system is often called the air conditioning package or pack. It is usually located in the lower half of the fuselage or in the tail section of turbine-powered aircraft [11].

Fig. 5 Air cycle air-conditioning [11]

Even with the frigid temperatures experienced at high altitudes, bleed air is too hot to be used in the cabin without being cooled. It is let into the air cycle system and routed through a heat exchanger where ram air cools the bleed air. This cooled bleed air is directed into an air cycle machine. There, it is compressed before flowing through a secondary heat exchange that cools the air again with ram air. The bleed air then flows back into the air cycle machine where it drives an expansion turbine and cools even further. Water is then removed and the air is mixed with bypassed bleed air for final temperature adjustment. It is sent to the cabin through the air distribution system. By examining the operation of each component in the air cycle process, a better understanding can be developed of how bleed air is conditioned for cabin use [11].
Most cabin temperature control systems operate in a similar manner. Temperature is monitored in the cabin, cockpit, conditioned air ducts, and distribution air ducts. These values are input into a temperature controller, or temperature control regulator, normally located in the electronics bay. A temperature selector in the cockpit can be adjusted to input the desired temperature. The temperature controller compares the actual temperature signals received from the various sensors with the desired temperature input. Circuit logic for the selected mode processes these input signals. An output signal is sent to a valve in the air cycle air conditioning system. This valve has different names depending on the aircraft manufacturer and design of the environmental control systems (i.e., mixing valve, temperature control valve and trim air valve). It mixes warm bleed air that bypassed the air cycle cooling process with the cold air produced. By modulating the valve in response to the signal from the temperature controller, air of the selected temperature is sent to the cabin through the air distribution system. [11].

Cabin temperature pickup units and duct temperature sensors used in the temperature control system are thermistors. Their resistance changes as temperature changes. The temperature selector is a rheostat that varies its resistance as the knob is turned. In the temperature controller, resistances are compared in a bridge circuit. The bridge output feeds a temperature regulating function. An electric signal output is prepared and sent to the valve that mixes hot and cold air. On large aircraft with separate temperature zones, trim air modulating valves for each zone are used. The valves modulate to provide the correct mix required to match the selected temperature. Cabin, flight deck, and duct temperature sensors are strategically located to provide useful information to control cabin temperature [11].

B. Vapor Cycle Air-Conditioning

The absence of a bleed air source on reciprocating engine aircraft makes the use of an air cycle system impractical for conditioning cabin air. Vapor cycle air conditioning is used on most non-turbine aircraft that are equipped with air conditioning. However, it is not a source of pressurizing air as the air cycle system conditioned air is on turbine powered aircraft. The vapor cycle system only cools the cabin. If an aircraft equipped with a vapor cycle air conditioning system is pressurized, it uses one of the sources discussed in the pressurization section above. Vapor cycle air conditioning is a closed system used solely for the transfer of heat from inside the cabin to outside of the cabin. It can operate on the ground and in flight. This cycle has been shown in Fig. 6 [11].

In the theory of refrigeration, energy can be neither created nor destroyed; however, it can be transformed and moved. This is what occurs during vapor cycle air conditioning. Heat energy is moved from the cabin air into a liquid refrigerant. Due to the additional energy, the liquid changes into a vapor. The vapor is compressed and becomes very hot. It is removed from the cabin where the very hot vapor refrigerant transfers its heat energy to the outside air. In doing so, the refrigerant cools and condenses back into a liquid. The refrigerant returns to the cabin to repeat the cycle of energy transfer [11].

V. APPROXIMATE ENERGY ANALYSIS

In this study, energy analysis for an air-conditioning system of Airbus A330-300 RR Trent 700 as a commercial aircraft has been performed for 289 people on board. It has been indicated in Fig. 7. Even though the maximum speed of the aircraft is 913 km/h, it is assumed to be cruising at the altitude of 11000 m (correspondingly 36100 ft) with a speed of 871 km/h. In the calculation of the cooling loads, generated heat and heat loss have been considered. For the generated heat value, heat generation by passengers, cabin crew, illumination systems, other equipment and solar radiation have been assumedly calculated. The heat loss from the aircraft fuselage at $T_{\text{cabin}} = 20 \, {^\circ}\text{C} (293.15 \, \text{K})$ cabin to the outside of the aircraft at $T_{\text{surface}} = -56.5 \, {^\circ}\text{C} (216.65 \, \text{K})$ has been found.

![Fig. 6 Vapor cycle air-conditioning [11]](image)

Mach number (Ma) for the flight conditions has been calculated with respect to Eq. (1):

\[
\text{Mach number } (\text{Ma}) = \frac{V}{a} = \frac{V}{\sqrt{\gamma R T_0}}
\]
Ma = \frac{V}{c} \tag{1}

Here, “V” symbolizes the aircraft speed and “c” stands for the speed of sound. For the aircraft, the cruise speed is \(V = 871\ \text{km/h}\) (correspondingly \(V = 241.94\ \text{m/s}\)). The speed of sound \(c\) is calculated by Eq. (2):

c = \sqrt{k R T} \tag{2}

In the equation, “k” is the heat capacity ratio and equals to \(k_{air} = 1.4\) for air. “R” is the specific gas constant and its value for air is \(R_{air} = 287\ \text{J/kgK}\). In the formula, \(T\) is \(T_{surface} = 216.65\ \text{K}\) for the outside of the aircraft. According to Eq. (2), the speed of sound has been found to be \(c = 295.04\ \text{m/s}\). After obtaining the speed of sound, Mach number in this condition has been determined as \(Ma = 0.82\) by Eq. (1). It is subsonic flow as \(Ma = 0.82 < 1\).

Heat transfer area for Airbus A330-300 RR Trent 700 has been obtained with respect to Eq. (4) and it has been found to be \(A = 1128.5\ \text{m}^2\).

\[
\Delta T = T_{cabin} - T_{surface} \tag{5}
\]

In Eq. (5), the temperature of the cabin is \(T_{cabin} = 20\ \degree\text{C}\) (293.15 K) and the outside temperature of the aircraft is \(T_{surface} = -56.5\ \degree\text{C}\) (216.65 K). Temperature difference \((\Delta T)\) has been considered by Eq. (5) and it is \(\Delta T = 76.5\ \degree\text{C}(76.5\ K)\).

\[
Q_{loss} = U A \Delta T \tag{6}
\]

In this situation, heat loss has been calculated by Eq. (6) and it has been found to be \(Q_{loss} \cong 25.9\ \text{kW}\) for the aforementioned case. After the heat loss has been evaluated, the next step is to calculate the heat generated in the aircraft. As it was mentioned before, a person generates heat between 80 – 100 W in terms of static situation. It has been assumed to be average 80 W of the heat generated per capita. Heat generated by people on board has been calculated with respect to Eq. (7):

\[
\dot{Q}_{people} = \text{(Number of people)} \times (\text{Heat gen. per capita}) \tag{7}
\]

Here, the number of people on board is 289 and average heat generation per capita is 80 W. The result has been obtained as \(\dot{Q}_{people} = 23.12\ \text{kW}\). Heat generation by the devices of the aircraft has been taken as \(\dot{Q}_{devices} = 2\ \text{kW}\).

For the lighting, there are 50 fluorescent lamps with 12 W for each and 150 fluorescent lamps with 35 W. Heat generation due to the lighting:

\[
\dot{Q}_{lighting} = \sum [(\text{Number of lamps}) \times (\text{Power of each one})] \tag{8}
\]

It has been obtained as \(\dot{Q}_{lighting} \approx 5.85\ \text{kW}\) by using Eq. (8) for the calculation.

In case the glass transmissivity is 40%, solar radiation acting on the glass area of \(A_{glass} = 8.31\ \text{m}^2\) has been calculated by Eq. (9) and total solar irradiance (TSI) has been taken into account as 700 W/m².

\[
\dot{Q}_{radiation} = \text{(Area)} \times \text{(Total solar radiance)} \tag{9}
\]

Here, \(\dot{Q}_{radiation}\) has been obtained for the glass transmissivity value of 100% and then calculated for %40 transmissivity as \(\dot{Q}_{radiation} \approx 2.33\ \text{kW}\) for these conditions.

Total heat generation has been found by using Eq. (10):

\[
\dot{Q}_{generated} = \dot{Q}_{people} + \dot{Q}_{devices} + \dot{Q}_{lighting} + \dot{Q}_{radiation} \tag{10}
\]

With respect to Eq. (10), \(\dot{Q}_{generated} \approx 33.3\ \text{kW}\) has been obtained for the daytime as it includes \(\dot{Q}_{radiation} \approx 2.33\ \text{kW}\). On the other hand, \(\dot{Q}_{generated} \approx 31\ \text{kW}\) has been calculated for the night time excluding \(\dot{Q}_{radiation}\) in the calculation.

### TABLE III

**MATERIALS USED IN THE FUSELAGE OF THE AIRCRAFT**

<table>
<thead>
<tr>
<th>Material (With thickness)</th>
<th>Thermal conductivity</th>
</tr>
</thead>
<tbody>
<tr>
<td>Inner coatings (L₁ = 0.002 m)</td>
<td>λ₁ = 1.4 W/mK</td>
</tr>
<tr>
<td>Honeycomb (L₂ = 0.015 m)</td>
<td>λ₂ = 0.02 W/mK</td>
</tr>
<tr>
<td>Insulation material (L₃ = 0.1 m)</td>
<td>λ₃ = 0.04 W/mK</td>
</tr>
<tr>
<td>Outer shell (L₄ = 0.0015 m)</td>
<td>λ₄ = 120.08 W/mK</td>
</tr>
</tbody>
</table>

In the fuselage of the aircraft, used materials have been indicated with the thickness value (L) in Table II. Moreover, thermal conductivity values (λ) for these materials have been presented. Inner heat transfer coefficient has been assumed to be \(\alpha_{inner} = 12\ \text{W/m}^2\text{K}\) and outer heat transfer coefficient has been considered as \(\alpha_{outer} = 300\ \text{W/m}^2\text{K}\) for the flight conditions.

\[
\frac{1}{U} = \frac{1}{\alpha_{inner}} + \frac{L₁}{λ₁} + \frac{L₂}{λ₂} + \frac{L₃}{λ₃} + \frac{1}{λ₄} + \frac{1}{\alpha_{outer}} \tag{3}
\]

Overall heat transfer coefficient \(U\) has been calculated by Eq. (3) and it has been found to be \(U = 0.3\ \text{W/m}^2\text{K}\).

\[
A = \pi DL \tag{4}
\]

Here, and the diameter of the fuselage is \(D = 5.67\ \text{m}\) as in Fig. 8 while the length of the fuselage is \(L = 63.69\ \text{m}\).

Fig. 8 Cross-sectional area of Airbus A330-300 RR Trent 700 [13]
After calculating the heat generation values for both the daytime and the night time separately, cooling loads provided by the air-conditioning system have been attained by using Eq. (11):

\[
Q_{cooling} + Q_{generated} = Q_{loss}
\]

(11)

Here, \( Q_{cooling} \approx -7.4 \text{ kW} \) as a maximum value has been evaluated for the daytime including the solar radiation. Besides, \( Q_{cooling} \approx -5.1 \text{ kW} \) as a minimum value has been calculated for the night time excluding the solar radiation. The negative sign in front of the cooling load shows that air-conditioning system works in the aircraft.

VI. CONCLUSIONS

The adjustment of temperature, pressure, humidity and oxygen intensity of the aircraft cabin is important when the flight conditions of a commercial aircraft are taken into account. Health problems especially for passengers on board could be seen due to adverse conditions. That is why; hot and pressurized air obtained from aircraft engine compressor zones is conditioned in the air-conditioning system to present comfortable ambience inside of the aircraft cabin. In present study, an air-conditioning system of Airbus A330 has been examined at the cruise altitude of 11000 m for 289 people on board. At this altitude for the aircraft cruising with 871 km/h (Ma = 0.82), cooling loads of cockpit (crew station), passenger cabin and other appliances required cooling in the aircraft have been obtained. The effective parameters on cooling load have been determined as temperature, pressure and air density of aircraft inside and atmospheric outside. In the calculation of the cooling loads, generated heat and heat loss have been considered. For the generated heat value, heat generation by passengers, cabin crew, illumination systems, other equipment and solar radiation have been assumedly calculated. The heat loss from the aircraft fuselage at 20 °C cabin to the outside of the aircraft at -56.5 °C has been found. To sum up, obtained cooling loads are 7.4 kW for the maximum value and 5.1 kW for the minimum value at these aforementioned conditions in terms of the daytime and night time depending on solar radiation, respectively. These maximum and minimum values have been attained with the negative sign in front of their values and it indicates that air conditioning system of this aircraft operates successfully under considered conditions.

DETERMINATION OF VIBRATION CHARACTERISTICS ON VERTICAL AXIS OF A FOUR CYLINDER GASOLINE ENGINE

FATİH CELLEK*, HAKAN ARSLAN*

*+, Mechanical Engineering Department, Kirikkale University, Kirikkale 71451, Turkey
fatihcellek@gmail.com*, arslan71@yahoo.com+

Abstract—The vibration characteristics on the vertical axis of a four cylinder 1.4 L Otto engine was investigated under partial throttle opening rates and different engine speeds, in the study. In the first part of the study, vibration measurements were made in terms of acceleration on the top of engine block. The vibration data were determined in 5 partial throttle opening rates and for 4 engine speed as RMS (Root mean square) and illustrated with graphs. With polynomial regression method, the characteristics equations for each throttle opening have been formed. In the second part, the measurements were made by changing engine speeds for each throttle opening and the obtained results were compared with the results determined from the equations.

Keywords—Engine Vibration, Polynomial Regression, Throttle Rate, Root Mean Square, Engine Speed

I. INTRODUCTION

In the internal combustion engines, the vibrations occur due to the motions of rotating, oscillating and linear moving parts. The engine block that mounted on the chassis periodically vibrates because of inertia forces and gas pressure forces [1,2]. The chassis vibration acts on the driver and passengers. So, the engine vibration must be kept under control. In recent years, there have been a lot of studies on the engine vibrations.

Öztürk and Karabulut have investigated the engine block vibrations of a one cylinder - four stroke diesel engine. They made a dynamical model of the piston, connecting rod, crankshaft and the engine block. The model was four degree of freedom system that includes the rotational motion of the crank, the rotational motion of the engine block with respect to the crank axis, horizontal and vertical linear motions of the block. In the analysis, it was determined that the block vibrations with respect to the crank axis are caused by gas forces and the vertical and horizontal vibrations are caused by piston mass and the unbalance of the crank [3].

In a study by Barelli at al., it has been detected that the most powerful vibration signals can be measured on the cylinder head depending on the engine load and combustion frequency in the internal combustion engines [4].

In the other study, Manieniyan and Sivaprakasam used diesel and the bio-diesel derived from mahu as a fuel, respectively. The vibration data as acceleration were measured from the cylinder head, bottom of the engine and crank bearings. The largest amplitude on the cylinder head has been detected when using bio-diesel. In the other points, the largest amplitudes have been obtained when using diesel [5].

Wongchai et al. have investigated the effects of the hydrogen-diesel blend on the engine vibration. Second order polynomial regression analyses were made to find a correlation between the percentage of hydrogen fuel and vibration amplitude. As a result of the study, it has shown that in response to increasing amounts of hydrogen, engine vibration amplitude decreases [6].

II. MEASUREMENT OF THE VIBRATION

In order to acquire the vibration data, Honda L13A i-DSI engine was used in the experiments as a test engine. This spark ignited gasoline engine has 4 cylinders, 1.4lt volume and the compression ratio is 10.8.

The test engine runs on a platform that is fixed the floor with the other parts of the setup (dynamometer, radiator, cooling water tank, fuel tank, battery etc.) schematic representation of the test engine and all setup is shown in Fig. 1.

Fig.1 Schema of the setup

A computer with a data acquisition card, signal conditioner, connector block and accelerometer was used for measuring the vibration. The top of the first cylinder head were selected
for vertical axis vibration measurements and the accelerometer was mounted on it.

The vibration amplitudes have been determined as acceleration in terms of m/s² in the tests and the each measurement lasted 5 s. The values were measured with varying engine speed, while the throttle rate was fixed.

In the first part of the experiments, the vibration data were obtained in 10%, 20%, 30%, 40% and 50% throttle opening rates and for 1400, 2000, 3000 and 4000 RPM engine speeds.

Amplitude - time for 10% throttle rate is shown in figure 3. The vibration levels can be seen on the graph for 4 different engine speeds simultaneously. The amplitude changings in response to varying engine speed can be realized easily.

Determinations of root mean square (RMS) values instead of vibration levels provide great convenience to find characteristic data. RMS values are calculated as:

\[
X_{RMS} = \sqrt{\frac{1}{n} \sum_{i=1}^{n} x_i^2}
\]  

(1)

RMS values were calculated by using Matlab program and the obtained results have been given in figure 4 for each throttle opening ratios.

III. DETERMINATION OF CHARACTERISTIC EQUATIONS OF EACH CURVE

In figure 4, it can easily be seen that all curves are almost parabolic curves. If these curves can be defined with quadratic equations, it enables to find not only relationship between engine speed and vibration amplitude but also intermediate values on the graphs.

In the study, polynomial regression method was applied to find the equations of the curves. The equations have been determined by Matlab program practically. The equations are shown in table 1. In the table, x values correspond to engine speed values.

<table>

<tr>
<td>50%</td>
<td>1.36 \times 10^{-2} \cdot x^2 - 4.56 \times 10^{-2} \cdot x + 50.74</td>
<td>0.9837</td>
</tr>
</tbody>
</table>

In the second part of the study, the measurements were made by changing engine speeds as 200 by 200 from 1400 to 4000 Rpm for each throttle ratio. The obtained results were compared with the results determined from the equations separately.

For all throttle rates, the comparison graphs are shown below in figure 5-9.
Main concluding remarks are as follows:

- The experimental study indicates that the vertical axis vibration amplitudes increase in response to increasing engine speed for all throttle rates.
- It is shown that the curve fitting techniques especially polynomial regression is applicable for estimating the intermediate vibration values of the engine.
- The fitted curves for all throttle opening rates are very close to the experimental curves.
- The coefficient of determination ($R^2$) values are more than 0.98.
- Generally, the difference between the values (obtained from fitted curve and experimental results) is less than 10% and maximum error is 6 m/s$^2$.

Energy Import Dependency And Seeking For New Energy Technologies
European Union Case
Şerife Özkan Nessimioğlu
Department of Modern Turkish History
Istanbul Technical University, Istanbul, Turkey
ozkanser@itu.edu.tr

Abstract— In this paper, energy poverty and as a result of this energy import dependency and its possible negative results have been examined by taking European Union (EU) into consideration. This analysis has two aims: the first one is questioning the European Unions’ energy security from supply perspective and the second one is investigating the solutions produced by European Union to get away or at least to reduce its energy import dependency. To guarantee its energy supply security at affordable price and to attain its targets about energy security, some action plans has being put into practice at energy technologies by the Union, especially about renewable energy technologies and energy efficiency. By analyzing them this study aims to give a perspective for other energy dependent countries such as Turkey. Because, as an import depended country at energy, Turkey has same supply security risks with European Union. Modeling the strategies developed and experienced by the EU at renewable energy and energy efficiency, to cope with energy import dependency, might give Turkey an opportunity to minimize drawbacks of its own import dependency problem.

Keywords— Energy Security, European Union, Strategic Energy Technology Plan, Renewable Energy, Energy Efficiency

1. INTRODUCTION

Today, for all countries in the world, to sustain development, one of the most important instruments is energy security. It is because of, without maintained energy supply, there are no electricity, heating, transportation and industrial production, which means no life for modern society. According to International Energy Agency (IEA), which established after a very serious energy supply security crises in 1974, after Yom-Kippur War, energy security is the uninterrupted availability of energy sources at an affordable price. For the Agency, long-term energy security mainly deals with timely investments to supply energy in line with economic developments and sustainable environmental needs. Short-term energy security focuses on the ability of the energy system to react promptly to sudden changes within the supply-demand balance [1]. At this point defining energy sources which are subject of energy security is crucial since lack of energy security is defined by giving priority to oil and natural gas. Oil and natural gas are principal conventional energy sources with coal. Their physical availability and pricing mechanism makes them subject of energy security in general for energy poor regions and countries such as the European Union. [2]

During last fifty years some energy crisis were seen in the world mostly because of regional wars at the Middle East. As outcomes of the oil crises of the 1970s and 1980s, oil price increased as a result of petroleum embargo of oil rich and exporter Arab governments [3]. Today, scarcity of fossil fuels is not just because of any political or military crises. Its because reserves of oil, natural gas and coal are running out while demand is globally increasing. Only coal reserves still appears to be sufficient longer than oil and gas as seen at Fig. 2 [4]. However, turning back to coal includes some other security questions about climate change, which could play an important role at rising global CO2 emission.

Fig. 1. International Energy Agency Energy Security Scheme

Fig. 2. Remaining Coal, Natural Gas and Oil Reserves in the World (2015)
The extent of the problem is not restrictable just with coming source shortage and climate issues. The remaining oil and gas reserves are concentrated in politically unstable countries and regions. If big consumer countries and regions cannot be successful at energy saving, efficiency and renewable energy policies, etc. it could be a real threat for their energy supply security and everything about maintain existence of their well-fare and economic development, which are related to it.

As one of the most developed region in the world, EU has been having problems at providing its energy security because of the big gap between the Unions energy consumption and energy production from fossil fuels. That makes the EU fragile to energy supply interruptions because of any reason and price volatility at energy market where producer countries have advantage against supplier countries. To cope with this problems and get its own energy security the Union has been being made investments and supported renewable energy projects as indigenous clean energy and additionally put into practice energy efficiency policy. Especially for last ten years the Union has gave momentum to his achievements to be successful at its energy security strategy. To understand this process, in this study first we are going to examine the energy outlook of the Union and then, as an example to energy technology action plans to the EU, Strategic Energy Technology Plan, in short SET-Plan, is going to be explained.

II. EUROPEAN UNION ENERGY OUTLOOK

Throughout the introduction, some aspects about energy security has been mentioned like, energy scarcity or poverty, unfair distribution of the rest of energy sources in the world, energy supply security and getting energy at affordable price, etc. To understand all those facts properly, first, we are going to set light to world energy outlook by some figures from IEA, European Commission and BP. After that, under light of all those information we are going to take a picture of, energy outlook of the EU to understand main problems about its energy security.

According to, International Energy Agency “World Energy Outlook 2014” by 2040, the world’s energy supply mix divides into four almost-equal parts: oil, gas, coal and low-carbon sources as seen at Figure 3. [5]

The world’s energy resources are plentiful and capable of meeting energy demand far beyond 2040; but many are also dispersed unevenly and they are not all inexhaustible as seen at Figure 2. While the assessed abundance of energy resources seldom changes dramatically from one year to the next, the circumstances surrounding their successful exploitation never stand still. [6]

According to BP, primary energy consumption is getting slower when we focus on per annum (p.a.) on the other hand cumulative demand growth says something else, at which %41 increment is expected between 2012 and 2035. [7] To cope the demand growth, 900 billion dollars is needed per year in upstream oil and gas development by the 2030s.

Investment of some $900 billion per year in upstream oil and gas development is needed by the 2030s although there are many uncertainties over whether this investment will be forthcoming in time. Here many obscurities could count. For example, the production of tight oil level starts to fall back in United States. Tight oil output levels off in the early 2020s and its total production eventually starts to fall back. The situation of Brazilian deep-water fields and Canadian oil sands output are still a conundrum. The sanctions that restrict Russian access to technologies and capital markets and – above all – the political and security challenges in Iraq could all contribute to a shortfall in investment below the levels required. The situation in the Middle East is a major concern given steadily increasing reliance on this region for oil production growth, especially for Asian countries that are set to import two out of every three barrels of crude traded internationally by 2040 [8].

![Fig. 3. Energy consumption by fuel between 1965-2035 and ten year increments by fuel between 1975-2035](image)

As seen at Fig. 4 [9] at the end of 2013, 13642 Mtoe energy was produced in the world. The share of petroleum and products is %30.9, solid fuels %29.4, natural gas %21.3, renewables %13.4, nuclear %4.7 and other fuels %0.3 at this production. Almost %33 of the production was made by United States and China, which are also biggest consumers in the world at the end of 2013. For the EU it is not the same.

![Fig. 4. World Energy Production by Region (Mtoe)](image)
Production of primary energy was accounted for by exploitation of limited resources uneconomical. May, at least in part, be attributed to supplies of raw materials downward development of EU in 2014 than it had been a decade earlier. The general economic crisis. When viewed over a longer period, the production in 2009 that coincided with the financial and rebounded following a relatively strong fall in energy.

When we look at Figure 5 [10], the EU is seen as the forth biggest energy consumer region in the world by %12 but according to Figure 4, it produced only %5.8 of the world energy. That means the Union is supplying more than half of its energy by import.

The dependency of the EU on energy imports, particularly of oil and more recently of gas, forms the backdrop for policy concerns relating to the security of energy supplies. Indeed, more than half (53.5 %) of the EU-28’s gross inland energy consumption in 2014 came from imported sources.

Production of primary energy in the EU-28 totalled 771 million tonnes of oil equivalent (Mtoe) in 2014. This continued the generally downward development observed in recent years, with 2010 the main exception as production rebounded following a relatively strong fall in energy production in 2009 that coincided with the financial and economic crisis. When viewed over a longer period, the production of primary energy in the EU-28 was 17.3 % lower in 2014 than it had been a decade earlier. The general downward development of EU-28 primary energy production may, at least in part, be attributed to supplies of raw materials becoming exhausted and/or producers considering the exploitation of limited resources uneconomical. [11]

In 2014, close to one quarter (25.5 %) of the EU-28’s total production of primary energy was accounted for by renewable energy sources, while the share for solid fuels (19.4 %, largely coal) was just below one fifth and the share for natural gas was somewhat lower (15.2 %). Crude oil (9.1 %) was the only other major source of primary energy production.

The growth of primary production from renewable energy sources exceeded that of all the other energy types; this growth was relatively uniform during the period covering 2004–14, with a small dip in production in 2011 as seen at Figure 6. [12] Over this 10 year period the production of renewables increased by 73.1 %. By contrast, the production levels for the other primary sources of energy generally fell over this period, the largest reductions being recorded for crude oil (-52.0 %), natural gas (-42.9 %) and solid fuels (-25.5 %), with a more modest fall of 13.1 % for nuclear energy. [13]

The use of renewable energy has many potential benefits, including a reduction in greenhouse gas emissions, the diversification of energy supplies and a reduced dependency on fossil fuel markets (in particular, oil and gas). The growth of renewable energy sources may also have the potential to stimulate employment in the EU, through the creation of jobs in new ‘green’ technologies. [14]

In the EU, renewable energy sources include wind power, solar power (thermal, photovoltaic and concentrated), hydroelectric power, tidal power, geothermal energy, biofuels and the renewable part of waste. Among renewable energies, the most important source in the EU-28 was solid biofuels and renewable waste, accounting for just under two thirds (63.1 %) of primary renewables production in 2014. Hydropower was the second most important contributor to the renewable energy mix (16.5 % of the total), followed by wind energy (11.1 %). Although their levels of production remained relatively low, there was a particularly rapid expansion in the output of wind and solar energy, the latter accounting for a 6.1 % share of the EU-28’s renewable energy produced in 2014, while geothermal energy accounted for 3.2 % of the total. There are currently very low levels of tide, wave and ocean energy production, with these technologies principally found in France and the United Kingdom. [15]
The latest information available for 2014 (see Fig.7) shows that electricity generated from renewable energy sources contributed more than one quarter (27.5\%) of the EU-28’s gross electricity consumption. [16] In Austria (70.0\%) and Sweden (63.3\%) at least three fifths of all the electricity consumed was generated from renewable energy sources, largely as a result of hydropower and solid biofuels.

The growth in electricity generated from renewable energy sources during the period 2004 to 2014 (see Fig. 6) largely reflects an expansion in three renewable energy sources, namely, wind turbines, solar power and solid biofuels. Although hydropower remained the single largest source for renewable electricity generation in the EU-28 in 2014 (43.9 \% of the total), the amount of electricity generated in this way in 2014 was relatively similar to that recorded a decade earlier, rising by just 12.1\% overall. By contrast, the quantity of electricity generated from solid biofuels (including renewable waste) and from wind turbines in 2014 was 1.8 times and 3.3 times as high as in 2004. The relative shares of wind turbines and solid biofuels in the total quantity of electricity generated from renewable energy sources rose to 27.4 \% and 18.0 \% respectively in 2014. The growth in electricity from solar power was even more dramatic, rising from just 0.7 TWh in 2004 to overtake geothermal energy in 2008, reaching a level of 92.3 TWh in 2014. Over this 10 year period, the contribution of solar power to all electricity generated from renewable energy sources rose from 0.1 \% to 10.0 \%. Tide, wave and ocean power contributed just 0.05 \% of the total electricity generated from renewable energy sources in the EU-28 in 2014. [17]

At the end of 2008, the EU agreed to set a target for each Member State, such that renewable energy sources (including liquid biofuels, hydrogen or ‘green’ electricity) should account for at least 10 \% of all fuel used within the transport sector by 2020. The average share of renewable energy sources in transport fuel consumption across the EU-28 was 5.9 \% in 2014, ranging from highs of 21.6 \% in Finland and 19.2 \% in Sweden (the only Member States with double-digit shares) to less than 1.0 \% in Spain and Estonia. [18]

The share of renewable energy in gross final energy consumption is identified as a key indicator for measuring progress under the Europe 2020 strategy for smart, sustainable and inclusive growth. This indicator may be considered as an estimate for the purpose of monitoring Directive 2009/28/EC on the promotion of the use of energy from renewable sources — however, the statistical system in some countries for specific renewable energy technologies is not yet fully developed to meet the requirements of this Directive; for example, ambient heat energy for heat pumps is not reported by many countries. Furthermore, for the calculation of the share the Directive requires hydropower and wind energy to be normalised to smooth the effects of variations due to weather; given the 15-year normalisation requirement for hydropower production and the availability of energy statistics (for the EU-28, starting from 1990), long time series for this indicator are not available. [19]

On 6 June 2012, the European Commission presented a Communication titled, ‘Renewable energy: a major player in the European energy market’ (COM(2012) 271 final), outlining options for a renewable energy policy for the period beyond 2020. The Communication also called for a more coordinated European approach in the establishment and reform of support schemes and an increased use of renewable energy trading among EU Member States. In January 2014, the European Commission put forward a set of energy and climate goals for 2030 with the aim of encouraging private investment in infrastructure and low-carbon technologies. One of the key targets proposed is for the share of renewable energy to reach at least 27 \% by 2030. These objectives are seen as a step towards meeting the greenhouse gas emissions targets for 2050 put forward in the Roadmap for moving to a competitive low-carbon economy in 2050 (COM (2011) 112 final).

One of the 10 priorities of the European Commission put forward in 2014 is an energy union. It is intended that a European energy union will ensure secure, sustainable, competitive and affordable energy. In February 2015, the European Commission set out its plans for a framework strategy for a resilient energy union with a forward-looking climate change policy in a Communication (COM(2015) 80 final). The Communication proposes five dimensions for the strategy, one of which is decarbonising the economy. [20]

III. EUROPEAN UNION STRATEGIC ENERGY TECHNOLOGY PLAN

The European Strategic Energy Technology Plan (SET-Plan) aims to accelerate the development and deployment of low-carbon technologies. It seeks to improve new technologies and bring down costs by coordinating research and helping to finance projects. The SET-Plan promotes research and innovation efforts across Europe by supporting technologies with the greatest impact on the EU’s transformation to a low-carbon energy system. It promotes cooperation amongst EU countries, companies, research institutions, and the EU itself. The SET-Plan includes the SET-Plan Steering Group, European Industrial Initiatives, the European Energy Research Alliance, and the SET-Plan Information System. [21]

The Integrated SET-Plan identifies 10 actions for research and innovation, based on an assessment of the energy system needs and on their importance for the energy system transformation and the potential to create growth and jobs in the EU;
- Addresses for these actions the whole innovation chain, from basic research to market uptake, both in terms of financing as well as in terms of regulatory framework;
- Adapts the structures set up under the SET-Plan to ensure a more effective interaction with Member States and stakeholders;
- Proposes to measure progress as part of the annual reporting of the State of the Energy Union via overall Key Performance Indicators (KPI’s), such as the level of
investment in R&I, as well as specific KPI’s to measure progress on the performance and cost-reduction for the priorities.

Low-carbon technologies such as photovoltaics, wind power, nuclear fusion or carbon capture and storage are essential to reduce greenhouse gas emissions and improve the sustainability of the energy system. The uptake of new energy technologies can also decrease the Unions reliance on external suppliers of fossil fuels, as well as spur job creation and economic growth. [22]

At the same time, technological investment is often expensive and commercially risky. Energy companies on their own may not deliver technological breakthroughs quickly enough. Public policy and investment, in partnership with the private sector, is therefore necessary to boost the development and deployment of low-carbon technologies for the future. To reach its low carbon energy targets the EU has a foundation programme, Horizon 2020, which is in accordance with SET-Plan targets. [23]

Under circumstances of SET-Plan, 446 project are being waged. For example, Biowalk4Biofuels, HESCAP, BIOCORE, ORECCA, VALORGAS, INTEGRIS, SUPRA-BIO, SUNSTORE, WAVESTAR, CACHET, etc. [24]

IV. CONCLUSIONS

As has been told through the study, conventional fossil fuels are coming to their end. If we take coal to the center, they will not be in the world almost after a century. This time is almost fifty fifty for oil and natural gas. That means as an energy import dependent region, not only the members of the European Union, but also all countries in the world need to be ready for a time without coal, oil and natural gas especially which are already not sufficient itself at fossil fuel sources.

The only problem, which the world will face, is not only energy poverty, related to high carbon technology, the world is also in danger to face with climate change that would be reason of a real catastrophe in the world. The EU has a real awareness about these two upcoming dangers as understood from its energy security policy. By its energy security supply policy, especially 2020 and 2030 renewable targets, the Union is taking measures for both, sustainable and affordable energy supply and reducing carbon emission. To reach its clean and domestic energy targets the EU has lots of programmes, which are supporting financial and political collaboration with other countries. The Unions energy strategy is a good model for other countries in the world. Especially which are energy dependent and fragile to external energy shocks and consume high carbon including energy sources like Turkey. The applications of the EU about renewable energy, smart cities, energy storage etc. need to be followed closely because it contains experience and positive results for other the countries which still does not has an action plan for near future.

Heat Transfer of Two Phases (Water – Air) in Horizontal Smooth and Ribbed Ducts

Riyadh S. Al-Turaihi*, Sarah Hasan Oleiwi*

*College of Engineering, Dept. of Mech. Eng., Babylon University {drriyadhalturaihi@yahoo.com, sarah.ha369@gmail.com}

Abstract— Computational fluid dynamics (CFD) was used to investigate the flow of water and air in smooth and ribbed duct. Temperature was applied for the top and the bottom of the duct where the ribs are located. The heat transfer coefficient were calculated at different location inside the ducts and the results was validated using several heat transfer coefficient correlations that was developed by other researchers. Three shapes of ribs was studied which are rectangular, trapezoidal, and triangle. Three water velocities and three air velocities was studied (0.4, 0.6, and 0.8 m/s), and (0.12, 0.15, and 0.18 m/s), respectively. The heat transfer coefficient increased by adding ribs, it also increased as the velocity of the flow increased.

Keywords— Heat transfer, Ribbed duct, Two phase, Ansys Fluent, CFD

1. INTRODUCTION

There are two types of techniques available to increase the heat transfer which are active and passive techniques. Passive techniques include additives of fluid, devices of swirl flow, extended and coated surfaces, and roughed surfaces anything that include applying special surface geometry. Active techniques include vibration of surface, acoustic or electric fields, and mechanical aids simply the techniques that require external power source (Manca O. et al. (2011)). Ducts and pipes that roughed with ribs are widely used in several applications such as ventilation, turbine blades, and heat exchangers (Ansari M. R. et al. (2013)). Ribbed ducts are commonly used for the enhancement of convection heat transfer since the presence of ribs increase the turbulent and produce flow circulation which increase the heat and mass transfer also the thermal boundary layer thickness are reduced by the ribs due to the secondary flow regions that appear near the wall which increase the heat transfer rate (Ansari M. R. and Arzandi B. (2012); Komeil M. et al. (2015)). Several researcher studied the ribbed channels, Song X. O. et al. (1996) compared the trajectories and particle velocities and particle impacts wall wastage by means of rib and smooth welding wall, experimentally and computationally. Both results showed that wall erosion are reduced by adding ribs on wall. Manca O. et al. (2011) Numerically investigated the angle between the ribbed surface and the direction of the fluid flow using three dimensional rectangular ribbed channel model. Ansari M. R. and Arzandi B. (2012) Experimentally investigated the air water two phase flow using ducts that are smooth and ribbed to show the effect of ribs height on the boundaries, they also presented a flow map diagram. Yemenici O. and Sakin A. (2013) Used the finite volume method to investigate the flow of air over heated ribbed wall, they showed that heat transfer are improved by the presence of ribs. Coletti F. et al. (2014) Used the particle image velocimetry two dimensional time resolved to study the turbulent flow within a rotating channel having ribs along one wall. They showed that both the centrifugal force and coriolis force effects the fluid dynamics as the ribbed wall is heated. Boukadoum A. B. and Benzaoui A. (2014) Performed a computational fluids dynamics simulation to analyze the flow and to study the convection heat transfer in solar air heaters duct having rectangular ribs. Komeil M. et al. (2015) Numerically investigated the ribbed tubes convection heat transfer using Al2O3-water nonfluid turbulent flow and different shapes of rib. They showed that its thermodynamically advantageous. Jaiswal S. and Aharwal K. R. (2015) Performed three dimensional numerical study using Ansys fluent to study the fluid flow characteristics and the heat transfer with in ribbed channel. In this work a computational fluid dynamics simulation was performed for a two phase (air-water) flow in ribbed channel. Three rib shapes was used (Rectangular, Trapezoidal, and Triangle) and the results compared with smooth channel to show the effect of ribs on the heat transfer coefficient. The results of the CFD two phase model was validated using heat transfer coefficient correlations that developed by Boyko L. D. and Kruzhilin G. N. (1967), Serizawa A. I. and Michiyoshi I. (1975), Shah M. M. (1981), and Kim D. and Ghajar A. J. (2002). And the results were in good agreement.

2. PROBLEM DESCRIPTION

Ribbed duct with two phase (air – water) flow flowing through it was investigated, figure (1a). Two dimensional geometry model was generated using SolidWorks 2013. The duct consists of a (146 cm) entrance section to insure a fully developed flow and (54 cm) ribbed heated section with (4.5 cm) height. Uniform temperature was applied on the top and bottom of the ribbed section. The inlet of air and water was given a special arrangement, detailed view of the inlet section are shown in figure (1b). Three different shapes of ribs was studied which as (rectangular, trapezoidal, and triangle) as shown in figure (2), smooth duct was also generated to show the difference made by the ribs. The ribs have a base width of (w = 1.5 cm) and height of (e = 0.8 cm) along with a bitch distance of (b = 4.5 cm). Three values of air and water velocities was investigated (0.12, 0.15, and 0.18 m/s), and (0.4, 0.6, and 0.8 m/s), respectively. Table (1) shows the tests that was performed with respect to the water and air velocities for each rib shape and for the smooth duct as well. Ansys
Fluent 15.0 was used to simulate the flow of air-water in a ribbed duct. Two phase mixture model along with the k-epsilon standard turbulent model were used using water as the primary phase and air as the secondary phase.

2.1. Mesh

Quadrilateral unstructured mesh was performed for the models using Ansys 15.0, the number of elements were (240121, 239009, 243329, and 245875) for rectangular ribbed, trapezoidal ribbed, triangle ribbed, and smooth duct. Three mesh sizes were used to check the mesh dependence and the accuracy of the results. Table (2) shows the number of element for the mesh sizes used. The percentage deviation of the heat transfer coefficient results with several heat transfer correlations are shown as well in table (2), for smooth duct. Figure (3) shows the initial mesh for the three types of ribs.
The equation general form is as \((\text{Guide } 2006)\).

Continuity, momentum and energy for mixture (Fluent User’s velocities. The mixture model solves the equation of flow of water and air in the ribbed duct. This model is used when the phases of a multiphase flow move at different velocities. The mixture model solves the equation of continuity, momentum and energy for mixture (Fluent User’s Guide 2006).

**I. Continuity Equation**

The equation general form is as \((1)\)

\[
\frac{\partial}{\partial t}(\rho_n \overline{u_n}) + \nabla (\rho_n \overline{u_n} \overline{u_n}) = 0
\]  

\text{(1)}

Where \(\overline{u_n}\) and \(\rho_n\) is the mass-averaged velocity and the mixture density, respectively, represented as \((2)\) and \((3)\)

\[
\overline{u_n} = \sum_{k=1}^{n} \alpha_k \rho_k \overline{u_k}
\]  

\text{(2)}

\[
\rho_n = \sum_{k=1}^{n} \alpha_k \rho_k
\]  

\text{(3)}

\(\alpha_k\) is the volume fraction of phase \(k\).

**II. Momentum equation**

The equation general form is as \((4)\)

\[
\frac{\partial}{\partial t}(\rho_n \overline{u_n}) + \nabla (\rho_n \overline{u_n} \overline{u_n}) = -\nabla p + \nabla \left[ \mu_n (\nabla \overline{u_n} + \nabla \overline{u_n}^T) \right] + \rho_n \overline{g} + \overline{F}
\]  

\text{(4)}

Where \(n\) is the number of phases

\(\overline{F}\) is a body force, \(\mu_n\) is the viscosity of the mixture represented as \((5)\), and \(\overline{u_{\alpha,\beta}}\) is the drift velocity for secondary phase \(k\) represented as \((6)\): \[
\mu_n = \sum_{k=1}^{n} \alpha_k \mu_k
\]  

\text{(5)}

\[
\overline{u_{\alpha,\beta}} = \overline{u_k} - \overline{u_n}
\]  

\text{(6)}

**III. Energy equation**

The equation general form is as \((7)\)

\[
\frac{\partial}{\partial t} \sum_{k=1}^{n} \alpha_k (\rho_k \overline{E_k}) + \nabla \sum_{k=1}^{n} \alpha_k \overline{u_k} (\rho_k \overline{E_k} + p) = \nabla (k_{\text{eff}} \nabla T) + S_k
\]  

\text{(7)}

Where \(S_k\) includes any other volumetric heat sources, \(k_{\text{eff}}\) is the effective conductivity, and \(E_k\) represented as \((8)\) for compressible phase or equal to \(h_k\) for incompressible phase.

\[
E_k = h_k - \frac{p}{\rho_k} + \frac{u_k^2}{2}
\]  

\text{(8)}

**IV. Turbulence model**

The turbulent model used for this computational study is k-epsilon standard mixture model. The equations general form for this model is as \((9a, b)\).
3. RESULTS VALIDATION

The heat transfer coefficient of the simulated model was validated using the two phase heat transfer correlations that were developed by Boyko L. D. and Kruzhihin G. N. (1967), Serizawa A. and Michiyoshi I. (1975), Shah M. M. (1981), and Kim D. and Ghajar A. J. (2002). The correlations formulas are as follows.

Developed a correlation to calculate the heat transfer coefficient for two phase in horizontal tube. They used the correlation to calculate the heat transfer coefficient through the condensation of steam for horizontal tube, they validated their correlation using experimental results.

\[ h_{TP} = h_l \left(1 + \frac{\rho_f}{\rho_g} - 1 \right)^{0.5} \]  \hspace{1cm} \text{(10)}

Where the liquid heat transfer coefficient evaluated as (11):

\[ h_l = 0.02 Re_f^{0.8} Pr_f^{0.4} \left( \frac{k_f}{D} \right) \]  \hspace{1cm} \text{(11)}

II. Serizawa A., Kataoka I., and Michiyoshi I. (1975)

Developed an empirical correlation to calculate the diffusivity ratio of the two phase (air - water) heat transfer coefficient to the single phase (water) heat transfer coefficient. The correlation, eq. (12), was used in this paper to calculate the two phase heat transfer coefficient. The single phase heat transfer coefficient are evaluated from Sieder E. N. and G. E. Tate (1936), eq. (13).

\[ \frac{h_{TP}}{h_l} = 1 + 462 X_{TT}^{-1.27} \]  \hspace{1cm} \text{(12)}

\[ Nu_t = 0.027 Re_t^{0.8} Pr_t^{0.33} \left( \frac{\mu_l}{\mu_g} \right)^{0.14} \]  \hspace{1cm} \text{(13)}

Where \( X_{TT} \) is the Martinelli parameter, and \( x \) is the flow quality, evaluated as (14, and 15), respectively.

\[ X_{TT} = \left(1 - \frac{x}{\rho_l} \right) \frac{\rho_f}{\rho_l} \left( \frac{\mu_l}{\mu_g} \right) \]  \hspace{1cm} \text{(14)}

\[ x = \frac{m_g}{m_g + m_v} \]  \hspace{1cm} \text{(15)}

Developed a correlation for horizontal and vertical ducts to calculate the two phase (water - air) heat transfer coefficient.

\[ h_{TP} = \left(1 + \frac{u_g}{u_l} \right)^{1/4} \]  \hspace{1cm} \text{(16)}

Where \( h_l \) is evaluated as (17).

\[ Nu_t = 0.023 Re_t^{0.8} Pr_t^{0.4} \left( \frac{\mu_l}{\mu_w} \right)^{0.14} \]  \hspace{1cm} \text{(17)}

Developed a heat transfer correlation for two phase (air - water) flow, the correlation are developed based on vertical pipes and different patterns experiments data. They modified the correlation to calculate the two phase heat transfer coefficient for horizontal pipes with good accuracy, eq. (18). Liquid phase heat transfer coefficient was evaluated using Dittus and Boelter (1930) heat transfer correlation (19).

\[ Nu_t = 0.0243 Re_t^{0.8} Pr_t^{0.4} \]  \hspace{1cm} \text{(18)}

\[ \alpha = \left[1 + \left( \frac{u_g}{u_l} \right) \left( \frac{1 - x}{x} \right) \left( \frac{\rho_l}{\rho_g} \right) \right]^{-1} \]  \hspace{1cm} \text{(20)}

The deviation percentage between the results is (7.04 %, 6.5 %, 2.71 %, and 18.85 %), respectively, as shown in figure (4). This correlation was compared with smooth duct since it was correlated based on smooth ducts and pipes experiments data.

Fig. 4 Comparison between the heat transfer coefficient of the current work and the correlation developed by Boyko L. D. and Kruzhihin G. N. (1967), Serizawa A. I. and Michiyoshi I. (1975), Shah M. M. (1981), and Kim D. and Ghajar A. J. (2002). At 0.15 m/s air velocity and different water velocities.
4. RESULTS and DISCUSSIONS

Two phase (water-air) flow through rectangular duct that roughed with different shapes ribs (rectangular, trapezoidal, triangle) was investigated using Ansys Fluent 15.0. three values of water and air velocities was studies. Figure (5) shows the local heat transfer coefficient for the duct for smooth and ribbed ducts, for several values of air and water velocities, the trend of the heat transfer coefficient is the same. In the smooth duct the values of the heat transfer coefficient is the same, as for the ribbed duct the value of the heat transfer coefficient are increased also a complex shape are appear, an amplitude are appear periodically. Figure (6) shows the local heat transfer coefficient for rectangular ribbed duct and smooth duct, this figure shows that the amplitude appear at a certain location which is the where the ribs are located. At ribs and the leading edge of the ribs the velocity is increased which increase the heat transfer coefficient, at the trailing edge the velocity are lower which give low value of the heat transfer coefficient. Figure (7) shows the average heat transfer coefficient for the three shapes of ribs with respect to the water velocity and at different values of the air velocity, as it seems the heat transfer coefficient increase as the value of water velocity increase. The same effect are appear as the value of air velocity increase but with less percentage increase as shown in figure (8). Increasing the velocity will increase the turbulence produced in the duct and the flow mixing will increase as well due to the presence of ribs inside the duct which conversely will increase the heat transfer coefficient. Figure (9) shows the Reynolds number effect on the average value of the heat transfer for smooth and ribbed ducts, as the Reynolds number increase the heat transfer increase for both smooth and ribbed ducts but the percentage increase are not the same, ribbed ducts have more heat transfer areas which mean more heat to be translated in to the duct. Heat transfer coefficient for rectangular ribbed duct increased by (73.97 %), as for the trapezoidal ribbed duct increased by (99.14 %), where the triangle ribbed duct increased by (135.65 %). Figure (10, 11, 12) shows the distribution of water and air inside the ducts for the three different shape ribs. The trailing edge of the ribs are place where eddy are formed and recirculation appear. As the velocity of water and air increased the circulation of flow in the duct increase. Figure (13) shows close view for the flow distribution across the rib, the flow at the leading edge of the rib are almost settle whereas at the rib the flow are separated and reattached after the trailing edge. At the trailing edge of the rib the eddy are formed and flow circulation appear. The area for the leading edge and the trailing edge behavior are at its biggest value for the rectangular ribs and at its smallest value for the triangle ribs. Figure (14) shows the temperature distribution for the three ribbed ducts, this figure shows the temperature are at its higher value at the trailing edge of the ribs and for the three ribs shapes.

Fig. 5 Effect of ribs on the local heat transfer coefficient at different values of air and water velocities

(c) Triangle ribbed duct

Fig. 7 Effect of water velocity on the average heat transfer coefficient at different air velocities
Fig. 8 Effect of air velocity on the average heat transfer coefficient at different water velocities

Fig. 9 Effect of Reynolds number on the average heat transfer coefficient for smooth and ribbed duct
Fig. 10  Rectangular ribbed duct (a) 0.4 m/s water velocity and 0.18 m/s air velocity  (b) 0.8 m/s water velocity and 0.18 m/s air velocity

Fig. 11  Trapezoidal ribbed duct at (a) 0.4 m/s water velocity and 0.18 m/s air velocity  (b) 0.8 m/s water velocity and 0.18 m/s air velocity

Fig. 12  Triangle ribbed duct at (a) 0.4 m/s water velocity and 0.18 m/s air velocity  (b) 0.8 m/s water velocity and 0.18 m/s air velocity
Fig. 13 Flow distribution of ribbed duct at 0.6 m/s water velocity and 0.18 m/s air velocity

Fig. 14 Temperature distribution of ribbed duct at 0.6 m/s water velocity and 0.18 m/s air velocity

CONCLUSIONS
In this paper the two phase heat transfer coefficient for ribbed and smooth ducts was investigated using Ansys Fluent 15.0 computational fluid dynamics. The coefficient of the ribbed ducts was compared with the smooth duct and found to be increased by 73.97 % for rectangular ribbed duct, 99.14 % for trapezoidal ribbed duct, and 135.65 % for triangle ribbed duct.
duct. It also found that the heat transfer coefficient increase as the velocity of the flow increase. The distribution of the water and air in the duct was shown as well as the temperature distribution, eddy was shown to be formed at the trailing edge of the ribs and the temperature found to be at its higher value at the trailing edge of the ribs and for the three types of ribs.

Abstract—In this study, RS232 asynchronous serial communication protocol was implemented on BZK.SAU microcomputer architecture. Thus, the deficiency of the BZK.SAU microcomputer architecture, which was designed for educational purposes, regarding the peripheral units, was resolved through the protocol created, and the experience which was essential for other serial communication protocols was gained. The aforementioned protocol was coded with the hardware description language (VHDL), synthesized on FPGA board, and proper functioning was verified through PC and ModelSim simulation program. In the second part of the study concerned, the mechanism was provided with the ability to perform the return process in the desired direction and angle using the FPGA-based keyboard without computer through Pan/Tilt mechanism formed on stepper motors with the software created with BZK.SAU Assm language which is the language of BZK.SAU microcomputer architecture. In this way, it was observed that the serial data transmitted between two FPGAs and the Pan/Tilt Mechanism connected to FPGA formed a basis for the embedded systems and moving associative mechanisms.

Keywords— BZK.SAU, FPGA, RS232, Stepper Motor

I. INTRODUCTION

FPGAs are programmable integrated circuits which allow designers to perform hardware functions such as a microprocessor, special hardware, memory structure, and external memory controller on a single integrated circuit. FPGAs are preferred in terms of cost and productivity, for they allow each function of every single element to be located on a single circuit board. Furthermore, FPGAs are more practical compared to ASIC in terms of developing applications on the circuit and re-programmability [2].

FPGAs are reprogrammable semiconductor devices containing multiple connections with the matrix structure. Because of their re-programmable structure and ability to function fast and collaterally, FPGAs are ideal integrated circuits for many different markets. They are used in many areas such as biomedical, air-defense, ASIC prototype design, automotive, consumer electronics, high-performance computing, and data storage, industrial applications, video-image processing, and wired-wireless communication. While FPGAs were preferred due to the low speed and capacity in the past, now they have become preferable for their operating speeds that can reach up to 500 MHz [2]. The FPGA integrated circuit located on Altera DE-2 70 board was used in the study concerned [1].

Quartus II is software developed by Altera to program the reprogrammable logical devices. Quartus II allows the analysis and synthesis of the designs in HDL language. It is highly successful software in the compilation of the designs within all these processes, making time-performance analysis, calculation of RTL diagrams, and simulation of different designs [3]. Quartus II software was successfully used in this study to program the FPGA integrated circuit [1].

Modelsim simulation software created by Mentor Graphics is an important tool to simulate designs created by hardware-based languages such as VHDL, Verilog, and SystemC [4]. The designs on which the studies were performed were simulated in Modelsim program [1].

Digital designs in this study were developed in VHDL. VHDL (Very High Description Language) is a special language created to describe digital electronic systems. It is particularly used to program logic-based integrated circuits such as FPGAs. VHDL was created by the USA [5]. One of the biggest advantages of the VHDL language is that it enables to make digital designs which work sequentially and collaboratively in a fast and flexible way [6].

Stepper motors are electrical motors converting the electrical signals which are applied sequentially into sequential movements. Controlling stepper motors of embedded systems such as FPGAs, in particular, has been taking place in the studies in recent years [7-8-9]. In the study performed, 64-step reduction unipolar stepper motors were used [1].

Among the studies carried on the realization of RS232 standard, which is a serial communication protocol, on FPGA, the Uart Module design and its integration into the microprocessor are at the forefront [10-11-12]. Therefore, to develop the concerned protocol was one of our fundamental aims.
In the doctoral thesis study on FPGA-based microcomputer named BZK.SAU, the RS232 serial communication protocol which is one of the protocols that are essential for data communication with the outer world was created with VHDL; and the control design, the software of which was created in BZK.SAU with BZK.SAU.ASSM language, was realized in the desired serial data transfer speed without loss [1].

Thus, each data compiled within BZK.SAU and sent to output serial recorders communicate with other FPGAs through RS232 communication protocol, and the data transfer takes places at the desired serial data transfer speed without loss and seamlessly [1].

The subheadings are as follows:

A. BZK.SAU Architecture, Serial Communication and the Position Control

II. METHOD AND MATERIAL

In this study, the FPGA shown as FPGA-1 in which BZK.SAU microcomputer architecture was embedded and the FPGA shown as FPGA-2 on which RS232 serial communication protocol was loaded were connected to each other with a single cable structure or with the cable structure manufactured as the standard for 9-pin headers. Thus, each data compiled within BZK.SAU and sent to output recorders communicate with other FPGAs through RS232 serial communication protocol, and the data transfer takes places at the desired serial data transfer speed without loss and seamlessly [1].

The designed RS232 asynchronous serial communication protocol was created with VHDL language into two parts, which were serial-data-sending part and serial-data-retrieval part, and fully integrated into the BZK.SAU microcomputer architecture.

In the second part of the study concerned, the control algorithm coding was done which had been designed within the BZK.SAU microcomputer architecture with BZK.SAU.ASSM language and the angular control on the stepper motors moving within a two-axis Pan-Tilt mechanism was achieved. The data input for the biaxial control within the concerned control system was realized through directional data received from the keyboard structure of BZK.SAU. Thus, in addition to the rotation of the open-loop control structure at the desired angle, the angular rotation characteristics of the stepper motors which they had for each step were realized thanks to this system. The biaxial control structure was named as Stepper Motor-1 and Stepper Motor-2 in the schematic illustration [1].

The directional and angular control of the stepper motors was realized through the stepper motor drive circuit connected to the GPIO-1 and GPIO-2 pinouts located on FPGA-2 [1].

The 16-bit data bus and address bus were used in BZK.SAU microcomputer architecture. The related study addressed 16-bit data bus 64Kbyte memory in BZK.SAU microcomputer architecture. In the BZK.SAU architecture designed, a VGA-type monitor with 640x480 pixels resolution was used. The monitor hardware was a hardware which worked only in text and single color (red) mode, and each character on the monitor screen was represented with 8x16 pixels. The related study works on DE2-70 FPGA board with the keyboard structure and the monitor [1].

In the doctoral thesis study on FPGA-based microcomputer named BZK.SAU, the RS232 serial communication protocol which is one of the protocols that are essential for data communication with the outer world was created with VHDL; and the control design, the software of which was created in BZK.SAU with BZK.SAU.ASSM language, was realized in the desired serial data transfer speed without loss [1].

Thus, each data compiled within BZK.SAU and sent to output serial recorders communicate with other FPGAs through RS232 communication protocol, and the data transfer takes places at the desired serial data transfer speed without loss and seamlessly [1].

The subheadings are as follows:

A. BZK.SAU Architecture, Serial Communication and the Position Control

II. METHOD AND MATERIAL

In this study, the FPGA shown as FPGA-1 in which BZK.SAU microcomputer architecture was embedded and the FPGA shown as FPGA-2 on which RS232 serial communication protocol was loaded were connected to each other with a single cable structure or with the cable structure manufactured as the standard for 9-pin headers. Thus, each data compiled within BZK.SAU and sent to output recorders communicate with other FPGAs through RS232 serial communication protocol, and the data transfer takes places at the desired serial data transfer speed without loss and seamlessly [1].

The designed RS232 asynchronous serial communication protocol was created with VHDL language into two parts, which were serial-data-sending part and serial-data-retrieval part, and fully integrated into the BZK.SAU microcomputer architecture.

In the second part of the study concerned, the control algorithm coding was done which had been designed within the BZK.SAU microcomputer architecture with BZK.SAU.ASSM language and the angular control on the stepper motors moving within a two-axis Pan-Tilt mechanism was achieved. The data input for the biaxial control within the concerned control system was realized through directional data received from the keyboard structure of BZK.SAU. Thus, in addition to the rotation of the open-loop control structure at the desired angle, the angular rotation characteristics of the stepper motors which they had for each step were realized thanks to this system. The biaxial control structure was named as Stepper Motor-1 and Stepper Motor-2 in the schematic illustration [1].

The directional and angular control of the stepper motors was realized through the stepper motor drive circuit connected to the GPIO-1 and GPIO-2 pinouts located on FPGA-2 [1].

The 16-bit data bus and address bus were used in BZK.SAU microcomputer architecture. The related study addressed 16-bit data bus 64Kbyte memory in BZK.SAU microcomputer architecture. In the BZK.SAU architecture designed, a VGA-type monitor with 640x480 pixels resolution was used. The monitor hardware was a hardware which worked only in text and single color (red) mode, and each character on the monitor screen was represented with 8x16 pixels. The related study works on DE2-70 FPGA board with the keyboard structure and the monitor [1].
B. Serial Data Delivery Algorithm and Its Simulation

RS232 serial communication protocol was coded into two parts with VHDL language in the thesis study performed. These two parts were designed as serial data-sending part and data-retrieval part.

Moreover, the digital structure used as a frequency divider in both designs was created in VHDL language as well. The algorithm and simulation in Modelsim of the related design are shown in Figure-2 and Figure-3. The designed communication algorithm was formed according to the RS232 asynchronous serial communication protocol, simulated and tried on the FPGA circuit board. Thus, the serial data stream between the real-time-running-system was realized. The experiment to test whether the circuit sending serial data worked correctly and at the desired speed was performed with the software called “RealTerm Serial Capture Program” [1].

C. Serial Data-Retrieval Algorithm and Its Simulation

The basic function that the serial data retrieval algorithm fulfills is to retrieve the serial data sent at the baud rate of speed and convert it into the parallel data. In order to determine whether the data coming from the 8-bit input register of BZK.SAU.FPGA are meaningful data, first of all, the fall time of the data line from logic 1 to logic 0 is checked in accordance with the RS232 protocol; if the received data at the first fall time is logic 0 data, it is recorded in the first vector or index which is called data buffer (0). That the data buffer (0) is at logic 0 level activates a signal called “Load”, and as a result of this, the following data are received into the same index. Because of the fact that data buffer (9) bit at logic 1 is the stopping bit within the framework of the RS232 protocol, it enables the transmission of the data buffer (1-8) data bits to the output in the following algorithmic step. Each step taking place in a particular design depends on a particular clock structure, as in all digital designs. At each rising edge of the clock, the next state within the code structure is passed. Thus, all states coded within the algorithm follow each other [1].

D. Pan/Tilt Mechanism and Stepper Motor Control Software

In this study, a code structure was created which enables the rotation in the desired direction and/or at the desired angle with BZK.SAU.Assm language within BZK.SAU microcomputer architecture. The algorithm enabling the mentioned movement system is shown in Figure-8.
The control software created with BZK.SAU.Assm language in the study concerned has the ability to move the Pan/Tilt Mechanism angularly in the desired directions. 9 of 59 code structures within BZK.SAU.Assm were used, and the movement algorithm is shown in Figure-8. Some of these commands are battery and memory commands, and some are input and output commands [1].

III. CONCLUSION AND DISCUSSION

The asynchronous RS232 serial communication circuit the design of which was made on BZK.SAU microcomputer architecture which was designed for educational purposes was the main purpose of the study performed. In this way, the elimination of the shortcomings of the peripheral units on BZK.SAU microcomputer architecture, which had already been brought into the literature, which are necessary to data-communication with the outer-world, ensures the originality of this thesis study. In addition, it is considered that the obtained knowledge and experience will be a base study for creating computer-based and device-based serial communication protocols such as USB, I²C, Ethernet, and for the control systems with angular position control embedded system base for biaxial PAN/TILT mechanisms created on stepper motors with software structure.

A Comparisonal Study on Unbalance Failure in the Perspective of Vibration and Electrical Consumption Analysis

Salih Seçkin Erol
Kilis 7 Aralik University, Faculty of Engineering & Architecture, Mechanical Eng. Dept. Kilis-Turkey
sserol@kilis.edu.tr

Abstract—In this research, condition of resonance effect which is a common problem for mechanical constructions has been studied in perspective of unbalance failure of a bearing. A test setup designed respect to case practices; constructed and located in laboratory conditions. A bearing in the electrical motor, that is one of the elements in the test setup, has been selected for gathering data in vibration and electrical consumption during the test. The purpose of the research is testing condition of unbalance failure and resonance for studying comparison in various predictive maintenance approaches. Test has been implemented under the electricity frequency of 40.5 Hz that induced the electrical motor for determining rotational speed. According to the analysis results, inspecting of unbalance failure and resonance problem has been detected more clearly by vibration analysis.

Keywords— electrical consumption, unbalance, resonance, vibration, fourier

I. INTRODUCTION

Energy efficiency maintenance techniques are in the stage of rapid development due to competitive markets and globalization. Mainly, enterprises of developing countries are in demand of high technology implementations for mechanical maintenance in order to leave classic techniques such as breakdown maintenance, periodic maintenance etc. Vibration based maintenance is one of the techniques which is used commonly in industries that prefer predictive maintenance. As long as since the stage of failure initiation, machines consume more electricity respect to the stress in machine elements. By studying data belongs to electricity consumption regarding voltage and current, it brings a newer approach on detecting failure types and severity respect to the signal processing. Vibration analysis is based on the signals those gathered as targeting on bearing, but electrical data is received over electricity usage of the motor. Interpretation of vibration analysis has algorithm based on rotation frequencies caused by the rotational speed; and electrical consumption analysis is based on signals of electrical frequency that is in use.

Nowadays, reliability concept is used more commonly in the development of manufacturing industries. Design of products with high reliability is needed, but against to deterioration in the life cycle of the product, maintenance is a method in maintenance [1]. Prognostic and diagnostic terms are known from medical areas and they are used for the machine health as well. Currently, a variety of sensors and some other equipments are used successfully in receiving signals for studying the root causes of the mechanical failures [2]. In order to cope with the competitive markets, assistance of the high technology such as sensor technology is crucial for the enterprises. On the other hand, investment on high technology does mean always positive results. Appropriate sensors for the target aim, qualified personnel and right interpretation of the data are other important factors for successful actions [3]. One of the failure detection methods for electrical motors is collecting signals of voltage and current and study them [4].

Electrically forced machines are very common in production areas. Breakdown of these machines brings many losses to the enterprises such as time loss, quality loss, capita loss. In order to prevent these kind of losses, maintenance need was born [5].

Machines have characteristic properties on failure types respect to the vibration signals oscillated. Machine failures are mostly studied under assistance of vibrational analysis [6]. Spectrum analysis is a method for identifying the frequencies of a signal. Fourier transform deals with signals that are studied respect to the time parameter as sine and cosines; and to the frequency parameter that is the same signal which is categorized according the frequencies [7].

II. MATERIALS AND METHODS

Test setup constructed through consisting of double inlet fan, AC induction motor, five feet of flexible coupling and frequency inverter. The test setup is constructed over a steel sheet and a steel tripod. The test setup is put up on a double-decker rubber sheet that is mounted between the test system and the tripod; also, a vacuum rubber below the feet of the tripod takes place over the floor. This system with a data acquisition card and an induction motor is communicated with monitoring system through a computer. Testing system in Figure 1 presents a real appearance from testing setup.
Frequencies took place in the test (T) and measured (M) are given in Table 1. Theoretical frequencies means the value set on the digital frequency changer; according to data studied during the application, actual frequency ranging had some losses. 1x is named as a frequency that is known as fundamental frequency; 2x, 3x and the upper orders are harmonics of the fundamental frequency. In Table 1, the frequency is presented with the symbol of f for frequency converter and harmonic order is shown with symbol of h.

Measurements are received during the tests at electrical frequency of 40.5 Hz and rotational level was measured as 2350 min⁻¹. Frequencies of faults and harmonics are studied for calculating the bearing and fan-induced vibrations of the testing setup.

Bearing relevant equations with the basic failure frequency calculations and respect to measurements are given in Table 2.

Tested bearing has been presented in Figure 2.
through an electronic device connected to electrical circuit of the motor and analyzed with its software.

**A. Vibration Analysis**

Under the effect of unbalance failure in axial direction, respect to the findings at frequency of 40.5 Hz; harmonic 1x is detected with the highest amplitude. 1x is the characteristic feature of unbalance failure. Similarly with the radial direction, signal at harmonic 1x has the highest amplitude with 0.785 m/s² but less than the radial direction which is 1.19 m/s². In comparison with highest five amplitude signals in axial and radial direction, four signals are detected at same frequencies as 39.06 Hz, 120.8 Hz, 78.13 Hz and 947.3 Hz. In the axial direction, natural frequency signal at 1027.8 Hz is excited by the bearing signal at 69xωc has been detected which does not exist in radial direction dominant signals.

![Figure 4. Spectrum in axial way](image)

Respect to the Figure 4 and Table 3, unbalance condition increased the vibration magnitude of signals at the element passing zone.

**B. Electrical Consumption Analysis**

Standart deviations in measurements are evaluated in perspective of electrical consumption, data is given in PSD analysis and trend analysis. Respect to PSD analysis in Figure 6, peaks can be seen at the orders of 40.5 Hz. Highest three amplitudes are on 40.5 Hz, 81 Hz and 121.5 Hz. According to the methodological approach of device software, band at the main frequency represents the condition of the rotor, band at the second order represents the unbalance failure and band at the third order represents the any other failure. The PSD analysis takes attention to rotor and unbalance failure.
According to the data gathered and processed; PSD analysis gives more detailed results in comparison with trend analysis.

Figure 6. PSD values

According to evaluation of trend analysis in Figure 7; in comparison with the reference level, unbalance indicator has not detected any change in the condition of unbalance effect respect to the load on wings.

Figure 7. Trending values

IV. RESULTS AND CONCLUSIONS

In this test study, resonance effects of a test construction have been studied under the unbalance condition of a bearing in an electrical motor with the excitation of electricity frequency at 40.5 Hz. Through predictive maintenance perspective; techniques of vibration and electrical consumption analysis are studied in order to identify the condition of a tested bearing under unbalance failure.

According to test results of vibration analysis; bearing failure frequencies and resonance frequencies are identified in spectrum domain under the effect of unbalance failure.

Electrical consumption analysis is successful on detection of unbalance failure in PSD analysis but not sensed in trend analysis. It is assumed that analysis programme of the measuring device is not designed for identifying resonance effect. But resonance effect may be studied in band of rotor or band of other; not exist sufficient data about it.

In comparison of vibration and electrical consumption analysis results; vibration analysis has been evaluated as more informative and superior tool for detecting the resonance features of the tested system in the condition of unbalance failure.

Abstract—In the recent decade, one of the most important topics in researches and developments is the studies performed in robotic and mechatronics applications. Especially, the mass production systems, automobile industries and military-defense products are continuously enhanced. They strictly follow and adapt the new methodologies, approaches, systems and tools created in robotic and mechatronics research world. Their common objective is to develop better autonomous / automation systems. While such autonomous systems are designed, some tools used for scanning and recognizing the working environment are required. Considering the efficiency, repeatability, accuracy and environmental conditions, laser scanning systems are generally preferred to meet these expectations. They are used for mapping the surrounding of the working area. If the system is mobile, they are also used for localization. In this study, a 3D laser scanning system based on a 2D laser scanning rangefinder is developed. The system consists of a rotating unit on which a 2D laser scanner is placed. Rotation is provided using a stepper motor. The rotation control of this unit is achieved using a motion controller. A high resolution encoder and encoder interface card are also plugged into the system to get the direct rotation angle information. By this way, the required feedback is supplied to the control structure developed. The use of high resolution encoder provides also getting rotational velocity with high accuracy. The position and velocity control of the rotating parts of the system are controlled using an ATmega based microprocessor. Not only the control issues of the rotating parts, but also data flow and process of the 2D laser scanner is performed in real-time. The decoding process of the laser sensor is done using an algorithm created in C++. In order to create the 3D map of the surrounding, the data coming from the laser scanner and the rotation angle information obtained from high resolution encoder are integrated under a mathematical model built in Matlab/Simulink. Many experiments are conducted and successful results are obtained.

Keywords—Localization, mapping, robotics, laser scanner.

I. INTRODUCTION

In the robotic and mechatronics research areas, developments have been constantly continued for the last decades. New ideas, modeling structures, control algorithms, tools, systems and machines have been proposed and taken place in the robotic and mechatronics world. In any robotic application, one of the important issues is the recognition of the working environment. In other words, the surrounding should be perceived and this requires some tools behaving like eyes. Cameras are commonly used for this objective. The negative side of using cameras is that they cannot be adapted to all robotic applications. For instance, the applications requiring high resolutions and accuracy may not be appropriate for adapting camera systems for recognition purpose. The use of cameras needs also high-rate computational efforts that can be performed by using high-performance computing systems. Furthermore, the light quality (in the case camera is used as a recognition tool) should be perfect for obtaining high accuracy. The solution adapted in such cases is to use laser scanning range finders. According to the working principles of the laser scanners, they provide 2 dimensional data for their surroundings. In the obstacle detection / avoidance applications, getting the information about the location of an obstacle is enough to plan the desired trajectory. In such a case, a 2D laser scanning range finder can effectively be used for achieving the task. If the shape of the obstacle in 3D space (rather than its location) is important, a 3D laser scanner would be used.

There are 3D laser scanners available in the market. Different models ranging from low to high resolutions can be obtained. In addition to low accuracy models, high accuracy and high quality models are offered to the customers. The disadvantage of these 3D laser scanning range finders available currently in the market is the cost of them. They cannot be affordable for the small-scale projects, student works, workshop applications and prototype developments.

In this study, a 2D laser scanning rangefinder based 3D laser scanning system is developed. The system consists of a mechanical frame and a rotational unit. The rotational unit is constructed by using a flat platform, rotational shaft, bearings and couplings. It is actuated using a stepper motor. A L298D motion controller is adapted to achieve the controlling purpose of the stepper motor. In order to increase the rotational accuracy of the laser scanning system, a high resolution encoder is coupled to the system. It is connected to the system using a gearbox mechanism. The motion control unit used for position and velocity controls of the stepper motor is commanded via using an ATmega based microcontroller. The rotation information coming from the high resolution encoder is decoded using an encoder input card manufactured by Quanser. A laser scanning range finder, Hokuyo URG-04LX, is located on the rotating unit of the system. Its data is processed using an algorithm created in C++. All the subsystems including data processing, data fusion and command generation for the controller are merged in
Matlab/Simulink environment. Using the Real-time workshop toolbox of Simulink provides the real-time control opportunity of the system. The 2D laser scanner data is easily combined with the rotation angle information in this computation environment.

The outline of this paper is constructed as follows: the next section is about the related studies. The problem statement is given in Section 3. The design and construction processes are presented in Section 4. Experimental studies and their details are also demonstrated in this section. The analysis and conclusion of the study is given in the last section of the paper.

II. RELATED STUDIES

There are number of studies related to developing a 3D laser scanning system in the literature. In this section, some of them are reviewed to see the current technology in the 3D laser scanning systems and make a comparison between the literature and the study proposed here.

A 3D laser scanner was developed for measuring uniform and dense shapes in dynamic environment. The 3D laser system was constructed based on a 2D laser scanning range finder that was mounted on a pan tilt base. The rotation of the pan tilt base gave the 3D shape measurement opportunity. The proposed system was supported by using a point clouds algorithm [1]. A low-cost and instant 3D laser scanning system was proposed. The system was designed for creating 3D models. It was aimed that the data obtained from the proposed system could be used for 3D printing tasks. In addition to mechanical parts of the overall system, computational and communicational parts were also designed. The performance of the system was presented via the number of experimental results [2]. A low-cost active 3D triangulation laser scanning system for indoor navigation of mobile robots was designed. A camera and laser scanner were integrated in a system and located on the movable part of a robot. The movable part was actuated using a servo motor. By this way 3D laser scanner based on a 2D laser sensors was created [3]. A cost effective and hand held 3D laser scanning system was developed. The system was designed for acquiring the optical 3D laser scan data. An automatic registration algorithm was also built for 3D shape modeling [4]. A new methodology to analyze coarse tree root using a 3D laser scanning system was developed. The study focused on obtaining solutions for the problems of constructing detailed 3D data acquisition and modeling its complex structure [5]. A high precision 3D laser measurement system was developed. The system was designed using multiple mobile robot cooperation. The robots, two of them were child and one of them was a parent, were suited with number of sensors and laser scanners. An algorithm was developed to achieve the data flow between the robots and coordination [6]. A high quality 3D laser scanning system for general vehicle usage was proposed. The system was constructed based on a 2D laser scanning range finder and point clouds algorithm. The methodology introduced was tested for an outdoor 3D navigation task [7]. An automatic planning of laser measurements for large scale environment was introduced. The system used multiple robots. One of the robots was suited with a 3D laser scanning system and the others were aimed for marking the targets. The algorithm proposed was able to process the large scale of 3D data to construct the working environment of the mobile robots [8]. A low-cost laser scanner with 360° field of view for mobile robotic applications was developed. The system consists of a 2D laser scanner and a rotating head part. The proposed system also provided an intrinsic calibration method for the device built. The integration of the scanning system with a mobile robot was also presented [9]. A laser scanning sensor system for outdoor service robots was developed. The study consists of design, manufacturing, implementation and experiments. The laser system was constructed based on a 2D laser scanner and a rotating unit which was actuated using an actuator. It consisted also a CCD camera installed to the system in order for increasing the measurement accuracy of the overall system. The sensorial subsystems and the actuator were integrated using an algorithm developed [10].

What distinguishes this study from the ones presented above is that a low-cost and high accuracy 3D laser scanning system is developed. The construction of the system needs very basic steps and it can guide the researchers for the further enhancements on laser scanning systems. A new methodology consisting of the data fusion, data mining and actuator control issues is also presented in this paper.

III. PROBLEM STATEMENT

The recognition of the obstacles is one of the important issues in robotic and mechatronics applications. In addition to recognizing the working environment, creating a safe space is the key factor for achieving a robotic task. The automation applications can also require such obligations for performing the desired objective. In an autonomous vehicle application, the obstacles should be detected so that the desired trajectory can be tracked. This task is depicted with a scenario in Figure 1-a. In this scenario, the four-wheeled autonomous vehicle is aimed to track a reference path indicated by blue-dashed-line. It moves with a desired forward velocity specified by $V_c$. A laser scanning range finder is mounted to the front mid-center of the vehicle so that the vehicle can be able to detect any obstacle, person, vehicle, etc. inside its desired path. The coverage of the scan of the laser scanner is specified via red-colored-circle. Three obstacles (shown by black-colored-solid-boxes) are located in front of the vehicle. The vehicle should detect them so that it can follow the desired path without having an accident. The expected detections of the obstacles by using the laser scanner are given in Figure 1-b. In this figure, the obstacles detected and the detection coverage between the laser scanner and the obstacles are indicated. The detection coverage is shown by red-colored-areas (Area-i, $i=1,2,3$). By this way, the position and orientation of the obstacles can be specified and the desired trajectory can be safely and effectively generated according to this information.
In this study, development of a 2D laser scanning range finder based 3D laser scanning system is focused. As shown in Figure 1-a, a 2D laser scanner scans its surrounding in 2D, that means a height information of an object cannot be obtained. The environment can be scanned by only slices. In this study, the number of slices is intended to increase from 0° to 180° (Figure 2-a) by using a rotating mechanism. The resultant scan coverage is expected as shown in Figure 2-b. A 3D coverage (a half of a ball) can be created using the system proposed in this study. The rotating mechanism is able to give a point clouds which can be used to recognize the objects with their complete shapes.

In this study, a laser scanner range finder (Figure 3) is attached to the scanning system developed. The placement of the laser scanner in the 3D scanning system and the CAD view are illustrated in Figure 4. The laser scanner used in this study is Hokuyo URG-04LX. The baudrate speed of it can be set to 19.2, 57.6, 115.2 and 500 Kbps. In this study, the speed is adjusted to 19.2 Kbps. The communication between the main computing unit and the sensor is performed via RS232 serial protocol. The angular resolution of the laser scanner is 0.360° (360° / 1024) and the scanner is able to scan its surroundings from 0° to 240° (Figure 3-b) with 10 Hz. The minimum and maximum measurement distances are 60 mm, 4095 mm, respectively. The angular resolution is about 1 mm.

Matlab-Simulink environment is utilized for achieving the computational and communicational tasks. The real-time workshop toolbox of Simulink is configured to perform the data flow processes and computational efforts.

Encoder input card that is used for counting the number of rotations is shown in Figure 5. It is manufactured by Quanser and able to work with the high resolution quadrature encoders.
The mechanical parts of the system manufactured are illustrated in Figure 6. The stepper motor, which has 1.80 step angle, works with 24 V DC voltage. It is connected to the rotating head with a mechanical combination consisting of a rotating shaft, bearings and couplings. Encoder is coupled to the system via a mounting unit and a gearhead having ratio of $\frac{1}{2}$. Mechanical frame is manufactured from steel. A safety limiter is also added to the system to protect the laser scanner from an undesired accident.

The block diagram of the system constructed is presented in Figure 7. The encoder input card and the laser scanner rangefinder run together inside Simulink. Laser data coming through RS232 serial port is decoded using the S-function feature of Simulink. Stepper motor control is achieved by an algorithm developed in C/C++ environment. It is driven via an ATmega based microcontroller. The encoder data, which is captured by the encoder input card (shown in Figure 5), is processed in Simulink as well.

2D laser scanning range finder data, which forms the 2D point clouds, are shown in Figure 8. In this experiment, the scanning processes introduced above are tested to detect the objects in 2D. The objects detected are indicated by red-colored-filled-circles. Note that the laser scanner is located at the point (0, 0).

The system introduced above is tested to detect the shape of a rectangular box. The laser scanning system is located inside a box and the performance of the algorithm is tested. The point clouds view of the experiment is presented in Figure 9. The results indicate that the dimensions and shape properties of the box can be obtained using the point clouds data.

V. ANALYSIS AND CONCLUSION

In robotic and mechatronics applications, mapping and localization are the important issues. In order to achieve such objectives, easy-to-use and easy-to-adapt recognition systems are needed. Furthermore, they should give accurate and reliable results. In this study, a 3D laser scanning system is developed so as to meet these expectations. The system is constructed based on a 2D laser scanning range finder sensor. A mechanical frame is designed and a rotating head is coupled with it. The rotating head on which the 2D laser scanner is mounted is actuated using a stepper motor. The rotation angle information is acquired via using a high resolution encoder.
The whole system is combined in Matlab/Simulink for real-time use. Many experiments are conducted and successful results are obtained. In the next plan, the laser scanning system will be adapted to a wheeled mobile robot so that the performance of it can be observed in real working environments.

ACKNOWLEDGMENT

The authors would like to thank to the infrastructure project of the Mechanical Engineering Department of Bulent Ecevit University (Zonguldak, Turkey), numbered 2013-77654622-03, for providing the laser scanner rangefinder and the encoder input card used in this research.

Abstract—A controller design for mechatronic system which capable of doing passive therapeutic exercises of patients who have upper extremity limitation is presented in this paper. Expectation from controller is it should produce torque values can exactly repeat degree values depended on time which were taken from first therapy exercises of patients. The designed controller tested with real angle values which was taken from during elbow therapy. Simulation results showed that the proposed control system has good performance at tracking the therapy trajectory. Also that control system may be used for mechatronic upper limb therapy system which can be produced.

Keywords—Controller design, limitation at human joints, therapeutic exercises, therapy system.

I. INTRODUCTION

Autonomous rehabilitation machines advantages realized by people day by day. Controllers are most important part of that machines so controller design is the most important topic. Several studies about human motion tracking, rehabilitation machines and controller design for that machines are outlined in this section.

Zhou et al. compared many human motion tracking methods with each other. Their conclusion is inertial sensors is the best method for human motion tracking in terms of ease of use and data accuracy [1-6]. Continuous passive motion device for shoulder is designed by Rasyid et al.. The device can be used for joint motion limitation [7]. Mihelj et al. used ARMin exoskeleton robot at their work and they proposed new patient-cooperative control strategy for upper limb rehabilitation device. They aimed provide support to patient with minimum intervention. In this way patient can use trajectory what he or she wants while reaching the destination point [8]. Birch et al. designed rehabilitation device can be used either continuous passive motion (CPM) or continuous active motion (CAM) for human hand rehabilitation. Device activelyresisting the movement at CAM mode and at CPM mode they used PD control [9]. Saputra et al. used microcontroller to control automatically working CPM device. That device use for knee joint rehabilitation. When patients feel pain, DC motor overloaded so device stops movement [10]. Dong et al. developed intelligent controller and prototype rehabilitation device for human joints [11]. Hassani et al. developed device that perform passive and active motions. That devices main objective is helping health staff [12]. Zhang et al. designed intelligent neural network controller for active rehabilitation device. They used BP neural network for estimation of human knee joint angle change [13]. Prashant et al. designed parallel rehabilitation robot for human ankle movement. They used kinematic analysis and genetic algorithm for optimization [14]. Rehabilitation robot for human ankle, knee and hip joints designed by Wang et al.. They used swarm algorithm for optimization problem [15]. Lee et al. placed artificial mechanism at human knee joint and they gave mathematical model for that artificial mechanism[16]. Chua et al. measured angle change of human hip and knee joints and they designed rehabilitation robot [17]. Yildirim and Eski designed neural network analyzer for human hip and knee joints and they used vibration data of human hip and knee joints [18].

In this paper, we designed controller with data's which are taken by using inertial sensors. This controller is tracking exercise trajectories for elbow joint.

II. DYNAMICS OF HUMAN UPPER LIMBS

There were several different modeling's including human upper limbs in the literature. In this paper, the assumptions were made that human arm consist of three rigid limbs and have three-degree of freedom. Each of the joints was modeled as one-degree of freedom joint.

Relationship between the external forces and displacements generated by external forces could be expressed by linear transfer function which generally called as mechanic impedance or admittance. Basic linear expression of one DOF (single joint) musculoskeletal system in Laplace domain:

\[ \dot{\theta}(s) = \frac{1}{Is^2 + Bs + K} [T_a(s) + T_e(s)] \] (1)

where \( \theta \) is the joint angle, \( I \) is the inertia moment, \( B \) is the joint viscosity, \( K \) is the joint stiffness, \( T_a \) is the torque of muscle and \( T_e \) is the external torque. Here, the visco-elastic joint features depending on joints itself, visco-elastic features of passive component of muscles and visco-elastic features of activated muscles. The muscles visco-elastic features can be divided into intrinsic system and reflexive system. \( B \) and \( K \) at Eq. 1 is include intrinsic system features but not include
reflexive system. The muscles reflexive torque can be modeled as:

\[ T_m(s) = -\frac{\beta_0 s + \beta_1}{\alpha s + 1} e^{-\tau s}(2) \]

where \( \beta_0 \) is the position feedback gain, \( \beta_1 \) is the velocity feedback gain, \( \tau \) is the loop delay and \( \alpha \) is the time constant. While using Eq. 1 for calculation of the human dynamics, if the reflexive torque is too small or muscle activation dynamics can be neglected, the joint dynamic equation will be second-order system [19].

Considering muscles are in fully relaxed condition and muscle activity will be nearly zero during the passive therapy exercises, the muscle reflexive torque \( T_m \) can be neglected because it will be nearly zero. According to this in Eq. 1 angle only depends on external torque and intrinsic system as Milner et al. [20] and Morita et al. [21] used at their work. So dynamic equations for human joints separately modeled as second-order system is given by:

\[ I\ddot{\theta} + b\dot{\theta} + k\theta = T \]

***III. System Modelling***

For designing controller, firstly we need the dynamic model of shoulder, elbow and wrist joint. We use Eq. 3 and Fig. 1 for modeling human joints.

\[ x = \begin{bmatrix} \dot{\theta}_1 \\ \dot{\theta}_2 \\ \dot{\theta}_3 \end{bmatrix} \]
\[ A = \begin{bmatrix} 0 & 1 & 0 & \ldots \\ -\frac{K_1}{I_1 + I_2 + I_3} & B_1 & 0 & \ldots \\ 0 & 0 & 0 & \ldots \\ 0 & 0 & 0 & \ldots \\ 0 & 0 & 0 & \ldots \\ \ldots & 0 & 0 & 0 \\ \ldots & 0 & 0 & 0 \\ \ldots & 0 & 0 & 0 \\ \ldots & 1 & 0 & 0 \\ \ldots & 0 & \frac{K_2}{I_2 + I_3} & \frac{B_2}{I_2 + I_3} \\ \ldots & 0 & \frac{K_3}{I_3} & \frac{B_3}{I_3} \end{bmatrix} \]
\[ \begin{align*}
\dot{x}(t) &= Ax(t) + Bu(t) \\
y(t) &= Cx(t) + Du(t)
\end{align*} \]

As you seen in the Fig. 1, Eq. 4 expressed for shoulder joint, Eq. 5 for elbow joint and Eq. 6 for wrist joint. State-space model for Eq. 4-6 is:

\[ I_1\ddot{\theta}_1 + B_1\dot{\theta}_1 + K_1\theta_1 = T_1 \]
\[ I_2\ddot{\theta}_2 + B_2\dot{\theta}_2 + K_2\theta_2 = T_2 \]
\[ I_3\ddot{\theta}_3 + B_3\dot{\theta}_3 + K_3\theta_3 = T_3 \]
For shoulder, elbow and wrist, dynamic parameters, which for fully relaxed condition and with minimum muscle activity of human extremities, given in Table I [19, 20, 22-24].

\[
B = \begin{bmatrix}
1 & 0 & 0 & 0 & 0 \\
0 & 1 & 0 & 0 & 0 \\
0 & 0 & 1 & 0 & 0 \\
0 & 0 & 0 & 1 & 0
\end{bmatrix}
\]

\[
C = \begin{bmatrix}
1 & 0 & 0 & 0 & 0 \\
0 & 0 & 1 & 0 & 0 \\
0 & 0 & 1 & 0 & 0
\end{bmatrix}
\]

\[
D = [0]
\]

For shoulder, elbow and wrist, dynamic parameters, which for fully relaxed condition and with minimum muscle activity of human extremities, given in Table I [19, 20, 22-24].

IV. EXPERIMENTAL AND SIMULATION RESULTS

At this section, data which are taken from patients has limitation on elbow joint and control techniques developed based on these data results are given. According to taken data from patients elbow joint, PID (Tune) and PID (ZN) control systems are designed. Matlab's PID tuning algorithm and Ziegler-Nichols algorithm are used to adjustment of PID's gain parameters and gain parameter given in Table II Transient state responses of control structures for step input are shown for the elbow joint at Fig. 2. As seen in Table III, the PID (ZN) control structure has given best results on rise time and settling time but overshoot.

Simulation results for proposed controllers with patient data's has shown at Fig.(3,4). Data's taken from patients who has elbow joint limitation. Patient - 1 is 61 years old male and has limitation at right elbow joint, Patient - 2 is 19 years old and has limitation at right elbow after fracture.

![Fig. 3 Elbow joint angular variations of patient 1 using a) PID (Tune) controller b) PID (ZN) controller](image)
As seen in figures, PID (ZN) control system has minimum steady-state error and giving better results on adapting with the PID (Tune) control systems.

V. CONCLUSIONS

In this paper, control structure designed according to taken data from patients who has limitation elbow joint and different physical specifications. According to experimental and simulation results, the PID (ZN) control system is better than PID (Tune) on adapting and it has minimum steady-state error. Although, PID (ZN) gives better results than PID (Tune), for future work other intelligent control structures will be simulated and compared with PID (Tune) and PID (ZN) control systems.

Gain Parameter Adjustment Methods Comparison of Controller for Autonomous Rehabilitation Device

Ikbal ESKI¹, Ahmet KIRNAP²

¹, ²Department of Mechatronic Engineering
Faculty of Engineering, Erciyes University
Kayseri, Turkey

{ikbal, ahmetkirnap}@erciyes.edu.tr

Abstract— PID controller design and comparison between two different gain parameter adjustment method for autonomous physical rehabilitation device is presented in this paper. This device will be capable of doing repeated therapeutic exercises of shoulder joint. That devices main objective is reducing physiotherapist work load. The controllers tested with real angle values. Comparison of simulation results showed Ziegler_Nichols adjustment method has better performance than Matlab's auto-tune method.

Keywords— PID controller, passive exercises, rehabilitation, autonomous control.

I. INTRODUCTION

Controller design for rehabilitation machines has become important topic since we realized that the rehabilitation machines advantages for therapeutic exercises. Studies about gathering data for controller, controller design and mechanism design for rehabilitation devices are outlined in this section.

Zhou et al. at their works about human motion tracking and human motion tracking for rehabilitation, tested many motion tracking methods and their comparisons proved that inertial sensors is easy to use and they gives high accuracy data for motion tracking [1-6].

Rasyid et al. designed continuous passive motion device. The device designed for shoulder joint. Device can be used after performing an operation or for patients suffering from joint motion limitation because of early stage of frozen shoulder [7]. Mihelj et al. proposed and evaluated a strategy for patient-cooperative control of rehabilitation devices for upper limbs. At their work they used ARMin robot which is exoskeleton robot. While designing the controller, they aimed provide support to patient with minimum intervention. In this way patient can use trajectory what he or she wants while reaching the destination point. Optimizing the trajectory depends on patients self during the therapy. Some patients might never achieve optimal trajectories; however they might still be able to reach the target with adequate robot support. That situation is the goal of their proposed control strategy [8].

Birch et al. designed mobile device for rehabilitation of human hand. That device used either continuous passive motion (CPM) or continuous active motion (CAM) exercises. They used proportional-derivative control for CPM mode. At CPM mode device working with preset waypoints and at CAM mode device actively resist the movement of patient. Device can use for both the MCP and PIP joints. They made this work non-clinic, and they are planning to evaluate this device with rehabilitation professionals [9]. Saputra et al. designed and evaluated automatically working CPM for human knee joint. System stops and turning to beginning point when patients feel pain. They have provided that with using Analog-Digital Converter (ADC). When the DC motor received load, the voltage decrease detected by ADC and after 1.5 seconds motor rotates again with another direction. They used microcontroller to control this system[10]. Dong et al. developed prototype rehabilitation device for controlling human joint movement. They designed intelligent controller that can perform movement to patient which is applied by therapist. That device provides both isometric and isokinetic movements [11]. Hassani et al. developed powered orthotics for helping health staff during rehabilitation and to perform passive and active motions [12]. Human knee joint angle change estimated by Zhang et al. with using BP neural network. Six patients join the experiment to verify the efficiency of neural network. That neural network used in robot design which for active rehabilitation exercises [13].

Designing parallel rehabilitation robot for human ankle movement was proposed by Prashant et al. They discussed optimization problem with using kinematic analysis and genetic algorithm for proposed robot [14]. Wang et al. designed rehabilitation robot for human ankle, knee and hip joints and they discussed stability and dynamic performance of robot. In addition they used swarm algorithm at optimization problem [15]. Lee et al. placed artificial mechanism at human knee joint and they gave mathematical model for that artificial mechanism[16]. Angle change of human hip and knee joint from volunteers measured by Chua et al. and they used that data for designing rehabilitation robot [17]. Yildirim and Eski used vibration data of human hip and knee joints at designing neural network analyzer [18].

Experts about physiotherapy has to decide right therapy exercises that the therapy angles which are suitable for patient and will not exceed the pain limit of patient. Right therapy exercises and angles are unique for patient because it depends on many variable. For this reason therapy exercises decided clinic. Because of the uniqueness of therapy, physiotherapist has to show therapy exercise to therapy system.

In this paper, we designed controller with data's which are taken by using inertial sensors. This controller is tracking exercise trajectories for shoulder joint.
II. DYNAMICS OF HUMAN UPPER LIMBS

There were several different modeling’s including human upper limbs in the literature. In this paper, the assumptions were made that human arm consist of three rigid limbs and have three-degree of freedom. Each of the joints was modeled as one-degree of freedom joint.

Relationship between the external forces and displacements generated by external forces could be expressed by linear transfer function which generally called as mechanic impedance or admittance. Basic linear expression of one DOF (single joint) musculoskeletal system in Laplace domain:

$$\theta(s) = \frac{1}{Is^2 + Bs + K}[T_e(s) + T_m(s)]$$

where $\theta$ is the joint angle, $I$ is the inertia moment, $B$ is the joint viscosity, $K$ is the joint stiffness, $T_e$ is the torque of muscle and $T_m$ is the external torque. Here, the visco-elastic joint features depending on joints itself, visco-elastic features of passive component of muscles and visco-elastic features of activated muscles. The muscles visco-elastic features can be divided into intrinsic system and reflexive system. $B$ and $K$ at Eq. 1 is include intrinsic system features but not include reflexive system. The muscles reflexive torque can be modeled as:

$$T_m(s) = -\frac{\beta_0 s + \beta_1 e^{-\alpha s}}{\alpha s + 1}\theta(s)$$

where $\beta_0$ is the position feedback gain, $\beta_1$ is the velocity feedback gain, $\tau$ is the loop delay and $\alpha$ is the time constant. While using Eq. 1 for calculation of the human dynamics, if the reflexive torque is too small or muscle activation dynamics can be neglected, the joint dynamic equation will be second-order system [19].

Considering muscles are in fully relaxed condition and muscle activity will be nearly zero during the passive therapy exercises, the muscle reflexive torque $T_m$ can be neglected because it will be nearly zero. According to this in Eq. 1 angle only depends on external torque and intrinsic system as Milner et al. [20] and Morita et al. [21] used at their work. So dynamic equations for human joints separately modeled as second-order system is given by:

$$I\ddot{\theta} + b\dot{\theta} + k\theta = T$$

III. SYSTEM MODELLING

For designing controller, firstly we need the dynamic model of shoulder, elbow and wrist joint. We use Eq. 3 and Fig. 1 for modeling human joints.

As you seen in the Fig. 1, Eq. 4 expressed for shoulder joint, Eq. 5 for elbow joint and Eq. 6 for wrist joint. State-space model for Eq. 4-6 is:

$$\dot{x}(t) = Ax(t) + Bu(t)$$

$$y(t) = Cx(t) + Du(t)$$

$$x = \begin{bmatrix} \theta_1 \\ \dot{\theta}_1 \\ \theta_2 \\ \dot{\theta}_2 \\ \theta_3 \\ \dot{\theta}_3 \end{bmatrix}$$

$$u_1 = \begin{bmatrix} T_1 \\ T_2 \\ T_3 \end{bmatrix}$$
For shoulder, elbow and wrist, dynamic parameters, which for fully relaxed condition and with minimum muscle activity of human extremities, given in Table I [19, 20, 22-24].

IV. EXPERIMENTAL AND SIMULATION RESULTS

At this section, data which are taken from patients has limitation on shoulder joint and control techniques developed based on these data results are given. According to taken data from patients shoulder joint, PID (Tune) and PID (ZN) control systems are designed. Matlab's PID tuning algorithm and Ziegler-Nichols algorithm are used to adjustment of PID's gain parameters and gain parameter given in Table II Transient state responses of control structures for step input are shown for the shoulder joint at Fig. 2. As seen in Table III, the PID (ZN) control structure has given better results on rise time, settling time and overshoot but steady-state error.

\end{bmatrix}
\]

\[
D = [0]
\]
Simulation results for proposed controllers with patient data’s has shown at Fig.3,4. Data’s taken from patients who has shoulder joint limitation. Patient - 1 is 61 years old male and has limitation at right shoulder joint, Patient - 2 is 62 years old male and has limitation at left shoulder after fracture.

As seen in figures, PID (ZN) has control system has better results than PID (Tune) on formed maximum error during movement.

V. CONCLUSIONS

In this paper, control structure designed according to taken data from patients who has limitation shoulder joint and different physical specifications. According to experimental and simulation results, the PID (ZN) control system is better than PID (Tune) on adapting and it has minimum steady state error. Although, PID (ZN) gives better results than PID (Tune), for future work other intelligent control structures will be simulated and compared with PID (Tune) and PID (ZN) control systems.

The Realization of a Control Algorithm and its PLC Based Program Able to Authorize Four Different Ranks of Priority to Elevator Users

Mümine YILDIZ*, Mehmet KARALI*

Dept. of Mechatronic Engineering Necmettin Erbakan University, Konya, Turkey

Abstract— Elevator software programs are currently unable to meet the required demand regarding elevator services of high-rise community and government buildings such as hospitals and social centers. Administrators, emergency room doctors and nurses in hospitals; authorities in public or governmental buildings (such as ministers, governors, rectors, deans); or managers, and staff working in community buildings wish privileged use of existing elevators. This isn’t only a personal privilege, but an institutional necessity; resulting in a second elevator assigned to VIP use. Regrettably, while such elevators are empty, others become too crowded and queues form up, resulting in frequent breakdowns. Not to mention the unauthorized use of said elevators causing problems in instances where an emergency is at hand. The solution of card and/or key systems on the other hand has become tedious and inefficient.

In this project, authorization rankings were assigned and special usage privileges given. Thus, in cases where VIP usage is needed, the elevator temporarily cancels out either totally or partially all other calls according to VIP ranking, resulting in the efficient use of elevators by preventing them from being inactive when there is no ongoing VIP usage. Algorithms have been written for authorized use and have been designed for flexible response using PLCs. This project utilizes a model encompassing a four rank authorization system (three VIP, and one normal) which, after a number of simulations, has been tested on a servomotor-powered mechanism. The project is planned to be expanded to incorporate up to a ten rank authorization system.

Keywords— Elevator Control, PLC (Programmable Logic Controller), Privileged Use of Elevators

I. INTRODUCTION

The prime objective sought of elevators is providing services to the maximum amount of users in minimum waiting period [1]. Researchers have utilized different approaches in studies to reach this goal. In [2] the author explained that; an ambient intelligence application that can model a group elevator timing control system was optimized with the help of a fuzzy-artificial immune recognition system. In the designed system, by using the optimization aspect of clonal choice algorithms of the fuzzy-artificial immune recognition system, average waiting periods of users were aimed to be lessened. In [3] the author explained that; the developed system can adapt to traffic in different conditions. As such, it hosts maximum amount of users with minimum waiting periods and takes them to desired floor while also saving energy through this performance. Thanks to expert rule based fuzzy logic supervisors, distinct traffic hours are identified. Relating to this classification more specified fuzzy logic is realized regarding every one of the model classes. In [4] the author explained that; the traffic models in buildings used for various purposes differ. Thus, in order to carry the maximum amount of people in the minimum amount of time, the algorithm for elevator control should be developed with this circumstance in mind. In the elevator system, by monitoring changes in the number and direction of user calls, and through incorporating a suitable control algorithm, the designated goal of carrying maximum people in minimum time was tried to be reached. In [5] the author explained that; this paper describes the development of 2 nine-storey elevators control system for a residential building. The control system adopts PLC as controller, and uses a parallel connection dispatching rule based on “minimum waiting time” to run 2 elevators in parallel mode. In [6] the author explained that; an elevator group supervisory controller is a control system that manages systematically two or more elevators in order to serve passengers as required. The elevator cars are assigned accordingly in response to hall calls, so as to optimize waiting time, riding time, power consumption, passengers’ comfort, etc. In this paper, the simplicity of ordinal structure fuzzy logic in making crucial supervisory control decisions is demonstrated. In addition, in order to further improve the performance, a new approach of ordinal structure fuzzy logic with context adaptation is demonstrated to implement an elevator group supervisory controller for a building with 15 floors and 4 elevator cars. Simulations comparing ordinal structure fuzzy logic algorithm with and without context adaptation, show that the former performs better.

As for this project; elevator traffic density was aimed to be lessened through the formulation of four different algorithms created for four differently ranked priority groups (rank1, rank2, rank3, normal), preventing VIP assigned elevators from being idle while providing for privileged (VIP) users through a password system the use of normal elevators and also allocating the call traffic of normal elevators to encompass all elevators. Problems which arise from the misuse of special purpose elevators in emergency situations were also prevented.
Through a password system, the elevator, in case of VIP usage, temporarily cancels out either totally or partially all other calls and sends the elevator according to VIP ranking of the caller. Elevator Control Algorithms:

1) Rank1 Mode: Being the highest privileged rank, answers the call in fastest manner. All calls before and after are canceled until caller has reached destination.

2) Rank2 Mode: Being a middle privileged rank, elevator answers Rank2 calls while higher privilege still remains with Rank1 calls. It answers cabin calls made before Rank2 call until Rank2 is reached, and answers Rank1 calls made afterwards, and Rank2 and Rank3 calls which are en route.

3) Rank3 Mode: Being a low privileged rank, Rank2 has higher priority. Calls made before Rank3 call are answered until Rank3 user is reached. Afterwards normal calls are not answered.

4) Normal Mode: Being the lowest rank, elevator calls matching elevator direction are answered with accordance to en route closeness, while calls in the opposite direction are answered after elevator course changes again accordingly with en route closeness.

When answering calls with the same priority the rule used for Normal Mode has been determined.

II. ELEVATOR CONTROL DESIGN

A. Hardware and Software

Designed elevator system is composed of mainly three parts; control system, interfacing for elevator system and elevator prototype.

1) Control Parts: Created algorithms were implemented with Panasonic FP-X programmable logic controller (PLC).

PLC's isolation is better than other controller system's isolation, because it is influenced less by temperature changes, moisture, noise and vibration. PLCs can also easily control many components in the market such as sensors, contactors and relays. It is easy to make revision on created systems. PLC devices provide the possibility of remote control. That is, it is possible to control the PLC control system device via the internet.

Panasonic FPX FPW Pro7 software is used to program the PLC. This software can write all FP series’ PLCs programs. It has five programming languages, which are the instruction list, ladder diagram, function block diagram, sequential function chart, and structured text. In this project ladder diagram programming languages are used.

2) Interfacing For Elevator System: For the elevator system human-machine interface, WinTR SCADA was used. Production of this software has begun in 2009 by Fultek, a Turkish company. Among its advantages are that it allows communication between the PLC of many different brands and that it is free for non-profit use.

The SCADA interface allows monitoring the up and down movement of the elevator and the opening and closing of its doors without the use of a prototype and easily testing the developed program and the finding of errors and problems. It is possible to enlarge the system within SCADA without the need for physical hardware.

3) Elevator Prototype: By using a servo motor for the application of experimental studies a prototype elevator has been created. The prototype system design was simplified through position control by taking advantage of the position control feature of the servo motor, without using limit switches. A system that uses a different motor can be easily integrated to this program, since the motor control program was formed as motor control subroutine.

B. Elevator Control Algorithms

1) Normal Mode: Single elevator traffic algorithms used to control the elevator system can be one of the following: Car-switch Operation, Automatic Operation, Signal Operation, and Collective Operation. In this project, Collective Operation Logic, which gives the least wait-time, was used to create the Normal mode algorithm. Collective operation answers same direction calls according to proximity and stores to memory opposite direction calls to be answered after direction change.

Rather than a flow control diagram, a logical solution has been opted via Karnaugh map by evaluating all possible working conditions.

Desired output in line with system logic has been ensured by evaluating the situation between different variables, mainly: the data of the movement of elevator, the directional input of the calls and the proximity of the calls according to one another.

A part of the table showing the output according to the possibility table created according to these variables has been given in Table I.

Output evaluation of the variables has been done as so: If elevator is going up, and if there is an up direction call, and it is also the closest call; then gives output. Every line in the probable situations table is evaluated according to this logic.

The Karnaugh solution which provides the result according to the created conditions is so:

\[ \text{[BCDGE + [BCDGF + B[C][H][GE + B][C][H][GF + AB][C][H][G + A][BCD][G + [BD][H[GE + BD][HGF + A][BD][HG + [BD][GE + [BDH][GF + A][BDH][G}} \]

When the Karnaugh solution is applied to PLC the program is generally formed of the networks where the Karnaugh solution is applied and the networks where the necessary variables are produced. For example, the processes of committing incoming calls to memory and resetting or networks where the closest call proximities can be obtained. The Figure 1 represents this situation.

Fig. 1 Process of PLC Program

2) Privileged Modes: By observing the same method to write the Normal mode program, the probable possibilities for Rank1, Rank2, Rank3 have been evaluated according to the required conditions and outputs were obtained. For the obtained results the Karnaugh analysis was used. The program blocks created were combined into an integrated program for four modes.

The transition conditions from normal mode to privileged mode, and from any privileged mode to another rank have been set. When in privileged mode, the collective operation will be used for other calls on the same rank. For example, when in Rank2, another Rank2 call will be accepted if on the way, if not it will be left for later.

2.1) Rank1: When in either Rank2, Rank3 or Normal mode, in order to respond to the Rank1 call, the elevator stops on the nearest floor and an announcement is made for the passengers to evacuate the elevator. Then, the elevator goes directly to the Rank1 user and performs the cabin call for Rank1 users. No calls other than another Rank1 call are accepted. When in Rank1, collective operation logic is used for incoming Rank1 calls. After the Rank1 call has been fulfilled, the elevator returns to Normal mode if there are no other Rank1 calls.
2.2) Rank2: When in Normal mode, the cabin calls before the Rank2 call will be performed, other floor calls will be canceled. After reaching Rank2 user, no calls other than Rank1 and Rank2 will be accepted. When in Rank2, collective operation logic is used for incoming Rank2 calls.

2.3) Rank3: When in Normal mode, all calls before the Rank3 call will be performed until the Rank3 user is reached. In Rank3, only Normal calls will not be accepted. If there is an incoming Rank2 call during Rank3 mode, the Rank3 user will be dropped off on a requested floor if it is en route. If in the opposite direction, the user will be dropped off at the nearest floor.

C. Results

In this study, by transforming privileged-use-only elevators into normal-use elevators, the traffic density on normal-use elevators has been distributed among all elevators, thus reducing elevator traffic. Furthermore, a PLC based controller has been added allowing four different ranks of privileged use with password. Elevator flexibility and a lower-cost solution for special use and possible emergency situations have been achieved through privileged use.

The created algorithms have been tested on the designed simulation program and prototype. Below is a scenario for testing and a simulation interface where the scenario movement can be observed.

Figure2: When elevator is on the 5th floor, an upwards call from the 2nd floor and a downwards call from the 3rd floor comes.

Figure3: When elevator reaches the 3rd floor, a cabin call from ground floor and a downwards call from the 2nd floor comes.

Figure4: The figure shows the elevator downwards movement to answer cabin call from ground floor.
Figure 5: After elevator reaches the 2nd floor, it takes cabin call from the 4th floor. It starts to move. It halts on the 3rd floor and it moves the 4th floor.

In the following studies, it is planned to increase the number of ranks of privileged use, and to add privileged use to group elevator systems.

Analysis of Suspension System for 3D Printed Mobile Robot

H.S. SUCUOGLU, I. BOGREKCI, P. DEMIRCIOGLU

1Department of Mechanical Engineering, Faculty of Engineering, Adnan Menderes University, AYDIN, TURKEY

{hihmisucuoglu, ibogrekci, pinar.demircioglu} @adu.edu.tr

Abstract—In this study, 3D printed mobile robot with suspension system was analysed using Computer Aided Engineering (CAE) methods. Spring and damping coefficients of the suspension system were determined. Structural and dynamic analyses were conducted after the selection of appropriate spring and damping coefficients to find structural strength and power requirement of mobile robot. The length of robot and the number of wheels were decreased to one third of the real to ease the analysis. A concrete road with the length of 1,000 mm and 10° inclination was created as ground to simulate the real world. Obstacles with the height of 80 mm were placed on different locations on the path of the wheels for the robot. The designed suspension system was consisted of; two dashpots connected to wheels and body through connecting components and a spring between two wheels to ensure the stability. Polylactic acid (PLA) was used as body material. In the structural part; the strength of the robot body and critical part (suspension leg) was computed by Finite Element Analysis (FEA). Safety factor values for body and critical component were found as almost 7 and 4, respectively. It was obtained from the analysis results that maximum equivalent stresses and strains (for body $\sigma_{max} = 3.4$ MPa, $\varepsilon_{max} = 3 \times 10^{-3}$ mm/mm and for critical component $\sigma_{max} = 6.5$ MPa, $\varepsilon_{max} = 6 \times 10^{-3}$ mm/mm) were occurred while robot was passing the obstacles. In dynamic analysis; robot was driven with three different speeds (0.25, 0.5 and 1 metre per second) on the same road conditions. The motor torque and force values, suspension system results (force and elongation), angular velocity of the wheels and power requirement of mobile robot were calculated. The results showed the power requirement of robot is 70 Watt when it is driven with maximum velocity.

Keywords—Computer Aided Engineering, Finite Element Analysis, Polylactic Acid, Suspension System, 3D Printed Mobile Robot

I. INTRODUCTION

Robots are increasingly entering the area of many technical studies and research. Recently; robotic industry is improving and evolving rapidly to satisfy the needs of markets, daily use of people, manufacturing, research projects and universities etc. [1].

Mobile robot is one of the most common type of robotic types. A mobile robot has unlimited movement to complete its mission. They can be used to perform a variety of tasks normally carried out by humans such as surveillance, exploration, patrol, fire searching-fighting, homeland security and care taker etc. [2].

A mobile robot system consists of a platform moved by locomotive elements. The locomotive system depends firstly on the environment that the robot operates. These environment can be aerial, aquatic and terrestrial. In the aquatic and aerial environments, the locomotive systems are generally propellers or screws. The locomotive system in terrestrial environment is complicated. Wheels, tracks and legs are the typical terrestrial locomotive elements [3].

Different types of suspension systems are used for mobile robots that operates at terrestrial environment to ease the adoption to usage area and to increase the flexibility and motion ability. Suspension systems of mobile robots are generally designed and produced using dashpots, return and compressing springs.

Rapid prototyping techniques are nowadays used in product development process. They allow for fast, low-cost and easy manufacturing series of components directly from the the component geometry stored in CAD model. This prototyping process allows for assessment of many aspects of functionality, dimensional, physical and esthetical adaptation of components in the developed product [4]. 3D printing technology is one of the most common types of rapid prototyping techniques. As 3D printers become more prevalent among users they are being used to manufacture more diverse objects. This has included components that either replace items normally purchased or are uniquely designed for the specific needs of the user in terms of geometry and function [5].

It is an easy and low-cost way of using 3D printing technology to produce the components of a mobile robot prototype. After CAD and CAE process; mobile robot for any environment can be created and checked for final product. It is a great way for designers and researcher to decrease the modelling and manufacturing time and cost. 3D printing technology opens a new way with the advantages summarized below [6]:

- Fast prototyping for mobile robot platforms
- Decreasing the time and cost of modelling and manufacturing
- Easy configuration and adaptation
- Motivation for the development of new types of products

In this article we focused on the development of 3D printed mobile robot with suspension system. After design process; solid state model of mobile robot was analysed using Computer Aided Engineering (CAE) methods. Spring and...
damping coefficients of the suspension system were determined. Structural and dynamic analyses were conducted. Important design and manufacturing parameters were determined using analyses and real world test results.

II. DESIGN OF 3D PRINTED MOBILE ROBOT

Mobile robot (Fig. 1) was designed using CAD tools. In the design process; several issues were considered such as compact size, modularity, time and cost. The most important point of the design was compliance with additive manufacturing technique for all of the components except wheels, electric motors and suspension system. Body and connection components were produced using 3D printing technology. The sizes, thickness, shape of the parts were taken into consideration that affect the manufacturing process using 3D printer. Complexity of the components were decreased to save time-material and to improve the robot’s performance.

![Fig. 1 Designed 3D printed off-road mobile robot](image)

A. Geometry and 3D Model

All of the parts of the robot were prepared using parametric solid modelling technique. The required connectors, channels and supports for the wheels, electric motors and suspension components were designed using technical data sheet and drawings. The assembly model was created and compatibility of the manufactured parts and commercially available components were checked in assembly model. Designed off-road mobile robot has six independent wheel-motor-suspension systems. The details of the traction system for the mobile robot are depicted in Fig. 2, Table I.

B. Suspension System Design

3D printed mobile robot was designed and manufactured as off-road vehicle prototype. So the suspension system was most critical for the operation at challenging terrain. It should be optimized for body stability, to improve the motion capability and to decrease the energy consumption.

For the suspension six dashpots and three return springs were used. Dashpots, were connected between wheel legs and body to climb and pass the obstacles. Springs were placed between wheels horizontally for motion and body stability.
Spring and damping coefficients were determined using catalogue values. The total weight of the robot was about 6 kg so load for each wheel was 1 kg. Using this information and catalogue values 5 different spring and damping coefficients were applied at Matlab Simulink simulation environment. (For Sys1; k=150N/m b=50 Ns/m, Sys2; k=250N/m b=75 Ns/m, Sys3; k=350N/m b=100 Ns/m, Sys4; k=750N/m b=125 Ns/m, Sys5; k=1,000N/m b=150 Ns/m). The optimum coefficient values were determined as 350 N/m and 100 Ns/mm for spring and damping respectively for flexibility and stability.

Using these coefficients; dashpots and springs were selected easily. The length of the aluminium dashpot shown in Fig. 3 was 11 cm that provides capability to the robot to pass the obstacles up to 10 cm without climbing.

Fig. 3 Selected dashpot for robot suspension system

C. Material of Mobile Robot

Rapid Prototyping Systems produce objects generally from acrylonitrile butadiene styrene (ABS) and polylactic acid (PLA). These materials have low enough melting temperatures to use in melt extrusion in a dedicated machine and high enough temperature for prints to retain their shape at average use temperatures [7].

Usually, plastics as PLA or ABS are used as raw material to feed 3D printers. However, environmental pollution made by plastics is a real problem to solve. For that reason, PLA is used more and more. It is biodegradable, thermoplastic and semi crystalline [8].

ABS; strength, flexibility, machinability, and higher temperature resistance make it often a preferred plastic for engineers, and professional applications. It is strong, flexible, with good machinability and a higher temperature resistance. These properties can make it more popular for use in professional applications. PLA; the wide range of available colours and translucencies attract those who print for display or general uses. When properly cooled, PLA seems to have higher maximum printing speeds, lower layer heights, and sharper printed corners. Combining this with low fault on parts make it a popular plastic for general printers, hobbyists, and schools [9]. Mechanical properties of PLA and ABS are given in Table II.

D. Manufacturing of Mobile Robot

All of the parts of mobile robot; connectors, suspension legs, bodies, motor-electronic protection cases and body shell were designed and manufactured using 3D printing technology and PLA material (Fig. 4). The weight of manufactured parts and commercially available components (wheels, motors, suspension elements and connection screws) were about 3.5 and 2.5 kg respectively. As a result an off-road light weight mobile robot prototype with 6 kg was designed and manufactured.

![Fig. 4 3D printing technology (a) 3d printer (b) PLA filament](image)
III. STRUCTURAL ANALYSIS

Structural analysis was conducted after the selection of suitable material, spring and damping coefficients to find structural strength for whole robot's body and critical components using Ansys Workbench Static Structural Module. Safety factors, maximum equivalent stresses and strains for whole body and critical component (suspension leg) were calculated.

The length of robot and number of wheels were decreased to one third of the real to ease the analysis. A concrete road with the length of 1,000 mm and 10° inclination was created as ground to simulate the real world. Obstacles with height of 80 mm were placed on different locations on the path of the wheels for the robot. The strength of the robot body and critical part was performed by Finite Element Analysis (FEA).

In the first part of structural analysis (Fig. 5); static loads were applied to mobile robot. These loads were; self-weight of the robot about 2.5 kg, other suppressed weights such as battery and electronic protection case (1.5 kg) and the forces caused by suspension leg motion while it was passing the obstacles.

A crash analysis was carried out with 1 and 2 m/s velocities in the second part of structural analysis (Fig. 6) Although the maximum speed of the robot was 1 m/s twice more impact force was applied because of slow down distance effect and for safety. The impact forces were calculated with formula shown below.

\[ F_s = \frac{1}{2} m \times V^2 \]  
\[ F = \frac{1}{2} m \times V^2 \times \frac{s}{s} \]  

Where:

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Fs</td>
<td>Slow down force (N)</td>
</tr>
<tr>
<td>F</td>
<td>Impact force (N)</td>
</tr>
<tr>
<td>m</td>
<td>Mass (kg)</td>
</tr>
<tr>
<td>V</td>
<td>Velocity (m/s)</td>
</tr>
<tr>
<td>s</td>
<td>Slow down distance (m)</td>
</tr>
</tbody>
</table>

Slow down distance was assumed as 8 mm using experimental application. Using the formula (1) and (2), the impact forces were calculated for 1 and 2 m/s velocities;

\[ F_s = \frac{1}{2} m \times V^2 / s = 1/2 \times 4 \times 1^2 / 0.008 = 250 \, N \]  
\[ F = \frac{1}{2} m \times V^2 / s = 1/2 \times 4 \times 2^2 / 0.008 = 500 \, N \]  

IV. DYNAMIC ANALYSIS

Dynamic analysis was carried out using Ansys Workbench Rigid Dynamics Module. Mobile robot was driven with three different speeds (0.25, 0.5 and 1 metre per second) on the same road condition with structural analysis. Rotational velocities were defined to wheels to create the displacement motion. Suspension leg connections were assigned as rotary joints. Joint loads were applied 50° to pass the placed obstacles. The required information for motor selection; torque and force values, suspension system results (occurred force and elongation), angular velocity of the wheels and power requirement of mobile robot was calculated in dynamic analysis (Fig. 7).

V. RESULTS AND DISCUSSION

A. Structural Analysis

Structural analysis results under static loads are given in Table III.
TABLE III
STRUCTURAL ANALYSIS RESULTS UNDER STATIC LOADS

<table>
<thead>
<tr>
<th>Criteria</th>
<th>Values</th>

<td>0.006</td>
</tr>
<tr>
<td>Safety factor for whole body</td>
<td>7</td>
</tr>
<tr>
<td>Safety factor for critical component</td>
<td>4</td>
</tr>
</tbody>
</table>

The total calculated maximum equivalent stresses for whole body and critical components were found about 3.5 and 6.5 MPa respectively. The calculated stresses are not overcome the strength of PLA material. Safety factor values for both body and critical components (7 for whole body 4 for critical component) showed that robot can operate under static loads safely. However, mobile robot’s prototype was designed for off-road operation. To get more reliable results; crash analysis with calculated impact force was conducted in structural analysis. 250 and 500 N forces were applied to robot front wheels to create the crash simulation.

Crash analysis results with 250 and 500 N impact forces are given in Table IV.

TABLE IV
CRASH ANALYSIS RESULTS

<table>
<thead>
<tr>
<th>Criteria</th>
<th>250 N</th>
<th>500 N</th>
</tr>
</thead>
<tbody>
<tr>
<td>Equivalent stress body (MPa)</td>
<td>5</td>
<td>12</td>
</tr>
<tr>
<td>Equivalent stress critical component (MPa)</td>
<td>13</td>
<td>27</td>
</tr>
<tr>
<td>Equivalent strain body (mm/mm)</td>
<td>0.004</td>

</tr>
<tr>
<td>Safety factor for whole body</td>
<td>5</td>
<td>2</td>
</tr>
<tr>
<td>Safety factor for critical component</td>
<td>2</td>
<td>0.9</td>
</tr>
</tbody>
</table>

As understood from the results that equivalent stresses caused by 250 and 500 N impact forces were almost twice and four times greater than occurred stresses with static loads for critical component. The calculated safety factor decreased from 4 to 2 with 250 N that arose from 1 m/s velocity crash.

The safety factor was found as 0.9 with 2m/s velocity crash. It can be understood that this component was broken with this applied speed. Critical component is not strong enough for crash scenario occurred with 2 m/s velocity. Crash test was also applied in real world application. It was observed that both in analysis and real world; suspension leg was broken at similar area (Fig. 8).

B. Dynamic Analysis

The power requirement of mobile robot was found as 18, 35 and 71Watt for 0.25, 0.5 and 1 m/s speeds. As the number of wheels and length of robot were decreased to one third of the real to ease the analysis the calculated power requirement was for one third of whole system. The total power requirement is about 213 Watt.

Using these information electric motors were selected with the values of 6 volt voltage and 6.2 ampere maximum current. Using 6 electric motors system can supply 223 Watt power and it is sufficient for calculated power requirement.

The other results of dynamic analysis are given in Table V. Dashpot and spring forces-elongations were found as 14 N-42 mm and 2.5 N and 7 N. Maximum torque requirements for electric motor were about 528, 618 and 1,000 N.mm for 0.25, 0.5 and 1 m/s speed values.
VI. CONCLUSION

In this study, 3D printed off-road mobile robot prototype with suspension system was designed and analysed using Computer Aided Engineering (CAE) methods. Spring and damping coefficients of the suspension system were determined. Structural and dynamic analyses were conducted to find structural strength and power requirement of mobile robot. After design and analysis stages body and connection components of mobile robot prototype were manufactured using 3D printing technology. The selected results obtained from analyses and real world application were presented. The safety factor of whole body and critical component were calculated as 5 and 2 in crash analysis with 250 N impact force that occurred when robot is driven with 1 m/s velocity. It can be concluded that the structural material (PLA) could ensure the safety when robot is charged with 250 N impact force.

Abstract—This research is aimed at developing a multi-body simulation model and balancing control of a single-wheel inverted pendulum. A virtual prototype of the system has been built by using Adams software and it is simulated in both Matlab and Adams software together. The Adams model has two inputs (disturbance and control) and two outputs (pendulum angle and wheel position). Proportional-integral-derivative (PID) controller is designed and applied in order to use balancing control simulation of pendulum angle. The modelling and control results show that the Proportional-integral-derivative (PID) controller can successfully achieve balancing control of the single-wheeled inverted pendulum. Also this paper can make an important contribution to background of two-wheeled robots, self-balancing transportation devices.

Keywords—PID Control, Modelling, Simulation, Self-Balancing, Single-wheel inverted pendulum.

I. INTRODUCTION

During the recent years, robots have become a basic and time-honoured practice for proving a variety of control systems and control theories. Thanks to their flexible and basic structures, two wheeled self-balancing robots perform well in poor work conditions and complex tasks (space explorations, topographical survey, dangerous goods transportation etc.). Also they can provide safe transportation for both goods and persons thanks to high mobility and rapid response abilities [1].

One and two wheeled self-balancing robots have been started to be seen in literature by 2000s and became more popular nowadays. Due to the fact that they have characteristics as multiple variability, nonlinearity and instability, they have chosen as an important field of study by researchers working on control theory. Stability, durability and controllability of a system can be easily examined with one-wheeled self-balancing robots [2-3].

One-wheeled self-balancing systems are consisting of a mobile robot and an inverted pendulum system. Since it is driven with two coaxial and independently controllable motors, movement of the system is not stable. In order to sense the acceleration along the vertical axis, gyroscope and accelerometer are used in these kinds of systems. In order to make the inverted pendulum stable both when it is on the move and steady, torque signals are generated and transmitted to motors [4-5].

Park and Jung designed a single-wheel mobile robot called GYROBO. They used remote control and sensors in order to both navigate and balance the robot. With PD controller and sensors (gyro, tilt and encoder), GYROBO was able to balance itself and follow the specified trajectory [6]. Cieslak et al. designed and built an one-wheel robot. They mainly focused on self-stabilisation problem and achieved the dynamic stability achieved [7]. Lee at al. designed a single-wheel inverted pendulum system. System was consist of a dc motor and two ducked fans. Pitch angle of system was controlled by dc motor and PD controller. Roll angle was regulated by PID controller and air pressure generated from fans [8]. In his study, Wang applied PID controller to stabilization control of different types of inverted pendulum. Study shows that PID controllers are very effective in this kind of systems [9]. There are similar studies which are conducted on two-wheel systems. Felix et al. designed a two-wheel self-balancing robot called JOE. In order to control this robot, they designed two independent space state models and made the system stand in balance successfully [10]. Wei and Yangmin Li designed PID controller and Linear Quadratic Regulator (LQR) controller and the system was simulated in Matlab, then these two controller methods were applied and results were compared [11]. Kalyoncu et al designed artificial neural network and fuzzy logic based (ANN+F) controller in order to control a two-wheeled robot. After that system was simulated in Matlab/Simulink and results were compared [12].

This paper presents developing a multi-body simulation model and balancing control of a single-wheeled inverted pendulum. An approximation model of the system is modelled by using Adams software. The Adams model has two inputs (disturbance and control) and two outputs (pendulum angle and wheel position) respectively. Where, pendulum angle which is the most important parameter needs to be controlled issued as feedback. Proportional-integral-derivative (PID) controller is designed and implemented for the purpose of balancing control of pendulum angle. Controller design procedure and controller efficiency are shown with graphics. One can understand that single-wheel inverted pendulum system can be simulated and controlled in Adams and Matlab.
II. MODELLING AND CONTROL

Modelling and controlling strategy and system model can be seen in Fig 1. To obtain the dynamic model of single-wheeled inverted pendulum, Adams software is used. Boundary conditions and dynamic loadings are performed in Adams. Thus, more realistic model is derived. Besides this, it is very important to Adams cooperate with Matlab.

![Fig. 1 Strategy of study and system model](image)

Single-wheeled inverted pendulum is able to move in only x direction. Inverted pendulum system is firstly modelled in Adams. System has two inputs (control and disturbance) and two outputs (pendulum angle and wheel position). Necessary boundary conditions like as connections, friction and movement etc. are defined in Adams. System parameters and boundary conditions can be seen in Table 1. Then, created system is exported to Matlab in order to perform controller design works in this software.

![Fig. 2 Block diagram of the system](image)

Time, direction and magnitude of disturbance force is determined and applied to top of the pendulum. 10 N impulse force is applied to pendulum in 1st second of simulation time through – x direction and then another 10 N impulse force is applied in 3rd second of simulation time through the opposite direction. The controller is always active during simulation period. Signal applied as disturbance can be seen in Fig 3.

![Fig. 3 Disturbance signal](image)

III. RESULTS AND DISCUSSIONS

Uncontrolled and controlled responses of the system are analysed after PID controller is designed. Uncontrolled pendulum angle and wheel position responses of the system under the disturbance force can be seen in Fig 4 and Fig 5. As seen in Fig 4, uncontrolled pendulum angle has oscillation under the disturbance force. However the displacement of wheel position is very low since there is friction between wheel and ground. Same result is seen in Adams simulation, also.

![Fig. 4 Pendulum angle of uncontrolled system](image)

</table>

General block diagram including system modelling and controller design can be seen in Fig 2. System is a MIMO (multiple input - multiple output) structure which consist of two inputs and two outputs. Inputs are defined as controller (torque, N.m) and disturbance (force, N). Similarly, outputs are defined as pendulum angle (deg) and wheel position (m). Here, pendulum angle which is the most important parameter needs to be controlled issued as feedback. Wheel position is analysed in order to view only motion trajectory.
Then, controlled system responses and simulation studies are analysed. Since system is nonlinear, PID coefficients are obtained by trial and error method. After trials, gains were defined as $K_p=-4$, $K_i=-0.02$ ve $K_d=-2.5$ for this study. Pendulum angle and wheel position responses of the system with PID controller can be seen in Fig 6 and Fig 7.

In order to make the system stable, necessary torque driven by controller can be seen in Fig 8.

**IV. CONCLUSIONS**

There is a lack of knowledge in simulating and controlling the one or more wheel inverted pendulum systems with Adams and Matlab. In this paper, it is shown that single-wheel inverted pendulum system can be simulated and controlled in Adams and Matlab. Also, for future works, this study forms a basis for simulation and control of one or more wheel self-balancing systems.

These kinds of systems have nonlinear characteristics. Efficiency of the software solutions is very important in developing realistic approaches to such kind of systems. In this study, it is shown that Matlab and Adams are efficient in simulating and controlling the nonlinear systems like inverted pendulums.

In this study, pendulum angle of a single-wheel inverted pendulum system is controlled under necessary boundary conditions. Controller design procedure and controller efficiency are shown with graphics. Also, necessary torque values are given in graphics. In this way, design parameters and required equipments for future works and experimental studies are determined.

Abstract—In this study, a particular mechanism is designed to obtain the mechanical properties of shape memory alloys (SMA). Mechanical behaviour occurring due to the super elastic properties is investigated by applying current to shape memory alloys via designed mechanism. Displacement, velocity, time, force physical effects of SMA springs is obtained for different current values, and active operating range of springs is determined. This acquired data are of importance in determining the area of use of shape-memory alloys.

This paper presents the structure of the designed mechanism, and datas of mechanical properties of shape memory alloys which is obtained by using this designed mechanism.

Keywords—SMA, Shape Memory Alloy, Super elastic, Actuator

I. INTRODUCTION

Shape Memory Alloy (SMA) is a term given to alloy group which have the ability to return to a predetermined shape or size when it exposed to heat [1].

Nowadays, smart materials are used extensively for industrial applications in the world. Shape memory alloys, which are located in the smart materials, have been investigated in terms of industrial applications in Turkey. They own up to %8 super elastic mechanical properties and this specification has attracted attention of the industry.

Shape memory alloys conserve their deformation shape at room temperature which transistives at high temperature. When electric current is applied to SMA, it heats and transforms from deformed shape to original shape. Shape memory alloys are used in many industrial field such as health, automotive, defence etc. SMA provides superiority in terms of more flexible, lightweight and miniaturization with shape memory effect. These superiorities ensure great advantages for developing of power transmission organs [2].

As a result of deformation of the shape memory alloy can return to its previous form with minimum work and it presents a new perspective that power output throughout phase conversion and power/weight ratio are more than other power transmission organs [3].

Advantages of actuators which are made of Shape memory alloys among other actuators;
• Quite and smooth operation in the smooth system
• Power/weight ratio is in desired level
• Steady state
• Engine with low energy

Shape memory alloys are functional materials because of their martensite transformation and converse transformation such as shape memory effect and super elasticity. Their basic characteristics are that they have two different shape and crystal structure under and above critical transformation temperature. These materials which could be deformed at relatively low temperatures could be return prior to their shape at higher temperatures [4].

Shape memory effect or shape memory issue is that at the main phase shape memory alloy which have a specific shape is cooled to the martensitic transformation temperature and changed the shape with outer impact and after this material return its first shape with increasing the temperature to the main phase temperature.

Fig. 2. Mechanism of memory function (a) austenite phase (b) transformation martensite phase (Mf) (c) deformation (d) transformation austenite phase (Af)

At the Fig. 2.a material’s internal shape transform to martensitic phase (Fig. 2.b) from austenite when it is cooled. At this temperature permanent shape deformation is given to the
material (Fig. 2.c). And this material is transformed into austenite phase when it is heated (Fig. 2.d).

In this study, an experimental set-up is developed to observe physical impacts such as depletion, force, velocity related to shape memory alloys’ super elasticity mechanical properties throughout shape memory alloys’ cooling and heating process [5].

II. DESIGN OF EXPERIMENTAL SET-UP

Obtaining properly material characteristics of titanium and nickel alloys, which is known NiTiNol in industry, have importance since they are widely used to produce biomedical applications and actuators, thus to know their mechanical properties is important to carry out numerical and analytical analysis and simulations. In addition to knowing the relationship between the estimated number of cycles and maximum permissible stress and strain.

In this way, to get mechanical findings two linear actuator is designed as an experimental set-up. With this set-up is aimed to be guide for determining the mechanical behaviour of the shape memory springs.

Shape memory alloys’ mechanical behaviour have great importance to design valve, actuator, mechanical muscle etc. and to investigate new industrial applications.

To obtain the purposed results, two different experimental set-up is designed.

A. Experimental Set-Up

Shape memory alloy behaviour to be tested in the set-up are measured by the Module-1 and Module-2 which are operated as an actuator. Shape memory springs are heated by electric current. High level current is necessary for deformation of springs because of that insulation is provided in areas where contact springs.

At the Fig. 3., experimental set up is observed which was designed to determine characteristic structures of the shape memory alloys.

Experimental set up works based on the principle of the linear actuator and its power supply is provided max. 5.5 A.

Fig. 4. Schematic of the control unit structure

Fig. 4. shows control unit structure for experimental set-up. There is a switch and it has module-1 and module-2. With this switch module is determined to be studied. Also running direction of the working module is also selected with the using key.

The cables used in the control unit is selected to be high current resistant.

C. Module-1

The purpose of Module-1 set-up is to examine the parabolic movement in the horizontal plane of an object which is have 1,2 kg weight. This object is moved under favour of shape memory springs which are mounted on the right and left plane of the object.

To be able to move the object, 2.5 to 5.5A current is respectively applied to both of the shape memory alloy springs which are the right and left plane.

Module-1 is designed to work of the SMA spring that it runs on the horizontal axis with the movable object weight of 1.2 kg. This mechanism is used shape memory springs which are have same mechanical properties and same number of turn. Movable object is positioned at the exact plane. Shape memory springs were stretched by the deformation to maintain a position in which the object is located. A pen is added in front of the movable object.

The experimental setup is powered with the help of designed control panel. Module-1 is activated from the control panel. The process is started by module-1 way according to the direction of the desired position right or left-positioning. When the system runs in the right direction, the SMA spring at right side will return to its original position with the shape memory effect. The same issue applies to work in the left direction of the object. This time the system is operated in the left direction when the system runs in the left direction and SMA spring return its original position with the shape memory effect.

Parabolic actions are scratching in the millimetres paper and these actions are measured. To analyze of the SMA spring

B. Control Unit
behaviour, system is exposed to electric current respectively 5.5 A, 5 A, 4.5 A, 4 A, 3.5 A, 3 A, 2.5 A at the right or left position, during the 10 s, 15 s and 20 s.

At the Fig. 7., scratching object movements are shown. These scratching are plotted during the 10s, 15s, 20s and between 2.5 A- 5.5 A electric current in the range of 0.5A. Thus, depending on the different times and different electric current ranges, SMA spring behaviour are observed and mechanical behaviour datas are recorded.

Fig. 6. shows the velocity gradient according to using electric current to SMA springs. It is shown that, when applied current is increased, SMA spring velocity is increased. According to Fig. 6., the highest acceleration and speed is identified in the 10s.

**D. Module-2**

A cylinder mechanism is designed with SMA spring for module-2. The purpose of this cylinder mechanism is to examine obtaining velocity in consequence of time-depletion datas. These datas are obtained by two SMA springs, which have same mechanical behaviour and different number of turn, 2.5A and 5.5A current range of working.

At this module, SMA springs have been used in different numbers with the same characteristics. One of the spring in the system is pulled and another one is pushed in the process. Because of the used cylinder length is fixed equal number springs are limited the movement of the piston. Therefore, using different number of turn is increased measurement distance and provided maximum extension.

Module-2 is activated from the control panel. The process is started by module-2 according to the direction of the desired position forward or back-positioning. For forward movement, switch is selected “right” position and it moves advanced end position.

For back movement switch is selected “left” position and cylinder moves its back end position. To analyze the SMA spring behaviour, system is exposed to electric current respectively 5.5 A, 5 A, 4.5 A, 4 A, 3.5 A, 3 A, 2.5 A at the right or left position, during the 10 s, 15 s and 20 s.
Fig. 8. shows the velocity gradient according to using electric current to SMA springs.

Speed differences at the forward and back movement are occurred for different number of turn of SMA springs.

III. CONCLUSIONS

In this study, an experimental set-up is developed to determine mechanical and working properties of the SMA that have great importance for industrial applications. By using experimental set-up, SMA materials are tested which have different number of turn and have same mechanical properties. Set-up successfully measured shape memory springs’ behaviour at the different electric current.

This study presents that the velocity of the SMA spring is proportional with applied electric current. With the increase of the applied current value, temperature of the springs increases and springs return their original shapes more quickly. Module-1 experiments are helpful to determine optimum working times. Module-2 experiments is shown that in addition of the current value, number of spring turn is decisive for spring velocity.

dogan.yildiz@omu.edu.tr, serap.karagol@omu.edu.tr

Abstract— Wireless Sensor Network (WSN) refers to a group of locationally dispensed and dedicated sensors for observing and recording the physical conditions of the environment and coordinating the aggregated data at a central location. To serve such new applications, localization is largely used in WSNs to define the current location of the sensor nodes. Time of Arrival (ToA) localization is one of the prevalent schemes due to its high estimation accuracy. ToA is a method to estimate the location of a target based on the correlation of the signals and calculating the distances from each anchor to the target by multiplying the speed of light and the time at which the signal is received. In our recent study, we propose Modified 3N algorithm in both 2D and 3D spaces. In the Modified 3N algorithm in 2D, three circles were used and in the Modified 3N algorithm in 3D four spheres were used to localize the target nodes in the network. In this paper, we use Normal, Beta, Weibull and Generalized Pareto distributed networks for localization and the localization performance of the networks are evaluated and compared using MATLAB simulations.

Keywords— Wireless Sensor Networks, Localization, Time of Arrival, Statistical Distributions, Modified 3N Algorithm

I. INTRODUCTION

In recent years, wireless sensors networks (WSNs) have allured considerable interest in numerous fields including disaster alarm, health, military, environment, building, car, and mining industries. They also have remarkable potential to ease our daily life activities. The deployment of sensors is based on the fact that sensors are most practical when they are spread in a multitude numbers, especially for collecting environmental map of a geographical area such as a rain forest, a complete building, or an agriculture field.

Once the sensors are spread in a sensor application, exact position information is of vital importance [1]. The position of the nodes has a significant role in many fields as routeing, surveillance and monitoring, military, environmental and health applications etc. Localization of a sensor node is fulfilled with the aid of neighboring nodes. The localization can be categorized as known location based localization, proximity based localization, angle based localization, range and distance based localization [2].

In this study, we used Time of Arrival Localization (ToA) method which is one of range and distance based localization techniques. The distance between the two nodes is estimated by measuring the duration of propagation of the signal between the two nodes. This requires clock synchronized nodes, utilizing the well-known parameters such as the speed of the signal and the carrier frequency is known as the ToA technique. In previous studies, this technique was used several studies. In [3], each sensor node exploits at least one orthogonal sub-carrier as its assigned marker, to reply the Neighbor Discovery (ND) and ToA estimation requests transmitted by target nodes. The target node utilises the orthogonality throughout sub-carriers to detect the transmitted markers and their corresponding delays [3]. A signal-circle analogy used by Barbeau et al. [4], is generally used analogous to the TOA distance measurement technique.

In literature, statistical analysis related to both localization and energy problem in wireless sensor networks are available in many studies. Kamyabpour et al. [5] use statistical tools to analysis dependency between Wireless Sensor Network (WSN) parameters and overall energy consumption. In this study, three statistical approaches (linear and non-linear correlation, p-value) are implemented to the consequence of detecting phase to extract the most efficacious parameters on WSN comprehensive energy consumption. The distribution of range estimation error is analyzed by Rasool et. al [6] using both graphical and computational goodness of-fit techniques, that are, empirical cumulative distribution function plotting, quantile–quantile plotting, probability density function plotting, kurtosis (K) test, skewness (S) test, linear correlation coefficient (γ) test, Anderson–Darling (A²) test and chi-squared (χ²) test. They proposed range inflation algorithm (RFA) which is based on A² test and it filters out the range estimations with high errors. In [7], equipped with moments, the optimal fusion rule (OFR) distribution is approximated by a Gaussian and Gamma distributions via moment mapping method. They showed that the Gamma distribution fits the OFR distribution to high extent when compared with Gaussian distribution. Tae Hong et al. [8] propose a new data filtering schema based on statistical data analysis. Through performance analysis, they show that the proposed schema does better from the Kalman filtering schema in terms of the number of messages transmission. In [9], the authors present the SA-TC algorithm for detecting and thus defending against this serious threat. It is based on the on-demand multi-path routings and uses statistical analysis and time constraint to identify the suspected links. Tsai et al. [10] report different aspects of a statistical analysis of four representative in-car wireless channels based on the received power data collected.
from a Binary Phase Shift Keying (BPSK) transmission experiment. They used Rayleigh, Log normal, Nakagami, Rice, and Weibull distributions in their study.

In our previous study, we used uniformly distributed network to localize the target nodes while Modified 3N algorithm is being run. But in this paper, we used Normal, Beta, Weibull and Generalized Pareto distributed networks for localization and the localization performance of the networks are evaluated and compared using MATLAB simulations.

II. TIME OF ARRIVAL BASED LOCALIZATION

Time of Arrival (TOA) is a method used to estimate the location of a target node based on the correlation of the signals. This method calculates the distances from each anchor to the target by multiplying the speed of the signal and the time at which the signal is received. This method requires the knowledge of the precise starting time of the signal transmitted, and the precise maintenance and synchronization of the clocks at the target and all the anchor nodes is involved.

In general, the field of sensor nodes is sparse in the sense that some nodes may have fewer than neighboring anchors to fully localize. In fact, they may have less than 3 neighbors. A well-known 3 Neighbor algorithm is as follows: Each node that is not equipped with a position-awareness device sends a position request message, a node that knows or can compute its position sends to it all its neighbors, and a node that
device sends it to all its neighbors, and a node that receives position messages from three different nodes, say A1, A2, and A3, can calculate its position as shown in Fig. 1 (a). However, this algorithm exhibits a deficiency: where a target node receives only two anchor nodes (A1, A2), locations, and two distance measurements, the target node fails to find its own location, due to the obvious ambiguity as shown in Fig. 1(b) [4].

![Fig. 1](image_url)

**A. Modified 3N Algorithm in 2D**

The following modification to the 3N algorithm is proposed in [13]. While the algorithm is being run, the target nodes that are localized are now position-aware and possess the capability to share their positions. This newly found position-aware node is introduced into the pseudo anchor list and the neighboring network is intimated of this change, and the gradual increase of the position-aware nodes in the network enable an enhanced localization performance.

<th>III. ANALYSIS OF TIME OF ARRIVAL SIMULATIONS</th>
</tr>
</thead>
<tbody>
<tr>
<td>A. Design of Simulation Environment</td>
</tr>
<tr>
<td>The simulation environment is designed for the quantitative performance study of the proposed modified 3N Neighbor algorithm in 2D. For simplicity and ease of presentation we limit the environment to 2 dimensions, but the Modified 3N algorithm is capable of operating in 3D. A heterogeneous node network containing a mix of anchor nodes that have the capabilities of ascertaining their own locations and the target nodes that are non-position-aware is generated as shown in Fig. 2. Blue circle nodes and red square nodes represent position-aware and non-position-aware nodes, respectively. A pseudo-anchor list is created that serves as a dynamic anchor list while the simulation is being run. As the new target nodes are localized, they are added to the list of pseudo-anchors, and the whole network is made aware of these newly localized nodes for the purpose of enhancing the performance of localizing other target nodes with the help of this new knowledge. The simulation creates a distance matrix that is generated using the Euclidean method of calculation of the distance between the anchor nodes. The connectivity of the nodes in the network (i.e., the average number of neighbors) is an important parameter that has a strong impact on the accuracy of most localization algorithms. This forms the basis for the generation of other modules needed, such as adjacency lists. This list of the nodes is in the communication range of that particular target node. From this adjacency list, each target node determines its neighbors. An approximated sphere is constructed, using the distance from the anchor node to the target node as the radius and the absolute position of the anchor as the center. The intersection of spheres gives a location estimate of the target node.</td>
</tr>
<tr>
<td>B. Simulation Results for 2D</td>
</tr>
</tbody>
</table>
| In this section, the localization capability of the TOA based localization algorithm is presented with exhaustive Monte-Carlo simulations, and the effect of the input parameters determining the self-localization environment for Modified 3N algorithm in 2D is also presented. The simulation environment to test the performance of the algorithm on all combinations of the context parameters is formulated. Each Monte-Carlo simulation is generated for a particular set of
input parameters and run 100 times with different fields and with randomly located nodes. The results are then averaged. The input parameters include the percentage of anchor nodes (position-aware and initially synchronized nodes), the number of target nodes, and the range of communication, as shown in Fig. 2. With the number of nodes varying from 50 to 400, the percentage of available nodes is localized in a square field dimension of 100x100 units. In some application scenarios, nodes may be mobile. In this paper, however, we focus on static networks, where nodes do not move, since this is already a challenging condition for distributed localization. Fig. 2 shows Normal distribution of 100 nodes with the range of 20 units.

Fig. 3 shows Pareto distribution of 100 nodes. Three parameters of Pareto function, tail index (shape, K), scale parameter sigma and threshold (location) parameter theta, are chosen as 0.1, 0.1 and 1 respectively. When K > 0 and theta is equal to sigma/K, the Generalized Pareto is equivalent to the Pareto distribution.

Fig. 4 shows Weibull distribution of 100 nodes. This distribution has two parameters which k > 0 is the shape parameter and \( \lambda > 0 \) is the scale parameter of the distribution. k and \( \lambda \) are chosen as 1 and 0.12 respectively for this simulation. Fig. 5 shows Beta distribution of 100 nodes. Two parameters of Beta function, \( \alpha \) and \( \beta \), are chosen as 4 and 2 respectively. Asymmetric distributions are obtained by choosing alpha and beta to be different.

Fig. 6 is produced by varying the percentage of anchor nodes from 10% to 35% for a constant communication range of 10% of the field dimension for normal distribution. X-axis is the number of nodes and y-axis is the percentage of target nodes localized. Modified 3N algorithm is run on Pareto, Weibull and Beta distributed environments as shown in Fig 7, Fig. 8 and Fig 9 respectively. The results show that Normal distributed environment is quite sensitive to the change of node numbers. Increasing number of anchor nodes does not change significantly on Weibull, Perato and Beta distributed environments. Among all distributions, Pareto distribution shows the best results.
IV. CONCLUSIONS

Two-dimensional localization in wireless sensor networks have been widely studied in literature. In this paper, the Modified 3N algorithm in 2D is introduced and this algorithm was tested on an environment created with Normal, Weibull, Pareto and Beta distributions.

For all environments, the simulations conducted have shown that the introduction of the knowledge of newly localized nodes into the network enhances its localization capability. If the nodes cannot be located by the 3N algorithm because of the limitations on range and sparsity of the anchors, then those nodes will not be localized by the modified algorithm either. The sensors that detect the movements of the objects are not considered in this paper. They will be addressed in our future work.

Robust Variable Structure Controllers for Axial Active Magnetic Bearing

Sinan Basaran¹, Selim Sivrioglu²

Gebze Technical University
Mechanical Engineering Department, 41400, Gebze, TURKEY
¹sbasaran@gtu.edu.tr, ²s.selim@gtu.edu.tr

Abstract— This work focuses on robust variable structure control of a rotor-axial active magnetic bearing system. The electromagnetic force generated by active magnetic bearing is highly nonlinear characteristics. On the other hand, the magnetic force coefficient is a calculated value and its real value is not truly identified, therefore, robustness is a great importance in the operation of the active magnetic bearings systems. On this works Lyapunov based three different type of variable structure controllers are proposed and experimentally tested. Robustness of the controllers were tested experimentally by creating some parametric uncertainty in the control system using an external disk mass attached to the rotor. The results of the controllers are also compared with conventional and linear robust controllers.

Keywords— Axial active magnetic bearings, sliding mode controller, high gain robust controller, high frequency robust controller

I. INTRODUCTION

Active magnetic bearings (AMB) are electromechanical devices that provide noncontact support between rotor and bearing via the control of electromagnetic forces. Magnetically levitated rotors have many useful advantages like frictionless rotation. Owing to this, active magnetic bearings allow rotors to reach high rotational speeds [1-2]. However due to the nature of magnetic field, magnetically levitated rotor systems are highly nonlinear and AMBs are represented by nonlinear mathematical models [3-4]. Nevertheless they can be linearized successfully around the operating point thanks to the restricted and very small air gap between AMB stator and rotor [5]. As a result, many linear and local controllers like PID or fuzzy logic controllers [6-7] have been successfully applied to AMB systems. These controllers can offer good performance around the operating point but outside these local regions where the effects of the nonlinearities become more evident. Model based controllers are developed to increase the performance of the AMB system. Due to the magnetic saturation and existence of eddy current effects identification of exact system parameter in a magnetic bearing system is not straightforward. Therefore, robustness is a great importance for this type systems. There are available works on magnetic bearing system using robust control and linear matrix inequality design for controlling the motion of a magnetic bearing system [8-9]. Linear robust control and nonlinear adaptive backstepping control approaches have been studied by many researchers to maintain robustness in magnetic bearing systems [10-12]. Variable structure control theory has been implemented for many nonlinear processes including magnetic bearings [13-15]. One of the main features of this approach is needs to drive the error to a switching surface after which the system is in sliding mode and will not be effected by and modelling uncertainties or disturbances. However, there are two main criticisms of these controllers when they are applied to mechanical systems, first ignoring the dynamics or physical properties of the mechanical system the controllers can do no better than other controllers that disregards the dynamics. Secondly, chattering is a common problem associated with the variable structure controllers.

The remaining of the work is organized as follows: The mathematical model of an axial magnetic bearing system is given in Section 2, while the control problem formulation and error system development are stated in the control design section. Respectively the sliding mode control (SMC), high gain robust control (HGR) and high frequency robust control (HFR) are designed and experimental results are given in the rest of the paper.

II. AXIAL MAGNETIC BEARING MODEL

The axial active magnetic bearing produces attractive magnetic forces by the opposite coil electromagnets to limit the rotor movements in z direction. The structure of axial bearing in xOz plane is depicted in Fig. 1 schematically. In this structure, a disk element is fixed to the rotor and a nominal gap z₀ exists between the opposite coils and the disk element in both side. A non-contact capacitive sensor is set to measure the axial displacement of the rotor. The aim of the control is to bring the disk element to the origin without any mechanical contact during levitation and rotation of the rotor. The parameters of the considered system are given in Table 1. Note that an external disk is possible to be fixed to the rotor to test the robustness of the controllers.

In this study, it assumed that the radial and the axial directions are completely separated. This means two radial active magnetic bearings support the rotor in the radial directions and during the control operation a complete noncontact situation is realized. As depicted in Figure 1, the magnetic force f₂ is nonlinear in nature and is generated by the coils of bearing in the following form.

\[ f_2 = f_r - f_0 = k \left( \frac{(z_0 - z)^2}{(z_0 - z)^2 - (z_0 - z_i)^2} \right) \] (1)
where $k$ is a constant related to the magnetic bearing parameters. To derive the dynamical equation of the proposed system a linearized magnetic force is assumed to have the following form.

$$m\ddot{z} = k_xz + k_i\dot{z}$$  \hspace{1cm} (2)

where $z(t), \dot{z}(t) \in \mathbb{R}$ represent the rotor position and acceleration, respectively. Also, $i_s(t) \in \mathbb{R}$ denote the control current signal. Besides $m \in \mathbb{R}$ is the mass of the rotor, $k_x \in \mathbb{R}$ and $k_i \in \mathbb{R}$ are the constants according to displacement to force constant $k_x = 4k(i_0^2/z_0^2)$ and current to force constant $k_i = 4k(i_0/z_0^2)$ where; $k_i = \mu_0N^2A/4$.

![Diagram of axial active magnetic bearing rotor system](image)

Fig. 1 Schematic representation of the axial active magnetic bearing rotor system

To ease the presentation of the subsequent control development, we divide both sides of the dynamics equation by the non–zero constant $k_i$ to obtain:

$$i_x = M\ddot{z} - Cz$$  \hspace{1cm} (3)

where $M \equiv m/k_i$ and $C \equiv k_x/k_i$. The compact form of the equation can be written as

$$i_z = W\phi$$  \hspace{1cm} (4)

where $W = [\ddot{z} - z]$ and $\phi = [M \ C]^T$.

### III. Design of the Controllers

In the considered axial bearing–rotor system, the objective of the control is to force the disk to the middle position with equal gaps in both sides. To this aim, define a position tracking error $e(t) \in \mathbb{R}$ and its double time derivatives, denoted by $\ddot{e}(t) \in \mathbb{R}$, as follows

$$e = z_d - z$$  \hspace{1cm} (5)

where the desired trajectory of the rotor is $z_d = 0$. The filtered tracking error $r(t) \in \mathbb{R}$ and its time derivatives for the analysis, denoted by $\dot{r}(t) \in \mathbb{R}$, as follows

$$r = \dot{e} + \alpha e$$  \hspace{1cm} (6)

$$\dot{r} = \dot{e} + \alpha \ddot{e}$$  \hspace{1cm} (7)

where, $\alpha \in \mathbb{R}$ is a positive control gain. Take time derivative of filtered tracking error and multiplied by $M$ both side of the equation

$$M\dot{r} = M\ddot{e} + M\alpha\ddot{e}$$  \hspace{1cm} (8)

Rearrange (7) by substituting (3), (5) and (6) into it as follows

$$M\dot{r} = M(\ddot{z}_d + \alpha \dot{e}) - C\dot{z} - i_z$$  \hspace{1cm} (9)

Design the obtained controller:

$$i_z = \bar{W}(t) + k_x r + k_i \int r dr + V_R$$  \hspace{1cm} (10)

where $\bar{W}$ is the best estimates function of the system parameters. The selection of $V_R$ defines the type of the controller. Note that the integral term is not consist on the variable structures controllers. However, experimental results have shown that the steady-state error occurs when levitating the rotor. Therefore, substituting the integral effect on control signal equation (10) more reliable results are obtained. The aim of this study is to apply variable structure control in the selection of $V_R$ to have better robustness in the control system.

### A. Sliding mode controller (SMC) design

Using equation (10), the first type controller input is defined as

$$i_{z_{-SMC}} = \bar{W}(t) + k_{x_s}r + k_{is} \int r dr + \rho_s \text{sgn}(r)$$  \hspace{1cm} (11)

For the stability analysis, a candidate Lyapunov function (12) and its derivative (13) are defined as

$$V = \frac{1}{2}M\dot{r}^2 + \frac{1}{2}k_{is}\xi^2$$  \hspace{1cm} (12)

$$\dot{V} = M\dot{r}\dot{r} + k_{is}\dot{\xi}\dot{\xi}$$  \hspace{1cm} (13)

</tbody>
</table>
where $\xi = \int r dr$ and the derivative of $\dot{\xi} = r$. The final form of derivative of $V$ is obtained by inserting equation (9) and (11) into the closed equation (13)

$$\dot{V} = M \dot{r} + k_{is} \ddot{\dot{r}} = (w(t) - \ddot{\omega}(t) - k_r \ddot{r} - \rho_s \sigma \dot{r} - k_{ig} \dot{\dot{r}}) r + k_{is} \ddot{r}$$

Since $\sigma(r) = (|r|/r)$, and $\ddot{\omega}(t) = w(t) - \ddot{\omega}(t)$ the equation (14) becomes;

$$\dot{V} \leq \ddot{\omega}(t) r - k_r \ddot{r}^2 - \rho_s |r|$$

Assume that there exists a $\rho_s(t) \in \mathbb{R}$ such that $\rho_s(t) \geq ||\ddot{\omega}(t)||$. The following upper bound can be formed;

$$\dot{V} \leq k_r \ddot{r}^2$$

Finally, the derivative of $V$ becomes

$$V > 0 \Rightarrow V \in L_{\infty} \Rightarrow \lim_{t \to \infty} V = V_{\infty}$$

It is clear that a global stability is maintained and all signals in the closed system are bounded.

**B. High gain robust (HGR) controller design**

The second type controller input is high gain robust controller defined as

$$i_{x-HGR} = \ddot{\omega}(t) + k_r \ddot{r} + k_{ig} \int r dr + \frac{\rho_s^2}{\epsilon} r$$

where $\epsilon > 0$ is a positive constant. For the stability analysis, the Lyapunov function given in equation (13) is used by replacing with the parameter $k_{ig}$. The derivative of $V$ is obtained as by inserting equation (9) and (18) in to the closed equation (13)

$$\dot{V} = \left( w(t) - \ddot{\omega}(t) - k_r \ddot{r} - \frac{\rho_s^2}{\epsilon} r - k_{ig} \dot{\dot{r}} \right) r + k_{ig} \ddot{r}$$

Assume that there exists a $\rho_s(t) \in \mathbb{R}$ such that $\rho_s(t) \geq ||\ddot{\omega}(t)||$. And in equation (19) replace $\dot{\ddot{\omega}}(t)$ with $\ddot{\omega}(t)$ and the following upper bound can be formed;

$$\dot{V} \leq -k_r \ddot{r}^2 + \rho_s |r| - \frac{\rho_s^2}{\epsilon} r$$

Rearranging equation (20);

$$\dot{V} \leq -k_r \ddot{r}^2 + \rho_s |r|\left(1 - \frac{\rho_s |r|}{\epsilon}\right)$$

**Case-1:**

$$\rho_s |r| > \epsilon \Rightarrow 1 - \frac{\rho_s |r|}{\epsilon} < 0$$

**Case-2:**

$$\rho_s |r| \leq \epsilon \Rightarrow 1 - \frac{\rho_s |r|}{\epsilon} \geq 0$$

Under these cases the derivative of the candidate Lyapunov function is transformed into the two different types:

**From case-1:**

$$\dot{V} \leq -k_r \ddot{r}^2$$

**From case-2:**

$$\dot{V} \leq -k_r \ddot{r}^2 + \epsilon$$

The worst case between case-1 and case-2, the derivative of the candidate Lyapunov function with the following upper bound can be formed;

$$\dot{V} \leq -k_r \ddot{r}^2 + \epsilon$$

therefore global ultimately upper bound stability is satisfied.

**C. High frequency robust (HFR) controller design**

The third type controller input is proposed as

$$i_{x-HFR} = \ddot{\omega}(t) + k_r \ddot{r} + k_{if} \int r dr + \frac{\rho_f^2}{\epsilon} r$$

Using the same candidate Lyapunov function for the stability analysis, the derivative of $V$ is obtained by substituting equation (9) and (25) to the equation (13)

$$\dot{V} = \left( w(t) - \ddot{\omega}(t) - k_r \ddot{r} - \frac{\rho_f^2}{\epsilon} r/|r| + \epsilon \right)$$

$$- k_{if} \dot{\dot{r}} r + k_{if} \dot{r} \dot{\dot{r}}$$

Assume that there exists a $\rho_f(t) \in \mathbb{R}$ such that $\rho_f(t) \geq ||\ddot{\omega}(t)||$. And in equation (26), replace the $\ddot{\omega}(t)$ with $\ddot{\omega}(t)$ and the following upper bound can be formed;

$$\dot{V} \leq -k_r \ddot{r}^2 + \rho_f |r|\left(1 - \frac{\rho_f |r|}{r|/| + \epsilon}\right)$$

Rearrange the equation and the following upper bound can be formed;

$$\dot{V} \leq -k_r \ddot{r}^2 + \rho_f |r|\left(\frac{\epsilon}{r|/| + \epsilon}\right)$$

where $\rho_f |r| \leq 1$; the derivative of $V$ becomes

$$\dot{V} \leq -k_r \ddot{r}^2 + \epsilon$$

therefore global ultimately upper bound stability is satisfied.

**IV. EXPERIMENTAL VERIFICATIONS**

The flexible rotor-active magnetic bearing experimental setup used in the control design study is shown in Figure 2. The experimental setup is a five axis controlled rotor-active magnetic bearing system and the radial and the axial bearings can be controlled separately. The axial magnetic bearing is located at the one end of the rotor and limits the rotor axial
movements. The air gap $z_0$ between the rotor and the touchdown bearing is set to 0.15 [mm].

In experiments, the controller implementations and the data acquisitions were performed using dSPACE DS1104 system. The working sample rate was selected as $T_s = 15 \text{ kHz}$ in all experiments. The best estimates of the system parameters were taken as $\varphi = [M \ C]^T = [10000 \ 0.3974]^T$. In experimental verifications, two cases were studied to understand the performance and robustness of the designed robust variable structure controllers. In the first case, experiments were carried out with the own weight of the rotor in the system. For the second case, an external disk mass was mounted at the end of the rotor as shown in Figure 3. After adding the disk mass, the total mass of the rotor became 5.204 [kg] and the increase in the rotor mass was about 8% percent. Adding an extra mass on the rotor imposes some parametric uncertainty to the control system and also some dynamic unbalance forces in the rotation of the rotor even in the axial direction due to imbalances in the external disk.

**A. Experimental Results of Variable Structure Controllers**

The variable structure controllers were tested at the rotor speed of 3000 rpm for two cases and the displacement of the rotor and the control input were observed for each cases of with and without disk. The results obtained with the sliding mode controller are shown in Fig. 4. As shown in these figures, small increases were observed in the amplitude of displacement and the control input when the external disk attached to the rotor. The parameters of sliding mode controller for both case were selected as $\alpha_s = 10, k_{rs} = 1000, \rho_s = 0.1$ and $k_{is} = 450$.

![Fig. 4 Sliding mode control results, (a) displacements, (b) control inputs](image)

The second results were obtained for the high gain robust controller as shown in Fig. 5. For this controller, the parameters were selected as $\alpha_g = 20, k_{rg} = 900, \rho_g = 0.0001, \varepsilon_g =$

![Fig. 5 High gain robust control results, (a) displacements, (b) control inputs](image)
0.000001 and $k_{ig} = 600$. Although increase in the amplitudes of responses with external mass were reasonable, some phase shifts were observed in the displacements and control inputs.

The high frequency robust control results were presented in Figure 6. In this controller, the parameters were $a_f = 25$, $k_{rf} = 1000$, $\rho_f = 0.001$, $\epsilon_f = 0.000001$ and $k_{if} = 500$. Much better results were obtained in displacements and control inputs compared to other variable structure controllers as shown in Figure 6.

![Figure 6](image)

**Fig. 6** High frequency robust control results (a) displacements, (b) control inputs

**B. Comparison of Experimental Results**

The results of variable structure controllers were compared with the results of conventional PID control and linear $H_\infty$ robust controller. These controllers were tested before for the same rotor magnetic bearing system [16] and were believed to have good performances. For the same test conditions and rotational speed of the rotor, the results obtained for PID control are shown in Figure 7. The robustness of PID control is weak against the parameter variation. The results of linear $H_\infty$ controller were presented in Figure 8. Since $H_\infty$ controller was designed by considering some uncertainty models, small increases in the amplitude of the rotor were observed with the disk mass.

The experimental results of the all tested controllers with external disk mass were presented in Fig.9 and without disk given in Fig.10. Also Table 2 shows RMS values of obtained experimental data. It can be detected that high frequency robust controller gives best results either in the amplitude of the rotor and the control inputs. The other two variable structure controllers have also reasonable results. The results of linear $H_\infty$ control shows the conservativeness of the controller with large control input values but almost no increase in the amplitude of displacements but some phase shifts were observed in the displacements and control inputs.

V. CONCLUSIONS

In this paper, three type of robust variable structure controllers have been designed and tested experimentally for a rotor-axial active magnetic bearing system. Robustness of the controllers were tested experimentally by creating some parametric uncertainty in the control system using an external disk mass attached to the rotor. RMS values from the obtained data of the displacements and the control inputs have shown a good comparison of the controllers. The high frequency robust controller results have shown much better performance in all tested controllers.

Abstract— The brushless direct current motors are often preferred in the industry due to their high development torques, efficiencies, speed and position controls. Especially, they are used with robotic, numeric-controlled machines, electrical vehicles, etc. One of the biggest difficulties of these motors is the closed loop operation of these motors with driver circuits and a controller. In this study, the speed control of the brushless direct current motors was made with PLC-based industrial computer by using the methods of PID and Fuzzy Logic. PLC based industrial computer of Beckhoff firm CX9020 was preferred as a controller. In this industrial computer, the software of the controller was developed by using Structured Text programming language of TwinCat 2.11 program. In experimental studies, the speed control of the brushless direct current motors is made with PID and fuzzy logic controller, according to the requested reference. The performances of the controllers were tested by using step, ramp and ladder functions. While PID controller gave better results in reference speed areas whose parameters were determined, fuzzy logic controller gave better results in variable references. Although PID is given as a ready block in PLC and PLC based controllers, fuzzy logic is under development in many of them. In this study, classical PLCs and PLC based industrial PCs, which did not have any fuzzy logic controller module, were transformed into intelligent controllers with Structured Text programming language. As a result of this, classical PLCs and PLC based industrial PCs can be used in intelligent control, which is very important for industry 4.0.

Keywords— fuzzy logic, speed control, industrial pc

I. INTRODUCTION

The brushless direct current motors (BLDC Motors) are electric machines used widely on applications requiring high efficiency and strength. They are used in many areas, especially in automotive and aviation industries, as an actuator [1]. The brushless direct current motors are often preferred for special implementations in the industry, compared to brushed direct current motors and asynchronous motors, due to their features such as speed-torque characteristics, high-dynamic-responses and high efficiencies [2]. Strength is very important for motors being used in automotive and aviation industries. They are preferred for almost every implementation in the industry because decay probability of brushes of brushed direct current motors under dynamic forces is high and efficiency and performance of asynchronous motors are low [3].

Speed control of a brushless direct current motor can be made by using the pulse width modulation (PWM) [4]. Requested input/output operations are widely used in the industry by using programmable logic controllers (PLC), and they are also used for motor speed control applications requiring high precision and accuracy [5]. For speed control of brushless DC motors, fuzzy logic controller can be used by integrating it in PID controller software [4,5]. Additionally, speed controls of brushless and brushed DC motors can be modeled on Matlab/Simulink platforms without any applications, and speed controls can be made by using a fuzzy logic controller [6]. At the present time, it is known that they are being used in electric vehicle technologies by making speed controls on permanent-magnet (PM) in-wheel electric motors [7].

Industrial PCs are the general name of Intel x86-based computer platforms manufactured for industrial purposes as in the definition. As an example for other platforms, PLCs, micro-controllers and DSP-based processors can be given. Main features which differ industrial PCs from commercial PCs are their high security, endurance under difficult conditions and suitability for long-term uses [8].

Industrial PC manufacturers in the World are Advantech, Allied Electronics, Aplex Technology, AutomationDirect, B&R Industrial Automation and Beckhoff Automation. In this study, speed control of a brushless direct current motor has been made in an experimental setup designed and prepared for the study conducted, by using fuzzy logic controller and PID controller on an industrial computer. On the industrial computer, fuzzy logic controlled has been executed in “Structured Text” programming language as software, and the performance of the software developed via smart controllers that are available to use in Industry 4.0 of which name is mentioned most often in recent years have been tested with experimental works thanks to the study.
II. MATERIALS AND METHOD

A. Preparing the Experimental Setup

Brushless direct current motors are hard-to-control applications. Relaying power components in motor driver circuits and reading the speed data on the encoder require speed and computational time. For testing these softwares developed because of these reasons, this problem has been preferred. Brushless direct current motors are used in robotics, numeric controls (NC), computer numeric controls (CNC) and precise implementations. Areas of usage are rapidly increasing. In the study, PID and fuzzy logic control has been chosen on speed control for the brushless direct current motor brand Oriental type BLH230KC-30 by using Beckhoff CX9020 industrial computer. The experimental setup has been designed and prepared in order to perform this implementation. 2 “two” motors have been used in the experimental setup, and they have been loaded with fixed load by connecting wheels to motor shafts with direct-connection and 2 “two” drums have been attached under them with a tangential-connection for the purpose of force application to the wheels. With the fixed load implemented, the motor is caused to consume 0.64 A(Ampere) current. Revs per minute during the motor run time has been read by encoders being used in the system, speed measurement has been performed via Beckhoff CX9020. With the thermocouple type “K” connected in between motors, mean temperature of the motors is determined, and the system is halted in case of the potential temperature increasing and high velocities being reached. The visual of the block diagram belonging to the study and the visual belonging to the experimental setup prepared have been given, respectively, on Fig. 1 and Fig. 2.

---

![Fig. 1 Block Diagram of the Study](image1)

![Fig. 2 Experimental Setup Prepared](image2)
B. Industrial PCs
Utilized in the study, CX9020 industrial PC of BECKHOFF automation firm is an Ethernet control system mounted on DIN rail, integrated with 1 GHz ARM Cortex™-A8 CPU. Connection for Beckhoff I/O systems has directly been integrated into CPU module. CX9020 consists of two microSD card slots, internal ram as nonvolatile memory, 128 kB NOVRAM and CPU. It externally contains two Ethernet RJ45 interfaces, four USB-2.0 interfaces and DVI-D interface. Operating system Microsoft Windows 7 CE can be run with TwinCAT 2.11 interface software without visuals or visualization [9].

C. Brushless Direct Current Motor
BLH230 series BLDC motors manufactured by Oriental brand are one type of motors manufactured by the firm that can work with high precision. For the control of the motor, a motor driver is provided, as well, for the user by the firm. In this way, the motor control can be made more easily and with more precision. By means of the sensors integrated on motor driver card, damages to the system are prevented with motor power-off system activating when there is over current, over heat and over strain [10]. There is a speed-torque graph given belonging to BLH230KC-100 brushless direct current motor in the Fig. 4, and pictures belonging to the motor and motor driver in the Fig. 5. According to Fig 4, take-off torque of the motor is 0.15 Nm and nominal torque is 0.12 Nm. 2500 rpm/min is the threshold value of the nominal torque provided by the motor. When the motor reaches to the maximum speed, the torque value is half of the nominal running torque (0.6 Nm). Suggested work area of the motor is between 0.12-0.15 Nm torque range and 100-2500 rpm/min revolution range.

D. Pid control system in use in the experimental setup prepared
PID control method is widely used in process control in industrial applications. Control systems engineers prefer PID controller because of its flexibility and reliability. The transfer function of a PID controller including proportional, integral and derivative terms are given in (1).

\[ K(s) = K_p + \frac{K_i}{s} + K_ds \]  

In equation (1), \( K_p \) is proportional gain, \( K_i \) is integral gain and \( K_d \) is derivative gain. By tuning coefficients of PID controller, it provides control for specific process requirements. The proportional term produces an output value that is proportional to the current error value. This proportional term is related to current state of process variable. The integral term is proportional to both the magnitude of the error and the duration of the error. When integral term is added to proportional term it accelerates the movement of the process towards setpoint and eliminates the residual steady-state error that occurs with a pure proportional controller. The rate of change of process error is calculated by determining the slope of the error over time. The rate of change is multiplied by derivative gain [11]. In equation (2), the error which is the input parameter of PID controller is calculated by the difference between measured value \((r(t))\) and the output of PID controller \((y(t))\). In equation (3), the output function of PID controller is given.

\[
ed(t) = r(t) - y(t) \]  
\[
y(t) = K_p e(t) + K_i \int_0^t e(t) dt + K_d \frac{de(t)}{dt} \]  

E. Fuzzy Logic Control
Fuzzy Logic is a logical structure that has come in sight as a result of an article published by Lotfi Zadeh in 1961. The fuzzy logic is based on fuzzy-set and sub-sets. When it is stated mathematically, the value of the entity is set as “1” when it is an element of the set, and set as “0” when it is not an element of the set, in terms of its relationship with the set. Fuzzy logic is an extension of classical set notation. In a fuzzy set, each entity has a membership degree. Membership degree of entities can have any value between (0,1) range and membership function is shown with \( M(x) \) [12]. In fuzzy logic deduction, linguistic varieties can be formed as membership functions of triangle type, trapezium type and cauchy type [13]. In the study, variables have been generated based on triangle type membership functions. Triangle membership function is given on Equation 4.
A \mu (x) \begin{cases} 0, & x < a_1 \\ \frac{x - a_1}{a_1 - a_2}, & a_1 \leq x \leq a_2 \\ \frac{a_3 - x}{a_3 - a_2}, & a_2 \leq x \leq a_3 \\ 1, & x > a_3. \end{cases} \tag{4}

Here \( \alpha_2 \) can be defined as a fixed value. Fuzzy logic presumes, depending on \( \alpha \) coefficient, that values close to \( \alpha_2 \) would be represented with the meaning assigned to this value. In other words, uncertainty in \( \alpha_2 \) can be reduced to minimum values with a \( \alpha \) coefficient that will be presumed or can be found based on the distribution.

In this study, engine rpm has been chosen as the process variable. System input variables have been defined as the revolution fault \( e \) between reference motor rpm and current motor rpm, and the change in revolution fault \( ce \). As system output variable, cycle change of the analog output signal sent to the driver circuit making the speed control of the motor.

\[ e(i) = ref(i) - (i) \]
\[ ce(i) = e(i) - e(i-1) \]

Here \( ref(i) \) is the reference number of revolutions required during the \( i \)th sampling, \( (i) \) is the present number of revolutions of the motor during the \( i \)th sampling, \( e(i) \) is the revolution fault during the \( i \)th sampling, and \( ce(i) \) is the change in revolution fault during the \( i \)th sampling.

The fault, the change in the fault and control variables are placed in the universal set. After the measurement of the system variables, input data measured is turned into suitable linguistic variables in a way that they would be labels of fuzzy sets. These linguistic variables are; PH: (Positive High), PM: (Positive Medium), N: (Null), NM: (Negative Medium), NH: (Negative High). A fuzzy set is defined by assigning a degree of membership value for each elements in the universal set. There are many types of membership function. Preference of those membership functions is up to the user.[14] Since this implementation requires a simpler calculation, triangle type membership functions have been preferred.

For the speed control of the motor, the fuzzy logic controller has been designed first, and fault, change in fault and variable data fuzzification has been made. After the fuzzificated data has been processed in rule basis, they have been defuzzificated and acquired as analog output data. Visuals belonging to fuzzificated membership functions of input and output variables of fuzzy logic controller and belonging to sample software codes developed via “Structured Text” language on Twincat program which is the industrial PC control interface are given on Fig. 6, Fig. 7, Fig. 8, Fig. 9, Fig. 10 and Fig. 11.

After the fuzzification of input and output data, rule base has been designed. While generating the rule base, responses of the motor has been considered and tested by interpreting expertly. On the Matlab/Fuzzy Logic Toolbox platform, a fuzzy logic controller sample has been designed and the controller output has been simulated on the said platform. The rule base is extremely important for implementing the requested output value by comparing the data of fault and changes in fault. Linguistic expression of the rule base in the Fig. 12, visual graph acquired from Matlab/Fuzzy Logic Toolbox platform in the Fig. 13 and part of the software developed belonging to rule base has been given in the Fig. 14.
After the necessary designs have been made for fuzzy logic control, software codes have been written on Twincat interface in order to execute the application. The study has been performed after all processes were completed, controls of the motors have been performed. Revolution data and heat data obtained from the motors have been processed with the controller, and the study has been completed according to the program developed. Additionally, with touch panel of Beckhoff CP6907, all variable information is displayed on the panel with an integrated study. On the panel, information of motor revolutions, heat and analog output value given by the controller has been shown. Screen image of the study has been given on Fig. 15.

III. EXPERIMENTAL STUDIES

During the experimental study, PID control has been compared with the results of fuzzy logic control. As reference to PID and fuzzy logic controllers, step, ladder and ramp functions have been applied, and the results have been obtained graphically on Twincat 2.11 Scope View software working integrated with Beckhoff. Response of PID and fuzzy logic controllers to the ladder function reference has been given in the Fig. 16.
In response to step function in the Fig. (16.a), motor revolution is reaching to the requested step value softer and steadier compared to the Fig. (16.b). It is seen that reference excess is high in the Fig. (16.b) and Fig. (16.d) while reference value is at 2500 rpm/min. In addition, after the reference value requested in the Fig. (16.a) has been reached, it is seen that the presence of oscillation is lesser than the Fig. (16.b) in step response. In the Fig. (16.c) it is seen that the engine revolution is reaching to the requested step value softer and steadier and that the presence of oscillation is lesser compared to the Fig. (16.d) in step response.

The response of the PID and fuzzy logic controllers to ladder type function reference is given in the Fig. 17.

In the ladder response in the Fig. (17.b), revolution of the motor is reaching to the requested reference value faster compared to the Fig. (17.a). However, revolution of the motor is reaching to the requested reference value softer in the Fig. (17.a) compared to the Fig. (17.b). As a reason for this, the cycle speed of the system shows a decrease since the software of fuzzy logic controller is rather heavy. Additionally, while the response of fuzzy logic controller at low revolution reference in responses in the Fig. (17.a) and the Fig. (17.c), there is oscillation in responses in the Fig. (17.b) and the Fig. (17.d). As the reason for the said oscillation, it is seen that process coefficients of PID controller being constant negatively affects the system response in reference values. Since the variables of fuzzy logic controller are defined linguistically, it does not change its response among defined reference values. According to the ladder response, in graphs of the Fig. (17.c) and the Fig. (17.d) acquired without applying load on the motor, it has been seen that the revolution of motor has dropped to the zero based on the oscillation from the rotor of the motor. In reference response in the Fig. (17.c), it is seen that the revolution of motor is reaching to the reference value softer and steadier, and there is seen lesser oscillation compared to the Fig. (17.d). Response of PID and fuzzy logic controllers to ramp type function reference is given in the Fig (3.3).

Fig. 17 Ladder response given by fuzzy logic controller under the load is (a), ladder response given by PID controller under the load is (b), ladder response given by Fuzzy logic controller without load is (c), the response given by PID controller without load is (d).

Fig. 18 Ramp response given by fuzzy logic controller under the load is (a), ramp response given by PID controller under the load is (b), ramp response given by Fuzzy logic controller without load is (c), the ramp response given by PID controller without load is (d).
In reference response in the Fig. (18.a), the revolution of motor is reaching to the requested step value with more oscillation and later steadiness. The reason for this is the slowness of the response of fuzzy logic controller to the rapidly-changing reference. However, although the reference was changing rapidly, while unwanted sawtooth response graph did not occur in the Fig. (18.a), it has been seen in low references in the Fig. (18.b). The reason for this is constant coefficients of P, Ki and Kd within the software of PID controller. In step response in the Fig. (18.c), it is seen that the revolution of motor is reaching to the requested step value softer and steadier, and lesser oscillation is seen compared to the Fig. (18.d).

IV. CONCLUSIONS

In this study, speed control of brushless direct current motor has been made by using fuzzy logic controller via an industrial computer. Responses given by fuzzy logic controller to the requested reference value have been obtained from step, ladder and ramp functions, and they have been compared via PID controller designed for the purpose of monitoring the performance of the responses given by the fuzzy logic controller. According to the results of system responses, although PDI controller runs at certain value ranges more efficiently, it has been seen that the controller efficiency was decreasing as the reference range was increased. However, since the fault variable is determined in the fuzzy logic controller linguistically, it is seen that increasing the value range of the reference does not affect the operation of the controller. Additionally, since the oscillation of the brushless direct current motor was being prevented, it has been seen that its system responses had been more efficient.

Since fuzzy logic controllers contain linguistic variables within, the implemented software generates a huge memory space in the memory of the hardware used. Implementations of fuzzy logic controllers are performed by using high-speed processors or electronic cards in general. As a result of the study, it has been determined that Beckhoff CX9020 industrial computer properly runs the designed fuzzy logic controller of which software was written. Having a major importance in the industry, industrial PCs supporting these sorts of controller structures is seen to be providing comfort and opportunity for applications having Industry 4.0 standards in terms of utility of industrial PCs due to their availability for coding and them being faster than PLCs used in the industry.

Abstract—In this study, progress and sort of electrochemical discharge machining (ECDM) that was developed to manufacture the micro features like micro grooves, micro pillar, micro holes and micro channels etc. were investigated. Many materials can be machined regardless of material conductivity, hardness and strength by ECDM using electro chemical machining (ECM) and electric discharge machining (EDM) combination. Researchers developed electrochemical discharge drilling (ECDD), turning (ECDT), grinding (ECDG), milling, dressing, trepanning, wire ECDM, die-sinking ECDM, rotary ECM, powder mixed ECDM, magnetic field assisted ECDM, vibration assisted ECDM methods. Pyrex, glass, stainless steel, cermet, soda lime glass, quartz, silicon nitride, zirconium oxide, borosilicate glass, diamond crystals, e-glass/epoxy composite, kevlar/epoxy composite and silicon wafer were used as a work piece. Effects of machining voltage and drilling depth on mean diameter, influence of tool travel rate on groove width and depth and effects of voltage types on micro holes accuracy and machining type etc were investigated. This review is to discuss the results of studies and applicability of this methods. It sums up also with a vision for future research in electrochemical micromachining.

Keywords—Electro chemical machining (ECM), electric discharge machining (EDM), electrochemical discharge machining (ECDM), micro machining

I. INTRODUCTION

Increase of utilization of micro scale products in wide range of science and technology fields leads researchers to investigate more about these fields. Electrochemical machining (ECM) only for electrically conductive materials, electric discharge machining (EDM) for electrically conductive materials and non-conductive materials only with specific set-up remain incapable of manufacturing of micro scale products. Thus, researchers have been tried to find new hybrid methods to manufacture micro scale products irrespective of material conductivity and strength. Electrochemical discharge machining (ECDM) that is a combination of ECM and EDM was developed by Kurafuji and Suda in 1968[1] but it was first described by physicists Hippolyte Fizeau (1819-1896) and Leon Foucault (1819-1868) [2]. The basic configuration of ECDM was shown in Fig 1[3]. Researchers developed new processes, the same with ECDM essentially, in times. In this study, these new kinds of ECDM processes and investigations to enhance material removal rate (MRR) of ECDM were analyzed.

II. ECDM IN LITERATURE

Before to develop the ECDM, researchers tried to understand the electrochemical discharge phenomenon. One of the first investigations on this is the effect of different power supply configurations and electrolytes in 1993 by Raghuram et al. [4].

Because, the critical voltage was important to determine the material removal rate and enhance MRR. Basak and Ghosh [5] developed a model and compare numerical results with experimental ones to predict the MRR. Besides, Ghosh [6] presented the principle and possibilities of ECDM. Among early works in literature, Bhattacharyya et al. [7] analyzed different process parameters on MRR and they attempted to specify the proper tool shape. Kulkarni et al. [8] were the other researchers to investigate the mechanism of the ECDM process. They paid attention to relation among the time-varying current, temperature rise and MRR. A mathematical model was developed to relate among machining parameters with process criteria by Sarkar et al. [9]. Conclusions showed that applied voltage had more effects on material removal rate, radial overcut and heat affected zone. Chak et al. [10] developed new tools for electrochemical discharge drilling to prevent the decrease on MRR with increasing machining depth. Spring-fed cylindrical hollow brass tool and spring-fed cylindrical abrasive tool were used to drill aluminum oxide (Al₂O₃). Coteate et al. emphasized the effects of some parameters (the voltage, the electrode tool diameter and the work liquid density) on the electrode tool wear [11], the effects of the input parameters on the tool wear and on the drilling speed [12], the effects of the voltage, the capacity of electric circuit on tool wear [13]. Chavoshi and Behagh [14] investigated and discussed the hole length and axial wear parameters and relation between them. That results were cited from the paper by Coteate[13].

Liu et al. [15] developed new wire ECDM process to machine particle-reinforced aluminium alloy 6061 and researched the influences of current, pulse duration and electrolyte concentration on MRR. Results indicated that most effective factor for the highest MRR is the applied current. Again, they [16] developed a grinding-aided model to machine particulate reinforced metal matrix composites (MMCs). This new method enhanced efficiency of machining and surface

Fig. 1 Basic cell configuration in electro-chemical discharge machining [3]
quality on MMCs. Also to predict of critical breakdown voltage they developed a model [17] corresponding with experimental results. Cao et al. [18] machined 3D micro-structures less than 100 µm in size and achieved good surface in spite of minimized structures (Fig 2). It was revealed that high voltage reduced machining resolution. Thus, they reduced required voltage by means of a load cell and the tool electrode with small layer depth.

Cheng et al. [19] investigated the influences of the machining parameters on gas film quality which is very important factor on machining quality. Again, they [20] used new process wire ECDM with electrolyte supplied in titrated flow to fabricate the micro-scale features. The results remarked that this new cost effective and environmental friendly process enable better machining outcomes with less width. Finite element based model for ECDM drilling was developed to predict discharge regime by Wei et al. [21]. Jiang et al. [22] determined spark energy to model spark generation and this finite element model were validated with experiments. They [23] also modelled gas film evolution and validated with experiments to enhance the machining efficiency and quality. The influences of process parameters of ECDM on MRR were researched for borosilicate glass and process parameters were optimized using Taguchi’s method by Paul and Hiremath [24]. Adding surfactant to electrolyte increased the current density and stabilized the current, hence provide better quality [25]. Razfar et al. [26] studied effects of different types of longitudinal oscillation on machining speed and hole depth. Results revealed that although vibration did not effect on the process with micro drill, it was quite effective such as MRR up to 40% with cylindrical rod. Hajian et al. [27] investigated effects of magnetic field orientation on ECDM performance and concluded that magnetic field orientation increased channel depth and surface quality. Behroozfar and Razfar studied characteristics on the plasma channel and material removal [28] and tool wear [29] during ECDM. Zhang et al. [30, 31, 32, 33, 34] developed new process, tube electrode high-speed electrochemical discharge drilling (TSECDD), shown in Fig 3, to machine cooling holes. Low-conductivity salt solution [30] enhanced machining surface and efficiency, increasing tube-electrode inner diameter increased MRR [31] on TSECDD. The performance of ECDD with super-high-pressure interior flushing [33] and internal and side flushing [34] were investigated with machining parameters effects.

Dhanvijay and Ahuja [35] studied machining parameters of stagnant and electrolyte flow method on ECDM and obtained the results that electrolyte flow method had a high MRR but a high diametric overcut that had been minimized. A mathematical model was developed by Kamaraj et al. [36] to predict the overcut of the surface that was important to protect the product dimensions. 304 stainless steel was drilled with ECDM process by Huang et al. [37] who established a new process using high-speed micro-electrode. Liu et al. [38] analysed the interpolar voltage and characteristics of current of a process using slotted metal wheel and mist-jetting electrolyte in ECDM to stabilize. Krötz and Wegener [39] developed a new process that was spark assisted electrochemical machining (SAEM). This process was stimulating more contact arcs in a period on the contrary of ECDM. This method presented that the finishing could be done with the same equipment.

III. CONCLUDING REMARKS

The aim of this study was analysing the ECDM investigations and new processes of ECDM. Researchers, especially investigated and emphasized the material removal rate that was very crucial to improve the ECDM process. It was seen obviously that applied current [15] is the most effective parameter on MRR. New tools [10], tool shapes [7] or new processes [26, 35] were developed to enhance MRR. Besides, applied voltage is very effective on MRR [9]. Yet, Cao et al. [18] emphasized that high voltage reduced the machining
resolution. Future works will be carried out in ECDM in the light of the results.

Abstract— Nowadays technology is developing rapidly and the adaptation of emerging technology to daily life is very fast. Within this context, production technologies are developing rapidly and parallel to this production instrument's costs are decreased. In this way, producers can make investments more easily by getting current technology. In parallel with industrial development, some parameters such lost time, labor, raw materials must reduce. When considering expected product variety, especially modification on the produced product is a difficult process. Revising of the production system according to the final product is substantially increased the amount of lost time. In addition, in this revision process previously realized investment is becoming inert and this quite increases costs. It is almost impossible the creation of a separate production line for each product in a company which has a lot of variety of products. Nowadays in this needed speed production process, instead of conventional production systems flexible manufacturing systems began to be preferred in the industry.

In this study, functions, components and the overall structures of the flexible manufacturing systems are described. Differences between traditional production systems and flexible manufacturing systems, and the advantages relative to each other were examined. In the study, Flexible Manufacturing Systems Laboratory within the Inonu University Arapgir Vocational High School was taken as an example.

Keywords— Flexible manufacturing systems, traditional production systems, factory organisation

I. INTRODUCTION

One of the major environmental factors that directly affect activity of the business is the economic system adopted by the country where the business [1].

Industrial businesses are organizations that meet the demands of customers, carry out the production function for it. Businesses should develop and establish a proper system for needs when performing their production.

Production Process is a process in which the materials are introduced as output after certain changes. Other processing activated where a process finished. As soon as a process starts the previous work is completed. Operations can be specified as a node and all the nodes constitute input-output system. [2]

A. Traditional Manufacturing Systems

The construction of traditional manufacturing systems is shown in Figure 1.

![Fig 1 Traditional manufacturing systems [1]](image)

It can be said to show a hierarchical structure of production systems. It is often used in the creation of this system is a hierarchical design approach. This approach can generate significant demand and limited production capability well in environments in which the solutions, but not enough. Classic hierarchical type of production structures, the not fully compatible with dynamic environment and leads to degradation in performance.

Traditional production types are summarized in comparison in Table 1:

<table>
<thead>
<tr>
<th>Machine Types</th>
<th>Features</th>

<td>General-purpose, Mobile</td>
<td>Special</td>
<td></td>
</tr>
</tbody>
</table>
Rapid changes in the technologies increase the efficiency of computer in the production and positive role of being used mathematical models in the production have attracted the attention of business owners and managers.

Some developments emerging in production can be summarized as follows:

- Computer Aided Manufacturing System
- Flexible Manufacturing Systems
- Material Requirements Planning
- Manufacturing Resource Planning
- JIT Production System
- Synchronized Manufacturing

B. Flexible Manufacturing system

Flexible manufacturing systems is defined as the production process can respond, automation and technology-intensive production is done, can be quickly directed to the production of production factors, the products are delivered to customers on time and can be rapidly respond to changes [3].

General characteristics of flexible manufacturing systems can be listed as follows:

- FMS can be used in business which has more varieties of products.
- FMS is used to produce different parts that in the same group.
- It includes general-purpose machinery and machine tools. Small scale changes can be made in the machine/equipment to produce different parts.
- Finished products, semi-finished goods and raw materials are able to move with automatic band and the carrier.
- A main computer controls the general-purpose machinery/equipment and material transport system.
- Production of different parts is possible with automatic changes on the machine.
- Staff intervention on production is minimized.

- From raw material input to finished product output, all process such as quality control, design, production are carried out the basis automation.

The definitions contained in different sources of FMS are as follows:[4]:

FMS is considered as the application of the Computer Integrated Manufacturing (CIM) concept, which composed from Computer Aided Design (CAD), Computer Aided Manufacturing (CAM) and Computer Aided Process Planning (CAPP).

FMS is an automated production type controlled by computers which designed for to produce more than one type parts effectively, consisting of the semi-independent workstations and material handling systems.

Main factors affecting the level of flexibility of a business can be listed as follows:

- Work Organization,
- Production Planning and Control Systems,
- Manufacturing Technology,
- Utilization Level of Computer Technology.

II. FLEXIBLE MANUFACTURING SYSTEM MODULES AT ARAPGIR VOCATIONAL SCHOOL

General view of Flexible Manufacturing Systems Laboratory

![Fig 2 General view (front)](image)

![Fig 3 General view (back)](image)
B. Testing Station

The Testing station detects the various properties of the work pieces inserted into it. It differentiates work pieces with the aid of an optical and a capacitive sensor [5].

C. Separating Station

The Separating station differentiates work pieces based on their drilled hole depth and separates them into two different material flow directions [5].

D. Processing Station

In the Processing station, work pieces are tested and processed on a rotary indexing table. On the rotary indexing table, the work pieces are tested and drilled in two parallel processes. A solenoid probe checks that the work pieces are inserted in the correct position. During drilling, the work piece is clamped. Finished work pieces are passed on via the electrical sorting gate [5].

E. Robot Station with MPS® Modules

This equipment level is created based on the basic design of the MPS® robot station and the two robot handling and robot assembly modules as an introduction to industrial robotics. The upstream station feeds the bodies of the pneumatic cylinders to be assembled to the robot via a slide. The robot determines the orientation of the bodies and places them in the assembly holder in the correct orientation. It takes the piston from the pallet and assembles it in the body. Controlled magazines feed the piston springs and cylinder end caps to the robot. The fully assembled pneumatic cylinder is then placed on a slide [5].
F. Assembly Station

The assembly station works in conjunction with the robot station. It supplies cylinder components for the assembly process [5].

![Assembly station]

G. Handling Station

The Handling station, electrical, is equipped with a flexible two-axis handling device [5].

![Handling station]

H. Pick & Place Station

The Pick&Place station is equipped with a two-axis Pick&Place module. Work piece housings placed on the conveyor are detected by an optical diffuse sensor. The work piece is transported to the pneumatic separator on the conveyor and detected by a second diffuse sensor. The Pick&Place module picks up a work piece insert from the slide and places it on the work piece housing. The complete work piece (housing and insert) is released by the separator and transported to the end of the conveyor [5].

![Pick & Place station]

I. Fluidic Muscle Press Station

The Fluidic Muscle Press station presses work piece inserts into the housings. The rotary/linear actuator (transfer device) moves the housing with the insert placed on it under the press. The pneumatic muscle performs the pressing operation. The finished work piece is then transported to the transfer position [5].

![Fluidic Muscle Press station]

J. Sorting Station

The Sorting station sorts work pieces onto three slides [5].

![Sorting station]
III. CONCLUSIONS

In this study, images of the equipment, experiment sets are designed by Festo Didactic training purposes. Each module can be matched with other modules. In this way it is possible to obtain improved diversity of the final product.

The manufacturing sector is constantly evolving according to evolving technology and growing needs. Requested product diversity has led to become outmoded of a single type production line. Therefore, instead of building new production lines to produce different types of the same product, revising this line is easier. In this regard with flexible production systems efficient results are obtained. Despite the high investment costs, in the long term it is seen that provided gain at costs and time.

Electronics of a Holonomic Rescue Robot with a Screw Drive Mechanism for Soft Terrain Mobility

Majid Mohammad Sadeghi, Emin Faruk Kececi

Department of Mechanical Engineering
Istanbul Technical University
Istanbul, Turkey
kececi@itu.edu.tr

Abstract—In rescue robotics, one of the most important features of the robot is the mobility, where the robot must be able to move inside the rubble to reach victims. In order to accomplish the difficult task of mobility, robots with different drive mechanism principles are built: ranging from serpentine motion to wheeled and tracked platforms. Another important feature of the mobility is holonomy, where the robot can move in any desired direction so that it can maneuver better in tight spaces. This paper reports design, prototyping and testing stages of a new mobility mechanism, namely a screw wheel drivetrain, where the wheels of the robot are screw shaped wheels. The special wheel design allows the robot to be holonomic and to perform well on soft terrain. The test results on the prototyped robot prove the system efficiency.

Keywords—Holonomic; screw wheel drive; rescue robot design; soft terrain mobility

I. INTRODUCTION

In the literature, rescue robots are designed to go over rough terrain with a high load carrying capacity [1]. However, when dust and broken pipelines are considered, the earthquake zone is a rather soft terrain and the mobility of the robot plays a vital role in the success of the mission. The real challenge in the design phase of a rescue robot is how to fit the necessary parts into the given dimensions so that the robot's size can be as small as possible and the load carrying capacity can be as high as possible. Since the distance needed to be traveled inside the rubble is not long, the speed of the robot is not so crucial. Especially when it is considered that a rescue robot needs to travel in a confined space, mobility becomes one of the most important features of the robot [2].

In this research, the mobility problem is solved with a holonomic drive mechanism, where the robot has the ability to maneuver inside a tight space because it can move in any desired direction with operator control. The uniqueness of the drive system is the wheel structure where the wheels are screw shaped and the driving motors are placed inside the wheels to create a more stable structure.

The drive mechanisms of rescue robots are wheeled, tracked, legged or any combination of these different systems [3, 4, 5, 6 and 7]. Shifting the center of gravity has also proven to help the mobility of the robot [8 and 9]. Moreover, there are also robot designs where serpentine and inchworm mechanisms are utilized [10 and 11]. The robots are compared to each other with many performance criteria such as: overcoming geometrical difficulties, volume capacity, weight capacity, energy necessity, reverse fall, failure durability, weight, dimensions, clearance, maneuver capability, falling resistance, velocity, number and size of motors, control difficulty, programming ease and manufacturing ease [12]. Even though it is not clear to the rescue robotic researchers which driving mechanism is better than the other, since different tasks will give different importance factors to the different properties, the mobility (overcoming geometrical difficulties) has the highest priority since the robot cannot achieve its task if it cannot reach to the desired operation point.

In order to solve the problem of mobility inside a confined space, omni-directional ability becomes very important. Omni-directional ability is reported in the literature with a spherical robot [13], differential drive [14], ball wheels [15], Synchronous drive [16] and Mecanum wheels [17] Fig. 1.

Spherical robots look like balls and they have the propulsion mechanism inside them. Just like a real ball they can roll in any direction over the terrain. However, the traction force is limited when it is compared to tracked robots. In order to increase the traction force, soft material is used for the outside wall of the robot, increasing the surface area of contact. The success of spherical robots is not clear because they are still at the ongoing research stage [13].

Differential drive robots consist of two independently driven wheels and robot body supporting castors. These types of robots are not completely holonomic, since they need to turn first in order to be able to move to the desired direction. This drive mechanism is good for indoors, but struggles outdoors, since the robot is a wheeled robot [14]. Tracked robots also act as differential drive robots but they have the same problem of not being holonomic.

In a ball wheel drive mechanism, the ball which has contact with the ground is driven by other interior wheels. Holonomy can be achieved, but when sand, mud or grass stick on the ball, the system’s characteristics change. Another fundamental problem with the ball wheel drive mechanism is that the theoretical clearance of the robot body can only be as high as the radius of the driven ball since the ball needs to be supported by the body of the robot in order to not fall [15].
A synchronous drive system is similar to a ball wheel drive system in that the wheels are driven by motors and they rotate about their own axis, usually with a belt or chain system. From the mobility point of view, a synchronous drive is not different than a ball wheel drive. On the other hand, the clearance of the robot can be increased if the drive motors are attached to the legs; however, this type of a robot is still a wheeled robot, where holonomy is achieved but the wheeled body disadvantages still exist.

The Mecanum wheel has a driven hub and idle rollers around it, which are 45 degrees to the axis of the hub. Typically 4 wheels are used on a vehicle where two left and two right handed wheels are used. When the wheels are driven in any direction, the vehicle can move and rotate in any desired motion.

Soft terrain can be described as a surface where the slippage and sinking occurs at the wheels of the robot. Sand, grass, mud, gravel, dirt and snow covered surfaces can be named as soft terrain. Slippage causes a difference in between the traction forces at the drive wheels, causing an orientation effecting the steering are explored and the parameters of the steering are explored as well as wheel model and wheel grousers design.

There are early screw wheel design robots; however, one design still uses rollers around the drive wheel which will have similar problems as Mecanum wheels and the other design lacks the kinematic and dynamic analysis, the control design as well as the total concept of skidding control in this type of structure.

The contribution of this paper is that it reports a prototype rescue robot especially designed for soft terrain mobility with a unique screw drive mechanism. In the following sections, the problem definition, the mechanical design and prototyping of the new screw driven omni-directional robot, the electronics system design and programming are explained. Test results prove the effectiveness of the concept and the necessity for slippage control.

II. PROBLEM DEFINITION

Soft terrain can be described as a surface where the slippage and sinking occurs at the wheels of the robot. Sand, grass, mud, gravel, dirt, snow, ice, dust and clay on the surface makes the surface a soft terrain. Slippage causes a difference in between the traction forces at the drive wheels, causing an orientation...
and speed error during the trajectory tracking of the robot body. Sinking of the wheels into the soft terrain also causes nonlinear traction forces and the has the same effect as the slippage. Moreover, the traction force generated by the wheels may not be enough for the robot to move again. Another issue with the wheeled, legged and tracked drivetrain systems is that the particles get inside the driving mechanism and stop the robot to work.

When other robot platforms’ performance on the soft terrain is investigated, the weight on the unit tire area becomes the most important factor. If the unit weight becomes higher, sinking occurs and if the unit weight is too less, the possible traction force which can be generated from each tire becomes too less to generate motion [27].

Spherical robots have a weight shifting mechanism inside the robot where by moving the center of gravity, moment is generated to roll the robot on the ground. The all-closed design gives the robot the advantage not being affected by the outside surface; however, the moment which can be generated is limited, causing the robot to have traction problems [13]. Differential drive, ball wheel, and synchronous drive are all wheeled robots. These robots are good for indoors but soft terrain such as sand, dirt, mud and grass stop these types of driving mechanisms. About Mecanum wheels it is reported that, slippage and vibration occur. Moreover, the ability to overcome obstacles is dependent on the direction of the motion [28]. In practice, sand and mud get stuck and stop the barrels to work on the Mecanum wheels.

Tracked robots have a bigger surface area to distribute the weight of the robot on the surface. However, sand, gravel, mud and grass get caught in between the drive train elements, the driven wheels and the track. Even in the track system with an idler, the mud or wet grass sticks to the innersection of the track and causes the track’s inner length to decrease. Since the position of the driving and driven wheels are not changed; the idler, if it exists responds. When the idlers cannot respond anymore, the pulling force on the track increases until the track breaks.

Another problem observed in practice is that the pulling resistance of grass is very high compared to its cutting. On grass terrain, when the robot is moving, the grass gets caught in between the rear wheel and the track. It does not rip apart and it can stop the robot if the robot cannot provide enough traction force to tear apart the grass.

A spring shaped wheel robot is reported [29] where the robot has 3 compression spring shaped wheels, aligned 120 degrees to each other around the platform. The robot is designed for rough terrain and since the wheels in this design are not filled inside, the pressure of the robot weight is not distributed to a wide area, so the robot will sink in soft ground. Moreover, because there are 3 screw wheels, the control is more difficult when it is moving in any given direction and the motors cannot be used at their highest speed.

In order to create a reliable platform to drive on soft terrain, a screw wheel driven robot is designed, manufactured and tested. The following sections explain the theory of the new wheel design as well as the physical manufacturing of the robotic system.

III. SCREW DRIVE ROBOT DESIGN, DYNAMICS AND CONTROLLER

The screw drive robot has 4 independently driven wheels with a screw shape allowing the robot to have the holonomic ability to move on the surface, Fig. 2 [30].

When the dynamical model of the robot is derived the equation of motion is found as

\[
D \ddot{q} = f(\dot{q}, \mu_i) + g(\dot{q}, \mu_i, \tau)
\]

(3.1)

where \(\mu_i\) is the friction coefficient effecting the \(i\)th wheel, the state vector \(\dot{q}\) and the control input vector \(\tau\) are formulated as \(\dot{q} = [u, v, r]^T\) and \(\tau = [\tau_1, \tau_2, \tau_3, \tau_4]^T\). The positive definite mass matrix \(D\), the term containing the unaffected dynamics from the control input \(f(\dot{q}, \mu_i)\) and the term containing the controllable dynamics \(g(\dot{q}, \mu_i, \tau)\) are formulated respectively as

\[
D = \begin{bmatrix}
    m & 0 & 0 \\
    0 & m & 0 \\
    0 & 0 & J
\end{bmatrix}
\]

(3.2)

\[
f(\dot{q}, \mu_i) = \begin{bmatrix}
    -mrv + CA(\mu_i - \mu_2) - CB(\mu_i - \mu_4) \\
    \frac{1}{R} (\tau_1 + \tau_2 + \tau_3 + \tau_4) \\
    \frac{1}{R} (\tau_1 - \tau_2 - \tau_3 + \tau_4) \\
    \frac{1}{R} (\tau_1 + \tau_2) + \frac{1}{R} (\tau_3 + \tau_4) - \frac{1}{R} (\tau_1 - \tau_2 + \tau_3 - \tau_4)
\end{bmatrix}
\]

(3.3)

\[
g(\dot{q}, \mu_i, \tau) = \begin{bmatrix}
    \frac{1}{R} (\tau_1 + \tau_2 + \tau_3 + \tau_4) \\
    \frac{1}{R} (\tau_1 - \tau_2 - \tau_3 + \tau_4) \\
    \frac{1}{R} (\tau_1 + \tau_2) + \frac{1}{R} (\tau_3 + \tau_4) - \frac{1}{R} (\tau_1 - \tau_2 + \tau_3 - \tau_4)
\end{bmatrix}
\]

(3.4)

A and B are described as

\[
A = \arctan\left(\frac{v + r l_f}{u - r l_i}\right)
\]

(3.5)

\[
B = \arctan\left(\frac{v + r l_f}{u - r l_i}\right)
\]

(3.6)

where \(m\) is the robot mass and \(J\) is the moment of inertia about the vehicle mass center, where \(r\) indicates the wheel, \(ti\) is
the driving torque applied to the i’th wheel and R is the wheel radius, u is the longitudinal velocity; v is the lateral velocity, \( \mu_d(\sigma) \) is the road surface friction coefficient which is a function of \( \sigma \) wheel slip ratio and \( l_p \) and \( l_r \) are the distances between the CM location and the front and the back axles respectively.

An adaptive controller is designed as

\[
\tau_d = Y \hat{\theta} - K_D \dot{s}
\]  
(3.7)

where \( K_D = K_D^T > 0, K_D \in R^{3\times3} \) is a gain matrix, \( \hat{\theta} \) is the estimate of \( \theta \), updated from an adaptive law. This control law could also be used for the ideal system \( D \dot{s} = -Y \theta + \tau_d \).

With the control law (3.7), the closed-loop system is

\[
D \dot{s} = Y(\theta - \theta_1) - Y_1(\theta_1 - \theta_2) - K_D \dot{s}
\]  
(3.8)

in which to design an adaptive control scheme to handle parameter uncertainties, for \( \dot{q} = [u, v, r]^T \) and \( \dot{q}_d = [u_d, v_d, r_d]^T \), the tracking error \( e \) and the filtered tracking errors \( s \) and \( \dot{s} \) are defined as

\[
e = q - q_d, \quad \dot{e} = \dot{q} - \dot{q}_d
\]
(3.9)

\[
s = \dot{e} + \eta \dot{e}, \quad \dot{s} = \dot{e} + \eta \dot{e}
\]  
(3.10)

where \( \eta \in R^{3\times3} > 0 \) is a diagonal gain matrix, \( K_D = K_D^T > 0, K_D \in R^{3\times3} \) is a gain matrix,

\[
Y(\hat{q}, \dot{q}, h) \in R^{3\times6}
\]

is a known parameters matrix function, \( \theta(m, J, \mu_1, \mu_2, \mu_3, \mu_4) \in R^{6\times1} \) is an unknown parameter vector and is formulated as

\[
Y(\hat{q}, \dot{q}, h) = \begin{bmatrix}
h_\text{e} & rv & 0 & 0 & 0 & 0 \\
h_\text{e} & rv & 0 & -CA & CA & CB & CB \\
0 & h_r & \dot{h} & CA & l_rCA & l_rCB & l_rCB \\
\end{bmatrix}
\]  
(3.11)

\[
\theta = [m, J, \mu_1, \mu_2, \mu_3, \mu_4]^T
\]  
(3.12)

**IV. ELECTRONIC SYSTEM DESIGN**

The remote control of the robot is achieved by use of a joystick, which is in fact a combination of analog and digital input devices. A standard Arduino joystick shield is used, which has 4 momentary push buttons to select and one 2 axis thumb joystick. The thumb joystick is in fact a potentiometer where with the motion of the thumb joystick, the resistance value changes and the position of the joystick can be concluded. Under the 2 axis thumb joystick, there is another built in select switch. This built in select switch becomes very handy, when the joystick is intended to control the rotation of the robot. The first 2 axis are controlled without using the built in select switch. The robot is driven on a 2 dimensional surface. When the robot is desired to be rotated about its own axis, the select switch is used to trigger the program and the joystick can start to control the motors in such combination that the robot turns clockwise or counterclockwise.

The motion of the joystick is transferred into command signals with the joystick microcontroller and it is transferred to the robot with a wireless unit, a Xbee 2.5 module. The parts of the joystick unit are shown in Fig. 3. By using Xbee shield and Joystick shield, it is possible to have a joystick unit with no connection wires, which is therefore less likely to fail.

When the robot is driven on soft terrain, random slippage occurs at any wheel. When the dynamical equations are carefully studied any change of the friction coefficient \( \mu \) causes trajectory tracking error of the robot platform position. The velocities of the platform in lateral and longitudinal axes and the rotational speed about the z axis are the system parameters \( \dot{q} = [u, v, r]^T \).

In order to measure these parameters a 6 axis IMU is used [31]. This sensor (SEN-10121) occupies an ITG3200 triple-axis digital output gyro where the rotational change \( \dot{r} \) measured and anADXL345 triple axis accelerometer where the acceleration in lateral and longitudinal axes \( \dot{u} \) and \( \dot{v} \) are measured. The integration of these measured variables provides the system parameters.

The wheel motors are driven with motor driver boards, namely MC33926, [32]. This H-bridge provides current feedback which is used to calculate the momentary motor torque \( \tau \), with the motor model.

The data received from the IMU unit and the current feedback from the motor drivers provide the necessary information to apply the control logic. For the application of the control algorithm an Arduino Mega 2560 with an ATmega2560 AVR microcontroller is used, [33].
direction is controlled with the joystick position. Toggling the switch makes the joystick program switch from surface motion to rotational motion. In rotational motion the robot turns about its own axis clockwise or counterclockwise.

The motion of the joystick and the switch position describe which signals are to be sent to the robot and the decoded signal is used to drive the motors. Table I shows which commands are sent from the joystick microcontroller to the robot microcontroller and how the motors turn and the robot moves. When the robot is stopped, the joystick sends “5” as a stop signal.

VI. TEST RESULTS

The wheels of the robot rotate like Mecanum wheels and Table I shows the directions of the motors depending on the desired robot motions. Tests conducted in which the steering, mobility, load capacity, remote control, endurance, weight, speed, incline angle and rolling angle of the robot were evaluated.

On the soft terrain, the robot performs very well, since weight distribution is achieved. When the weight of the robot (4020 grams) and the wheel dimensions (70 mm diameter) are considered, the robot has 0.095 gr/mm2 pressure at the maximum sink level. This low pressure level at the wheels allows the robot to drive well on the soft terrain, allowing it to stay on the surface of a sandy terrain.

When the robot moves on muddy or grassy ground, the grass does not cause any problem since it cannot get in between the moving wheel and the stationary drive motors. Inside each wheel unit a Dunkermotoren G30.2 motor with a PLG 30 gearbox is used where the rated speed of the motor is 3000 r/min and the reduction ratio is 36. Considering the wheel diameter being 70mm, the theoretical speed of the robot is calculated as 18.32 m/min. However, in reality the speed of the robot in longitudinal axis is found as 5.2 m/min and in lateral axis is measured as 16.4 m/min. The speed difference comes from the different working principles of the wheels in these different axes. In lateral motion, the wheels are rolling and the speed of the motor is close to the theoretical speed. However, in longitudinal motion, the screw threads need to move the robot and because of the slippage, the speed of the robot decreases. On a muddy surface, the speed of the robot decreases in both directions, but the decrease depends on the surface friction and cannot be compared to the flat surface speed.

When the robot is moving on a hard surface, lateral and longitudinal motions do not have significant slippage. However, longitudinal motion has a slippage problem, causing the robot steer to the right or left depending on the surface friction difference. The robot requires on board slippage control to adjust the wheel speeds to compensate for skidding errors. In order to eliminate the slippage errors, the track depth on the wheels can be improved for better traction, at the moment the depth is 3.5 mm and the width is 10 mm. The wheel surfaces can also be improved by covering the surfaces with softer material to achieve better traction.

The wireless connection is achieved with an XBee module and it is measured that within 112 meters in an open field it could receive reception. Inside a building, because of the walls, this distance drops down to 14 meters. The wall thickness and quality changes the reception distance.

The robot motors require a total of 0.78 ampere current on a flat surface with 12V DC. Considering the battery has a 3.2 Amphour energy capacity, the robot has approximately 4 hours of endurance. On the experimentation, the robot battery was able to last 2.7 hours and when it was measured the voltage level was at 9 Volt. At this voltage, the motors cannot generate meaningful moment to drive the robot anymore on a soft terrain.

Ditching capacity is measured and found as 140 mm, which is higher on the lateral direction of the robot. Load carrying capacity of the robot depends on the brackets connecting the wheels to the main body plate. 3 kg is successfully carried by the robot, but a change in center of gravity should be taken into consideration when the load is placed at the back or the front of the robot.

The center of gravity is at 56.88 mm above the surface where the clearance of the robot is 65 mm. This low center of gravity assures the robot to be stable on a tilted surface. However, when compared to the theoretical sideways (65.53 degrees) and frontward tilting angles (80.68 degrees), the actual sideways angle is 17.033 degrees and frontward tilting angle is 11.655 degrees measured on a wooden surface. The reason for this difference is the friction coefficient in between the surface and the robot wheels. This fact also shows how the current wheel material, polyethylene, is good for manufacturing but not suitable for traction reasons, and the wheels should be covered with a softer material.

The wheel brackets play a vital role on clearance, center of gravity and load capacity of the robot. Increasing the height of the brackets will increase the clearance; however, it will also

Fig. 5 Tracking performance in the Y axis (lateral motion).
raise the center of gravity, causing the sideways and frontal tilting angles to decrease. Making the brackets from thicker material will only increase the weight of the robot by fractions; however, it can improve the load carrying capacity.

Since the robot motion is created when the wheels are cancelling lateral motion when it is moving on the longitudinal axis, the tracking error needs to be compensated on both axes at the same time. In order to test the controller efficiency, the tracking performance of the robot motion is tested both in the longitudinal and lateral axes on the flat sandy surface. The reference trajectory input is given as programmed and the actual value of the trajectory is measured via IMU.

Fig. 4 and Fig. 5 shows the longitudinal and lateral motion respectively. Both in Fig. 4 and Fig. 5, the red line shows the reference trajectory while the blue line shows actual trajectory. In Fig. 4 at first 6 seconds while the robot is only moving in longitudinal direction the tracking is achieved as seen on Fig. 5 the motion on the lateral direction is also successfully cancelled to keep the lateral tracking as desired. Similar trajectory tracking is achieved in between 8 to 15 seconds while the lateral tracking is controlled, longitudinal tracking is also achieved.

VII. CONCLUSIONS

In this study a screw wheel drive mechanism for a rescue robot is examined. This design is durable for soft terrain especially for sandy, muddy and grassy surfaces. The wheel structure as well as the mechanical and electrical structures of the robot are explained in detail. A physical prototype was built and tested for mobility, speed and endurance. The test results show that the screw wheel drive mechanism works well on soft terrain conditions. Because of the different slip ratios at each wheel a controller was implemented to compensate for the tracking error.

Abstract—One of the most common used methods for determining mechanical properties of engineering materials is tensile test. In this study, portable micro tensile tester that low strength materials have enough capacity to do tensile tests has been designed and produced. Stress and strain in tester have been real time followed by wireless communication with an interface prepared in LABVIEW. Performed tester is workable-sized with needed atomic force microscopy to study micro- and macro structure of materials together. Due to being portable-sized of tester, it can be used in classroom in materials science education. Snapshot of sample and stress-strain curve are real time followed with the camera placed on the tester at the same time.

Keywords— tensile tester, tensile test, mechanical properties, stress-strain behaviour, material science education

I. INTRODUCTION

Deformations on the material under the effect of external forces and endurance strength that the material showed under the said effects are named as mechanical properties of materials. Mechanical properties of materials are a very important factor in engineering designs.

The most common testing method used in determination of mechanical properties of materials is tensile test [1]. In a tensile test, test samples prepared are held from their two edges and exposed to the load by uniaxial tensing [2]. Data of strength and elongation generated on the sample are recorded during the test. Tensile test ends upon the breakage of the test sample.

The tester used in order to examine micro structure of materials are named as atomic force microscope (AFM). In order to design and manufacture micro and nanocomposite materials, the connection between mechanical properties of material and the microstructure should be understood well [3]. In this study, in order to understand the connection between microstructure and mechanical properties of materials, a portable horizontal micro tensile tester has been developed, which provides the association between AFM and the tensile test. Standard testers are usually positioned vertically and are in large scales. Those sorts of testers are not possible to work with AFM.

In order for mechanical properties of materials to be understood and evaluated by students can be difficult. The tester carried out can be used in classroom in materials science education due to its portability unlike other testers. During the test, in order to help students to understand mechanical properties of materials, a camera has been placed on the tester. In this way, snapshot of changes in the material during the test and strength and elongation data of the material can be real time followed. Control of the tester has been performed via Programmable Logic Controller (PLC). In order for elongation and load data to be displayed and for tester to be controlled by the user, an interface has been designed on LabVIEW platform. For the communication between the interface and PLC, OLE for Process Control (OPC) has been used.

II. DESIGN OF THE TENSILE TESTER

A. Design Concept

Block diagram of the tensile tester carried out in the study is given in the Fig. 1 A test sample connected to the tester is exposed to a tensile stress at a speed determined by the user. Tensile stress is performed with the step motor’s spinning and the moving holder’s advancing. Deformation and load are emerged on the sample remained between the fixed and moving holder. Elongation data occurred on the sample is measured via magnetic linear encoder respectively. Strength occurred on the sample is measured via load cell. With the data obtained, stress-strain behavior belonging to the sample is acquired.

On the simplified drawing of the mechanism of the tester given in the Fig. 2, upon the rotation of the propulsion motor F, the movement is transferred to the thread rod B over belt-pulley H. Upon the thread rod starting to spin, panel C moves and generates tensile stress on the sample A. Stress on the sample is measured via load cell E. Amount of elongation occurred on the sample is measured via magnetic linear encoder connected to the moving panel.

In order to generate tensile stress, single threaded rod embedded with linear rails on two sides has been used on tester. The reason for preferring the single threaded rod is to ensure the stress axis being equal on the sample. Possible deflections will occur on sample edges equally and simultaneously [3]. It guides linear rails and the moving clamps of the tester to advance through the movement axis linearly. Belt-pulley mechanism on the device, has been preferred instead of coupling connection in order to prevent the increase in linear size of the tester. This tester has been designed in micro size
and horizontally in order for AFM to be able to take images over the sample.

Before manufacturing the tensile tester, three-dimensional modeling of all electronic hardware and mechanical parts on the device has been performed. Thanks to three-dimensional modeling, faults that may occur after the manufacture have been determined and possible financial losses have been prevented. Mechanical parts that could not be off-the-shelf procured have been manufactured at CNC vertical processing center. Modeled image and manufactured image of the tester is given in the Fig. 3.

B. Load Measurement

The amount of the load occurred on the sample during the test is measured via load cell branded CAS attached to the tester (e.g. Fig. 3). Load cell with 500 kgF capacity has been preferred due to its size and reasonable cost. Tensile stress sensitive load cell generates stress in proportion to amount of load that it carries. Stress generated has been connected to the analog inputs of PLC by using load cell amplifier.

C. Measuring Elongation Data

Amount of elongation occurred on the sample by the tester is measured via magnetic linear encoder (e.g. Fig. 4) The amount of elongation, occurred on the sample upon the advancement of the moving clamp attached under the moving clamp of the tester, is measured via magnetic linear encoder. Measurement precision of the amount of elongation is limited with the resolution of linear encoder. Resolution of elongation measurement of the tester is 5 µm. Encoder having transistor output produces pulse signal at every 5 µm distance. These pulse signals are applied to PLC inputs and each pulse signals are counted by PLC. At the end of these countings, amount of elongation occurred is calculated until the sample breaks off. Magnetic linear encoder has been preferred due to its very small size and reasonable cost. If the one wishes to increase the measurement precision, linear encoders with high resolution can be preferred.
D. Motor

In order to generate 3 kN maximum tensile stress with the tester, step motor with encoder and reducer having 3.0 Nm torque is used (e.g. Fig. 6). The motor used has 5:1 gearbox. Via the interior encoder connected to motor shaft, steps of the motor are followed and a new step is procured instead of the missing steps of the step motor. In this way, closed loop control is made and the reference speed determined is kept constant during the test.

Step motor used has 1.8 ° step range. The step motor is driven in a way that it would revolve 1 round with 40,000 pulse signal by using half-step driving technique. Based on the reduction rate of the motor, although theoretical advancement precision is in nm resolution with threated rod, measurement precision of the tester is 5 µm based on the linear encoder.

E. Control System

PLC devices are the devices that may contain all devices necessary for controller technique, that can do programming via both programming consoles and computers, and automatically control the automation system that we wish to control with the program written, and that work on the basis of the digital system. PLC system controls many machines and systems with its analog-digital input/output connections, and it is an integrated system that makes assignments to the output units by using numeric processes, and timing, numerator, data processing, comparing, sorting and input information for this purpose, and that consists of input-output, memory, CPU and programming parts. Additionally, there are many internal (assistant register) relays and time limit relays within the device.

Control of the tester has been performed via Siemens S7-1212C PLC. A product of Siemens firm, S7-1200 PLC has a project design software, and an Ethernet port for the purpose of easy connection and communication between controllers and HMI units. There are 6 high-speed numerators on S7-1200. 6 high-speed numerators, consisting of three-input 100 kHz and three-input 30 kHz, can be used in order for counting and frequency measurement. Four integrated high-speed outputs can be used in order to do pulse train (PTO) up to 100kHz speed or pulse width modulation (PWM). When it is set as PTO, it is possible to perform speed and position controls of servo or step motors. When it is set as PWM, it is possible to control the motor speed, position of the valve or the heater circuit.

PTO signal required for the control of the step motor in the tester is generated by PLC: With PTO, departure and halting ramps can be adjusted for advancing at desired speed in the linear system and for the step motor.

Linear encoder used on the tester has been connected to the high-speed input of PLC and elongation data is calculated based on these input signals. By turning load cell signals into digital signals via ADC input placed on the PLC, real time load measurements have been performed.

Control unit of the tester is assembled on the switchboard (e.g. Fig. 7). All connection wires between the switchboard and the tester are separated from each other via sockets. In this way, the tester is divided into two during replacement and can be carried by one person.
F. Graphical User Interface Software

In order to operate the tester and to follow the data, a user interface working on computer has been designed on LabVIEW platform. Through this software, programs are written via a graphical view by connecting functional dots to each other with the help of lines containing data flowing within. This programming language is named as “G”.

The user interface has been generated by providing communication between S7-1212C PLC used on the tester put into practice and LabVIEW software (e.g. Fig. 8) This communication is provided via NI OPC Servers which is a LabVIEW extension package supplied by National Instruments (NI). OPC (Ole for Process Control) is a standard constituted for the communication of real time data. It is used for the communication between SCADA systems and the devices, such as PLC, sensor and actuator which are used especially in industrial automation systems.

Memory spaces of S7-1212C PLC has been reached by using NI OPC Servers software. Control of the tester has been performed by conducting reading and writing processes on the determined memory spaces by the interface. Additionally, by using the extension named LabVIEW NI Vision Development Module, snapshot of the sample can be monitored on the interface screen via the camera on the tester.

The communication between PLC and LabVIEW has been provided by using Ethernet based wireless communication system. The device has been made available for access through wireless network by connecting an access point on the Ethernet port placed on PLC. In this way, the wireless connection between the interface and the tester is provided.

G. Specifications of the Tensile Tester

Samples in special sizes are used on the tester manufactured. Sample sizes and technical properties of the tester that can be used are given below:

- Maksimum sample size: 2mm thick, 80mm long, 10mm wide
- Minimum sample size: 0.1mm thick, 50mm long, 1mm wide
- Maksimum tensile force: 3.0 kN.
- Maksimum strain: %100 (for a 60mm long sample)

III. EXPERIMENTAL STUDIES

Via the tester manufactured, tests at various speeds have been implemented on acrylonitrile-butadiene-styrene (ABS) sample. ABS material is a light and firm polymer that is used in products manufactured with mold and 3D print technologies. Pipes, automotive parts, protective helmets and plastic parts of electronic devices are only some of its areas of use. The sample used in the tester has been manufactured by using 3D printer.

In experimental studies, the sample has been exposed to tensile stress at 1mm/min speed. At all of the separated tests, it has been determined that the maximum tensile stress, elasticity module and maximum elongation values occurred until breakage were matching to each other. Graphs obtained (e.g. Fig. 9), has been taken via interface generated on LabVIEW platform. Images of the same sample have been taken at 5mm/min speed. In the graph (e.g. Fig. 10) obtained, a significant amount of decrease in elongation of the test sample. It has been seen that the maximum tensile stress had been decreasing as a result of the tensile test (e.g. Fig. 11) conducted at 1mm/min on ABS material having a low fill rate.
IV. CONCLUSIONS

As a result of this study, a compact, low-cost and portable tensile tester has been realized. Considering its sizes, the tester can work under AFM. It has been determined that the stress should be at the same area while AFM is taking images. Best results would be gained by using two moving clamps on the tester manufactured, instead of one moving clamp. Due to cost increase, this modification will be performed later.

Due to reasonable cost, small sizes, wireless communication feature and integrated camera of the tester, it can be used in materials science educations.

Abstract— In this paper, a servomechanism subject to teleoperation is considered. Since the teleoperation itself can result in large amount of time-delays, it can be difficult to control such mechanisms in order to accomplish the desired task. From the robust control viewpoint, a methodology that guarantees the stability in worst case is essential. Based on a simple methodology to find the delay independent stabilizing gain regions, by forming the magnitude polynomial and employing the root locus technique, the stability of the robot is guaranteed, even in the worst case: the system becomes stable even if the connection has huge amount of time delays. This fact is evidenced first by the simulations. To perform the simulations, without any knowledge about the motor parameters, the motor is modeled by a global optimization methodology, named Genetic Algorithm in order to obtain a valid model for the system as accurate as possible. Then the resulting gains are applied to the real system, the results of which are found in accordance with the simulation results; the stability of the operation is not affected by the time-delay.

Keywords— Teleoperation System Control, Time-Delay Systems, Robust Control, Low-Order Controllers, Delay Independent Stability

I. INTRODUCTION

Teleoperation is one of the invaluable control methodologies which is especially ideal for the unfavourable environmental conditions, such as underwater or mountainous terrains and for the processes that is dangerous for human life, such as nuclear plants, toxic chemical reactions etc. This methodology has been more widely used especially for a few decades due to the advances of the internet based technologies [1]-[2]. Nevertheless, the most important drawback of this methodology is the phenomenon of the propagation time-delay, amount of which can be huge. Moreover, the amount of time-delay can be affected from operational conditions and hence can be changed operation to operation [3]-[7].

From the mathematical point of view, for Linear Time Invariant (LTI) and Single Input Single Output (SISO) systems, time-delay term adds infinite number of poles in the closed-loop. As a result, analyzing the performance of time-delay systems, even assessing the stability becomes more complicated in such systems [8]-[12].

As might be expected from the operational and the mathematical viewpoints, the amount of the time-delay may considerably attenuate the overall control performance, even it may lead the system to instability. As the stability is the first and the foremost important requirement of the design, an effective methodology providing the time-delay independent stability is essential from the robust control viewpoint.

In [13], an effective and simple methodology to compute all gains providing time-delay independent stability is given for SISO-LTI systems. This method is based on the stability analysis given in [8] and it consists of forming the magnitude polynomial, sketching the resulting root locus with the suitable transformations of the variables and searching the regions of gains for which any positive real roots do not exist.

Using the methodology given in [13], a servomechanism subject to teleoperation is considered in this paper. The motors are selected as Dynamixel MX-106T [14] and as the motor parameters are not explicitly given, the global optimization method, named Genetic Algorithm (GA) is employed to obtain a proper model of the motors. Then using the obtained mathematical model, all gains providing time-delay independent stability is computed as proposed in [13], and it is shown that the simulation results are as expected. To verify the simulation results in the real environment, the resulting gains are applied the servomechanism subject to teleoperation under different scenarios, i.e. for different values of time-delay. Then it is shown that, the application results are in accordance with the simulations, i.e. the stability of the system is not affected by the time-delay even if the time delay takes huge values, such as 12 seconds.

The paper is organized as follows: The second section is devoted to the theoretical background, in order for the readers to follow the paper easily. In this section, the methodology given in [13] is presented and the brief summary about the GA is given, respectively. In the third section, it is explained how
the mathematical model of the motors are obtained and the methodology given in [13] is applied to this model, i.e. all the gains providing time-delay independent stability is calculated. In the fourth section, the simulation and the real system results are shown, in a comparative manner. In the last section, further discussions are given and the possible extensions of this study is stated.

II. THEORETICAL BACKGROUND

In this section, the methodology for the computation of all gains providing time-delay independent stability proposed in [13] will be briefly explained and the Genetic Algorithms (GA) will be briefly overviewed, respectively.

A. Calculation of All Gains Providing Time-Delay Independent Stability Using the Root Locus

In this subsection, the methodology given in [13] will be briefly explained. Since this subsection is a summary only, the reader is referred to [13] for further discussions and explanations.

To begin with, let the interested control scheme is given in figure 1.

![Diagram](image-url)

Fig. 1 The interested control scheme

Where the G(s) and the C(s) is given as follows:

\[ G(s) = \frac{N(s)}{D(s)} e^{-st} = \frac{b_n s^n + \ldots + b_1 s + b_0}{a_m s^m + \ldots + a_1 s + a_0} e^{-st} \quad C(s) = k_p \quad (1) \]

Where N(s), D(s) and C(s) denote the numerator - the denominator polynomials and the P type controller respectively. Additionally, L symbolizes the nonnegative time-delay of the system.

Apparently, when L=0, i.e. the system is delay-free, the characteristic structure of the closed loop system constitutes a polynomial; i.e the closed loop poles are finite in number and it is easy to determine the stability of the system. However, when L takes the values greater than zero, the closed loop structure begins to constitute an expression named quasipolynomial, which possess infinite number of roots; resulting in infinite number of closed-loop poles. Additionally, these poles move in the s plane with the change of the L value.

To track these movements in terms of stability problem [8], let an infinitesimally small L is introduced to the system. In that case, the number of the closed loop poles become infinite, and these new poles appears at infinity in the s plane. From the stability viewpoint, all of these roots must occur in the left half s plane. To sum up, if the following conditions are satisfied, all the new roots occur in the left half plane:

i) m<n, i.e. the system is strictly proper, or

ii) m=n, i.e. the system is biproper and \(|k_p b_n/a_0|<1\)

In other words, if the system is strictly proper, all the new roots occur in the left half s plane without any further condition. If the system is biproper, an additional condition have to be satisfied about the ratio of the principal coefficients, i.e. \(|k_p b_n/a_0|<1\).

Assuming that either of these conditions are satisfied, the roots begin to move in the s plane with the increase of the L. When L reaches to a critical value, say Lcr, a pair of roots begin to locate on the imaginary axis just before changing their half planes, which is crucial as it implies a possible stability change. When such a situation happens, the closed loop expression satisfies the following equation:

\[ D(j\omega) + e^{-j\omega L}k_pN(j\omega) = 0 \Rightarrow e^{-j\omega L} = -\frac{D(j\omega)}{k_pN(j\omega)} \quad (2) \]

Obviously, this expression implies two condition to be satisfied:

\[ |-D(j\omega)/k_pN(j\omega)| = 1 \quad (3) \]

\[ \angle -D(j\omega)/k_pN(j\omega) = -\omega L \quad (4) \]

The first one can be considered as the magnitude condition, which determines the location of the closed loop pole pairs on the imaginary axis, just before changing their half planes. The second one can be thought as the phase condition, from which, the corresponding L value, i.e. Lcr is determined.

If the magnitude condition given in (3) is elaborated, the following equivalent condition can be obtained:

\[ W(\omega^2) := D(j\omega)D(-j\omega) - k_p^2N(j\omega)N(-j\omega) = 0 \quad (5) \]

As might be expected, the roots of this equation correspond to the solution of (3). Apparently, (5) is a polynomial of \(\omega^2\) implying that the closed loop poles crosses the imaginary axis as pairs by locating at \(\pm j\sqrt{\omega}\). Moreover, it is independent of L and its roots change with \(k_p\).

Clearly, the complete imaginary axis crossing of the closed-loop poles, i.e. possible stability changes with respect to time-delay are governed by (5). Then if there can be found some \(k_p\) values and/or regions such that (5) has no positive real roots, it can be stated that for these \(k_p\) values, no pair of closed-loop poles cross the imaginary axis i.e. there is no stability change. Since (5) is a polynomial that is independent of L, this situation does not change with the L values; implying that the stability of the time-delay system is not affected by the time-delay.

In this way, if (5) is elaborated, it can be observed that the problem can be converted into a simple root locus sketch. To accomplish that, let the following variable transformations are done in (5):

\[ v := \omega^2, \quad \alpha := k_p^2 \quad (6) \]

\[ A(v) := D(j\omega)D(-j\omega), \quad B(v) := N(j\omega)N(-j\omega) \quad (7) \]
If both sides of (5) are divided into A(v) along with the other transformations above, (5) can be rewritten as

\[ 1 - \frac{B(v)}{A(v)} = 0 \]  

(8)

Obviously, this defines a negative root locus in the v plane. The all needs to be done is to interpret this root locus whether there exists a gain values and/or intervals such that (8) has no positive real roots. If such an \( \alpha \) gain value and/or interval can be found, for those gains (5) has also no positive real roots, implying that no root pair can cross the imaginary axis, regardless of the value of L. Obviously, by considering (6), those \( \alpha \) gain values are squared gains and needs to be retransformed into \( k_p \) values again. Let such a squared gain interval \((\alpha_1, \alpha_2)\) is found for which (8) has no positive real roots. Then from (6), the corresponding gains can be given as the following intervals:

\[ k_p \in \left( -\sqrt{\alpha_2}, -\sqrt{\alpha_1} \right) \cup \left( \sqrt{\alpha_1}, \sqrt{\alpha_2} \right) \]  

(9)

To sum up, for those gains, the stability of the system given in (1) is not affected by the time-delay; if the delay-free system is stable (unstable) the time-delay system is stable (unstable) for all values of L.

**B. Genetic Algorithms (GA)**

Here, a brief overview of the Genetic Algorithms is given, and the reader is referred to [15] for much more detailed explanations.

Genetic Algorithms are known as their robustness and usefulness as optimization algorithms. In principle, GAs are search algorithms based on mechanics of natural selection and natural genetics. They combine survival of the fittest among the string structures with randomized yet structured information exchange to form a search algorithm with innovative flair of natural evolution [15].

In general, it can be mentioned that GA mainly works at three stages which are briefly described below:

1) **Reproduction**: The stage where the candidates are copied by their fitness function values.

2) **Crossover**: The stage where some parts of the candidates are changed within themselves.

3) **Mutation**: The where the randomization is applied.

**III. IDENTIFICATION OF THE SYSTEM AND THE CALCULATION OF THE TIME-DELAY INDEPENDENT STABILIZING GAINS**

In this chapter, it will be described how the system model is obtained and using the obtained mathematical model, the corresponding gains will be calculated employing the methodology explained in the subsection II-A.

**A. Identification of the System**

As mentioned before, the utilized motors are selected as the Dynamixel MX-106T. It is a permanent magnet direct current (PMDC) motor and all the necessary information and all operating conditions about the motor can be found in [14].

However, since the motor parameters are not explicitly known, a system identification process is taken into account from the real data obtained from the motors. However, before describing the identification process, it is desirable to discuss the model properties of the servomechanisms.

In general a permanent magnet direct current (PMDC) motor can be modeled by the following equations:

\[ \tau_m = \tau_L + J_m \frac{d\omega_m}{dt} + B_m + \omega_m \]  

(10)

\[ V_a = V_b + L_m \frac{dI_a}{dt} + R_m I_a \]  

(11)

\[ \tau_m = K_B I_a \]  

(12)

\[ V_b = K_s \omega_m \]  

(13)

where \( \tau_m \) and \( \tau_L \) represent the motor and load torque, \( J_m \) and \( B_m \) represents the equivalent inertia and the viscous damping at the armature, \( V_a \) and \( V_b \) represents the applied voltage and the back electromotive force (back emf), and the \( K_B \) and \( K_s \) represent the motor torque and the motor back emf constants, respectively. The corresponding block diagram of such a servomechanism can be seen in figure 2.

![Fig. 2. Block Diagram of a Servomechanism](image)

From the equations and the block diagram it is clear that, the transfer function from the input \( (V_a(s)) \) to the output \( (\theta_m(s)) \) results in a third order system and can be given as follows:

\[ G(s) = \frac{K}{s^3 + as^2 + bs + c} \]  

(14)

To obtain a valid mathematical model, the real data are taken from the motor to employ them in the system identification toolbox of the MATLAB. The inputs applied to the motor and the output of the motor can be seen in the figure 3.

Using the data shown in figure 3, and with the priori of the order of the model, the parameters given in (14), i.e. K, a, b and c are obtained, and they are used to determine the initial ranges for the GA. These obtained parameter values are shown in the Table I.

Also, the parameters for GA are shown in Table II. In this table, the population size is the number of candidates, crossover
fraction is the factor for reproduction, mutation is selected as constraint dependent, the nonlinear constraint is the penalty factor and iteration is the number of iterations.

\[
G(s) = \frac{11520.33}{s^3 + 449.371s^2 + 4103.139s + 11599.107} \quad (15)
\]

To show the validity of the model, the model output and the actual motor output is compared in figure 4.

As the last, the obtained motor parameters from the GA is shown in the Table III.

\[
\begin{array}{|c|c|}
\hline
\text{Parameter} & \text{Value} \\
\hline
\text{K} & 11520.33 \\
\text{a} & 449.371 \\
\text{b} & 4103.133 \\
\text{c} & 11597.107 \\
\hline
\end{array}
\]

In other words, the transfer function of the servomechanism given in (14) can be written as follows:

\[
G(s) = \frac{11820.461}{s^3 + 532.478s^2 + 4786.245s + 11816.266} \quad (15)
\]
In the block diagram, the reference input is the angular position input produced by the master operator, C(s) is the proportional controller, the values of which will be calculated in the next subsection, and \( L_1 \) and \( L_2 \) is the propagation delay from master to slave operator and vice versa respectively, along with \( G(s) \) is the obtained transfer function of the servomechanism.

Supposing that the propagation delay from master to slave is \( L_1 \) seconds and from slave to master is \( L_2 \) seconds, the closed-loop transfer function, \( P_c(s) \) becomes as follows:

\[
P_c(s) = \frac{11520.33e^{-L_1s}}{s^3 + 449.371s^2 + 4103.139s + 11599.107 + 11520.33e^{-L_2s}}
\]

### B. Calculation of All Time-Delay Independent Stabilizing Gains

In this subsection, based on the mathematical model given in (16), all the stabilizing gains providing time-delay independent stability will be computed using the methodology summarized in the subsection II-A.

To begin with, it is noticeable to mention that, the polynomials \( N(s) \) and \( D(s) \) given in (1) are as follows in (16):

\[
N(s) = 11520.33
\]

\[
D(s) = s^3 + 449.371s^2 + 4103.139s + 11599.107
\]

along with a time-delay of \( L=L_1+L_2 \) seconds.

To compute all the time-delay independent stabilizing gains, if the polynomial is formed as suggested in (5), the following is obtained:

\[
W(\omega^2) = \omega^4 + 193728\omega^2 + 6411145\omega^2 + 134539283 - 132718003\omega^2 = 0
\]

If the transformations given in (6)-(7) is done, the polynomials \( A(\nu) \) and \( B(\nu) \) is found as follows:

\[
A(\nu) = \nu^3 + 193728\nu + 6411145\nu + 134539283
\]

\[
B(\nu) = 132718003
\]

Considering these new polynomials and variables in (19) and dividing the both sides by \( A(\nu) \) gives the following root locus problem:

\[
1 - \alpha\nu^3 + 193728\nu^2 + 6411145\nu + 134539283 = 0
\]

![Fig. 7. The root locus of (22) (complete)](image-url)
The corresponding root locus is sketched via MATLAB, and can be seen in figure 7. The initial roots of the locus can be found as $v_1 = -193694.92$ and $v_{2,3} = -16.548 \pm 20.513j$. Since the initial roots are extremely far from each other, the zoomed in version of the root locus can be seen in figure 8.

To interpret the root locus, it is clear from the figures that, there is no positive real roots for $\alpha = 0$. When $\alpha$ begins to increase, the complex conjugate roots break into the real axis, and one of them moves to positive real axis by passing the point $v=0$ for a critical value of $\alpha$, say $\alpha_{cr}$. For $\alpha$ values greater than $\alpha_{cr}$, the corresponding root always locate at the positive real axis, thereby, there exists always a positive root on the real axis. Then it can be summarized that there is no positive root of (22) for the $\alpha$ values such that $\forall \alpha \in (0, \alpha_{cr})$.

In order to compute the $\alpha_{cr}$, if the corresponding $\alpha$ is found at the point $v=0$ using the root locus arguments, the following is computed:

$$1 - \alpha \frac{132718003}{v^3 + 193728v^2 + 6411145v + 134539283} = 0$$

(23)

The critical $\alpha$, i.e. $\alpha_{cr}$ is found as 1.0137. Then it can be concluded that (22) has no positive real roots for $\forall \alpha \in (0, 1.0137)$.

To obtain the corresponding $k_p$ values, if $\alpha$ is retransformed into $k_p$ using (9) gives the $k_p$ set:

$$k_p \in (-1.0068, 0) \cup (0, 1.0068)$$

(24)

Obviously, for these gains the stability of the closed-loop time-delay system is independent of time-delay, i.e. the stability of the time-delay system is identical of the delay-free one. Then all need is to check whether the delay-free system is stable for those $k_p$ values. Computation of the stabilizing gains of $P_c(s)$ given in (16) for $L=0$ is straightforward and can be found as follows:

$$-1.0068 < k_p < 159.0434$$

(25)

It is clear from (25) that for the gain values given in (24), the delay-free system is stable. Therefore, it can be concluded that for gain values given in (24) the time-delay system given in (16) is stable, regardless the value of the time-delay.

**IV. SIMULATION – THE REAL SYSTEM RESULTS**

In this section, for the gain values given in (24), the responses of the slave operator to the signals produced by master operator are obtained under different scenarios, i.e. under different values of propagation delays. From both simulations and the real system responses, it can be observed that the system is stable and the real system results are in accordance with the simulation ones.

In addition, for the gain values outside of the given region in (24), it is also shown that the stability of the system is not independent of the time-delay and the system can be unstable for smaller propagation delays.

To overcome the intrinsic steady state error problem, a pre-amplifier is put after the input signal. The utilized simple block
diagram in both simulations and for the real system is shown in figure 9.

Here, the $K^*$ is the gain of the pre-amplifier the value of which is the inverse of the steady state value of the system. Using the gain set given in (24), with a priori of possessing a stable closed-loop system in (16), the gain of the preamplifier can be computed via final value theorem as follows:

$$K^* = \lim_{s \to 0} \frac{1}{T(s)} = 1 + \frac{11599.107}{11520.33k_p}$$  \hspace{1cm} (26)

At first, the controller value, i.e. $k_p$ is taken as 0.5 and the simulation-real system results under different propagation delays are shown in figures 10-11. From the figures, it is clear that the system remains stable even if the total propagation delay is 12 seconds.

After that, the $k_p$ is selected as 0.85, more close to the borders of the $k_p$ set given in (24). In this case, the system remains stable even under the total propagation delay of 12 seconds. The simulation-real system results are shown in the figures 12-13.

As the last, the $k_p$ is selected as 1.05, which is in the close proximity of the given set in (24), but out of borders. Although the selected $k_p$ is very close to the borders of the set, it is clear from the simulation-real system results that, the robust stability is no longer guaranteed, i.e. the system is unstable, although the total propagation delay is 4 seconds. The results can be seen in figures 14-15.
In this paper a servomechanism subject to teleoperation is considered. The teleoperation can possess huge time-delays and these delays may vary operation to operation, which makes developing efficient control strategies extremely difficult. Since the stability is the first and the foremost important criterion for all of the control systems, the robust stabilization of such servomechanisms with respect to huge and varying time-delays is taken account. To achieve this goal, an efficient method in the literature is employed, and such kind of a mechanism is robustly stabilized in both simulations and in a real environment.

Since the interested controller is P type only, the robust stabilization problem is the only focused one in this paper. Along with the robust stabilization problem, the other performance criteria are planned to be taken into account employing more complicated controller structures such as PD and lead/lag in the possible future publications.

Abstract—In this study, a momentum control system is developed with microcontroller to help the vehicle operators safely utilize on-vehicle mobile crane. Balance measures like boom angle and the pressure on cylinder are controlled with a microcontroller and crane control is regulated depending on the previously recorded limits on microcontroller. Developed system aims to minimize operator originated accidents and provides solution to ensure work safety sanctions.

Keywords—Overturn, momentum control system, balance control system, vehicle-mounted mobile cranes

I. INTRODUCTION

Systematic and scientific studies done in order to avoid the conditions which can be harmful for health includes labor and worker safety [1]. In this context, on-vehicle mobile cranes used in heavy work conditions are considered extreme hazardous class in occupational safety and health. Accidents mostly occur while operator is using the crane. Accidents like crane overturn and load drop endangers both labor and worker safety. Figure 1 shows possible outcomes of such an accident.

A force’s ability of turning effect about a point or axis is called momentum. This effect causes cranes to overturn depending on the load pressure on vehicle. System which keeps this effect in safe area by determining load position to vehicle is called momentum control systems. Lately, many studies are conducted to prevent risks and control dangerous situation while operation cranes because of law regulations like occupational health and safety [3]. Studies for important conditions to be considered are investigated while selecting position sensors are analyzed to select sensors for the control system [4]. The system provides a flexible control with feedback which regulates the swings formed because of pressure on boom control cylinder hydraulics with respect to it angle then cranes with and without this control system are compared [5]. An electronic control system is designed and tested in the light of previous studies and according to present conditions-needs to help crane operators operate the crane in safety movement boundaries. In addition, this safety system is a must by the law because of the European Standards.

II. MATERIAL METHOD

This study consists of the input that feeds the control unit and the output generated in accordance with these inputs. With the help of LCD on the control unit, crane operator can see the angle and pressure readings. There is a bypass button for critical situations, a USB jack for serial communication with computers and an emergency button to shut down the system is available on the control unit. Designed control unit is shown in Figure 2.

Figure 1. Mobile Crane Accident [2]

Figure 2. Control Unit
The control unit is designed with 18F4550 microcontroller. This microcontroller reads the angle sensors, pressure sensors and sensors on remote control. In accordance with these inputs, it turns the valves on and off. Microcontroller runs a program which is programmed with Proton Basic programming language. For recording the critical angle and pressure value, an external 24C256 EEPROM is used. This EEPROM keeps the data even if power is cut and thus it is used as a permanent memory.

Since the microcontroller doesn’t have enough input ports for the control system, an CD4067 integrated circuit is used. 32 inputs of CD4067 are controlled by 0,1,2,3, pins of PortA and and outputs of integrated circuit is read form 4., 5. pins of PortA. By this way, only 6 pins of microcontroller are used.

ULN2803 integrated circuit has 8 Darlington transistors. These Darlington transistors are formed with 2 NPN transistors. This integrated circuit transfers the data from remote control valves, buttons and hoist switches to CD4067 integrated circuit inputs. Circuit is fed with 12 V battery because Lm2576T-5 step-down switching regulator, sensors over the crane and valves operate with 12 V. Other integrated circuits like TTL and CMOS operate with +5V. A power module is designed to convert +12V TO +5V and its scheme can be seen at Figure 3. This circuit can convert input voltages in between 7 – 40V to 5V.

Pressure and angle sensors provide analog outputs between 4mA and 20mA. These are converted to voltages between 200mV and 1V with help of a 50ohm resistor connected to their output. This voltage is amplified by factor of 5 using an INA122 instrumentation amplifier to voltages between 1V and 5V. These outputs then read by ADC ports of Pic18F4550 microcontroller and turned into numerical values for angle and pressure. 5 integrated circuits are used as shown in Figure 4.

A desktop application is written in C# programming language for computers. Prepared application is shown in Figure 5.
This software provides an interface for the crane manufacturer, to create a safe movement area for the crane mechanism depending on the mechanical technical properties and capacity and to upload this information to microcontroller. Depending on the cranes current angle positions (Angle1, Angle2) and the pressure values on boom cylinder (Pressure1, Pressure2, Pressure3) are calculated as maximum limit values and sent to Pic18F4550 microcontroller over USB port. In addition, these values are stored in a database to be uploaded to other control units for same type of cranes with the aim of saving time.

III. RESULTS AND CONCLUSIONS

In this study, minimization of operator originated accidents for on-vehicle mobile cranes aimed and tested. In testing phase, the intended and unintended mistakes an operator could do are prevented by the control system and the operator warned both vocally and visually. Inadequate number of input pins of 18F4550 is compensated using CD4067 multiplexer integrated circuit thus system stability and reliability is improved via including necessary information (angle, pressure, boom status, direction of rotation, oil temperature, etc.) provided successful results for this study and future studies. Materials used in this study are easily accessible, so that the momentum control system can be developed and produced in our country. This study shows that, outrigger legs of the mobile crane which stabilizes it, should be included in calculations by determining the expanded length of the legs and adjusting the safe movement areas according to it.

Abstract—In this paper, a simple methodology is proposed based on the dominant pole placement approach for arbitrary order time-delay systems. Discretization of such systems to avoid the formidableness of the infinite number of poles, and applying the strategy proposed in this paper, a pair of the closed loop poles can be assigned to the desired locations, whereas the remaining ones are guaranteed to be located inside a disc with the predetermined radius in the z-domain. To prove the validity of the method, the proposed algorithm is applied to a servomechanism in a real environment; whose approximate model is derived as a second order system with time-delay with the help of system identification toolbox of the MATLAB. Then it is shown that the proposed controller values satisfy the desired performance criteria; and the actual response of the system is in accordance with the theoretical one.

Keywords—Discrete Control Systems, Time-Delay Systems, PID Controllers, Dominant Pole Placement.

I. INTRODUCTION

Time-delay, which is almost an inevitable phenomenon for most of the physical systems, can be loosely defined as the amount of time elapsed until the effects of the input signal can be observed at the output. Although time-delay has some positive effects on a system, generally speaking, it has adverse effects on any kinds of systems [1].

From the mathematical point of view, for Linear Time Invariant (LTI) and Single Input Single Output (SISO) systems, this adverse effect is mostly caused by the fact that the time-delay term brings infinitely many poles to the closed-loop system in the s-plane. As might be expected, dealing with such a situation becomes extremely difficult; either at analysis or at synthesis level.

Moreover, this fact also makes the straightforward stability checks almost impossible for such kind of systems. As another result, not only the analysis-synthesis tasks but also determination of the stability is much more complicated than the delay-free systems. This can be evidenced by the proposed stability methods available in the literature [2]-[3].

Since the first and the foremost important criterion for a controller is to stabilize the system, computation of all stabilizing controllers is important for much of the control tasks. This brings many advantages to the designers such as avoiding recurring stability checks when the performance criteria of the system need to be changed, which may be extremely time consuming especially for time-delay systems. Again, as an expected result, computation of all stabilizing controllers in the controller parameter space is not an easy task for time-delay systems [4]-[7].

However, in most of the control systems, only the stability itself is not sufficient. Therefore, computation of all stabilizing controller set meeting the desired performance criteria (such as overshoot, settling time, etc.) is meaningful; which can be thought as a proper subset of all stabilizing controller set.

Apparently, one of the most popular methods to accomplish this requirement is the dominant pole placement. However, as stated before, since the time-delay systems have infinitely many poles in the closed-loop, such an achievement is extremely difficult, especially for PID type low-order controllers with limited parameters. On the other hand, the PID controller and its variants have been still the leading utilized controller form in industry up to 95% [8]. Due to the popularity of this control structure, there are some methods available in the literature about the dominant pole placement with PID controllers for time-delay systems [9]-[11].

An important strategy to circumvent this difficulty might be digitizing the system. Since the equivalent transfer function in the z-plane no longer possess infinitely many poles; instead it begins to possess additional finite number of poles at \( z = 0 \), the number of which is a function of the sampling time. As
might be expected, such a situation facilitates the dominant pole placement process [12]-[13].

Based on the strategy defined above, a digitized PID design providing dominant pole placement for time-delay systems in the z-plane is proposed in this paper. Apparently, the given system is digitized and its transfer function is expressed in the z-domain. Then based on the performance criteria, the location of the dominant poles is computed. After that all the controller set for which the closed-loop system possess a pole pair at the desired location, is computed in terms of the $K_p$ parameter. In order to provide the remaining roots to locate in a disc with a predetermined radius, the Nyquist method is employed. To verify the proposed methodology, the method is applied to a servomechanism in the real environment. Since the employed motor parameters are not explicitly known, the continuous transfer function of the servomechanism is obtained via MATLAB system identification toolbox as a second order system in the s-plane.

It is worth noting that, the predetermined radius plays a key role for the system to behave as desired. In general, it can be said that, the smaller the radius, the greater the performance. However, when the radius is selected too small, the resulting controller set may result in an empty set. Therefore, based on an numerical calculations, the minimum achievable length of the radius is also obtained graphically in this paper.

The paper is organized as follows: In the second section, the complete methodology is expressed in two steps. In the first one, it is mentioned how the controller parameters are obtained in terms of $K_p$ in order for the characteristic expression to comprise the desired dominant roots. In the second one, using the Nyquist criterion, the required range of $K_p$ is calculated in order for the non-dominant roots to be placed in the disc with the predetermined radius. In the third section, the method is applied to a servomechanism in the real environment. To apply the method, the transfer function of the system is obtained as a second order one in the s-plane, employing the system identification toolbox of the MATLAB. Moreover, all $K_p$ values are computed and plotted for each value of the predetermined radius in the $K_p - r$ plane. From that plot, the minimum achievable radius length, i.e. the maximum dominance factor of the dominant poles can be easily determined.

II. DISCRETE PID CONTROLLER DESIGN

A. Calculation of the PID Controller Parameter Set to Assign the Dominant Pole Pair

A discrete-time transfer function of a system in general form can be given as follows.

$$G(z) = \frac{N_c(z)}{D_c(z)}$$  \hspace{1cm} (1)

The PID controller in discrete-time domain can also be given as follows.

$$F(z) = \frac{N_F(z)}{D_F(z)} = \frac{(K_p+K_i+K_d)\omega^2 - (K_p+2K_d)\omega + K_d}{z(z-1)}$$  \hspace{1cm} (2)

The characteristic equation of the closed-loop system with unity feedback is expressed as below.

$$P_c(z) = D_F(z)D_c(z) + N_F(z)N_c(z) = 0$$  \hspace{1cm} (3)

Here, it is aimed the dominant pole pair to be assigned to the points $z_{1,2} = \sigma \pm j\omega$ in z-plane using a PID controller. It is clear that the closed-loop characteristic equation should be satisfied by the dominant poles; therefore, (3) can be written as below.

$$D_F(\sigma + j\omega)D_c(\sigma + j\omega) + N_F(\sigma + j\omega)N_c(\sigma + j\omega) = 0$$  \hspace{1cm} (4)

The equation given above can be solved by equating its real and imaginary parts to zero,

$$\begin{align*}
(D_{F1m}D_{c1m} - D_{FRe}D_{cRe}) + (N_{F1m}N_{c1m} - N_{FRe}N_{cRe}) &= 0 \\
(D_{FRe}D_{c1m} + D_{F1m}D_{cRe}) + (N_{FRe}N_{c1m} + N_{F1m}N_{cRe}) &= 0
\end{align*}$$  \hspace{1cm} (5)\hspace{1cm} (6)

where

$$D_{F1m} = Im[D_F(\sigma + j\omega)], \quad D_{FRe} = Re[D_F(\sigma + j\omega)]$$

$$D_{c1m} = Im[D_c(\sigma + j\omega)], \quad D_{cRe} = Re[D_c(\sigma + j\omega)]$$

$$N_{F1m} = Im[N_F(\sigma + j\omega)], \quad N_{FRe} = Re[N_F(\sigma + j\omega)]$$

$$N_{c1m} = Im[N_c(\sigma + j\omega)], \quad N_{cRe} = Re[N_c(\sigma + j\omega)]$$

It can easily be seen that in (5) and (6), only the expressions $N_{FRe}$ and $N_{F1m}$ consist of unknown parameters (PID controller parameters); therefore, if $N_{FRe}$ and $N_{F1m}$ is solved, it is possible to obtain,

$$N_{FRe} = -\frac{N_{c1m}Y - N_{cRe}X}{Z}$$  \hspace{1cm} (7)

$$N_{F1m} = -\frac{N_{c1m}X + N_{cRe}Y}{Z}$$  \hspace{1cm} (8)

where $X$, $Y$ and $Z$ defined as follows to avoid complexity.

$$X = D_{F1m}D_{c1m} - D_{FRe}D_{cRe}$$

$$Y = D_{FRe}D_{c1m} + D_{F1m}D_{cRe}$$

$$Z = N_{c1m}^2 + N_{cRe}^2$$

Note that, it is possible to obtain following expressions for a discrete PID controller,

$$N_{FRe} = K_d(\left(-\left(1+\sigma^2\right)\omega^2\right) + K_p(\left(-\sigma + \sigma^2 - \omega^2\right) + K_d\left(\sigma^2 - \omega^2\right)$$  \hspace{1cm} (9)

$$N_{F1m} = K_d\left(2\sigma - 2\right)\omega + K_p\left(2\sigma - 1\right)\omega + K_d\left(2\sigma\omega\right)$$  \hspace{1cm} (10)

Thus, discrete-PID controller parameters $K_i$ and $K_d$ can be obtained in terms of the parameter $K_p$ with the help of the expressions (7) and (8) as below.
\[
\left( \frac{K_d}{K_i} \right) = \frac{1}{\pi} \left( \frac{-1 + \sigma - \omega^2}{a^2 + \omega^2} \right) \left( \frac{N_{G_{in} x + N_{G_{ex} y}}}{z} \right) - \frac{1}{\pi} \left( \frac{\frac{1}{\sigma} - \omega^2}{a^2 + \omega^2} \right) K_p^2
\]

where,
\[
\Delta = -2\omega (-\sigma + \sigma^2 + \omega^2)
\]

As a result, the discrete-PID controller parameter set, which assigns dominant poles to the points of \( z_{1,2} = \sigma \pm j\omega \) in \( z \)-plane, is obtained in following form.
\[
S := \{ F(K_i(K_p), K_d(K_p), K_p) \mid \forall K_p \in \mathbb{R} \} \quad (12)
\]

This set defines a line in \( (K_p, K_d, K_i) \) 3-dimensional parameter space. On the other hand, it should be considered that the controller set given in (12) assigns dominant poles to the points of \( z_{1,2} = \sigma \pm j\omega \); however, the remaining poles can be located anywhere (including unstable region) in \( z \)-plane depending on the parameter \( K_p \). Calculation of the subset of PID controller parameter set, which assigns the remaining poles in a disc of radius \("r"\) in \( z \)-plane, is explained in the next section.

### B. Calculation of the Subset to Assign Remaining Poles

After obtaining the expressions of PID controller parameters \( K_i \) and \( K_d \) in terms of the parameter \( K_p \), those parameters can be replaced in the closed-loop characteristic polynomial. Thus, the closed-loop characteristic polynomial only depends on the parameter \( K_p \). In addition, it is clear that this characteristic equation also comprises the dominant pole pair; therefore, following equation can be written.

\[
P_c(z, K_p) = (z^2 - 2\sigma z + \sigma^2 + \omega^2) P_e(z, K_p)
\]

Here, the polynomial \( P_c(z, K_p) \) is constructed by the unassigned closed-loop poles. It is desired the roots of polynomial \( P_e(z, K_p) \) to be located in a disc with radius \( r^m \) in \( z \)-plane where \( r = \sqrt{\sigma^2 + \omega^2} \) and \( m \) is defined as dominance factor. If the corresponding \( K_p \) interval is found, then it is possible to obtain a subset of the PID parameter set obtained earlier such that dominant pole placement is carried out successfully, as given below.

\[
\tilde{S} := \{ F(K_i(K_p), K_d(K_p), K_p) \mid \forall K_p \in (k_p^-, k_p^+) \} \subset S
\]

The problem, which is stated as the roots of polynomial \( P_c(z, K_p) \) to be located in a disc of radius \( r^m \) in \( z \)-plane, can be converted to the stability problem of the polynomial \( \tilde{P}_e(z, K_p) = P_e(r^m z, K_p) \). In order to solve this problem, there are several methods such as Jury test, Routh-Hurwitz criterion with the help of bilinear transformation. However, as the order of closed-loop system is increased, the inequalities (probably nonlinear) obtained from Jury or Routh table may become very complex to reduce. For this reason, in this study, the interval of stabilizing \( K_p \) gain is calculated with the help of Nyquist theorem by reconstructing the polynomial \( \tilde{P}_e(z, K_p) \) as follows.

\[
1 + K_p \tilde{G}(z) = 0
\]

In the Nyquist stability analysis, it is desired to find the gain interval in which the number of unstable closed-loop poles (\( Z \)) is zero with the help of the number of unstable poles (\( P \)) of open-loop system and the number of encirclements (\( N \)) of the Nyquist plot around a critical point.

\[
N = Z - P
\]

Here, the number of unstable poles of \( \tilde{G}(z) \) and thus the number of encirclements required of Nyquist plot can be calculated. After that, desired \( K_p \) interval that satisfies the required number of encirclements can be found.

Note that, it is not always possible to provide dominant pole placement because \( \tilde{S} = \emptyset \) can be found after the calculations. This means that there is not any PID controller which satisfies the desired performance criteria and dominance factor in the closed-loop.

### III. Simulation and Implementation Results

In this section, proposed discrete-PID controller design is applied to the position control problem of a DC motor and success of the proposed method is firstly demonstrated on simulation environment in MATLAB and then on real environment. The DC motor system [14] to be controlled is illustrated in Figure 1. Due to the fact that motor parameters are unknown, open-loop transfer function is obtained with the help of system identification toolbox of MATLAB.

![Fig. 1. DC motor system to be controlled.](image)
As a result, the open-loop transfer function of the DC motor system is given as below.

\[ G(s) = \frac{36.64}{s^2 + 15.6s + 36.62} e^{-0.2s} \]

Discrete transfer function of the system with the sampling time of \( T = 0.05 \) seconds is found as follows.

\[ G(z) = \frac{0.027487 + 0.035636z}{z^2 + 1.39532z - 0.45841} z^{-4} \]

In the closed-loop, it is desired transient response of the system to satisfy 5% overshoot and 2 seconds settling time. Corresponding dominant pole pair in \( z \)-plane is then given as below.

\[ z_{1,2} = \sigma \pm j\omega = 0.9 \pm j0.0947 \]

It is now possible to obtain the discrete-PID controller parameters \( K_i \) and \( K_d \), which assign dominant poles to the desired locations in the closed-loop, in terms of the parameter \( K_p \) using the expression (11) as follows.

\[ K_i = 0.02833 + 0.1171 K_p \]
\[ K_d = -2.3815 + 5.0454 K_p \]

If those parameters are replaced in closed-loop characteristic polynomial and written in the form given with (13),

\[ P_c(z, K_p) = (z^2 - 1.7997z + 0.81873) P_e(z, K_p) \]

where \( P_e(z, K_p) = z^6 - 0.59558z^5 - 0.0369z^4 - 0.0372z^3 - 0.036726z^2 + (0.2196K_p - 0.1195)z + (0.1694K_p - 0.07996) \)

Let the remaining (unassigned) poles to be 4 times away from the dominant pole pair in \( z \)-plane (i.e. in a disc with radius \( r = 0.67 \)). First of all, it is required to obtain the polynomial \( \bar{P}_e(z, K_p) = P_e(r^m z, K_p) \) in order to convert the problem to the stability problem.

\[ \bar{P}_e(z, K_p) = 0.090727z^6 - 0.08065z^5 - 0.00745z^4 - 0.0112z^3 - 0.0165z^2 + (0.147K_p - 0.08)z + (0.1694K_p - 0.07996) \]

After that, the obtained polynomial should be rearranged as given in (15) to be able to draw Nyquist plot. If the required calculations are done, Nyquist plot of the transfer function \( G(z) \) is drawn as in Figure 3.

Since the open-loop system has \( P = 3 \) unstable poles, the number of required encirclements is \( N = -3 \) for the stability of the polynomial \( \bar{P}_e(z, K_p) \). The tight interval, which satisfies the desired number of encirclements, can be seen from the Nyquist plot. If required calculations are carried out, intersection points of Nyquist plot and real axis and thus interval of the \( K_p \) is found as below.

\[ K_p \in \left( \frac{-1}{-1.7104}, \frac{-1}{-0.56426} \right) = (0.58466, 0.63928) \]

On the other hand, if the dominance factor (m) is left as a free parameter instead of assigning a value, a polynomial with 2 free parameters is obtained. If one of the stability tests is applied such as Jury test directly (or by gridding one of the parameter if higher order system is under consideration), the resulting inequalities define a region in \( K_p - m \) plane. Thus, the smallest radius in which unassigned poles can be located is found. Figure 4 shows this region for the considered DC motor example.
As a result, the PID controller set which assigns dominant poles to the desired points and keeps remaining poles inside a disc of radius $r = 0.67$ is found. For instance, if $K_p = 0.63$ is selected from the interval,

$$K_i = 0.1021$$
$$K_d = 0.7971$$

and the discrete-PID controller transfer function

$$F(z) = \frac{0.7971 - 2.2242z + 1.5292z^2}{z (z - 1)}$$

is obtained. Pole-zero map of the closed-loop system with proposed controller is given in Figure 5. It is seen from the figure that all poles, except dominant pole pair, are located in desired region.

![Fig. 5. Pole-zero map of the closed-loop system.](image)

Designed PID controller is firstly applied to the system model in simulation environment and then applied to the DC motor system. Resulting closed-loop step responses are shown in Figure 6 together.

![Fig. 6. Closed-loop responses in simulation and real environment.](image)

It can be seen from the figure that the settling time of DC motor in the closed-loop is around 2 seconds which is equal to the desired value and the overshoot is around 6% which is very close to the desired performance specification. The value of the overshoot is found to be slightly different because one of the closed-loop zeros are located relatively close to the dominant pole pair.

IV. CONCLUSIONS

In this study, discrete-PID controller set, which assigns dominant poles to the desired locations in $z$-plane and keeps remaining poles away from the dominant pole pair to guarantee a chosen dominance factor, is found. Controller design method is firstly explained and then demonstrated on DC motor example. It is shown that with the designed discrete-PID controller, non-dominant poles are located inside a disc with chosen radius whereas the dominant poles are assigned to the pre-determined locations in order to satisfy desired transient response. Furthermore, it is also shown that the resulting transient response of the DC motor is very close to the desired response in the closed-loop. Thus, success of the proposed PID controller design method is verified.

Proposed design method is carried out through the closed-loop system poles; however, closed-loop zeros, which are located in the dominant region, can also affect the transient response. This can be stated as the only drawback of the proposed method. It is planned future work to include consideration of the effects of closed-loop zeros during the controller design.

Design and Implementation of a Microcontroller Controlled Digital Mahya

Adem Golcuk, Mustafa Buber, Ramazan Kursun

Abstract— Mahya is a string of lightened inscriptions set up between two minarets of mosques during Ramadan nights. In this study, a microcontroller controlled digital mahya which can be programmed with a remote control was designed using digital fonts. Two counts of Pic16F877A microcontroller were employed; one on the mainboard and the other in the remote control. Moreover, one Pic12F675 microcontroller was used for each letter on the mahya. The software installed on the microcontrollers was prepared using the PicBasicPro language. 3 counts of different texts can be stored in the remote control module of the mahya and the desired text on the mahya is sent from the remote control to mahya via serial communication. The mahya designed for this study is made up of 30 digital letters and each letter consists of 14 segments. All letter segments are pre-written using the PicBASIC PRO program. Printed circuits were prepared in a workshop setting and then it was started setting up between the minarets of a mosque.

Keywords— Include at least 5 keywords or phrases

I. INTRODUCTION
Mahya is the lightened inscriptions hung between the minarets of double-minaret mosques during the Ramadan month. It has two meanings in Arabic; ‘life’ and ‘monthly’. The main goal of setting up mahyas is to give nice messages to people and lead them to good deeds and benevolence. In the early periods, mahyas were used to be set up with oil candles strung over the ropes. Today, mahya and the art of mahya is the lightened inscriptions hung between the minarets of double-minaret mosques during Ramadan nights. In this study, a microcontroller controlled digital mahya which can be programmed with a remote control was designed using digital fonts. Two counts of Pic16F877A microcontroller were employed; one on the mainboard and the other in the remote control. Moreover, one Pic12F675 microcontroller was used for each letter on the mahya. The software installed on the microcontrollers was prepared using the PicBasicPro language. 3 counts of different texts can be stored in the remote control module of the mahya and the desired text on the mahya is sent from the remote control to mahya via serial communication. The mahya designed for this study is made up of 30 digital letters and each letter consists of 14 segments. All letter segments are pre-written using the PicBASIC PRO program. Printed circuits were prepared in a workshop setting and then it was started setting up between the minarets of a mosque.

II. MATERIAL AND METHOD

In the Microcontroller Controlled Digital Mahya implemented, the software inside the microcontroller was written using the PICBASIC PRO program. Printed circuits were prepared using the ARES printed circuit program that comes inside the Proteus Professional software pack. Moreover, before circuits were passed to printed circuit, microcontroller codes and working principles of integrated circuits were tested in the ISIS Professional[5] which is an electronic simulation program. Printed circuits were prepared in a workshop setting using the ironing method at the testing stage. After successful results were obtained at the testing stage, printed circuits for serial production were prepared by firms that could do this job professionally.

2.1 Serial Communication Technique
Serial communication technique is preferred for the purpose of reducing complexity, lowering the cost and enabling the ease of control in the businesses, automation systems and factories with many motors and machines. It also has advantages such as programming the system upon request, not needing to install additional data line for the subsequently added devices to circuit. Serial communication has a broad range of usage in today’s world. The communication in the computer devices like modem, printer, floppy, hard disk, optical drives and the communication between the microprocessors are conducted in a serial form. In addition to these, serial form communication is also used in the cases where it is targeted to reduce the number of line [5-8].

Serial Communication Software; Pic Basic Pro commands enabling serial communication are as follows:

Data sending command:
SEROUT2 VERIOUT,188,["S","U",DATA1]
This command transmits data at 4800 baud rate. It transmits the letters “S” and “U” before sending BITLER1 data.

Data receiving command:
SERIN2 VERIIN,188,100,ATLA,[WAIT ("SU"),DATA1]
This command reads the data sent at 4800 baud rate and transfers the data coming after the regularly sent letters “S” and “U” to BITLER1 variable[5].

2.2. Structure of the Implemented System...
The system we designed basically consists of three modules. The circuit formed for our first module is the ‘Main Board’ section which sends via serial communication the letter information that has to appear in displays and it is put together on the minaret with displays. The second one is the display module that shows letters. Pic12f675 microcontroller was used for each letter in this module. This microcontroller sends data that come from the main board via serial communication to 74HC595 integrated circuit which drives the segments of the display. The third module consists of remote control system. The user prepares the text that he wants to show on the mahya using this remote control system and transmits these data to mainboard through serial communication. Figure 1 shows the structure of the designed system.

![Figure 1 - Mahya Block Diagram](image1)

### 2.2.1 Mainboard Module
This module ensures the control of the designed system. It sends and receives data using serial communication technique via both the display module and the Keypad Module. A Pic16F877A microcontroller was used for this module. Data programmed by the user in the Keypad module are read through serial communication and saved to internal EEPROM of the 16F877A microcontroller. It sends the necessary data to display module for the the user-programmed text to appear in displays.

### 2.2.2 Control Module
This module helps to program the inscription that is to be shown in the mahya. It has a 16F877A microcontroller, a keypad with 16 buttons and an LCD display.

### 2.2.2.1 Pic16F877A Mikrodenetleyicisi
As in the mainboard module, a 16F877A microcontroller was used in the control module too. This microcontroller reads the data coming from the keypad module and these data are shown in the LCD display. After being programmed in the control module, the text which is to be shown in the displays is sent to the mainboard module through serial communication. The software installed to this microcontroller was written using the PicBasicPro programming language.

#### 2.2.2.2 Keypad module
This module is composed of 16 buttons and controlled with the 8 ports (PORTD) of the microcontroller. It operates with the same operating logic of cell phone keypads. For instance, the number 2 shows up in the display when first pressed on the key 2, the letter A appears when pressed a second time and B and C in sequence. The user uses this module to be able to program the inscription to be shown on the mahya.

#### 2.2.2.3 LCD Display
A 2x16 LCD display was used in this study. The user takes advantage of this display while programming the mahya. The text that appears on the LCD display is sent to the mahya. 8 ports (PortB) of 16F877A microcontroller was used in order to control the LCD display.

### 2.2.2 Display Module
30 counts of this module were designed since the implemented mahya consisted of 30 letters. Figure-2 shows printed circuit and circuit diagram of the display module.
2.2.1.1 14 Segment Display

A 14 segment display in Figure-4 was prepared to show the characters of the text made up for the mahya. 2 segments were added so as to show Turkish characters. One of these segments was placed over the letter and the other one beneath the letter. Strip leds were used to light these segments.

2.2.1.2 12F675 Microcontroller

This microcontroller receives data coming from the mainboard through serial communication and then send these data to 74HC595 integrated circuits so that the letters can appear on displays. It has 8 pins and 6 I/O ports. The software written for this microcontroller checks whether data coming from the mainboard module through serial communication belongs to itself or not. If the data belongs to itself, it also reads the rest of the data and transmits it to 74HC595 integrated circuit. Because output ports of 74HC595 integrated circuit are connected with Display segments, the requested letters show up in display.

2.2.1.3 74HC595 integrated circuit

This is an 8 bit shift register integrated circuit. It reads data coming from 12F675 microcontroller through SPI serial communication protocol and images these data at its 8 output (QA-QH) [9]. 2 counts of this integrated circuit were used for each letter.

III. CONCLUSIONS AND RECOMMENDATION

Electronic components of a Mahya stretched between the minarets of mosques during the Ramadan months were created and described in this study. The most important difference between the implemented mahya and today’s mahyas is that it was designed using digital fonts and that it enabled to program desired inscriptions with a remote control. Thus instead of showing only one text, it can show different texts on different days throughout the Ramadan month between two minarets. The circuits designed for the mahya were tested in a workshop setting. After hardware and software problems that occurred during the testing stage were resolved, the system was put into use with its final version. A view of the implemented mahya can be seen in Figure-5. The results of tests showed the employability of digital mahya.

Abstract—This paper presents an off-line simulation tool for PUMA robot manipulator which is commonly used various purposes such as material handling, welding and surgery. This new tool using UNITY game engine software provides powerful real-time simulation and verification of robot manipulator designs. PUROLAB allows users to design his/her own virtual robot laboratory including objects and conveyer systems and test the real-time systems. PUROLAB has very powerful Graphical User Interface (GUI) that provides users to understand fundamental of robot kinematics easily.

Keywords—Robotic Simulation tools, Off-Line Robot Programming, GUI, Robot Test Software

I. INTRODUCTION

Robot programming is one of the main issues of robotics. There are two different programming issues in robotics, namely off-line and on-line programming. Off-line programming is a method of planning, generating, simulating and verifying a robot program at a remote computer. It presents several advantages to operators and designers [1-4]. Some major advantages can be described as follows: i) The robot motion can be designed, modified and simulated before performing in real-time, ii) Off-line programming provides flexibility. Several times a program can be modified without interrupting the robot task, iii) since robot program is prepared away from the robot, the programmer is free of robot accident, iv) it provides fast correction of any error occurred in the robot program.

There have been several robot simulation tools developed until now. Das et al. [5] developed a simulation tool named as RCAAAD (Robot Computer Aided Analysis and Design). It permits designers to analyze and optimize their designs. The Robotics Toolbox for Matlab [5] presents many helpful applications to the users such as such as kinematics, dynamics and trajectory generation. Although it is very useful simulation tool its GUI is very week like RCAAD. Nethery and Spong [7] developed Robotica that includes about 30 functions for kinematics, dynamics and animations of robots. Since Robotica is required set up Mathematica before loading actual program, Robotica does not provide GUI. Nayair [8] developed Robotect that is windows-based graphical user interface robot simulation tool for especially modelling and analyzing manipulator designs. Zlajpah [9] developed a simulation toolbox for redundant planar manipulators only. Zlajpah’s simulation tool does not support GUI. ROBOOP [10] is developed for synthesis and simulation of robot manipulators. Bingul et al. [11] developed RoboSim for modeling, visualization and performance analysis of serial robot manipulators. Turnell et al. [12] presented SimBot for development of autonomous robots. Vollmann [13] developed a simulation tool for KUKA. This simulation tool does not provide any interactive GUI. Alfs et al. [14] developed a simulation tool for designing for advanced robots. Kucuk and Bingul [15] developed a robot simulation toolbox to improve the understanding of robotics fundamentals through interactive GUI. Other simulation tools can be found in [16,17,18,19,20,21]. Table 1 illustrates some important properties simulation tools developed until now.

In this paper, an off-line robot simulation tool is developed for PUMA robot manipulator which is an extensively used in industry for performing several tasks such as material handling, welding and surgery. This new tool is developed by using Unity game engine software that provides very powerful interactive GUI facilities for operators to perform several applications. Unity developed by Unity Technologies [22] is a game engine software that is used for preparing video games, consoles and mobile devices. It provides operators to use real world parameters in their animations. Another advantage of using Unity game engine is to have possibility for designing his/her own GUI without limiting himself/herself traditional custom application forms. High-resolution graphics library of Unity game engine allows operators to use earlier prepared models in any future application. The main advantages of PUROLAB over the other simulation tools given above can be summarized given as follows.

i) PUROLAB is developed by using Unity game engine software that offers very powerful GUI facilities to perform several applications interactively.

ii) PUROLAB provides users to design his/her own virtual robot laboratory including objects and conveyer systems.
In this section, forward kinematics, inverse kinematics and trajectory planning is shortly introduced to provide robotics fundamentals.

### A. Forward kinematics

Forward Kinematics is the first stage to design a new serial robot manipulator. It is a mapping from joint coordinates to Cartesian coordinates and an easy problem for serial robot manipulators. The homogeneous transformation matrix for each joint is derived to compute the forward kinematics. D-H [23] parameters are used for obtaining homogeneous transformation matrix for a joint:

\[
{i-1}{i}{j}\mathbf{T} = \begin{bmatrix}
\cos \theta_i & -\sin \theta_i & 0 & a_i \\
\sin \theta_i \cos \alpha_i & \cos \theta_i \cos \alpha_i & -\sin \alpha_i & -\sin \theta_i \sin \alpha_i \\
\sin \theta_i \sin \alpha_i & \cos \theta_i \sin \alpha_i & \cos \alpha_i & \cos \theta_i \cos \alpha_i \\
0 & 0 & 0 & 1
\end{bmatrix}
\]

Where \( \theta_i \) is the joint angle, \( \alpha_{i-1} \) is the twist angle, \( a_{i-1} \) is the link length, and \( d_i \) is the joint offset. The forward kinematics of the end-effector with respect to the base frame is described as follows:

\[
0_T = {0}_1 T_2 T_3 \ldots
\]

where \( T \) illustrates the transformation matrix of a joint. The forward kinematics can also be expressed as follows:

\[
{T}_n = \begin{bmatrix}
r_{11} & r_{12} & r_{13} & p_x \\
r_{21} & r_{22} & r_{23} & p_y \\
r_{31} & r_{32} & r_{33} & p_z \\
0 & 0 & 0 & 1
\end{bmatrix}
\]

Where \( r_{ij} \) and \( p_p \), \( p_y \), \( p_z \) are the elements of rotation matrix position vector, respectively \( (i = 1, 2, 3) \). For a six jointed robotic manipulator the forward kinematics can be described as follows.

### II. BACKGROUND

In this section, some important robotics simulation tools are described:

<table>
<thead>

</tbody>
</table>

iii) PUROLAB allows operators to visualize the fundamental robotic applications like the forward kinematics, inverse kinematics and trajectory planning in more efficient way.

iv) PUROLAB allows operators to change the link parameters of PUMA robot manipulator to see interactively the structure of the solid model.

v) PUROLAB provides operators to enable a better understanding of orientation and positioning in three dimensional spaces.

vi) PUROLAB provides the user to locate the PUMA robot manipulator, conveyor systems and objects in any place in the workspace.
\[ 0^T = 0^T(q_1)0^T(q_2)0^T(q_3)0^T(q_4)0^T(q_5)0^T(q_6) \] (4)

where \( q_i \) is the revolute or prismatic joint variable for \( i^{th} \) joint.

**B. Inverse Kinematics**

Although the forward kinematics is easy problem, the inverse kinematics is difficult and complex problem. The inverse kinematics solution is also computationally expensive. The nonlinearities make the inverse kinematics problem more difficult to solve.

Inverse kinematics problem is a mapping from Cartesian coordinates to joint coordinates. The link transformation matrices are described as below to solve the inverse kinematics \([24]\).

\[ \begin{bmatrix} 0^T \\ 0^T \end{bmatrix} = \begin{bmatrix} 0^T \\ 0^T \end{bmatrix}^{-1} 0^T 1^T 2^T 3^T 4^T 5^T 6^T \] (5)

Since \( \begin{bmatrix} 0^T(q_i) \end{bmatrix}^{-1} \begin{bmatrix} 0^T(q_i) \end{bmatrix} \) equals identity matrix. The above equation simplifies as follows

\[ \begin{bmatrix} 0^T \end{bmatrix}^{-1} 0^T = 1^T 2^T 3^T 4^T 5^T 6^T \] (6)

Where \( 0^T 6^T \) includes the given orientation and position data. The following equations can be derived in a similar way.

\[ \begin{bmatrix} 0^T 1^T 2^T \end{bmatrix}^{-1} 0^T = \frac{1}{2} 3^T 4^T 5^T 6^T \] (7)

\[ \begin{bmatrix} 0^T 1^T 2^T 3^T \end{bmatrix}^{-1} 0^T = \frac{1}{3} 4^T 5^T 6^T \] (8)

\[ \begin{bmatrix} 0^T 1^T 2^T 3^T 4^T \end{bmatrix}^{-1} 0^T = \frac{1}{4} 5^T 6^T \] (9)

\[ \begin{bmatrix} 0^T 1^T 2^T 3^T 4^T 5^T \end{bmatrix}^{-1} 0^T = \frac{1}{5} 6^T \] (10)

Lower dimensional approach \([25]\) presents another important equation to solve inverse kinematics.

\[ 2^T 3^T 4^T 5^T = 2^{-1} 0^T 1^T 0^T 2^T 3^T 4^T 5^T \] (11)

**C. Trajectory Planning**

Trajectory planning is one of the vital issues of robotic manipulators since it is required to execute the desired task with acceptable performance \([26]\). Trajectories must provide smooth motion to provide high tracking accuracy. Rough and jerky motions cause vibration and errors in joints. In general, robot trajectories are first planned off-line and then the end-effector tracks the planned trajectory on-line. There are several trajectory planning algorithms such polynomial \([Craig]\), trigonometric \([27]\), quartic \([28-29]\), B-spline \([30]\) and cubic spline \([31]\) are used in robotics. In this paper a 7th order polynomial is used for trajectory planning.

**III. OVERVIEW OF SIMULATION TOOL**

Some important applications are illustrated for describing the features of PUROLAB in this section. The new simulation tool PUROLAB includes applications of forward kinematics, inverse kinematics and trajectory planning. The mainframe and flowchart of PUROLAB are given Figure 1 and Figure 2, respectively.

![Mainframe of PUROLAB](image1)

**Fig. 1. Mainframe of PUROLAB**

![Flowchart of PUROLAB](image2)

**Fig. 2. Flowchart of PUROLAB**

After clicking “Opens Scene” button, the new window given by Figure 3 appears on the screen. Figure 3 provides user to design kinetic parameters (lengths and radiuses) of his/her own robot, conveyer system and objects. This feature is an important advantage of PUROLAB over other simulation tools.
tools described in Table 1. In this application, link lengths for
PUMA robot manipulator is designed as \( h_1=2 \), \( d_2=4 \), \( l_2=18 \) and \( d_4=14 \) and \( d_6=0 \);

![Image](image1.png)

**Fig. 3.** Kinematic parameters design window

A. Forward Kinematics

There are two options to perform forward kinematics, namely F.Kin-1 and F.Kin-2. These options of PUROLAB can be activated by clicking F.Kin-1 and F.Kin-2 buttons as illustrated in Figure 4.

![Image](image2.png)

**Fig. 4.** Application screen of F.Kin-1, F.Kin-2, Inv.Kin-1 and Inv.Kin-2

1) Forward Kinematic -1

In order to perform Forward kinematics-1, “F.Kin-1” button is selected from the application screen on Figure 4. In F.Kin-1 mode, each joint angle is activated by using sliders. The operator can perform tune or gross motion by using sliders. Tune motion can be performed by using arrow buttons on the keyboard. Gross motion is performed by using only mouse. The present position and orientation of the end-effector can be displaced by using “Current Status” button at the bottom of the slider control panel. An example of F.Kin-1 application is given on Figure 5 where \( \theta_1 = 43^\circ \), \( \theta_2 = -19^\circ \), \( \theta_3 = 4^\circ \), \( \theta_4 = -4^\circ \), \( \theta_5 = -17^\circ \) and \( \theta_6 = 0^\circ \).

![Image](image3.png)

**Fig. 5.** Forward Kinematic -1: Joint motion with sliders.

The position and orientation of end-effector is obtained by clicking the current status button as in Figure 6. Moreover, 'Reset Sliders' button on the same window brings the manipulator zero position.

![Image](image4.png)

**Fig. 6.** Current status of end-effector

2) Forward Kinematic-2

In forward kinematics-1 mode, manipulator joints are separately actuated. On the other hand in forward kinematics-2 manipulator joints are activated at the same time. User can operate the manipulator by entering the each joint value into the text boxes as illustrated in Figure 7. In this example, The joint angle values are designed as follows: \( \theta_1 = 43^\circ \), \( \theta_2 = -19^\circ \), \( \theta_3 = 4^\circ \), \( \theta_4 = -4^\circ \), \( \theta_5 = -17^\circ \) and \( \theta_6 = 0^\circ \). When the operator clicks the “move” button, the manipulator goes from the zero position to the final position and orientation as in F. Kin-1.
B. Inverse Kinematics

There are two options to perform inverse kinematics, namely I.Kin-1 and I.Kin-2. These options of PUROLAB can be activated by clicking I.Kin-1 and I.Kin-2 buttons as illustrated in Figure 4.

1) Inverse Kinematics -1

PUROLAB in inverse kinematics mode finds the joint angles according to the desired position and orientation of the end-effector in terms of the base frame. The orientation of the end-effector can be performed by using one of RPY-fixed, Euler, and RKT angle sets. Roll, pitch, yaw and Euler angle sets are commonly used in robotics. Although there are twelve roll-pitch-yaw and Euler angle sets that can be used for orientation, \( \begin{bmatrix} R_{xyz}(\alpha, \beta, \gamma) &=& R_z(\gamma)R_y(\beta)R_x(\alpha) \end{bmatrix} \) roll-pitch-yaw angles given by equation 12 and \( \begin{bmatrix} R_{xyz}(\alpha, \beta, \gamma) &== R_x(\alpha)R_y(\beta)R_z(\gamma) \end{bmatrix} \) Euler angles stated by equation 13 are used in this simulation tool.

\[
R_{xyz}(\alpha, \beta, \gamma) = R_z(\gamma)R_y(\beta)R_x(\alpha) = \begin{bmatrix}
1 & 0 & 0 \\
0 & c\beta & s\beta \\
0 & -s\alpha & c\alpha
\end{bmatrix} \begin{bmatrix}
c\gamma & -s\gamma & 0 \\
s\gamma & c\gamma & 0 \\
0 & 0 & 1
\end{bmatrix}
\]

\[
R_{xyz}(\alpha, \beta, \gamma) = R_x(\alpha)R_y(\beta)R_z(\gamma) = \begin{bmatrix}
1 & 0 & 0 \\
0 & c\beta & s\beta \\
0 & -s\alpha & c\alpha
\end{bmatrix} \begin{bmatrix}
c\gamma & -s\gamma & 0 \\
s\gamma & c\gamma & 0 \\
0 & 0 & 1
\end{bmatrix}
\]

PUROLAB allows operator to test each inverse kinematics solution of the PUMA robot manipulator. Since \( d_6 \) is accepted as zero PUMA robot manipulator has 16 inverse kinematics solutions in this application. An example of I.Kin-1 application is given on Figure 8. The position of the end-effector is accepted as \( p_x=18, p_y=4 \) and \( p_z=7 \). The orientation of the end-effector is designed by using \( R_{xyz}(90,0,0) \) Euler angle values.

2) Inverse Kinematic -2

In this mode, PUROLAB allows user to automatically generate a trajectory with several via points. When operator selects an object in the workspace, robot manipulator grips the object according to the objects position and orientation in terms

Fig. 8. Designing position and orientation of end-effector for an inverse kinematics application.

Fig. 9. An inverse kinematic application with Euler angle set.
of base frame of the robot manipulator. Operator clicks “Add Via Point” button to add a via point on the desired trajectory. Operator brings the manipulator to another via points by simply moving the object with mouse. Several via points can be selected to design a trajectory. Manipulator performs a motion passing through these via points with 7th order polynomial. An example of I.Kin-2 application is given on Figure 10 where five via points is selected for the trajectory.

Fig. 10. An example of I.Kin-2 application

CONCLUSIONS

In this paper an off-line simulation tool (PUROLAB) for PUMA robot manipulator is developed by using UNITY game engine software which provides very powerful interactive GUI facilities for operators to perform several applications. “PUROLAB” successfully performs forward kinematics, inverse kinematics and trajectory planning. PUROLAB has some important features: i) PUROLAB allows user to design kinematic parameters of her/his own robot, conveyer system and objects, ii) PUROLAB allows operator to test each inverse kinematics solution of the PUMA robot manipulator separately, iii) PUROLAB allows user to automatically generate a trajectory with several via points iv) PUROLAB has very powerful GUI and high-resolution graphics library that provides operatorsto understand fundamental of robot kinematics easily.

Prototyping Multiaxis 3D Weaving: Fabrication 3D Preforms for Composites

Kadir Bilisik*
*Department of Textile Engineering, Faculty of Engineering, Erciyes University, 38039 Talas-Kayseri, Turkey
kadirbilisik@gmail.com

Abstract—Advanced preforms for textile structural composites have been made as multiaxis three-dimensional (3D) flat and circular woven preforms. Methods to weave these preforms were developed and some preform structural parameters were evaluated. Preform specifications were identified and some elastic properties of the composites were calculated. These methods and structures could be considered as feasible.

Keywords—Advanced preforms, Textile structural composites, 3D flat weaving, 3D circular weaving, carbon fiber

I. INTRODUCTION

Textile structural composites could be considered as alternative materials since they are delamination free and damage tolerant [1, 2]. The fabrication of a textile preform is made by weaving, braiding, knitting, stitching and non-woven techniques and they can generally be chosen based on end use requirements. Originally, 3D preforms were classified as yarn interlacement types. 3D preforms can be fabricated by specially designed automated looms, or existing looms that can be modified and made near-net shape to reduce scrap [3]. However, it is mentioned that they have low in-plane properties, partly due to through-the-thickness fiber reinforcement. Multiaxis 3D weaving is a relatively new concept and, additionally, bias yarn sets are introduced to the orthogonally structured preform. It is expected that multiaxis 3D preforms may enhance in-plane properties [4-7].

In this study, multiaxis 3D flat and circular woven preforms were developed to overcome the limitations of 3D preforms.

II. MATERIALS AND METHODS

A. Principles of Multiaxis 3D Flat and Circular Woven Preforms

The multiaxis 3D flat woven preform has five yarn sets as bias(+), warp (axial), filling and Z-yarns while the multiaxis 3D circular woven preform has five yarn sets as (+)-bias, axial, circumferential, and radial yarns. In Fig. 1, the schematic views of the unit-cells of multiaxis 3D flat and circular preforms are given.

In multiaxis 3D flat woven preform a new method called “tube-carrier weaving” was used. The warp yarns are arranged in a matrix of rows and columns within the required cross section. It looks to be a loose network for laying the yarns in between adjacent warp yarns. The filling yarns are laid down between each adjacent warp yarn row. They have double ends and are deposited through the preform length. The bias(+) and bias(−) yarns have two sets in which each set has the same number of warp yarn ends in each row. They are positioned in both surfaces of the preform, and are oriented toward the preform surface at an angle. Z-yarn ends are positioned between each warp column through the preform thickness. They lock all other yarn sets to provide the structural integrity of the preform.

In multiaxis 3D circular woven preform, there are two preforms developed according to “radial crossing” and “radial in-out” principles. The axial yarns are arranged in a matrix of circular rows and radial columns within the required circular cross-section. It looks like a spare network for laying the yarns in between adjacent axial yarns. Circumferential yarns are laid down between each adjacent axial yarn row. These are single-ends and deposited through the preform length. Bias yarns have two sets. They are positioned on both surfaces of the preform. First pair of bias yarns are placed on the outer surface and second pair of bias yarns are placed on the inner surface of the circular preform, but there is a circumferential yarn between bias(+) and bias(−) yarns. Bias yarns are oriented to the preform surface at an angle. Radial ends are positioned between each axial row through the preform thickness. They lock all other yarn sets to provide structural integrity of the preform where odd-numbered radial yarns are crossing the structure to the inner diameter, but even-numbered radial yarns are crossing the structure to the outer diameter. Whereas in the case of radial in-out, all radial yarns are crossing the structure to the inner diameter or the outer diameter.
B. Fiber and Matrix Specifications

Carbon fiber (PAN based Thornel™ T-300) was used to produce the multiaxis 3D flat and circular preforms. Specifications of carbon fiber and epoxy matrix (Tactix™ 123) are given in Table I.

C. Carbon Preforms Produced by Multiaxis 3D Flat and Circular Weaving Methods

Fig. 2 shows the carbon preforms produced by multiaxis 3D flat and circular weaving methods. Two types of multiaxis 3D flat carbon woven preforms (Preform-1 and Preform-2) and one type of multiaxis 3D circular carbon preform (Preform-3) were produced. The preform structures are given in Table II.

In multiaxis 3D flat woven preforms, the bias(+) and bias(−) yarns are 6 K, the warp yarns are 12 K, the filling yarns are 6 K and the Z-fibers are 3 K carbon fibers used. In multiaxis 3D circular preform, the axial yarns are 12 K, the circumferential yarns are 6 K, the radial yarns are 1 K and ±bias yarns are 12 K carbon fiber used.

III. RESULTS AND DISCUSSIONS

A. Multiaxis 3D Flat Carbon Woven Preforms

In multiaxis 3D flat woven preforms, the width ratio is the main processing parameter to influence the preform fabrication during weaving. A proper tensioning system in the Z-yarn may be required in order to avoid unnecessary excessive pressure on the filling yarns, which causes local yarn distortions in the preform structure and it becomes an important processing parameter. Preform-1 and Preform-2 were the same architecture except for the bias yarn orientations. Bias yarn sets can be arranged between 15° and 75° through the in plane of both surfaces of the preform. The bias yarn orientations in Preform-1 and Preform-2 were 30° and 40°, respectively. The fractional volume results measured at preform and the calculated elastic constants are given in Fig. 3.
Results showed that the various preform structures can be crossed and radial in the preform. A new method called “tube carrier weaving” was developed. A new method called “tube carrier weaving” was used to produce multiaxial 3D flat woven preform. “Radial crossing” and “radial in-out” weaving principles were both used to produce multiaxial 3D circular woven preforms. Results showed that the various preform structures can be made thin and thick wall simple cylinders and circular complex shapes for the benefit of especially technical textile and composite industries.

Abstract— In this work, microstructure and tensile behaviours of AlC added PM steels were investigated. The microstructure of the PM steels was characterised by optic microscope and SEM. Results indicated that 0.2 wt. % AlC added PM steel showed the highest values in yield strength (YS) and ultimate tensile strength (UTS). However, when the amount of AlC content increased from 0.2 to 0.5 wt.%, yield strength, ultimate tensile strength and elongation decreased.

Keywords— Powder metallurgy; Powder metallurgy steels; AlC; Microstructure; Mechanical properties.

I. INTRODUCTION

The production method of some parts which have been used especially in the automotive industry recently is completely based on the powder metallurgy. The production method of powder metallurgy is used as independent production choice in the manufacturing sector because its distribution of quality is homogeneous, its content is controllable and its cost per unit is low [1-2].

Microalloyed steels are described as the steels which include niobium, vanadium and titanium between % 0,05 and %0,20 percent. With the application of various hardening mechanisms and suitable thermomechanical processes, microalloyed steels are the group of materials which have superior features like high strength, high toughness, low ductile to brittle transition temperature, perfect weldability and resistance to corrosion. A great proportion of the microalloyed steels are produced as flat and tube products and in the recent years, the production of microalloyed steels for forge purposes has gained speed. Moreover, the production of microalloyed steel is carried out with the powder metallurgy method although it is not in the desired level in our day [3-4].

Certain studies are available in the literature about the relationship between the production of PM steel and microstructure mechanical properties. For instance, Erden et al. produced in their studies Ti and V microalloyed steel with the method of PM. They carried out the sintering process at 1150°C during 60 minutes and confirmed that yield strength and tensile strength increase as Ti and V ratios (% 0.1-5% 0.2) increase. They based it on the formation of precipitates like TiC(N) and VC(N) during the sintering and post-sintering cooling period [3-5].

In this study, microalloyed steel production is performed in the desired compound by adding 45% graphite powder into the Fe powder and 0.1-0.2% and 0.5% AlC as weight. Sintering process for the produced block samples was carried out at 1150°C during 1 hour at argon atmosphere. Along with the analysing of the microstructure specifications of samples like grain size, density and porosity, mechanical features were determined by implementing tensile test.

II. EXPERIMENTAL STUDY

In this experiment, steel samples were produced in the desired compound with the method of powder metallurgy. The effect of AlC ratio on the microstructure and mechanical features was examined. Microalloyed steel was produced by being mixed in the chemical compounds given in Table 1. Tensile and hardness tests, density, porosity, microstructure, ferrite-pearlite ratio and average grain size were calculated for the produced samples [6]. The results were compared to one another. Before the mixing process, powder was weighed in the ratios, the chemical composition of which is given in Table 1, on a digital precision scale which has 0.0001 precision. The weighed powders was mixed with a three axis Turbula brand mixer without marbles during one hour. Zn-stearate was used as greaser.

Mixed powders transformed into blocks by being pressurized unilaterally at 700 MPa pressure in a mould which is in the form of a tensile sample that is suitable to the standards of ASTM (E 8 M) powder metal material. Sintering process was carried out in argon atmosphere at 1150°C during one hour. Sintered tensile samples were tensile tested at 1 mm/min tensile speed. Stress- strain % diagrams are obtained after each experiment. The differentiation of the mechanical features is determined owing to the alteration in the AlC ratio as percentage weight in
the chemical compound by calculating the yield strength (0.2%), tensile strength and % (percentage) elongation values of the samples from these diagrams. Hardness measurement was carried out by using Vickers hardness measurement method with 0.5 kg load and hardness measurement were done from 5 different parts of the sample. Pre-tensile test images of the tensile samples are given in the Figure 1.

Microstructure examinations were carried out with Nikon Epiphot 200 brand optical microscope which has X50-X1000 zooming capacity. These images are intended to be qualified enough to represent the whole microstructure by capturing different size of images from the different parts of each sample. Etching process was carried out by sinking the samples into 2%-8% Nital solution during 4-8 seconds. After the etching process was completed, etched surfaces were cleaned with methanol and dried and then made ready for the examination under optical microscope. Density of the samples was measured with the density measurement tool according to Archimedes principle. Ferrite and pearlite ratios of the powder metal steels were determined by using the metallographic point counting method which is introduced by Gladman and Woodhead [6].

III. EXPERIMENTAL RESULTS AND DISCUSSION

A. Microstructure

Microstructure images of the samples are given in the Figure 2. As can be understood from the Figure, the structure comprises of ferrite and pearlite phases in all AlC ratios. When the microstructure images in the Figure 1 are examined, it is detected that there are partially uncovered pores on the grain borders. It is reported that tiny and round-shaped pores do not reduce the strength although it is stated in various sources that porosity affects the strength negatively [7-8].

In the Table 2, post-sintering densities and pore amounts (%) of the samples which have different ratios of A1C are given. It is observed that with an increase in the A1C ratio, post-sintering density of the samples does not change significantly and remain close to one another. The mechanical features of the components which are produced with the powder metallurgy method are related to pore ratio. Pores behave as the centres on which the tension is intensified and they contribute to crack propagation as well [6-7].

As can be seen in the Table 2, it is observed that pearlite amount is 32.25 % in the Alloy 3 while it is 21.6 % in the Alloy 1. It is an expected situation. With the A1C addition, there is a slight increase in the carbon ratio in the matrix. The A1C that is added increases the carbon ratio inside the matrix by dissolving during the sintering process. The carbon inside the matrix constitutes the cementite phase by uniting with iron and it is thought to increase the amount of the pearlite. It was also

</tbody>
</table>
observed that the average grain size decreased to 18.6 µm in the Alloy 3 while it is 29.7 µm in the Alloy 1. A1N precipitate is thought to arise during the sintering and post-sintering cooling processes and thereby preventing the grain growth. With an increase in the carbon ratio, pearlite amount is observed to increase and average grain size is observed to decrease. It is an expected situation. The studies supporting this result are available in the literature [8-9]. It is observed that average grain size increases a little with an increase in the A1C ratio as weight from 0.2% to 2%. This can be thought to result from the formation of big A1C precipitates on the borders of the grains [9-10]. The fact that precipitates pile up on the borders of the grains leads to an increase in the amount of the pores. Therefore, the big precipitates which arise lead to the growth of the average size of the grain because they can’t prevent the grain growth adequately.

B. Mechanical Properties

Table 3 demonstrates the yield strength, tensile strength, percentage elongation and hardness values while Figure 2 demonstrates the tensile-elongation diagrams of the sintered samples. As can be seen in Table 3 and Figure 2, when A1C ratio increases to 0.2% as weight, there is an increase in the yield and tensile strength and there is not a change in the percentage elongation values generally. Carbide, nitride and carbonitride precipitates which are formed by A1 element enable material to be small grained by preventing the austenite grain size and recrystallization of the austenite. The strength increases with more grain boundary on the small grained structure and the prevention of the dislocation movement by this grain boundary. Reduction in the grain size contributes to percentage elongation of the material. Along with these, the precipitates that are formed up contribute to the increase of the yield and tensile strength with various strength increasing mechanisms like precipitation hardening, dispersion hardening and clustering hardening [11-13].

</tbody>
</table>

However; there is a decrease in the yield strength, tensile strength, hardness and percentage elongation values when the amount of the A1C which is added to PM steels increased from 0.2 % to 0.5 % as weight. This situation can be attributed to the decrease in the density in the 0.5 % A1C alloy ratio. Such features as strength, ductility and conductivity are dependent on the density; in other words, porosity and pore pattern [8]. Besides, high proportion of A1C inside the steel leads to the brittle of the material and reduces the strength by leading to over-precipitation hardening [10].

IV. GENERAL CONCLUSIONS

Holding three different compound ratios (%0.1 – 0.2 and 0.5), A1C alloyed PM steel is produced by implementing cold pressurizing and sintering at argon atmosphere and the following results below are obtained from this experiment.

Alloyed steel which is added A1C is able to be produced with powder metallurgy method. Solid solution hardening and precipitation hardening which arises during the sintering process or post-sintering cooling process increase the strength of the steel. 0.2 % A1C added PM steel is observed to have the highest yield strength and tensile strength.

0.1% and 0.2% A1C added alloyed steel samples exhibit smaller grain size compared to nonalloyed steels. This situation results from prevention of the grain growth by carbide and nitride particles formed up. Moreover, in the steel sample which is added 0.5% A1C as weight, increase in the grain size is observed. The reason for this can be thought as the formation of A1C and A1C(N) precipitates at bigger sizes on the borders of the grains. Yield strength and tensile strength decreased with an increase in the amount of the A1C from 0.2 to 0.5 as weight.

Abstract – In this study, epoxy composites were synthesized using tuff as filler and three types of plasticizers. Physico-mechanical and thermal properties of the epoxy composites were investigated with different analyses and tests. Well-dispersed epoxy composites were obtained according to XRD and SEM results. The epoxy composite including 3 wt% tuff had maximum tensile strength and elongation at break values as 244.7 MPa and 2.947%, respectively. Incorporation of plasticizers especially PEG decreased brittleness of the composites. Adhesion percent of neat ER slightly decreased with the addition of tuff and plasticizers. It was determined that corrosion resistance of the composites was not affected negatively in different corrosive solutions. The water sorption of the composites decreased with tuff; however plasticizers especially PEG caused to increase water sorption. The decomposition temperature of the composites were improved with tuff addition in spite of a slight reduction in initial decomposition temperatures with plasticizers.

Keywords - Composite, epoxy resin, volcanic tuff, physico-mechanical and thermal properties

I. INTRODUCTION

Polymer composites are well-known as one of the most promising advanced materials in many engineering applications [1]. Epoxy based polymer composites have attracted interest due to many advantages of epoxy such as high strength, low shrinkage, great chemical resistance, and heat stability [2]. Epoxy resins are widely used in the fields of electronics, adhesives, coatings, and composites [3]. Flammability and brittleness are unfortunately among drawbacks of epoxy resins which restrict usage capacity of them [4-5]. So, flexible polymers, inorganic solid particles, elastomers, and natural particles are utilized to decrease brittleness in addition to flammability degree [6-7]. While soft materials have plasticizing properties to reduce hardness, rigid solid particles generally improve thermal resistance for epoxy resins [8].

Volcanic tuffs which consist of siliceous and aluminous components are cheap and abundant inorganic materials in Turkey. The tuffs have been effectively evaluated as admixture in pozzolanic cements and surrounding material for modelling the ground heat exchange in air conditioning process etc. recently [9-10].

In this study, epoxy composite materials including tuff were synthesized. Physico-mechanical and thermal properties of the materials were examined with different analyses and tests. And also, the effects of three types of plasticizers on the properties of these epoxy composites were investigated.

II. MATERIALS AND METHOD

A. Materials

NPEF 170 based on bisphenol F epoxy resin and the tuff were used as matrix system and filler, respectively. The chemical composition of tuff was Na$_2$O 4.8%, MgO 0.3%, Al$_2$O$_3$ 14.0%, SiO$_2$ 71.5%, P$_2$O$_5$ 0.1%, K$_2$O 4.1%, CaO 1.0%, TiO$_2$ 0.4%, MnO 0.1%, Fe$_2$O$_3$ 2.8%. The hardener commercially known as Epamine PC17 had aliphatic amine structure. 2,4,6-tris(dimethylaminomethyl)phenol was used as an accelerator. Three types of plasticizers were polyethylene glycol (PEG-400), diethylene glycol (DEG) and monoethylene glycol (MEG).

B. Preparation of Epoxy Composite Materials

The tuff by the weight of 0, 3, 5, 10, and 15 and epoxy resin (ER) were mixed mechanically to provide well-dispersed blends. After the sonication was applied to blends for chain mobility of ER, the hardener by 25 wt% was added to blends. In the following step, the accelerator was dropped to blends and they were poured into the mould. The curing and post-curing conditions were adjusted as 40 °C for 4 h and 80 °C for 4 h, respectively. In the second part of the experiment, another epoxy composites were prepared with the addition of fixed 5 wt% tuff and plasticizers at 5 wt% under same experimental method.

C. Characterization of Epoxy Composite Materials

X-ray diffraction (XRD) measurements were performed at a scan rate of 2 min$^{-1}$ in the range of 10 - 80$^\circ$ using Bruker D8 Advance X-ray diffractometer. Surface morphology of epoxy composites were investigated at an accelerating voltage of 20 kV using SM Zeiss LS-10 scanning electron microscope (SEM) after gold-coating of epoxy composites to prevent charging. Tensile properties were examined using Stretch and Pressing Equipment TST-Mares/TS-mxe at constant rate of 5 mm/min until fracture. Hardness of the epoxy composites were determined using Shore Durometer TH 210 tester with calculating arithmetic mean of data taken from front and back surfaces of epoxy composites. Adhesion ability of epoxy
composites was evaluated as per Lattice notch method [11] and adhesion percent was calculated using the following equation:

$$\text{Adhesion, } \% = \left( \frac{a - b}{a} \right) \times 100$$  \hspace{1cm} (1)

where $a$ is the total number of the squares on the steel surface and $b$ is the number of squares separated from steel surface. The corrosion resistance of the epoxy composites was examined with observing them in 3\% NaCl, 10\% H$_2$SO$_4$, 10\% NaOH solutions for two weeks at room temperature [12]. Water sorption test was carried out as per ASTM D 570 Standard for two weeks at room temperature. Water sorption percentage was calculated using the following equation:

$$\text{Water sorption, } \% = \left( \frac{m_1 - m_2}{m_2} \right) \times 100$$  \hspace{1cm} (2)

where $m_1$ is the mass of sample at any time and $m_2$ is the initial mass of sample. Thermogravimetric analyses (TGA) were carried out using Lab. METTLER STAR SW thermal analyzer under the N$_2$ atmosphere with heating rate of 10 °C/min.

III. RESULTS

XRD patterns of neat ER, tuff, and epoxy composites including 5 wt\% tuff and plasticizers are shown in Fig. 1. The tuff intensively exhibited characteristic peaks between 20 and 40°, while neat ER had only broad peak at about 20°. The peaks belonged to tuff were almost disappeared when the 5 wt\% tuff was added to neat ER. And also, no sharp peak was observed with the addition of 5 MEG, DEG, and PEG to the epoxy composite including 5 wt\% tuff, respectively. It can be deduced from the XRD results that uniform dispersion of tuff and plasticizers was most likely obtained in the neat ER. SEM images of neat ER and epoxy composites including 5 wt\% tuff and plasticizers are shown in Fig. 2. Typical smooth morphology of neat ER that is generally evidence of brittle structure was shown in Fig. 2a. It was clearly seen homogeneous dispersion of 5 wt\% tuff in the neat ER in Fig. 2b. Although a small agglomeration was observed for epoxy composite including 5 wt\% MEG in Fig. 2c, well-dispersed structure was obtained for epoxy composites including 5 wt\% DEG and PEG in Fig. 2d and Fig. 2e, respectively.
Tensile strength ($\sigma$), elongation at break ($\varepsilon$), and hardness values of neat ER and epoxy composites are shown in Table 1. The maximum $\sigma$ and $\varepsilon$ was observed for epoxy composite including 3 wt% tuff; however more than 3 wt% tuff addition decreased $\sigma$ and $\varepsilon$ values. Due to rigid structure of tuff, an increase in hardness of the epoxy composites was determined. When the effect of plasticizers on the tensile properties of epoxy composites was investigated, epoxy composite including MEG had the lowest $\sigma$ and $\varepsilon$ values. These plasticizers especially PEG decreased brittleness of the epoxy composites owing to its flexible structure.

Table I Tensile Properties of Neat ER and Epoxy Composites

</tr>
</tbody>
</table>

The adhesion percent of neat ER, 96%, negligibly decreased until 90% with increasing amount of tuff. It can be explained that incorporation of tuff to the neat ER may slightly decrease cross-linking density of ER chains. The adhesion percent of epoxy composite including 5 wt% tuff decreased from 94% to 90 and 88% with the addition of DEG and PEG, respectively. However, any change in the adhesion percent was not identified for epoxy composite including MEG.

At the end of the observations for corrosion resistance of epoxy composites to different environmental conditions, there was no difference in the appearance of the epoxy composites and corrosive solutions. In other words, any crack, swelling, fracture was not determined for epoxy composites. And also, any color change was not observed in the epoxy composites and the corrosive solutions.

Water sorption of neat ER and epoxy composites as a function of immersing time in water is shown in Fig. 3. It was clearly seen that water sorption of neat ER, 0.88%, efficiently decreased with increasing amount of tuff. It can be expressed with the barrier effect of tuff which limits water penetration to the epoxy composite. The effect of plasticizers on the water sorption capacity of epoxy composite including 5 wt% tuff is shown in Fig. 4. The water sorption of epoxy composites increased with the incorporation of plasticizers especially PEG. A remarkable increase was identified with PEG addition.
due to more hydroxyl groups in its structure that tend to combine with hydrogen in water molecules.

The effect of plasticizers on the water sorption of epoxy composites including 5 wt% tuff is shown in Fig. 6. The plasticizers slightly decreased initial decomposition temperature of epoxy composite including 5 wt% tuff; however the residue values of epoxy composites including plasticizers were quite close to epoxy composite including 5 wt% tuff.

TGA curves of neat ER and epoxy composites including tuff are shown in Fig. 5. It was obviously seen that decomposition temperatures of neat ER was enhanced with the addition of tuff. The residue which limits to release combustible gases at 700 °C for neat ER was increased from 20.50% to 29.20% with adding 10 wt% tuff. Thermal resistance of tuff was higher than neat ER, so thermal stability of the epoxy composites was improved. The effect of the plasticizers on the thermal properties of the epoxy composite including 5 wt% tuff is shown in Fig. 6. The plasticizers slightly decreased initial decomposition temperature of epoxy composite including 5 wt% tuff; however the residue values of epoxy composites including plasticizers were quite close to epoxy composite including 5 wt% tuff.

IV. CONCLUSION

Epoxy composites including tuff at different weight ratios were easily prepared. In addition to this experiment, the effect of plasticizers on the physico-mechanical and thermal
properties was investigated. XRD and SEM results showed that good interaction between neat ER and tuff and/or plasticizers was achieved in spite of a small agglomeration in the epoxy composite including MEG. The epoxy composite including 3 wt% tuff had the highest σ and ε value among the others. While the hardness of epoxy composites was increasing with the tuff addition, plasticizers decreased brittleness of the epoxy composites. The epoxy composites including PEG were less brittle than the other composites. The adhesion capacity of neat ER did not deteriorate with the incorporation of tuff and plasticizers. The corrosion resistance of the neat ER was preserved under the influence of tuff and plasticizers addition. An increase in the amount of tuff decreased water sorption of the epoxy composites; however plasticizers especially PEG led to increase water sorption of the composites. Thermal stability of the epoxy composites was enhanced with the tuff addition. Although initial decomposition temperatures of the composites slightly decreased with plasticizers, decomposition temperatures in high temperatures were quite close each other in all composites.

Abstract—Nano calcium carbonate (CaCO$_3$) is used to enhance mechanical performance of fiber reinforced polymer composites (FRPs). In the present study, the influence of nano CaCO$_3$ particles have been examined by using the low-velocity impact tests on carbon fiber reinforced laminated epoxy nanocomposite to determine its impact response. At the beginning, several rates of nano CaCO$_3$ particles which are quoted epoxy (1 to 3 wt %) were dispersed into acetone, than this solution was added into epoxy resin. After acetone was removed via vacuum oven, nanocomposites were manufactured by low cost Vacuum Assisted Resin Infusion Method (VARIM). The test performed according to ASTM-D-7136 standard with 2, 2.5 and 3 m/s impact velocities on 100 x 150 mm tests specimens. Considering to impact force and displacement versus interaction time entail results, nano CaCO$_3$ particles provided significant improvement on impact damage resistance. The highest damage resistance and more efficient energy absorption observed addition of 2 wt % nano CaCO$_3$ particles as an optimal ratio.

Keywords—Epoxy modification, nano calcium carbonate, impact behaviour, vacuum resin infusion method (varim)

I. INTRODUCTION

The mechanical property of neat epoxy matrices can be enhanced by modifying to provide high stiffness and strength [1]. In this regard, nanoscale reinforcements have attracted considerable attention to modifying epoxy in the field of conducting polymer nanocomposites to ensure good mechanical properties, excellent electrical and thermal conductivities for many applications [2-4]. There is a relationship between low-velocity impacts and a series of micro-cracking generated in the matrix during the impact event [6]. These sub-critical cracks may not produce to damage, but cause local stress redistribution and energy concentration. Nanocomposites provide opportunities causing new fracture behaviour beyond those found in conventional materials [7].

The nanocomposites containing different nanoparticles have been further employed as the matrix material to produce nanoparticle modified fiber reinforced polymer composites (FRPs) that possess improve the mechanical and fracture properties [7-9]. However, so far few studies have been reported on CaCO$_3$ nanoparticles modified carbon fiber reinforced polymer composites (CFRPs) [10]. The aim of this paper is to investigate the low-velocity impact response of CaCO$_3$ nanoparticles modified carbon fiber reinforced laminated polymer composites.

II. MATERIALS AND PROCEDURE

A. Nanocomposite Manufacture

The epoxy resin as the commercially available diglycidylether of bisphenol-A (DGEBA) supplied by Momentive Hexion Inc. Nano-CaCO$_3$ was purchased from Shandong Dazhan Nano Materials Co. Carbon fiber fabric and the all other vacuum infusion equipments were provided by Dost Kimya Inc., Turkey. The area density of carbon fiber was 300 g/m$^2$ and each bundle consisted of 12000 filament.

Due to the importance of the dispersion of nanoparticles within epoxy resin, initially the nano-CaCO$_3$ which are quoted epoxy (1 to 3 wt %) were dispersed into acetone, than this solution was added into epoxy resin. The mixtures were stirred for 30 min with an ultra sonicator. The mixture was heated up to 70 °C for 24 h in a vacuum oven to remove the acetone from epoxy mixture. After acetone was removed via vacuum oven, curing agent was added in to the epoxy mixtures appropriate with supplier instructions and the mixture was mixed manually for 5 min. Neat epoxy suspension was also prepared same conditions for control.

Carbon fiber reinforced epoxy matrix laminated nanocomposites were prepared by means of VARTM. Six layers of woven carbon fabrics (350 mm×500 mm) were cut and the fiber preform was stacked on VARTM loom. In contrast to the standard VARTM methods, firstly hand lay-up method applied on each woven carbon fabric layers, and the resin impregnated woven fiber were put into a vacuum bag. In this way, filtering of nanoparticles by fiber was also prevented. After degassing, the temperature was increased to 80 °C for 1 h, at 120 °C for 2 h. After curing process, the system was cooled gradually down to the room temperature, so as to avoid the unwanted shrinkage in the laminates.

Finally, the cured panel was taken out and specimens were cut according to ASTM-D-7136 standard.
B. Experimental Techniques

The produced composite laminates have been subjected to low-velocity impact tests in accordance with ASTM-D-7136 standard. Impact tests were performed with a drop tower by adjustable the height of impactor. The impactor has a hemispherical shape with a spherical hardened steelhead of 12 mm diameter and 6.35 kg mass.

The force variations were measured by a sensor in millivolts scale. The interaction force variations between the impactor and the sample were recorded using NI Signal Express software. The sampling rate of data acquisition system is 10 kHz. As described in the regarding standard, the Newton’s second law was used to express the velocity and displacement of impactor versus time [11]. The tests were repeated three times at 2, 2.5 and 3 m/s impact velocity levels.

To prevent the repetitive impacts on the composite specimens, system has an anti-rebounding mechanism which catches immediately the impactor after completed the initial impact.

Data received from the force sensor during impact were processed by using Newton’s second law. It is known that first integration of acceleration as a function of time gives the velocity and second integration gives displacement.

III. RESULTS AND DISCUSSIONS

The low velocity impact performance of the neat and nanoparticle modified composite materials were evaluated using different parameters that have been performed in literatures which include the force-time, the absorbed energy-time and force-displacement interactions [12–14].

A. Force-time curves

Fig. 1 shows the force responses for the four different CFRP laminate specimens which include different nano-CaCO₃ particles range from 0 wt% to 3 wt% depend on 5, 10, 15 Joules impact energy levels. It is seen that the general behavior of the specimens show differences in terms of peak load and beginning slope which is parameters of materials rigidity. Also Fig. 1 demonstrates that the maximum peak load value and slope are achieved in case of 2 wt% CaCO₃ nanoparticles loading.

On the other hand, 3 wt% CaCO₃ nanoparticles loading causes decline both achieved maximum force and slope. It is believed that this deterioration of performance is caused by locally nanoparticle agglomeration.

When the figures (Fig. 1.a, Fig. 1.b and Fig. 1.c) are compared, it is clearly seen that as the impact energy increases, the peak force on the specimens are increase.

Another noticeable issue is evolution of interaction time. Fig. 1 demonstrates that 2 wt% CaCO₃-Epoxy/CF is relatively exhibited shortest interaction time. By the reason of the enhanced rigidity of modified composite laminates, bending capability is reduced and therefore interaction duration is decreased the moment of impact.

Fig. 1. Force and time curves at different impact velocity level for neat and modified specimens (a) 2 m/s, (b) 2.5 m/s, (c) 3 m/s.

B. Force-displacement curves

Fig. 2 shows the relation between impact force and displacement for composite laminates at different impact energy levels. It is observed that curves exhibit nearly linear behavior at the beginning of the curves. After reaching peak force value, the force decreases non-linearly.
The slope of force-displacement curves is criteria of bending stiffness under impact loading [11]. Inter-layer and intra-laminar interaction play important role in this region. Increasement of slope indicates that the better interfacial interaction than neat epoxy specimens. 2 wt% CaCO\(_3\) nanoparticles loading indicates well matrix-fiber interactions.

Fig. 2 clearly illustrates that as the impact energy increases, the contact force and the displacement also increase which is associated with damage amount in laminates.

C. Energy-time curves

Energy-time curves of laminates are seen in Fig.3. Rebound energy and absorbed energy relation are shown as representatively for one specimen in Fig. 3.a. It is clearly seen that in case of 3 wt% CaCO\(_3\) nanoparticle loading, laminates absorbed more energy. This situation also means that material is more destroyed. Because the absorbed energy increases, this energy will be exert to damage formation in laminates. In addition, the minimum energy absorption occurs in 2 wt% CaCO\(_3\) nanoparticles loading.

Fig. 2. Force and displacement curves at different impact velocity level for neat and modified specimens (a) 2 m/s, (b) 2.5 m/s, (c) 3 m/s.

Fig. 3. Energy and time curves at different impact velocity levels for neat and modified specimens (a) 2 m/s, (b) 2.5 m/s, (c) 3 m/s.
IV. CONCLUSIONS

The experimental results for the low velocity impact response (impact velocity at 2, 2.5 and 3 m/s) of nanocomposites have been presented in this paper. Three types of nanocomposite specimens prepared from modified epoxy resin. Neat epoxy samples prepared for control. After modifying with nanoparticles, the impact peak forces and slope of force-time curves increase, which means that the nanoparticles enhance the rigidity of carbon fiber reinforced epoxy composites.

The impact properties of the 1 wt% and 2 wt%-Epoxy/CF nanocomposites are higher than 0 wt% and 3 wt%-Epoxy/CF specimens owing to better adhesion at the fiber-matrix and laminate interface.

Impact behavior gradually reduce in condition of increased nanoparticle content because that the nanoparticle agglomerates produce the inhomogeneous particle shape and increase the composite brittleness.

Abstract — There are many studies have been carried out about nanomaterials in the last decade. Under the guidance of these studies, the mechanical properties of composite materials can be changed by adding nanoparticles. Multi-wall carbon nanotubes (MWCNT) and nanoclays (NC) have been well known nanoparticles, which can be used to develop mechanical properties of diglycidyl ether of bisphenol A (DGEBA) epoxy composite materials due to their superior properties. In this paper, effects of hybridization with NC and MWCNT were investigated for epoxy modification. At the beginning, nanoclay epoxy nanocomposites were prepared by conventional casting in stainless steel mold to detect optimum ratio of nanoclay range from 1 to 5 wt %. According to the result of mechanical test, optimum ratio of nanoclay particles was found at 2 wt %. Then, 0.1, 0.3, 0.5, and 0.7 wt % MWCNT added into epoxy resin which includes 2 wt % nanoclay to find out the contribution of MWCNT on mechanical properties, respectively. Scanning Electron Microscopy (SEM) and optical microscopy analysis techniques were used to understand the toughening mechanisms of the nanocomposites.

Keywords— hybrid epoxy, mechanical performance, multiwall carbon nanotube, nanoclay, nanocomposites

I. INTRODUCTION

Polymers materials especially thermosets have been commonly used for adhesives, various engineering parts and matrix for composite materials due to their superior mechanical properties compared to thermoplastic polymers. However, they have usually weak fracture properties such as toughness, brittle and vulnerable crack. The addition of nanoparticles to polymers increases its strength and sometimes decreases the toughness due to particles agglomerate, inappropriate concentration. Nanoparticles have been widely studied by researchers for enhancement of mechanical properties of polymer composite materials. Carbon nanotubes (CNT) have demonstrated high properties to improve the mechanical properties of polymers and electrical properties [1-2]. Florian et al. studied the effect of different CNT on tensile test and fracture toughness [3]. Schadler et al. studied MWCNT/epoxy composites under tensile and compressive loading and found compressive modulus of the composite to be higher in MWCNT/epoxy composite compared to the neat composites [4].

However, CNTs are both expensive and unhealthy [5]. Cheap organic materials like nanoclays are also popular for composites. Nanoclays, which are layered structures, can be reinforced the matrix to improve mechanical properties. Also, they use for thermal and moisture barrier inside of matrix due to their thermal stability and environmental degradation resistance properties [6]. Chowdhury et al. [7] studied thermal and mechanical behaviour of nanoclay-epoxy composites. They obtained best mechanical strength for 2 wt. % of nanoclay. Bagherzahed et al. studied increasing barrier and anticorrosive properties with increasing nanoclay content [8]. Kim et al. studied fracture toughness of epoxy adhesive with nanoparticle additives such as mixed carbon black and nanoclay in epoxy [9]. Islam et al. studied that modified fiber epoxy composite with 2 wt. % NC and 0.3 wt. % MWCNT on 3 point bending test, dynamic mechanical analysis and low impact test [10].

In this study, NC/Epoxy nanocomposites were produced from 1 to 5 wt %. According to the result of mechanical test of NC/Epoxy nanocomposites, optimum ratio of nanoclay was found at 2 wt %. 2 wt % nanoclay and 0.3, 0.5, 0.7, and 1 wt % MWCNTs have been added epoxy matrix. Tensile test and Flexural test have been conducted to characterize the modified epoxy and then compared to neat epoxy composites.

II. MATERIALS AND PROCEDURE

The epoxy resin and MWCNT were supplied by Momentive Hexion Inc. Nanoclay was purchased from Esan Chemical Industry.

The NC 2 wt% and MWCNT weight content was varied 0.3, 0.5, 0.7 and 1 wt%. The acetone and powder NC/MWCNT were stirred for 30 min with an ultra sonicator. Epoxy was added after dispersing process in NC/MWCNT/Acetone and evaporated acetone at 70 °C for 24 hours. Then, curing agent was mixed NC/MWCNT/Epoxy. The mixture was ultrasonicated for 30 min and degassed at 25°C/0.6 bar for 30 min. The steel mold (Fig. 1 (a)) covered with release agent and mixture was poured into preheated mold Fig.1 (b)-(c). Curing was performed at 80 °C for 1 h, at 120 °C for 2 h and then it was slowly cooled to room temperature in the oven. Then, specimens were unmold from steel mold, which made according ASTM D7264/ D7264M-07 standards for flexural test and ASTM D4762 - 11a for tensile test. All samples were removed from mold and conventionally polished with SiC.
sandpapers with grit numbers of 800 to minimize effect stress concentration caused by sharp edges. Also, flexural specimens have been cut in accordance with test standards.

III. RESULT AND DISCUSSION

A. Flexural Test Results

At the beginning, three point bending tests were conducted to understand the effect of nanoclay matrix modification on flexural behaviour. Flexural load-deflection curves of modified NC/Epoxy with as a function of different weight percentages of nanoclay in the epoxy resin showed in Fig. 2. It is clear from this figure that flexural load and deflection values of the modified epoxy loaded with 1 and 2 wt% nanoparticles are much greater than neat epoxy sample. However, the flexural loads were decreased in case of the epoxy containing 3, 4 and 5 wt% nanoparticles. This reduction in the load was related to the nanoparticle agglomerations.

Then, according to result of flexural test of NC/Epoxy nanocomposites, 2 wt% NC ratio was used for NC/MWCNT/Epoxy nanocomposites’ flexural test. The curves of NC/MWCNT/Epoxy nanocomposite with 2 wt% NC and 0.1, 0.3, 0.5 and 0.7 wt % MWCNT in the epoxy matrix shown in Fig. 3. Although, loaded with 2 wt% NC and 0.1% MWCNT nanoparticles did not change significantly, it can be seen that the curves values of NC/MWCNT/Epoxy nanocomposite loaded with 2 wt% NC and 0.3 wt% MWCNT nanoparticles are greater than neat one in Fig. 3. Loaded with 0.5 and 0.7 wt% MWCNT nanoparticles did not show good mechanical properties.

Table 1 summarizes the loads and deflections at the peak loads both NC/Epoxy and NC/MWCNT/Epoxy nanocomposites. The flexural test result of NC/Epoxy nanocomposites with 2 wt% have increase of 40.1 %. On the other hand, 2wt% NC – 0.3 wt% MWCNT/Epoxy nanocomposite have increase of 19.2 % compared to 2 wt% NC/Epoxy and increase of 67.1 % compared to neat epoxy composites.

B. Tensile Test Results

Stress-strain curves of different weight percentages of NC/Epoxy are shown in Fig.4. It can be seen highest increase of the tensile strength and strain is achieved with the 2 wt% nanoclay loading. Also this figure show, tensile properties are deteriorate in case of over the 2 wt% nanoclay loading. It is believe that this event occur due to the agglomerations of nanoclay.
The optic micrograph of the neat epoxy sample displayed smooth fracture surface after the flexural test, due to their innate the poor toughness as shown in Fig.6 (a). The optic micrograph of 2 wt% NC/Epoxy indicated more ductile and plastic deformation region in Fig. 6 (b) compared to neat epoxy sample. The optic micrograph of 2 wt% NC – 0.3 wt% MWCNT modified nanocomposites showed a rough fracture surface with evidence of relatively plastic deformation, indicating a relatively ductile fracture surface compared to 2 wt% NC/Epoxy samples (Fig. 6 (c)). These differences clearly show the higher fracture toughness of NC and MWCNT modified epoxy resin compared to that of the neat epoxy and NC modified epoxy resin. The evidences of 2 wt% NC – 0.3 wt% MWCNT/Epoxy like rough surface, plastic deformation were more than others.

C. Analysis of Fracture Surface

To better understand the toughening effect of NC and MWCNT on the nanocomposites, flexural and tensile fracture surfaces of the NC/Epoxy and NC/MWCNT/Epoxy nanocomposites were observed using SEM and optical microscope.

Table II summarizes the stress and strain curves at the peak loads both NC/Epoxy and NC/MWCNT/Epoxy nanocomposites. The tensile test result of NC/Epoxy nanocomposites with 2 wt% have increasement of 37.03 %. On the other hand, 2 wt% NC – 0.3 wt% MWCNT/Epoxy nanocomposite have increasement of 34.37 % compared to 2 wt% NC/Epoxy and increasement of 84.12 % compared to neat epoxy composites.

Fig. 5 Tensile curves of NC/MWCNT/Epoxy nanocomposite

Fig. 4 Tensile curves of NC/Epoxy nanocomposite

Fig. 6 Fracture Surface after flexural test

After the tensile test, fracture surface images can be seen in Fig. 7. Congruently, Fig. 7 (a) shown that neat epoxy sample displayed smooth fracture surface and it has a poor toughness. Besides, the optic micrograph of 2 wt% NC/Epoxy shown rough and plastic deformation area in fracture surface compared to neat epoxy composite sample in Fig. 7 (b). In the surface image of 2 wt% NC – 0.3 wt% MWCNT, it can be seen sharp plastic deformation and rough yielding area (Fig. 7 (c)). Consequently, these evidences of NC/MWCNT/Epoxy nanocomposite were more than other fracture surfaces.

Fig. 7 Fracture Surface after tensile test

In order to understand the improvement of toughness mechanism in 2 wt% NC – 0.3 wt% MWCNT/Epoxy nanocomposite, SEM images of fracture surfaces are shown in Fig. 8. The SEM micrographs of 2 wt% NC in the epoxy matrix are shown in Fig.8 (a). The fracture morphology of the 2 wt% NV/Epoxy specimen shows very homogenous nanoparticle dispersion in Fig.8 (a). There are a number of toughening mechanisms in literature which can be associated to the amount of energy absorbed and fracture toughness increases as the
main toughening mechanisms are crack pinning and crack bridging [11-12]. Nanoparticle bridging mechanism is clearly seen in 2 wt% NC/Epoxy nanocomposite (Fig. 8 (b)). Also, both crack pinning and bridging mechanisms can be seen in 2 wt% NC – 0.3 wt% MWCNT/Epoxy specimens (Fig. 8 (c)).

toughness mechanisms such as crack pinning, nanoparticle bridging were apparent in the SEM micrographs and these mechanisms related to amount of energy absorbed. Fracture toughness increase with these mechanisms.

IV. CONCLUSIONS

Experimental results show that the 2 wt% NC and 2 wt% NC – 0.3 MWCNT modification significantly improved flexural strength of epoxy nanocomposite compared to neat epoxy by 40% and 67%, respectively. This tendency for tensile strength has maintained to be 37% and 84%, respectively. The results of the conducted experiments show that the NC and MWCNT modification in epoxy resin enhance flexural and tensile properties of nanocomposites. Fracture surface analysis such as optic and scanning electron microscopy supported this conclusion. Plastic deformation, ductile and yielding area can be seen in optical images for nanocomposite materials. Besides, toughness mechanisms such as crack pinning, nanoparticle bridging were apparent in the SEM micrographs and these mechanisms related to amount of energy absorbed. Fracture toughness increase with these mechanisms.

Abstract—The aim of this study is to investigate the effect of SiC particle size on the hardness, wear and exfoliation corrosion behaviour of AA7075-SiC composites. For this purpose, various size (8, 32 and 82 μm) and amount (wt.%10 and %15) of SiC particles have been added into AA7075 aluminium alloy powders and O35x30 mm cylindrical blocks were produced by pressing. These pressed powder metal compacts are extruded at 480 °C as 12 mm dia round bars. Then, T6 heat treatment was applied to AA7075-SiC<sub>p</sub> composites aged at 120 °C for 24 hours after solution heat treatment at 480 °C for 2 hours. In order to identify the hardness and abrasion strengths, hardness and wear tests were performed to all samples under same conditions. Exfoliation corrosion behaviour of composites was determined using EXCO corrosion test solution prepared according to ASTM G34-Standard test method. Experimental results showed that with the increase of SiC<sub>p</sub> amount in the composites, the hardness and wear resistance increased, but exfoliation corrosion resistance decreased.

Keywords—Include at least 5 keywords or phrases

I. INTRODUCTION

AA7075 alloy have excellent formability in addition to high strength, good corrosion resistance [1] and low density [2]. They are used for high strength structural applications such as aircraft parts and sporting goods [2]. Nevertheless, their applications are sometimes limited because of their low hardness and wear strength. However, these properties can be improved by precipitation and/or introducing second phase particles into the metal matrix [2].

Aluminium matrix composites have the advantage of mixing two or more different materials with opposite properties and are produced by different technological processes such as powder metallurgy [1], stir-casting [3], infiltration[4], extrusion [2]. In aluminium matrix composites, SiC is widely used as a second phase [5–8]. The powder metallurgy method allows the introduction of secondary particles into the base metal matrix in the solid state [2].

The present study is aiming to fabricate the AA7075 aluminium matrix composites reinforced with micro-sized SiC particles by using powder metallurgy and hot-extrusion processes, and investigate their wear and exfoliation corrosion behaviour.

II. EXPERIMENT

AA7075 powders (<74 μm) with chemical composition, presented in Table 1, were blended with different weight (10 wt.% and 15 wt.%) and particle size fractions (8, 32 and 82 μm) of SiC powders (Fig. 1). After blending, the powder mixtures were pressed into a die to form compact shape of 35 mm diameter and 30 mm length under 350 MPa pressure. The compacts were hot-extruded at 480 °C with an extrusion ratio of 8.5:1 as 12 mm diameter round bars (Fig. 2). In order to reduce wall frictional effects, mould release oil was used on the extrusion die surfaces. The extruded rods were cut in lengths of 15 mm. For the T6 heat treatment process, the specimens were solidified at temperature 480 °C for 2 h and quenched in water, then aged at a temperature of 120 °C for 24 h in air.

Fig. 1 AA7075 alloy and SiC ceramic particles
The structure, morphology and chemical composition analyses of samples were performed using a field emission scanning electron microscope (SEM), (Carl Zeiss Ultra Plus FESEM equipped with EDX). Microhardness measurements were made using a Qness Q250M Macro Hardness Tester employing an indenter of 10 mm diameter and a load of 31.25 kgf on surfaces of polished samples. Each hardness value is the mean value of five measurements. The friction coefficient and wear resistance of specimens were tested using a computer aided pin-on-disc type apparatus (UTS Tribometer T10/20) at the linear sliding speed of 1 m/s under load of 40 N in a sliding distance of 1000 m in dry ambient environment at 24-25 °C with humidity 46 ±2. AISI 52100 steel with 62 HRC hardness was used as counter-disc.

The exfoliation corrosion (EXCO) tests were performed according to ASTM G34-01[9]. The corrosion tests were performed using EXCO solution for different immersion times of 4, 8 and 16 h. The tested temperature was 25 ± 2 °C and the solution-to-sample surface area ratio is 30 ml/cm².

III. RESULTS AND DISCUSSION

Density graph of extruded AA7075 alloy and AA7075-SiC<sub>p</sub> composites were given in Fig. 3. The density of extruded AA 7075 alloy is 2.58 g/cm³ while the relative density is 2.82 g/cm³. This result shows that the samples have about 7% of microporosity. AA7075 alloy have a finely dispersed pore structure, according to its microstructural images (Fig. 4a-b). This figure shows that as the amount of SiC increases, the densification increases. But, when the amount of SiC (for 32 and 82 µm) reached 15 wt%, the densification declines. This is due to the agglomeration of SiC particles during the extrusion process with increasing the SiC percent.

Fig. 3 The variations of density with SiC particle content and size.

As shown in Fig. 4c-h, the porosity content increases as SiC weight fraction increases lead to decrease of porosity. Indeed, the plastic working causes to closing pores during hot extrusion [3]. In addition, it is thought that the hard particles in the matrix structure help to plastic deformation. As a result of increasing plastic deformation, porosity decreased. However, the amount of particles increases above the critical level leads to agglomeration and porosity increases [10, 11]. Also, Fig. 4 shows that SiC particles are finely dispersed in the AA7075 matrix structure.

The influence of SiC particles content and size on hardness is shown in Fig. 5. Considering this figure, by increasing the amount of SiC, composite hardness increases since its hardness is much higher than that of AA7075 alloy [10, 11]. Some other studies report that increasing the amount of hard ceramic particles in the matrix would result in more dislocations that increases the hardness of the composite [12]. Considering Fig. 5 also, it shows that decreasing the particle size will increase the composite hardness. The hardness values of AA7075-SiC
composite samples with 8 and 32 µm are harder than that of AA7075-SiC composite samples with 82 µm particles. This situation is described in two ways. One reason is the greater interfacial area between the hard and soft phases. And the other is that the defects in the coarse-grained particles are more than the fine-grained ones which results in its easy fracture under tension [11].

Weight loss of AA7075 alloy and AA7075-SiC composites as a function of particle content and size at load of 40 N is shown in Fig. 6.

Ceramic particle reinforced AA7075 matrix composite shows better wear behaviour compared to the AA7075 alloy. In the composite samples, the wear rate reduces by the increasing particle content and size. In general, the reduction in wear rate is influenced by the size of reinforcement and volume fraction of reinforcement [13]. It is thought that the reduction of wear rate depending on increasing of particle size is related to contact surface area between particle and matrix. With increasing particle size in the matrix provides more contact surface area and mechanical bonding strength between particle and matrix.

The worn surface images of AA7075 alloy and AA7075-SiC composite samples were given in Fig. 7. As shown in the figures, the worn surfaces consist of long grooves which are the result of abrasive wear mechanism.

After exfoliation corrosion test, the variation of weight loss with corrosion test period, and SiC particle content and size are shown in Fig. 8. Ceramic particle reinforced AA7075 matrix composite shows better corrosion resistance compared to the AA7075 alloy. In the composite samples, the corrosion rate increases by the increasing particle content and size.

It is though that the porous surface of AA 7075 alloy samples causes an increase in the contact surface area between the corrosion solution and sample and it provides corrosion solution to penetrate into the material. Therefore, the corrosion rate in the alloy sample is greater than the composite sample. In the composite samples, the addition of ceramic particles to the matrix decreases the porosity of the composite. Also, the ceramic particles in the matrix cause a decrease in the contact surface area. Therefore, the weight loss caused by corrosion decreases depending on the reduction of surface area exposed to corrosion.
IV. CONCLUSIONS

In the present study, wear and exfoliation corrosion behaviour of AA7075 alloy and AA7075-SiC\(_p\) composites fabricated using powder metallurgy and hot extrusion were investigated. The following results were obtained:

- AA7075 alloy and AA7075-SiC\(_p\) composites were successfully fabricated using powder metallurgy and hot extrusion.
- The density of AA7075 alloy increased with addition of SiC particles.
- By increasing the amount of SiC, composite hardness increases since its hardness is much higher than that of AA7075 alloy.
- The addition of ceramic particles to AA7075 matrix composite shows better wear and exfoliation corrosion behaviours compared to the AA7075 alloy.

Abstract— Adhesive bonding of wood enables sufficient strength and durability to hold wood pieces together and thus produce high quality wood products. However, it is well known that many variables have an important influence on the strength of an adhesive bonding quality. The objective of the present paper is to predict the bonding strength of spruce (Picea orientalis (L.) Link.) and beech (Fagus orientalis Lipsky.) wood joints subjected to soaking by using artificial neural networks. To obtain the data for modeling, beech and spruce samples were subjected to the soaking at different temperatures for different periods of time. In the ANN analysis, 70% of the total experimental data were used to train the network, 15% was used to test the validation of the network, and remaining 15% was used to test the performance of the trained and validated network. A three-layer feedforward back propagation artificial neural network trained by Levenberg–Marquardt learning algorithm was found as the optimum network architecture for the prediction of the bonding strength of soaked wood samples. This architecture could predict wood bonding strength with an acceptable level of the error. Consequently, modeling results demonstrated that artificial neural networks are an efficient and useful modeling tool to predict the bonding strength of wood samples subjected to the soaking for different temperatures and durations.

Keywords— Neural network, bonding strength, prediction, wood, soaking

I. INTRODUCTION

Adhesives allow wood industry to use small dimension wood pieces to produce bigger dimension products, and therefore the strength of the adhesive bonding is of great importance for the wood products [1]. The main role of an adhesive in a product is to transfer the stress from one substrate to another. This means that an adhesive bond needs sufficient durability to hold together the joints produced under different conditions [2]. On the other hand, understanding and controlling the adhesive bonding of wood is a challenging task due to the heterogeneous nature of wood [3].

ANNs are a powerful data modeling method capable of defining complex and nonlinear relationships between input and output parameters related to any processes or systems without the need of any assumptions [4]. In recent years, ANNs have been one of the most attractive fields of the artificial intelligence and has been widely employed in solving the problems such as optimization, classification, prediction and pattern recognition in engineering applications [5], [6]. Unlike traditional modelling approaches, ANNs are capable of learning from examples or training patterns, storing the knowledge in their weights and bias values and use them to predict future values [7]. Due to these advantages, ANNs have been increasingly considered to model the bonding strength of various materials in engineering applications. Taşkın et al. [8] tried the ANN approach to model the bonding characteristics of SiCp reinforced aluminium alloy metal matrix composites. Sancak [9] used the ANN technique for modeling the bonding strength of lightweight concretes. Golafshani et al. [10] modeled the bond strength of spliced steel bars in concrete by means of a ANN. Wang et al. [11] predicted heavy aluminium wire wedge bonding strength by means of the ANN modeling. On the other hand, the use of ANN technique to solve computational problems in wood science has increased rapidly in last two decades. Details of studies carried out to predict wood characteristics with ANN approach were are given as follows. Ceylan [12] modeled drying characteristics of wood by developing a neural network model. Tiryaki et al. [13] employed the ANNs for minimizing the wood surface roughness in machining process. Yang et al. [14] modeled the mechanical properties of heat treated wood using a neural network. In another study, Esteban et al. [15] predicted the modulus of elasticity of wood by an ANN. In another study regarding the strength properties, Tiryaki and Aydin [16] trained a feed-forward ANN to model the compression strength of heat treated wood. Moreover, due to the importance of adhesive bonding of wood and wood products, substantial modeling activities have performed during the last decades with ANN models established with different variables. Ozsahin and Aydin [17] developed an intelligent model which is capable of predicting the optimum veneer drying temperature to ensure a quality bond formation in plywood manufacturing. In another study, Demirkir et al. [18] optimized manufacturing variables for the optimum bonding strength in plywood manufacturing by the ANN modelling. 

With regard to solid wood, Tiryaki et al. [19] used the ANNs to model the optimum bonding strength of wood joints.
subjected to different temperatures and machining conditions. In another study, Tiryaki et al. [20] designed a neural network structure for modeling the influences of amount of adhesive, pressing pressure and its duration on the joining strength. Finally, in the study of Bardak et al. [21], the influences of pressing conditions on the bonding quality of different wood species were predicted by means of a multilayered neural network. These intensive efforts on estimating the bonding strength characteristics revealed that ANNs were quite useful in modeling the bonding characteristics of various engineering materials.

Our purpose in the present modeling study was to predict the bonding performances of wood samples exposed to different soaking temperatures and durations by means of artificial neural network approach, which is one of the soft computing techniques.

II. ARTIFICIAL NEURAL NETWORKS

ANN is computational intelligence method that can cope with complex problems with a capacity to learn by examples. As a robust and versatile modeling tool, ANN has proved to be successful in the solution of various problems in a number of engineering fields [22]. There are different types of ANNs based on the parameters such as neuron configurations and their connection types, and training procedure. Based on a general acceptance, it is possible to say that multilayered perceptron (MLP) trained with the back propagation algorithm is the most popular network structure for engineering applications [23].

The MLP usually comprises an input layer, a few hidden layers and an output layer [24]. The neurons of a MLP network are connected from a layer to the next one by weights \( w_{ji} \). A neuron in any layers of the network gets information \( x_i \) from all the neurons of the previous layer. It gathers information \( \text{net}_j \) weighted by factors corresponding to the connection and the bias \( \theta_j \), and transmits output values \( y_j \) computed by applying an activation function to \( \text{net}_j \) [4]. Fig. 1 defines the general function of a neuron.

![General functioning of an artificial neuron](image)

An ANN needs a training process to perform a desired task. Training is a process of adjusting the connection weights by a learning procedure. After the training process, the network can be employed to make decisions or define associations in new input data sets. It is important to state that the weights gain meaningful information after training whereas they have no meaning before training. For training, the backpropagation is known as one of the most robust algorithms [24]. The details of ANNs are given in Tiryaki and Aydin [16].

III. MODEL DEVELOPMENT STAGES

A. Data collection

The first stage in developing a neural network model is to collect the required data for modeling [25]. In this modeling study, the required data for the intended ANN model were experimentally obtained through soaking experiments carried out under different temperatures and durations. For this purpose, the experimental samples of bonding strength with dimensions of 150 × 20 × 10 mm were thus prepared flawlessly. Fig. 2 represents the dimension of experimental samples of the bonding strength.

![Experimental samples of bonding strength](image)

Ten experimental samples were prepared for each variation in order to ensure the reliability of the measurements. Thus, a total of 320 samples were prepared for four different soaking temperatures, four different soaking durations and two wood species (4 × 4 × 2 × 10). The prepared wood samples were subjected to soaking for different temperatures (20, 40, 60 and 80°C) and durations (10, 20, 30 and 40 min). After soaking process, the wood samples were acclimatized at 20 ± 2 °C and 65 ± 5% relative humidity to achieve a moisture content of 12%. The experiments were performed according to BS EN 205 [26] standards. Eq. (1) was used to calculate the strength values of the experimental samples.

\[
\sigma_y = \frac{F_{\text{max}}}{a \times b} \quad (1)
\]

Where; \( \sigma_y \) gives the value of the bonding strength, \( F_{\text{max}} \) refers maximum load at the break point, \( a \) and \( b \) constants represent the width and length of glued face, respectively.

Following the completion of the experimental procedure, the bonding strength data obtained were grouped into three sub-sets to start the modeling process; training, validation and testing. 70% of all experimental data (twenty-two data) were used for training the intended model. The remaining 30% of the data (ten data) were equally divided for validation (five data) and testing (five data) of the network.

B. Network structure

The detection of the appropriate size of the network in designing a neural network is extremely important. As seen in
Fig. 3, a three-layer ANN structure was determined as the optimum architecture for this study.

A three-layer feedforward ANN model with one hidden layer was constructed and a backpropagation algorithm was used to train network. Levenberg–Marquardt algorithm was selected as learning algorithm in the present study. Each layer of the network is linked to the next layer, but no connections exist among the neurons located within the same layer. The first (input) and third (output) layers of the network include the input variables (wood species, soaking temperature and soaking duration) and output variable (bonding strength), respectively. Since there is no certain rule to decide the number of hidden layer neurons, various combinations were tried in terms of hidden layer numbers and their neurons. After trial and error procedure, best results with minimum errors were obtained with 3-6-1 neuron configuration for input, hidden and output layer, respectively. Here, the important point was to detect the optimal number of hidden layer and its neurons, since the number of input and output layers and their neurons is evident, as discussed above. As shown, the network architecture of the bonding strength prediction model has one hidden layer and six hidden neurons. Already, in the literature, it was reported that one hidden layer is mostly sufficient to solve engineering problems [23], as found sufficient for the present study.

\[
\text{RMSE} = \sqrt{\frac{1}{N} \sum_{i=1}^{N} (t_i - \hat{t}_i)^2}
\]

(3)

\[
R^2 = 1 - \frac{\sum_{i=1}^{N} (t_i - \hat{t}_i)^2}{\sum_{i=1}^{N} (t_i - \bar{t})^2}
\]

(4)

Where, \(t_i\) is the actual output, \(\hat{t}_i\) is the network output, \(N\) is the number of samples and \(\bar{t}\) is the mean of network outputs.

IV. RESULTS AND DISCUSSION

Table 1 gives the actual values, network output and % errors of the prediction as a result of neural network analysis. As seen from Table 1, in most cases, the ANN predictions are very close to the actual values. In other words, the developed ANN model is capable of giving very near prediction values to actual data of the bonding strength.

The performance of the model developed for bonding strength prediction was evaluated. This evaluation was mainly done for both confirming the goodness-of-fit of the model and the prediction accuracy of the bonding strength. As mentioned before, RMSE, MAPE, and \(R^2\) performance measures were considered to assess the performance in making the prediction of the established neural network. In the evaluation process,
the smaller values of the RMSE and MAPE mean the better prediction. On the other hand, with respect to the $R^2$ criterion, better prediction requires higher values.

The criterion of the $R^2$ is widely employed in order to demonstrate the level of the relationship between actual and network outputs. Fig. 4 indicates graphical presentation of the fit between the actual and network outputs of the bonding strength of soaked wood, for training, validation and testing.

The RMSE values were found to be 0.073 for training, 0.325 for validation, and 0.217 for testing. Among evaluation criteria, the MAPE criterion is very critical, and in the literature, many researchers have judged the performance of the model by computing the MAPE [20], [21], [28]. Thus, it was considered to be the primary criterion in terms of prediction accuracy. For the current study, the MAPEs were found to be 2.864% for training, 6.652% for validation, and 6.253% for test. In other words, the MAPEs of the designed model range from 2.864% to 6.652%. These results of the MAPE have demonstrated that the performance of the developed neural network in modeling the bonding strength of soaked wood is adequate. A comparison of the actual and predicted strength values for training, validation and testing stages is provided in Fig. 5.

Fig. 4 The graph of relationship between actual and network outputs of bonding strength: (a) training, (b) validation and (c) testing.

As seen in Fig. 4, the $R^2$ values were found to be 99.92% for training phase, 99.75% for validation phase, and 99.11% for the testing phase in neural network model. These values of the $R^2$ are considered adequate for the bonding strength of soaked wood and thus the developed ANN structure can be employed effectively to make predictions.

Fig. 5 Comparison of actual and ANN prediction, and error values of bonding strength: (a) training, (b) validation and (c) testing.
From Fig. 5, it is possible to see that the predicted values were found to be close to the actual values. In addition, the model outputs generally overlapped with the actual outputs. As expected, the matching of the predicted values and actual values especially in the training data set is excellent. With respect to the comparative graphs of the bonding strength prediction and actual results, it can be said that the established network was successfully trained and exhibited a reasonable accuracy in the prediction of the bonding strength behavior of the soaked wood. These results confirmed that a well-trained ANN is capable of predicting the strength of joints designed under different conditions. Furthermore, as mentioned before, ANNs can describe nonlinear characteristics of the existing variables in the process without any assumptions. It is possible to claim that this flexibility of ANNs makes it more suitable for predicting the bonding characteristics of soaked wood.

V. CONCLUSION

In this study, a feed forward backpropagation network was proposed in order to model the bonding strength of soaked wood. In training period of the network, Levenberg-Marquard learning algorithm was employed. The best prediction results of the ANN were found in the network configuration of 3-6-1. In the proposed model, the values of $R^2$ were over 99% for all data sets, respectively. In addition to the $R^2$, the performance criteria such as the RMSE and MAPE regarding the prediction errors for all data sets were within acceptable ranges. All these show that the learning ability of ANN for estimation is very good and the use of this method may strongly be suggested to eliminate laborious and time consuming experimental investigations. It is possible to say that ANNs are more economical to detect the bonding behavior of the wood soaked under different temperature and durations.

Friction Welding of AZ91 and 316 L Stainless Steel
Osman Torun
Afyon Kocatepe University, Bolvadin Vocational School, Department of Machine, Turkey
otorun@aku.edu.tr

Abstract—316 L stainless steel was provided by private firm. AZ91 alloy was melted under argon atmosphere in a furnace and casted in metal mold. Samples were machined to fit size. Friction welding process was performed for various friction durations under 100 MPa forging pressure and 50 MPa friction pressure at 1000 rpm friction speed for different friction times. Microstructure of welding zone and fractured surface were examined with scanning electron microscopy (SEM). Microstructure studies indicated that welding interfaces were continuous and void-free. The shear strength values of the welding zone and matrix were determined. Fractured surface was examined with scanning electron microscopy.

Keywords—Friction welding, 316 L, magnesium alloy, AZ91, stainless steel.

I. INTRODUCTION

Magnesium alloys have good features such as low density, good damping characteristics, dimensional stability, machinability and low casting costs and hence recently attracted greater attention in academic research and, especially in fields of the aerospace, automobile and electronic industries. To extend the applications of magnesium alloys, the bonding of Mg and other metals is necessary [1-3]. Austenitic stainless steels are noted for their high strength, exceptional toughness, ductility, and formability. They exhibit considerably better corrosion resistance than martensitic or ferritic steels, and they also have excellent strength and oxidation resistance at elevated temperatures [4]. The various fusion and solid-state welding techniques can be applied to these steels. The heat of fusion welding causes grain coarsening in the heat-affected zone and solidification cracking in the weld metal [5].

Recently, many automotive and aerospace components have been produced by using magnesium alloys and austenitic stainless steels. Therefore, the bonding of these dissimilar alloys has become critical for components manufacture. The use of conventional fusion welding methods to join these alloys has limitations due to the distinct differences in their physical and metallurgical properties [6-9]. Friction welding is one of the available joining techniques, and it has been used successively in metals and alloys [10–14]. In the present study, cast AZ91 magnesium alloy and 316 L stainless steel were welded by friction welding and microstructure and mechanical properties of the welded samples were examined.

II. EXPERIMENTAL STUDIES

The alloy AZ91 (Mg–9Al–1Zn) was melted in a graphite crucible in vacuum furnace under argon atmosphere at 750 °C. Then the molten metal was cast into metal molds with 10 mm diameter under protective gas. 316 L stainless steel samples were received a private firm. The samples were machined to 8 mm diameter and 50 mm height.

The friction welding experiments were carried out by a continuous-drive friction welding machine at a constant forging pressure of 100 MPa, forging time of 5 s, and rotational speed of 1000 rpm and different friction times (Table 1). The friction welding process was given schematically in Fig. 1.

![Fig. 1 Schematic illustration of the friction welding process.](image-url)

After welding, the welded samples were cut perpendicular to the welding interface. The surfaces of the welded samples were ground with 1200 grinding paper and polished with 1 µm diamond paste, and then the samples were examined with scanning electron microscopy (SEM). The chemical compositions of the weld zone and the base alloys were determined using energy dispersive spectroscopy (EDS). Shear tests were performed to determine the strength of the weld interface using an electromechanical universal test machine (Shimadzu AG-IS-250) at room temperature. A specially designed specimen holder (Fig. 2) was used to measure the shear strength. Three samples were tested for each welding condition. The fractured surfaces of the welds were observed by SEM.
III. RESULT AND DISCUSSION

Flash formation was observed in all welded samples because of plastic deformation during welding. Friction time plays an important role in the flash formation. More plastic deformation occurs because of the longer the friction time, which produce higher heat in the weld interface. Thus, the burn-off (axial shortening) increases with the increase in plastic deformation (Table 1). The different physical and mechanical properties of the materials exhibit different deformation rates during the friction welding [15].

316 L stainless steel has greater strength at elevated temperatures compared with AZ91. Therefore, 316 L stainless steel shows much less deformation than AZ91 alloy during friction welding and much more mass is transferred to the flash from the AZ91 side.

SEM micrograph of welded samples for 5 s is shown in Fig. 3. It can be clearly observed that a diffusion zone forms at the weld interface for all of the welded samples. The increase in temperature, which depends on the friction time, accelerates the diffusion of atoms. The composition of the diffusion zone of the welded samples was determined by EDS analysis. The analysis shows that the diffusion zone present at the interface consisted of Fe, Al, Cr, Ni, Mg atoms (Fig. 4).

The shear strengths of the welds and the base alloys are shown in Fig. 5. Test results demonstrated that the values of the shear strength of the welded samples increase with increase of friction times. This observation indicates that the increase in the shear strength is related to the magnitude of the accumulated heat input, which depends on the friction time. 3 s friction time was not high enough to produce the required heat for the friction welding, compared with the 5 and 7 s treatment. The shear strength of the sample welded for 5 and 7 s was as high as that of the sample of AZ91 welded.

![Fig. 4 The composition of diffusion zone of the welded sample for 5 s.](image)

![Fig. 5 The shear strengths of the welds and the base alloys.](image)
Fig. 6 shows the SEM fractographs belonging to the AZ91 side and the 316 L side of the welded sample that were treated for 5 s. The SEM and EDS analysis indicated that the failures took place in AZ91 side during the shear test. However, this situation was not observed for all of the welded samples. While the sample welded for 3 s fractured from interface, the samples welded for 5 and 7 s fractured from AZ91 sides. These findings support the trends observed in the shear strength values. The welded samples that have higher shear strengths fail from AZ91.

IV. CONCLUSION

In this study, the friction-welded AZ91 alloy and 316 L stainless steel were free of pores and cracks. Microstructure studies showed the presence of diffusion zone at the weld interface. While the shear strengths of the welds increased with an increase in the process time. A minor variation in the shear strength values was observed between 5 and 7s friction time. The best welding parameter combination was found to be a friction pressure of 50 MPa, and a friction time of 5 s because the axial shortening was minimized.

University avenue 27310 Şehitkamil / Gaziantep, Turkey

Abstract

Hole-EDM drilling is a different type of electrical discharge machining (EDM) processes, i.e. sink-EDM and wire-EDM. Although hole-EDM drilling uses the same principles as other EDM methods, a constantly rotated hollow electrode and pumping of dielectric fluid through the electrode tube are the two distinct features. This process has been alternatively used for producing holes in turbine blades, fuel injectors, medical equipment, cutting tool coolant holes, hardened punch ejectors, plastic mould vent holes and wire EDM starter holes. In this study, a comparative investigation of fast hole drilling of die steel, namely as DIN 1.2379 using EDM method was performed in order to explore the influence of electrode material, i.e. brass and copper electrode materials. The comparisons were made from the results of material removal rate (MRR), electrode wear rate (EWR) and scanning electron microscope (SEM) images of the white layer thickness (WLT) taken from the machined hole surfaces. The experimental results reveal that the brass electrode has comparatively better MRR and lower EWR. However, the SEM images show that brass electrode produces less damage and WLT on machined surfaces than copper electrode for this material.

Keywords: Electrical discharge machining, Fast hole drilling, Electrode, Brass, Copper

I. INTRODUCTION

Electrical Discharge Machining is a non-traditional machining process that has become a well-established machining process in manufacturing industries throughout the world and has replaced drilling, milling, grinding and other traditional machining operations. EDM is capable of machining geometrically complex or hard material components that are precise and difficult to machine. EDM processes are classified into die-sinking EDM, Wire-EDM and Hole-EDM. The electrode of die-sinking EDM has the reversed shape of the part to be machined. Wire-EDM uses thin wire, ranging from 0.02 to 0.36 mm in diameter electrode and Hole-EDM uses tabular electrodes have diameter from 0.3 to 6.0 mm.

Drilling small holes is one of the basic metalworking processes; nearly 40% of all production time is spent to produce holes. Conventional drilling techniques cannot be employed to produce small-size holes on difficult-to-cut materials as tool wear/breakage and slow machining rates lead to inaccurate hole dimensions and unacceptable surface quality. The performance of advanced parts such as turbine blades and combustion chambers depend on very large number of small holes for cooling hot components. Typical cooling hole diameters and aspect ratios are in the range of 1–4 mm and 40–200, respectively [1]. Drilling process of small hole, which has the large depth to diameter ratio, is very difficult by using traditional methods. For some materials, which have greater strength and hardness like carbide, tool steel and super alloys, it is nearly impossible. Electrical discharge machining process removes microchips from the workpiece by means of a series of repeated electrical flushing. The EDM process is achieved by applying a succession of discrete discharges between the tool (cathode) and the workpiece (anode), separated by a dielectric fluid. EDM small-hole drilling process is a highly economical method for drilling fast and highly precise holes into all types of conductive materials, either hard or soft [2]. The process is used for production of fuel injectors, venting holes of injection moulds, coolant holes of injection cutting tools, hardened punch ejector holes, wire-EDM starter holes, holes in turbine blades and other similar operations [3] [4] [5].

The most important performance parameters in the EDM process are the surface roughness (Rₐ), the material removal rate, and the electrode wear (EW) [1]. Asperities produced by electrical discharge machining are covered by a multitude of overlapping craters, which results in the formation of corresponding workpiece profiles with a specified accuracy and surface finish, and also white layer (recast layer) is generated in all EDM processes [6]. Eyerciglu et al. [1] reported that the effect of electrical parameters is more significant than the effect of the other parameters on EDM small hole drilling process. Kuppan et al. [7] reported that MRR is affected by duty factor, discharge current and electrode rotation, whereas pulse on-time and discharge current influence the surface roughness value. Singh et al. [8] studied the effect of machining parameters over output performances of ram-EDM of Al-SiC composite and reported that MRR, taper, radial overcut and surface roughness increase while the current and pulse on-time settings were higher. In small-hole EDM drilling, the effects of non-electrical parameters on MRR were researched by Cao et al. [9] Ekmecki et al. [10] studied the effects of pulse energy on geometry and surface damage of the blind holes machined by micro-EDM. Yilmaz and Okka [11] researched the influence of number of channels in the electrodes on performances of small-hole EDM drilling process by using titanium alloys as workpiece material. They reported that the single channel electrode is better than the multi-channel electrode to obtain higher MRR; however, the surface roughness is better when using multi-channel electrode. The effects of input parameters on the response parameters such as average surface roughness (Rₐ) and average
circularity of the drilled holes in nickel-based super alloy was studied by Yadav et al. [12]. Jannamane and Muttamara [13] investigated the influence of EDM parameters on MRR, EWR and tapered hole of martensitic stainless steel AISI 431. The recast layer was much thinner with this oxygen-assisted machining method. Gov [14] investigated that the effects of the dissolved oxygen in the coolant on the hole EDM performance parameters such as material removal, electrode wear, surface roughness, over cut, taper and white layer thickness. The results showed that the increasing in the oxygen dissolution in the coolant, improving the performance parameters. The variations of machining performance outputs were experimentally investigated with the varying machining parameters for metal powder mixed dielectric liquid in EDM by Ėğun et al. [15] it is reported that the type and concentration of the powder in the dielectric fluid and the pulse-on time were effective performance parameters of EDM process. The powder-mixed electrical discharge machining was examined using SiC powder mixing in water dielectric liquid by Ekmekeci et al. [16]. The experimental studies revealed that the surface morphology drastically affected the additives as means of secondary discharges and particle migration from dielectric liquid. In this study, electro discharge hole drilling processes was applied to DIN 1.2379 tool steel by using single channel brass and copper electrodes. In the study the electro erosion parameters ($T_{on}$, $T_{off}$ and C) kept constant and the effect of the current and electrode materials on the performance parameters such as material removal rate, electrode wear rate and the SEM images of the white layer thickness was examined.

II. MATERIALS AND METHOD

Experiments were performed by using JS EDM AD-20 type hole electrical discharge machine which is available in Mechanical Engineering Department of Gaziantep University. The samples were prepared by 10×10×40 mm DIN 1.2379 die steel which were cut by wire electro discharge machining. Each face of the samples was ground by using 320 to 2000 size emery papers gradually and polished by using 1 µm diamond suspension before drilling. Single channel 2 mm diameter brass and copper electrodes were used for drilling the holes which were drilled on the centre of the machined polished faces vertically (Fig. 1). The major electrode material properties are given in Table II. Experiments were performed in 3 repetitions and the performance parameters were defined by average of these three measurements. The EDM parameters; current (I), arc on time ($T_{on}$), arc off time ($T_{off}$), and capacitance (C) were chosen as the optimum values which were proposed by Eyericioğlu et al. [1] The list of the EDM parameters are given in Table I.

In this study, the performance parameters are defined as material removal rate (MRR), electrode wear rate (EWR) and the SEM images of the white layer thickness (WLT) of the workpiece surface.

A. Material Removal Rate

EDM is defined as the high-energy sparks that occur between the workpiece and electrode cause material removal and evaporation. In EDM process, the material removal rate is defined as the amount of material removal at unit time. In EDM process high MRR is intended and the studies are performed at this situation. In this study, the specimens were weighed before and after the experiments by using 0.1 mg sensitive Shimadzu AUX220 digital balance. The machining time was measured by using digital stopwatch. And the machining speed was calculated by equation (1).

\[
MRR \left( \frac{mg}{min} \right) = \frac{\text{initial weight} - \text{final weight}}{\text{Machining time}} \tag{1}
\]

B. Electrode wear rate

In EDM process, high temperature sparks provide the chip removal from the workpiece at the same time these sparks erode the electrode. This erosion is known as electrode wear in EDM process. In EDM drilling process, machined geometry is directly related to the electrode wear, so the minimum electrode wear gives better geometric performance on workpiece. In this study, the electrodes were weighed before and after the machining by 0.1 mg precision digital balance. And the electrode wear was calculated by using equation (2).

\[
EWR \left( \frac{mg}{min} \right) = \frac{\text{initial weight} - \text{final weight}}{\text{machining time}} \tag{2}
\]
C. SEM Images of White Layer

In all types of EDM processes, white layer is generated, related to the high electrical discharge that is caused by the high temperature generation and sudden cooling between the workpiece and electrode. This white layer has the very hard and brittle properties. Thermal stresses are generated in the white layer and it causes the micro cracks which lays from white layer to main material [17]. These micro cracks tend to develop from the white layer to main material and they decrease the fatigue strength and service life of the part [17]. In this experimental study, the cross sectional SEM images were taken by using Jeol JSM-6390 LV electron microscope and the white layer thickness were measured by using these images.

III. EXPERIMENTAL RESULTS

D. Material Removal Rate

In this study, two types of tubular electrodes were used. The effects of electrodes and current on MRR for DIN 1.2379 die steel are presented in Fig. 2. When material removal rate is considered according to the current, the MRR is decreased as the current increased for both electrode types. The better MRR was obtained at 10 A current value. When MRR of the electrode types are compared, brass electrode has the best MRR than the copper for all current levels. As in the case of copper, material removal rate is lower than that of the brass. This might be due to melting temperature of copper electrode (1084 ºC) which is higher than that of the brass electrode (900 ºC). It is obvious that copper has higher thermal conductivity (391 W/m.K) and less electrical resistivity than brass (159 W/m.K). Thus, the discharge energy produced while EDM machining has profound effect on brass in terms of higher MRR.

Moreover, although copper material has less electrical resistivity and higher melting temperature than brass alloy, the MRR results show that brass electrodes would be more preferable in terms of having higher MRR. It is to be the reason of that comparatively low thermal conductivity of brass as an electrode material does not allow the absorption of much of the heat energy, and the most heat is utilized in removal of material from the workpiece of low melting temperature [18].

E. Electrode Wear Rate

In EDM process, high energetic electrical spark erodes the workpiece and picks off the particles from the workpiece surface nonetheless it erodes the electrode and picks off the particles from the electrode respectively. Normally, electrode wear is related to the electrical parameters of the EDM process. In this study, the electrical parameters of $t_{on}$, $t_{off}$ and capacitance (C) were taken constant and the effect of the current and electrode materials on the electrode wear rate was examined. Electrode wear is mostly depending on the electrode materials and energy of discharge among the other factors such as pulse duration/interval, polarity, dielectric etc. [19]. When the EWR results are examined, Fig. 3 clearly shows that the material removal of copper is in lower rates than that of brass electrode for all current values. Brass electrode undergo lower electrode wears compared to the copper electrode. Since copper has higher melting point and thermal conductivity than that of brass. Also, higher MRR rates that cause lower EWR. Therefore, brass electrode can be used in order to consume less amount of electrode compared to copper electrode material.

F. White Layer Thickness

Through the EDM drilling of holes, recast layers were generated at the side wall of each hole. The recast layer thickness at the wall of the hole was measured since it is the surface subjected to continuous machining throughout the hole drilling process. SEM images of the EDM drilled surfaces were taken in order to compare the effects of the electrode material on white layer of workpiece surface. From the examination of the surface characteristics, it was observed that EDM fast hole drilling process produces globules, debris, pockmarks, melted drops, varying size craters on surface.

To ensure that the recast layer thickness measured was representative of the entire recast layer, a 400 µm sample length of recast layer thickness was extracted for measurement. Furthermore, as recast layer thickness was not uniform throughout the sample length, a representative average recast layer thickness was determined. It is seen in Fig. 4, white layer thicknesses of the EDM drilled holes were changing from 11 µm to 19 µm from 10 A to 12 A, respectively. The reduction in WLT is about 40% for 10 A current value comparing to 12 A. Also, the white layer creation is less for brass electrode compared to the copper electrode. It was observed from the Fig. 5, white layer, melted drops, craters and cracks are more
pronounced when using copper electrode. This also makes the surface rough and having uneven surface profile.

IV. CONCLUSIONS

The outcomes of this study can be concluded as:

- Nearly 20 percent decrease in MRR has been achieved by using the brass electrode. This provides a significant improvement of the machining time for EDM drilled deep holes.
- MRR is decreased as the current increased for both electrode types. The better MRR was obtained at 10 A and brass electrode.
- Electrode wear rate is reduced approximately 12% by using brass electrode. This means reduction in electrode cost. (i.e., manufacturing cost).
- EWR is decreased as the current increased for both electrode types. The better EWR was obtained at 12 A and brass electrode.
- It can be expected that the service life and fatigue strength of the workpiece will be improved by decreasing the white layer thickness.

Abstract— Blanking process has an important usage in manufacturing and has become a necessity in several major sectors like automotive, sheet metal forming industry and etc. Although the general aspects of blanking seem simple, the shearing mechanisms and the governing parameters have a complex relationship and directly affect the surface quality of the blanked part. Also the lack of prediction capabilities in experimental studies leads to time, money and labour consuming trial and error procedures. Usage of FEM based programs to simulate blanking to obtain numerical results and observe the shearing mechanism is a cheap and a detailed way for industrial applications. In this study five different clearances (%1, %3, %5, %10 and %20) and two different thicknesses (t:2 and t:3) were used to simulate the blanking process. Simulations were executed by using the FEM program, Deform 2-D. Investigations were made on the parameters related to crack progression like indentation angle, rollover angle and depth, crack initiation and crack propagation angles. The results of the present paper are in agreement with the results of experimental studies.

Keywords— Blanking process, Sheet metal, Process parameters, Shearing mechanisms.

I. INTRODUCTION

Blanking is an effective process in sheet metal processing industry; but as in every production cycle, blanking process has a downside which is; generally, a subsequent deburring is required after blanking so that the processing time and labor costs are increased. Elimination of burr formation may eliminate the final finishing process totally and therefore the cost. The overall goal is to improve the blanked parts surface quality in such a way that the produced part does not need to be reworked.

In blanking, although the process seems simple, achieving a good surface quality relies on many parameters. Clearance which is the most effective parameter, material type, material thickness, shape of the component, tool geometry and many other parameters are directly in conjunction with each other [1]. This is the reason that makes blanking a complex and a difficult process to predict. This lack of prediction leads to time, money and labour consuming trial and error procedures, especially for experimental studies.

As an alternative approach, usage of FEM based programs to simulate blanking for obtaining numerical results and observing the shearing mechanism is a cheap and a detailed way for industrial applications.

For many years, researchers have been trying to model the blanking process by using FEM approaches. Some models tried to assess the parameters like; clearance, friction and mesh adaptivity [2, 3]. But these studies didn’t take the sheared edge formation into the account which is highly necessary to be predicted. In order to improve this gap, new approaches have been developed. Faura et al [4], tried to predict optimum clearance by presenting crack propagation angles throughout the sheared edge. Hambl et al, studied the same concept and also integrated neural networks to predict burr heights and to optimize the blanking process [5, 6, 7]. However, the results especially the optimum clearance value was given more than %10 which is so high to obtain a good surface quality. Prediction of burr formation [8, 9, 10] and sheared edge quality [11, 12, 13] in blanking have been investigated also by other researchers. They used different programs and behaviour laws to predict the ductile fracture phenomenon in blanking. As a result, the general acceptance is that if a good surface quality is desired, clearance value has to be %5, if low blanking forces are desired, clearance has to be at least %10 and above. Hereby, they stated that it’s up to the practitioner’s choice between quality and energy efficiency.

In this study, to observe the claims stated by previous researchers; five different clearances (%1, %3, %5, %10 and %20) and two different thicknesses (t:2 and t:3) were used to simulate the blanking process. Simulation were executed by using the FEM program, Deform 2-D. Investigations were made on the parameters related to crack progression like indentation angle, rollover angle and depth, crack initiation and crack propagation angles.

II. PROCESS PARAMETERS

A. Ideal Cutting Condition

The ideal cutting condition is where the punch load is the lowest for energy conservation and the quality of the blanked part is so good that no extra labour is needed to correct the defects on the blanked part surfaces.

Good surface quality depends on the deformation path of the shear zone which is directly affected by the clearance.
blanking process, clearance \(c\) is taken as a percentage of the sheet thickness and defined by:

\[
\frac{100(D_m - D_p)}{2t} \text{(\%)}
\]

(1)

Where \(D_m\) is the lower die diameter, \(D_p\) is the punch diameter and \(t\) is the thickness of the strip material.

The ideal cutting condition is achieved when the angle \((\beta)\) which is the angle of real crack propagation direction and angle \((\theta)\) which is the angle of ideal crack propagation direction coincides with each other. If this condition can be procured, the blanked part has burr free surfaces.

If the crack propagations don’t coincide, secondary crack formation occurs that creates lower surface quality. The directions of angle \((\beta)\) and angle \((\theta)\) were illustrated in Figure 1. As can be seen, real crack propagation direction doesn’t coincide with the ideal crack propagation direction, creating secondary cracks. The equalization of ideal crack propagation angle \((\theta)\) and the angle of the direction of crack propagation \((\beta)\) giving the ideal cutting condition can be expressed as:

\[
\Phi = \beta - \theta \cong 0
\]

(2)

The ideal crack propagation angle can be expressed by [5]:

\[\theta = \arctan \left( \frac{c}{t - u_p} \right)\]

(3)

Where \(c\) is the clearance; \(t\) is the sheet metal (workpiece) thickness and \(u_p\) is the punch penetration corresponding to the first crack initiation within the sheet.

During the blanking process, shearing of the workpiece happens in a narrow zone called the shear band. The stress and effective strain are defined as \(\sigma\) and \(\varepsilon\).

Fracture criterion was chosen Normalized Cockroft and Latham. The criterion states that the fracture occurs when the effective strain reaches the critical value expressed as:

\[
\int_0^f \left( \frac{\sigma^*}{\sigma} \right) d\varepsilon = C
\]

(4)

where \(\sigma^*\) is the maximum principal tensile stress, \(\varepsilon^*\) the fracture strain and \(C\) is the critical value. The effective stress and effective strain are defined as \(\bar{\sigma}\) and \(\bar{\varepsilon}\).

During the blanking process, shearing of the workpiece happens in a narrow zone called the shear band. The stress ratio \(\frac{\sigma^*}{\sigma}\) is assumed to be constant throughout that band where the deformation is highly concentrated. Therefore this assumption may be implemented into Cockroft and Latham criterion and approximated by \(\varepsilon^* = C^*\) at the shear band. This approach postulates that a crack initiation occurs at the point of the sheet whose effective strain first reaches the fracture strain of the work material [4]. The program uses element deletion method to iterate the meshing procedure and deletes an element when the critical values are satisfied. But element deletion may cause volume degradation and lead to miscalculations. To prevent and limit this situation, a very fine
mesh has to be used where a probable fracture occurrence is expected. To achieve a very dense mesh, 10000 isoparametric quadratic elements were used as the element meshes of the sheet. The geometrical model of the blanking process and the FEM meshes of the workpiece can be seen in Figure 3.

![Image of mesh and FEM meshes](image.png)

Fig. 3. The geometrical model of the blanking process and the FEM meshes of the workpiece.

**D. Experimental setup**

The front view of the designed die and its components were given in Figure 4. The die consists of six components; upper die block (1), punch holder (2), punch (3), fixed stripper (4), lower die (5) and lower die block (6).

The upper die block, punch holder, fixed stripper and lower die block were made of St 37 steel whereas the guide rods on the upper die block, punch and lower die were made of heat treated AISI 4140 for long durability.

All experiments were made by a hydraulic press which had adjustable speed and loading capabilities.

![Image of experimental setup](image.png)

Fig. 4. The front view of the designed die for experiments.

**E. Material Model and Experimental Parameters**

AISI 304 stainless steel was used for both simulation and experimental studies. AISI 304 is a very common type of stainless steel used in different kinds of industrial applications. AISI 304’s usage areas can vary from simple hypodermic needles to moderate applications like marine industry and heavy industry zones like nuclear plants [14].

Mechanical properties of AISI 304 were given in Table 1.

Sheet thickness was taken as t=2 mm and t=3 mm, die diameter as 10 mm and clearances were taken as %1, %3, %5, %10 and %20 for all experiments. Velocity and loading had been kept constant for all simulations and 12 tons at constant speed of 0.01 m/s were used to execute the blanking processes.

**III. RESULTS AND DISCUSSION**

The microscopic image of a blanked part and the image taken from Deform program were given in Figure 5. As can be seen that crack propagations and related zones are similar between experimental and simulation results. The numerical values gathered from experiments and simulations (Punch load, stroke, blanking energy, etc.) are also similar. Blanking energy difference between simulation and real experimental values were given in Figure 6.

![Image of microscopic and simulation images](image.png)

Fig. 5. The microscopic image and the simulation image of a blanked part (t=2 mm, clearance: %5).

![Image of energy change](image.png)

Fig. 6. Blanking energy change for simulation and real experiments. According to clearances.
A. Crack Propagation Angles

The difference between real crack propagation angle (β) and ideal crack propagation angle (θ) was calculated according to Φ=β−θ condition. The condition postulates that the closer Φ to zero, cleaner the blanked surface. The differences (Φ) according to clearances for t=2 mm and t=3 mm were given in Figure 7.

The results showed that workpiece thickness had an effect on crack propagation. The closer values to zero were found when the clearance was %3 for t=2 mm and %5 for t=3 mm. Also, as the clearance increased, the difference between real crack propagation angle (β) and ideal crack propagation angle (θ) increased which resulted in low surface quality. (+) and (−) values mean that the real crack propagation followed a direction below ideal crack propagation direction when the value was (+) or real crack propagation followed a direction over ideal crack propagation direction when the value was (−).

In previous researches [4, 15], it was suggested that the ideal clearance is between %10 and %12 for AISI 304 and t=1 mm which is highly unlikely because as the thickness increases, the clearance increases for ideal cutting condition. They also claimed that real crack propagation angle (β) remains nearly constant for all clearance values and only ideal crack propagation angle (θ) changes. Results showed that θ has to increase with increasing clearance because Formula 3 is the representation of a geometrical aspect but β also increases with increasing clearance. The only difference is the path that β follows (below or top of θ) with changing clearance.

As can be seen from Figure 8, indentation angle (α) was the lowest at %3 clearance for t=2 mm and the lowest at %5 clearance for t=3 mm which are in agreement with results found concerning crack angles.

B. Indentation Angle

Indentation angles (α) change for t=2 mm and t=3 mm according to different clearances were given in Figure 8.

Indentation angle (α) with a small value is important to achieve a good surface quality because it is the value of how the blanked part gets bent from cutting edges through its middle section on the upper portion. In case of too tight clearance (1%), indentation angle (α) increases because of the high punch loading. The behavior is same with loose clearance (10% and more) because the distance increases between punch and die’s cutting edges. In both cases the workpiece bends more.

C. Rollover Depth and Rollover Angle

Rollover is the bending of the lower portion of the blanked part due to the pulled materials into die cavity. In a blanking process, creation of rollover is not a desired situation. Results show that there is a connection between indentation angle (α), rollover depth (Rs) and rollover angle (Ra).

Rollover angle is directly affected by rollover depth and indentation angle. Rollover angle increases or decreases with rollover depth’s behavior. In case of too tight clearance (%1), high punching load tries to bend the edge of the blanked part for more rollover. Rollover depth behavior to that exerted force is less than expected because there is a little gap between die cavity. However it’s still higher than rollover depth created by %3 and %5 clearances. For clearances more than %10, although the punching load is much lower, more material is pulled between the die cavity that results in the increase of rollover depth. This also increases rollover angle.

If indentation angle increases which means more bending of the upper portion, the lower portion of the workpiece also bends outwards. This bending also increases the rollover angle. The opposite is also valid.

In Figure 9 and 10, it can be observed that rollover angle and depth is minimum at %3 clearance for t=2 mm thickness and minimum at %5 clearance for t= 3 mm thickness. These results are in correlation with indentation angle and ideal crack parameters.
IV. CONCLUSION

Blanking of an AISI 304 workpiece with two thicknesses (t=2 mm and t=3 mm) was executed for this study. Five different clearances (%1, %3, %5, %10 and %20) were used to achieve blanks with 10 mm diameter. behaviours of crack propagation angles, indentation angles, rollover angles and rollover depths were observed. Results can be summarized as below:

- Clearance has a very important necessity in blanking process. All blanking parameters are dramatically altered with changing clearance.

- The optimal clearance value where the surface quality is greatest that creates the ideal cutting condition is dependent on the material kind and thickness. In this study, all parameters became aligned with each other at %3 clearance for t=2 mm and %5 clearance for t=3 mm. But, claiming that the optimal clearance is between %3 and %5 for all kinds of materials is highly unlikely. However, it’s observed that %10 clearance doesn’t have any good result in surface quality and also in blanking energy which some researchers suggested the opposite.

- Too tight and too loose clearances, also give low surface quality, but as mentioned, it’s dependent on the material type and should be investigated.

- As the material gets thicker, all process parameters have tendency to increase.

- Indentation angle (α), rollover depth (Rd) and rollover angle (Re) have a close relationship with each other which are also driven by the change in clearance. It can be stated that the ideal cutting condition on a blanked part can be achieved at a clearance where the crack propagations are towards each other, has minimal indentation angle, has minimal rollover depth, has minimal rollover angle and has minimal blanking energy.

Abstract—In recent years, demand of meso/miniature scale sheet metal part with different geometry has increased dramatically. Pins for IC-carriers, fasteners, micro screws, lead frames, micro-cups and connectors, cell phones parts, as well as medical implants are the typical examples of these parts. In sheet metal forming processes, the geometry of the formed part follows the geometry of the die. Sheet metal forming can be divided as rigid die and flexible die according to die material. Flexible-die forming process is a versatile metal fabrication process is used in commercial aerospace, automotive and military applications. This process uses a flexible pressure carrying medium to replace a rigid punch or die. In forming process flexible material has different roles on forming the metal parts such as a punch, or for tube bulge forming etc. In this study, forming processes requires only a single rigid tool half and polyurethane with different hardness is used as flexible material and experimental data from forming operations are presented briefly.

Keywords—Sheet Forming, Miniature Forming, Flexible Die, Formability, Meso-scale forming.

I. INTRODUCTION

Sheet metal forming processes are the one of the main manufacturing processes and widely used to produce complex parts. Some developments introduced in metal forming processes during the last 50 years. These developments include the use of unusual tools like those using high hydraulic pressure fluid, flexible tools. Flexible tool using in metal forming is a new process to produce sheet metal parts with complex shapes by flexible pressure carrying medium, such as rubber or polyurethane, as a die. Main advantages of flexible forming are low cost tooling, protection of surface of the metal in contact with the flexible tool from scratches, variability of process.

Rubber forming had its onset in the last part of the 19th century, as in [1]. In this review, several processes are individuated: the Guerin process (which used an enclosed rubber pad), the Marform process (with addition of an independent blank-holder), the Verson-Wheelon process (which used a comparatively lighter press with an inflatable rubber bag), bending, sheet metal drawing embossing, blanking and piercing, and bulging are performed using flexible tools. Also, urethanes were considered the best materials for flexible tools because of their good oil and solvent resistance, good wear resistance, high thermal stability and load-bearing capacity. Aluminum sheet forming was studied by using flexible die made of neoprene or commercial rubber, as in [2]. They concluded that flexible forming is capable of producing, from thin aluminum alloy sheet, shallow formed parts with good surface finish and little metal thinning. Tooling costs are reduced considerably as only one shape block to be manufactured per component. In addition, time of production is low because of versatility of flexible material. Several techniques that were recently developed and utilized to fabricate sheet metal parts in macro scale, as in [3]. In this review, the urethane has different roles in these techniques on forming the metal parts that are: 1) as a punch, 2) as a clamp, 3) for tube bulge forming, 4) for creating blanking-holding force in deep drawing, 5) as a soft and flexible male punch for redrawing and reverse drawing. The influence of grain size effects on micro channel forming was studied in [4]. In this study, aluminum sheets that are annealed with different temperature and polyurethane with different hardness values are used. They concluded that annealed at a higher temperature sheets has better formability. It has been found the softer polyurethane can form the micro channel deeper.

Scales for processes and materials are generally classified as nanoscale (<100 nm), microscale (100 nm to 100 µm), mesoscale (100 µm to 10 mm) and macroscale (>10 mm). A comprehensive summary of the recent state-of-the-art for Micro/Meso Mechanical Manufacturing (M³) is given in the NSF workshop report [5]. Meso scale manufacturing has wide application areas. Biotechnology, medicine, avionics, communications are some of these areas. Specifically, mechanical watches, small motors and bearings, lenses for cameras and other parts of cell phones, mesoscale fuel cells, biomedical implants, mesoscale molds and many others [6]. In this study, flexible forming of Al 1050 aluminum sheet with 1 mm thickness is investigated. In particular, metal to metal contact die and metal to flexible contact die is compared in case of forming failures. As flexible material polyurethane with two different hardness values are used to form simple shapes.

II. METHODS AND PREPARATION

A. The Rigid Dies

One type rigid dies were used in experimentation, as shown in Fig. 1. It is used to form spherical geometry. Punch has 7.5 mm radius tip and female die has a gap which has 35 mm
diameter and 16 mm depth, as shown in Fig. 2. To produce backward force to punch, spring with 0.6 N/mm of stiffness was used. All rigid dies were made from specimen plain carbon steel (AISI 1020).

and diameter of the polyurethane were 16 mm and 35 mm respectively.

B. The Flexible Materials

Polyurethane with 20A and 40A hardness, as shown in Fig. 3, was used as a female die for this study of which the mechanical properties [7] can be found in Table I. The height

<table>

</tr>
</tbody>
</table>

C. The Aluminium Sheet

A thin aluminium sheet, Al 1050, with thickness of 1 mm was used for forming test. Tensile test were conducted on dog-bone shaped specimens in SHIMADZU AG-X machine. The specimens were 175 mm length and 30 mm wide with 50 mm gauge length. Test was carried out 1 mm/min of rate. The aspect of some specimens after tensile test is shown in Fig. 4. The stress-strain graph of test is shown in Fig. 5. The yield strength of 90±5 MPa was measured along longitudinal direction.
Forming process was carried out in two ways on SHIMADZU AG-X machine. In first way metal to metal contact forming was applied, flexible material was not used. In second way flexible forming was carried out by means of the Guerin process. The flexibility of the process and its capability of drawing relatively complex parts, the protection of the workpiece surface by flexible rubber and its low tooling costs are some of the advantages of this process. Aluminum blanks was cut from sheet with 44 mm diameter by using TRUMPF 4002 laser cutting machine. In flexible forming, flexible material was put in female die gap and forming process was conducted as shown in Fig. 6. All forming tests were carried out at 1 mm/s.

III. EXPERIMENTAL RESULTS AND DISCUSSION

A. Metal to Metal Contact Forming

In this case effect of depth of penetration was evaluated by using five different penetrations (4, 6, 8, 9, 10 mm). By increasing penetrations during forming, several failures were observed especially tearing of sheet near the contact area of punch tip and sheet. Fig. 7 shows occurrence of tearing and effect of penetration to formed profiles.

These distances were measured by KEMCO Fanamation CMM machine. In 9 and 10 mm penetration experiment, nearly at 17 mm of distance tearing was observed.

B. Metal to Flexible Material Forming

20A hardness polyurethane was put in female die gap. When punch force is applied on polyurethane, it has elastic deformation consisting of two parts: one deforming to die cavity and the other generating the binder force on the flat portion of the die. Six different penetrations (4, 6, 8, 8.5, 9.5, 10 mm) were applied to specimens. Effect of flexible material to sheet profile is shown in Fig. 8.
40A hardness polyurethane was conducted same as 20a flexible material. Effect of 40A flexible material to sheet profile is shown in Fig. 9.

In all forming types, tearing was observed at 10 mm penetration. It is obvious that sheet profile by formed 20A polyurethane are higher than 40A, Figs. 10, 11 and 12 shows the aspect of specimens after forming in metal to metal contact forming with 9 mm penetration, metal to 20A polyurethane forming with 9.5 mm penetration and metal to 40A polyurethane forming with 9.5 mm penetration. Also figure Fig. 13 shows the comparison of these sheet profiles after forming operation.

Softer polyurethane can provide to deform the sheet into die cavity better than the harder polyurethane since elastic deformation of softer polyurethane is bigger than harder one that could cause the sheet to be deformed into die cavity when the same condition applied. Figs. 13, 14 and 15 shows the first three penetrations (4, 6, 8 mm) for all forming operations.
IV. CONCLUSION

In this study, series of experiments were conducted on Al 1050 with 1 mm thickness to investigate the flexible material on forming process. As a die material, effect of polyurethane hardness has been discussed. So;

- Formability of sheet has been increased in in flexible forming with appropriate flexible material.
- Softer polyurethane contacts the material surface more than harder one. Due to this condition, load distribution on material surface becomes more uniform and this causes more uniform deformation.

Abstract—The purpose of this article is to investigate the effect of different particle contents of nano-silica on the tensile and flexural properties of intralaminar carbon/Kevlar hybrid composites. Twill 2/2 woven carbon/Kevlar fiber was used as reinforced fiber with epoxy resin. Five weight fractions (0.5%, 1%, 1.5%, 2.5% and 3%) were used for production of laminated composites. Then, test samples were produced according to ASTM standards. Results showed that addition of nano-silica to carbon/Kevlar composite increased the tensile and flexural strength. Nano-silica contents of 3 wt% gave the highest tensile strength and 1.5 wt% gave the highest flexural strength among the other ratios.

Keywords—Carbon/Kevlar fiber, nano-silica, hybrid composite.

I. INTRODUCTION

In recently years, the applications of polymer composites have been increased and that attributed to mechanical properties improvement by adding high strength fibers to brittle matrix. Furthermore, this improvement may be increased with using rigid inorganic particulate filler within polymer matrix, which leads to increase the applications of polymer base composites. These applications can be very useful such as medical industries, renewable energy application, automobile, aviation and aerospace. Some researchers [1, 2] toughened epoxy matrix by incorporating thermoplastics and rubber particles. Both of them cause mixture viscosity elevation after mixing with epoxy resin, which lead to difficulties in lamination process and thus decreasing in modulus and strength values. Therefore, using rigid particle can improve the mechanical properties of composite. Marjetka and conradi [3] concluded that the filled of a polymer matrix with nano-silica particles gives significant increase in the modulus and strength of the matrix to the overall composite properties. Alsaadi and Erklig [4] also reported similar findings, such that the maximum improvement of tensile strength, tensile modulus, flexural modulus and flexural strength were improved by 17.8% for the 17.8%, 11.3%, 32.0% and 36.4% at nano-silica particle content of 1.0 wt% compared to unfilled polymer composite. Jumahata et al. [5] studied the effect of nano-silica with 5–25 wt% particle content on the tensile stress-strain results of epoxy A 40 wt% nano-silica/epoxy. They found that the incorporation of a well-disperse nano-silica improved the tensile modulus and strength of about 38% and 24%, respectively. Singh et al. [6] presented a review of the kevlar fiber characterizations. They indicated that the anisotropic nature of the Kevlar fiber was due to its unique properties such as higher strength to mass ratio and modulus. Manjunatha [7] examined the tensile and fatigue behavior of nano-silica particles modified glass fiber reinforced epoxy (GFRP) composite, the tensile strength increased by about 19% and 5%, whereas the modulus increased by about 17% and 7% in the bulk epoxy and GFRP composite. Ferreira et al. [8] reported that the addition of nano clays within woven bidirectional Kevlar fabric/epoxy composites reduced the strength and increased the stiffness of the composite in both tension and bend loading, respectively. Dong et al. [9] studied the flexural behavior of hybrid composites reinforced by S-2 glass and T700S carbon fibers in an intra-ply configuration. The specimens were manufactured using the hand lay-up process and tested in a three-point bend configuration. It was shown that, utilization of intra-ply hybridization could improve the flexural strength and flexural modulus. Pincheira et al. [10] investigated the effects of aramid fibers contribution on mechanical properties of a twill weave hybrid carbon–aramid fiber reinforce epoxy composite. They concluded that the presence of aramid fiber presents a more ductile response with respect to the carbon reinforcement. Woo and Kim [11] studied the high strain-rate failure characteristics of the carbon/Kevlar hybrid composite that subjected to compressive loading. They found the failure process of the carbon/Kevlar hybrid woven composite showed initial matrix fracture and then brittle carbon fiber breakage. Subsequently, multiple failure mechanisms appeared, such as fiber-matrix debonding, fiber pull-out, excessive deformation and breakage in the Kevlar fiber tips including splitting and fibrillation. Wan et al. [12] used the two-step surface treated carbon/Kevlar hybrid fibers-reinforced composite with varying fiber–matrix interfacial bonding to show a positive hybrid effect on flexural strength, indicating the existence of hybrid effect is related to the nature of fiber-matrix interface.

Based on the above researches, researchers have been investigated tensile and flexural properties of the nano-particle modified composite laminates. To the best of found knowledge, researchers in literature did not inspect the effect
of nano-silica content on tensile and flexural properties of intralaminar carbon/Kevlar fiber reinforced epoxy (CKRE) composite. In this work, the tensile and flexural of CKRE composite were calculated with the use of nano-silica particles. In addition, the nano-silica variation of 0.5, 1.0, 1.5, 2.5 and 3 wt% contents were incorporated with CKRE composites.

II. MATERIALS AND METHODS

Epoxy risen (Momentive-MGS L285) mixed with the hardener (Momentive-MGS H285) by a stoichiometric ratio of 100:40. Carbon/Kevlar twill 2/2 woven with areal density of 190 g/m² and thickness 0.23 mm are used as reinforcement in the lamina and it has high impact resistance and tensile strength. All above materials were supplied by DOST Chemical Industrial Raw Materials Industry, Turkey. Nanosilica was obtained from Grafen Chemical Industries, Turkey with a high purity 99.5%, average particle size of (15 nm), specific surface area (300 m²/g), and bulk density (0.05 g/cm³). Eight Layers of carbon/Kevlar were prepared to show hybridization effects. The composites prepared for this study by adding silica nanoparticles filler in epoxy resin with five different weight percentage fractions as 0.5, 1.0, 1.5, 2.5 and 3.0 wt%. Epoxy resin was mixed with nano-silica particles for 20 minutes after that the hardener was added and mixed to obtain homogeneity, afterword the mixture was poured upon the layers layer after layer to the last one (8 layers) (Fig. 1), then laminated fabrics was laid on the flat mold (Fig. 2) and subjected to 120 kPa pressure for 1 h curing time with 80°C temperature (Fig. 3). Then, the composite laminates were cooled to room temperature under pressure for three hours at least. Finally the composite laminate removed from the mold to get a fine finished composite plate.

The produced composite laminate in size of 220 mm × 200 mm was cut to the required size specimens according to the standards ASTM D 638 [13] for tensile test and ASTM D 790 [14] for flexural test, by using CNC machine. The produced tensile and flexural test specimens were given in Fig. 4.

Fig. 4 (a) Tensile specimens, (b) flexural specimens.

III. MECHANICAL TESTS

The tensile and flexural properties of the composite specimens were determined at room temperature using the Shimadzu testing machine AG-X series (Kyoto, Japan) (Fig. 5a and b). Suitable specimens were prepared with size of 165 mm × 13 mm for a gauge length of 50 mm for tensile test and 200 mm × 12.7 with span to thickness ratio of 32:1 for flexural test. The thickness of tensile and flexural specimens was in range of 2.5±0.1 mm due to variation of nano-silica content. The crosshead speed was 2 mm/min for tensile test and 3 mm/min for flexural test. At least four specimens were tested for each composite and the average value was depended.

The flexural properties were determined from the test machine data’s by using the following equations.

\[
\sigma_F = \frac{3P_{max}L}{2bh^2}
\left[1 + 6\left(\frac{D}{L}\right)^2 - 4\left(\frac{h}{L}\right)\left(\frac{D}{L}\right)\right]
\]  
\[
\varepsilon_F = \frac{6Dh}{L^2}
\]  

Where L, b and h are the span, width and depth of the specimen, respectively, D is the maximum deflection before failure and P is the load at a given point on the load-deflection curve.
Therefore, the highest improvement of flexural strength was obtained at 1.5 wt% content of nano-silica with maximum increment of 54.2%. The flexural tests showed a linear response of the stress-strain curves (Fig. 7) of the studied composites, then the fracture was occurred and the flexural strength decreased gradually. This figure also indicates that the failure strain is significantly increased with addition of nano-silica particles. As shown in Fig. 8, the specimens failed at the specimen center by bending load that failure was started with matrix cracking then fibers breakage and carbon/Kevlar layers delamination between compression and tension sides.

**IV. RESULTS AND DISCUSSION**

Table I displays the tensile and flexural properties of CKRE and CKRE-NS composites for various nano-silica contents. As shown in Fig. 6 and corresponding data in Table I, the addition of nano-silica always improved composite tensile strength at the studied percentages. The maximum improvement in tensile strength is 46.8% at particle content 3 wt%. Moreover, the elongation at break also increased with the addition of nano-silica particles. Hence, the elongation at break increased by 32.5% with addition of nano-silica having 3 wt%. All the specimens were broken without any nicking and the fracture surfaces were flat (Fig. 8), that means the specimens fail in a brittle fashion during tensile test. Besides, there was no effective reducing in the cross sectional area of the specimens. In addition, whether it was filled or unfilled with nano-silica particles, the tensile samples were failed at higher stress. This suggests that the nano-filler-matrix interaction is very strong therefore the nanocomposites exhibited higher strength compared to the pristine intralaminar hybrid composites.

As shown in Table I and Fig. 7, flexural strength has been improved by addition of nano-silica particles to the CKRE. Hence, the composite flexural strength was increased from 428 MPa for unfilled CKRE to reach 659 MPa with nano-silica content of 1.5 wt%, afterword flexural strength follows the trend of decreasing to reach 474 MPa at content of 3 wt%.

**Fig. 6 Tensile stress-strain curves of the composites.**

This improvement of tensile and flexural properties attributed to the chemical compatibility of the nano-silica particles with epoxy resin and S-glass fibers in the composite laminate system. Furthermore, the flexural properties were degraded when nano-silica content exceeded 1.5 wt% and that may be ascribed to the particle aggregation phenomena which forming weaknesses in composite laminate and decreasing flexural strength.
V. CONCLUSIONS

The effects of nano-silica particles with variation in content on tensile and flexural properties of the carbon/Kevlar fabric/epoxy composites were inspected. The highest improvement of the tensile and flexural strength for CKRE-NS composites was obtained at nano-silica content of 3 and 1.5 wt%, with maximum increment of 46.8% and 54.2%, respectively. Generally, the tensile and flexural failure strains of the CKRE-NS composites were increased. Indeed the above mechanical properties were improved with nano-silica addition. Hence, this performance indicates the good adhesion strength and chemical compatibility of the nano-silica particles with carbon/Kevlar fabric/epoxy composite system.

Abstract—In this study, the tensile performance of epoxy adhesive with inclusion of micro-scale perlite particles was investigated for glass-epoxy laminates adhesively bonded single-strap repairs. Micro-scale perlite particles were used as additive material with different mass contents (plain, 5, 10, 15% wt) within the epoxy resin. Composite laminates were weakened by opening circular cutout at the center of them, then repaired by a circular and same composite laminates. The repairmen of the weakened laminates was explored two different patch ratios between patch and cutout diameter, incorporating adhesive epoxy with different perlite particle inclusions. Results showed that tensile strength of repaired samples reached its maximum value when perlite filler content is at 10 %.

Keywords—Composite, Patch repair, Adhesive, Perlite, Fiber

I. INTRODUCTION

The usage of the adhesives has been increasing as a process of the material repair to enhance the service life of damaged parts [1-3]. The adhesively bonded patch repairs reduce stresses around the crack of damaged region by performing load transfer through patch into panel and thereby prevent the crack tip from opening and growing [4]. As the usage of the high performance of adhesives and repairs, the repair of the load carrying components and structures may significantly contribute the improvement of the stress and stiffness. Two types of the patch repairs are available according to geometric shape of the samples: (1) Double (symmetric) sided and (2) single (asymmetric) sided configurations. These types of repairs were used in engineering applications depending on practical applications and space availability [4-5].

The adhesive properties are an important parameter for performances of the bonded composite repair. Bachir et al. [6] investigated the performance of the adhesives at the crack tips, showing that high shear modulus of the adhesives yields the stress intensity factor. They showed that adhesive properties can be optimized to increase performance of the repair by the reduction of the adhesive failure.

Filler is the most commonly used in the reinforcement of polymer matrix composite materials. Many studies related with the effect of particulate filler on mechanical properties of polymer composites can be found from literature [7-9], indicating that stiffness can be improved by the inclusion of the micro or nano scale particles. Sumita et al. [10] indicated the effect of particle size by replacing micro scale silica with its nano scale counterpart. They found that incorporation of nanoparticles resulted the higher mechanical properties for polymer composites. Several researchers [11-14] have shown the improvement of the strength of adhesive joints such as adding powders, particles, random and woven fibers to the adhesive layer.

It is evident from literature survey that mechanical properties of polymer matrix composites were significantly affected by particle content, particle size and particle/matrix adhesion. Present study aims to investigate the mechanical performance of S-glass fiber reinforced composite laminates having adhesively patched composite laminates with a central hole. Epoxy as an adherent was modified by incorporating microscale perlite filler for different epoxy/perlrite filler mixing ratios. The load bearing capacity of samples was explored in terms of force-deflection relation and results were compared with each other for different patch ratios. In addition, damaged surfaces were identified after the tensile tests.

II. MATERIALS AND PROCEDURES

A. Production of test samples

The material used for both composite laminates and patch is S-glass/epoxy prepreg supplied by Küçükparmak Company in Turkey. An epoxy resin (MOMENTIVE-MGS L285) with hardener (MOMENTIVE-MGS H285) at a stoichiometric ratio
of 100:40 was used as the matrix. The major mechanical properties of both epoxy and S-glass fiber are listed in Table 1.

Hand lay-up technique using a hot press was used for fabrication of composite samples with curing procedure as shown in Fig. 1. Both composite plates and patches are designed in stacking sequence of [0/90]S during the production process.

Cured laminates were cut in the size of 100x50 mm size of the shape using a controlled CNC cutting machine. For notched samples, a central hole of the 10 mm size was drilled, which yields the patch repair ratio (patch diameter (D) to hole diameter (d)) as 2 and 3. Patch diameters used for patch ratios were 20 and 30 mm, respectively. During the process, a sandpaper was used to be polished samples, surfaces of the samples are first polished with fine grade sandpaper and followed by cleaning with acetone before bonding.

In the present study, epoxy based adhesive was used for joining of patches. While gluing the patches with adhesive, micro-scale perlite fillers were mixed with adhesive epoxy by different mass ratios as 0, 5, 10 and 15 % wt, respectively. Perlite filler has been used as additive material within the epoxy resin and mixing ratios were provided in Table 2.

### B. Tensile tests

Tensile tests were performed a controlled tensile test machine of Shimadzu AG-X with a load carrying capacity of 300 kN at cross head speed of 1 mm/ min as shown in Fig. 2 (a). Test samples were prepared as shown in Fig. 2 (b) and schematically illustrated in Fig. 2 (c). Three samples were tested for each groups and their average results were taken as a final result. Load bearing capacity and degree of patch repair improvement of the samples were identified and compared. The failure and fractured surfaces of the samples were also observed and reported by comparing for different patch repair ratios.

### III. RESULTS AND DISCUSSIONS

Patch repair performances of the samples were examined with two different patch repair ratios (2 ad 3). Tensile properties were measured for different mass ratios of perlite particle by mixing adhesive epoxy. The results of the tensile tests were listed in Table 3. Force-deflection relations and their maximum values were illustrated in Fig. 3. As can be seen from the results, incorporation of microscale perlite particles was resulted a significant increase in tensile strength, while further
increase in perlite content in the epoxy resin caused a reverse effect, showing the decrease of tensile strength values. All curves showed the similar trend. Maximum tensile force has been increased up to 10% wt content of perlite, then the value was decreased rapidly. This is attributed the distribution and weight percentages of particles in the adhesive epoxy, resulting the higher strength between particle-matrix interphases. According to test results, maximum patch repair performance in tensile strength (10% wt content of perlite particles) was recorded as 16.5 % for D/d=2 and 20.9 % for D/d=3 compared with the pure epoxy adhesive. This is also attributed the distribution and weight percentages of particles in the epoxy, resulting the higher strength between particle-matrix interphases. However, opening a central hole resulted the reduction of tensile strength about 60 %. When notched samples are patched with different patch ratio and epoxy adhesive properties, the samples of 2T-10 and 3T-10 have shown the highest improvement in tensile properties compared with others.

Some fractured samples after tensile tests were illustrated in Fig. 4. It can be observed that the damaged surfaces of the repaired composites are mainly affected by the material behaviour of the adhesive epoxy in terms of particle filler content. The increase of perlite content in the adhesive resulted the increase in brittle behaviour of the adhesive which led to decrease in load bearing capacity of the samples.

Fig. 3. Patch repair performance of the samples

Fig. 4. Some fractured test samples after the tensile tests

### IV. CONCLUSIONS

The influence of perlite particle inclusion patch repairmen of S-glass reinforced composite laminates were investigated by mixing within the adhesive epoxy resin with different contents (5, 10, 15 and 20 % by mass of particle loading) of perlite filler. As a result of this study, following conclusions can be drawn:

- A lower content of particulate inclusion significantly increases tensile strength and further increase in Perlite content causes the reverse effect, resulting the decrease of load carrying capacity,

- In the case of Perlite filler content is at 10%, tensile strength reaches its maximum value due to the improved particle matrix interphase strength,

- Patch repair performance of the samples with D/d=3 is greater than samples with D/d=2,

- Maximum patch repair performance in tensile strength (10% wt content of perlite particles) was recorded as 16.5 % for D/d=2 and 20.9 % for D/d=3 compared with the pure epoxy adhesive,
• It can be observed that the damaged surfaces of the repaired composites are mainly effected by the material behaviour of the adhesive epoxy in terms of particle filler content,

• Consequently, joining performance of composite laminates can be improved by mixing of Perlite filler with an adhesive epoxy at low weight percentage of Perlite filler, contributing the resolve an important engineering problem during the service.

Effect of Olive Pomace on the Mechanical Property of glass fiber reinforced epoxy composites.

Ahmet Erklig*, Ahmed Shihan*, Mohamad Alsaadi**

*Gaziantep University, Faculty of Engineering, Mechanical Engineering Department, Gaziantep 27310, Turkey.
**University of Technology, Materials Engineering Department, Baghdad 10066, Iraq

Abstract—This work aims to study the effect of the mixing of natural particles of micro-size olive pomace (OP) on the tensile and flexural properties of glass fibre reinforced polymer composite (GFRP). Hence, the mechanical behaviour of recycled olive pomace filled glass fibre reinforced epoxy composites was studied in order to develop an engineering material for industrial applications. The modifying of GFRP was conducting by adding six weight fractions of olive pomace (0.5, 1, 2, 5, 10, and 15%) with a grain size of (75 μm). The composite specimens were prepared by hand lay-up technique and cut according to ASTM standards. It's found that the highest values of flexural and tensile strength happened at 5 wt % of OP filler. Also, the tensile results showed that with more addition of OP above 5% the elongation at break decreased. The flexural modulus was improved with addition of OP particles in GFRP composite.

Keywords— Glass fibre, olive pomace, polymer composite, Hybrid composite.

I. INTRODUCTION

Olives are among the most extensively cultivated fruit crops in the world. The total world production of olives and virgin olive oil was reported to be 20.8 and 3.27 million tons, respectively, for the year 2010 [1]. Olive cultivation is particularly widespread throughout the Mediterranean region and plays an important role in its economy, local heritage and environment protection. The largest olive-producing countries are located in the Mediterranean and Middle Eastern regions providing 98% of the total cultivated surface area, and 99% of the total olive fruit production [2].

Turkey is ranked among the leading olive-oil producers, with over 180 million olive trees grown on 0.7 million hectares cultivation area and an average annual production amounting to 500 thousand metric tons table olive production annually and olive oil production annually. However, a major problem which significantly affects the environmental sustainability of this agricultural activity is the disposal of residues generated from the industrial extraction of olive oil [3].

In recent years, many studies were dealt with utilizing cellulose fillers like palm kernel shell, olive pomace, pineapple leaf, wood, coconut shell as fillers within organic polymers. Therefore, the synthetic fillers were replaced through utilization of natural fillers as reinforcement in thermoplastic and thermoset polymer composites in an attempt to minimize the cost, increase productivity and enhance the mechanical properties of the product [4]. Fillers and fibers like olive pomace, oil palm empty fruit bunch, kola nitride wood fiber, as well as several fillers such as rice husk were used as reinforcing agents for different thermoplastic and thermosetting plastic resins [5, 6]. There is an overwhelming interest in filler and natural fiber reinforced polymers owing to their ease of processing and low cost as some of these fillers are regarded as waste. In the development of epoxy/eggshell particulate composites, the density and hardness values of the epoxy/eggshell particulate composites increased steadily with the increasing eggshell addition, compressive strength, flexural strength and impact energy increased [7]. The effect of untreated and treated coconut shell reinforced unsaturated polyester composites were studied and it was observed that the mechanical and thermal properties of unsaturated polyester/coconut shell composites were enhanced [8].

Qutaiba [9] Studied on sustainable reinforced polymer composite by using olive pits powder as a filler material for epoxy resin. The influence of the untreated and treated olive pits powder on the mechanical properties of the composites was examined. The results show significant improvements in mechanical properties for composites reinforced with treated olive pits than composites reinforced with untreated olive pits. Koutsomitopoulou et al. [10] illustrated the effect of olive pits powder reinforced polylactic-matrix. This study was focused on recycling potential of some waste materials, such as olive pits, i.e. the solid phase derived from an olive oil mill, blended with thermoplastic polymers and used for the production of new materials applied in manufacturing containers and formworks. An increase in the tensile modulus but a decrease of the flexural strength may be due to the poor interfacial bonding between olive pit powder and polylactic. Gharbi et al. [11] investigate the effect of the incorporation of the olive nuts flour up to 60% loading in unsaturated polyester on the flexural properties, impact strength, thermo-mechanical properties and water absorption behavior. The olive nuts flour was prepared from the exhausted solid olive oil mills after mechanical grinding treatment. A steady enhancement in the flexural modulus was noted by the olive nuts flour.
incorporation. Therefore, the applying of glass fiber in a natural particulate-filled polymer to produce cheapest composite laminates having varied applications and good properties like high stiffness, strength, thermal stability and resistance to chemical hurt [12,13].

The aim of this study is to investigate the tensile and flexural properties of S-glass fiber reinforced epoxy (GFRE) composite filled by olive pomace particles with particle content of (0.5, 1, 2, 5, 10, and 15%). The composite specimens were prepared using hand-layup technique, in addition they cut and tested according to ASTM standards.

II. MATERIALS AND METHODS

In order to manufacture composite specimens, woven Glass fiber with an areal density of 200 g/cm² was used as a reinforcement material in the composite laminate (Fig. 1a). Epoxy resin (Momentive-MGS L285) with hardener (Momentive-MGS H285) in a stoichiometric ratio of 100:40 was used in the common matrix. The modifying of GFRP composite was conducting by using six weight fractions of olive pomace (Fig. 1b) as 0.5, 1, 2, 5, 10, and 15% with a grain size of (75 μm). Composite laminates were prepared using hand lay-up method by mixing olive pomace with epoxy resin (Fig. 2) for 20 minutes then hardener was added, the mixture was applied to the glass fibers layers until all the 8 layers. Then, modified laminate with dimensions of 250 mm ×200 mm were subjected to 0.1 Mpa pressure in the flat mold for 1 h curing time with 80°C temperature. Composite laminates were cooled to room temperature under the pressure (Fig. 3).

III. MECHANICAL TESTS

After the production process, the test specimens were cut from the composite sheet to the required size as per ASTM standards (D638–10) [14] for tensile test and (D-790) [15] for the flexural test, by using CNC machine. The produced tensile and flexural test specimens are given in Fig. 4, and their dimensions are illustrated in Fig. 5. The thickness of the composite laminates was measured in range of 1.85±0.25 mm. Mechanical properties of the composite laminates were obtained using the Shimadzu AG-X series testing machine (Shimadzu Corporation, Kyoto, Japan) (Fig. 6). Suitable specimens were prepared with size of 165 × 13 mm for a gauge length of 50 mm for tensile test and 200 × 12.7 with span to thickness ratio of 32:1 for flexural test. The tensile and flexural properties of the composite specimens were determined using crosshead speed of 2 mm/min for tensile test and 3 mm/min for flexural test. At least three specimens for tensile and four for flexural were tested for each composite, and the average value was calculated.
IV. RESULTS AND DISCUSSION

Table I displays the tensile properties of GFRP and GFRP-OP composites for various olive pomace contents. As shown in Fig. 7 and corresponding data in Table I, the tensile strength of unfilled GFRP composite is 339.75 MPa. After this content the tensile strength was degraded. Moreover, the elongation at break (followed same behavior of strength) also was decreased then increased with the addition of olive pomace particles then decreased. Therefore, the elongation at break reached maximum with increment of 22.6% at OP content of 5 wt%. All the specimens were broken without any nicking and the fracture surfaces were flat (Fig. 8), that means the specimens fail in a brittle fashion during tensile test. Besides, there was no effective reducing in the cross sectional area of the specimens. Therefore, the samples of GFRP-OP composites show a brittle style. In addition, whether it was filled or unfilled with olive pomace particles, the tensile samples were failed at higher stress.

Fig. 8 Tensile specimens after testing.

As shown in Table II and Figs. 9 and 10, flexural strength has been improved by addition of olive pomace particles to the glass fabric/epoxy composite. Hence, the composite flexural strength was increased from 465.56 MPa for unfilled GFRP to reach 630.90 MPa with olive pomace content of 5 wt%, afterword flexural strength follow the trend of decreasing to reach 291.81 MPa at content of 15 wt%. Therefore, the highest improvement of flexural strength was obtained at 5 wt% content of olive pomace with maximum increment of 35.5 %. The flexural tests showed a linear response of the stress-strain curves (Fig. 9) of the studied composites, then the fracture was occurred and the flexural strength decreased suddenly. This figure also Table II indicates that the failure strain is decreased with addition of olive pomace particles.

Furthermore, the flexural modulus enhanced with addition organic particle of OP, which modulus was increased from 17.84 GPa for unfilled GFRP to 24.24 GPa at OP particles of 5 wt%, then decreased to 18.41 GPa at OP particles of 15 wt% (Fig. 10). The maximum increment of flexural modulus was 35.9%

As shown in Fig. 11, the specimens failed at the specimen center by bending load, that failure was started with matrix cracking then fibers breakage and Glass/epoxy layers delamination between compression and tension sides.

Fig. 7 Tensile stress-strain curves of the glass fiber reinforced epoxy composite filled with olive pomace.

![Graph](image.png)

To sum up, this improvement of tensile and flexural properties attributed to the chemical compatibility of the olive pomace particles with epoxy resin and S-glass fibers in the
composite laminate system. Furthermore, the tensile and flexural properties were degraded when nano-silica content exceeded 5 wt% and that may be ascribed to the particle aggregation phenomena which forming weaknesses in composite laminate and decreasing flexural strength.

The highest improvement of the tensile and flexural strength for GRFP-OP composites was obtained at olive pomace content of 5 wt%, with maximum increment of 15.9% and 35.5%, respectively. Generally, the flexural modulus was enhanced. Indeed the above mechanical properties were improved with olive pomace addition. Hence, this performance indicates the good adhesion strength and chemical compatibility of the olive pomace particles with glass fabric/epoxy composite system.

REFERENCES

V. CONCLUSIONS

The tensile and flexural properties were affected according to tensile and flexural tests results of glass fiber reinforced epoxy composite filled with olive pomace particles with variation in content. The highest improvement of the tensile and flexural strength for GRFP-OP composites was obtained at olive pomace content of 5 wt%, with maximum increment of 15.9% and 35.5%, respectively. Generally, the flexural modulus was enhanced. Indeed the above mechanical properties were improved with olive pomace addition. Hence, this performance indicates the good adhesion strength and chemical compatibility of the olive pomace particles with glass fabric/epoxy composite system.
Effect Of Density And Blend Rates Of Composite Panels Reinforced With Polyester Fibres To Tensile Resistance

Abstract— Using of composite materials are getting important for many areas like aviation and defence industry, land and marine transportation, energy, infrastructure and construction sectors due to increasing necessity for alternative materials nowadays. Therefore; in competitive markets having increased consumption and production of materials, manufacturers are in tendency to add difference and functionality on their products. One of important ways of creating difference and functionality is to choose most available production methods and processes simultaneously with materials and carry out all of these in low costs.

In this research, composite materials reinforced with polyester fibres which are known with low cost and high strength features, were obtained by using a resin as bonder. Phenol formaldehyde was preferred as bonder resin by the reason of having low thermal conductivity, high bonding, good water resistance and low cost characteristics during the production of composite materials. Blend consisted of opened polyester fibres together with bonder, was pressed in patterns at 130 °C. Composite materials were produced in two different densities and four blend rate. Tensile tests were applied to all composite samples to observe the performance in areas which they can be used. Obtained test results were evaluated by making essential interpretations.

Keywords— Composites, Polyester, Fibres, Phenol formaldehyde, Tensile test.

I. INTRODUCTION

Materials are generally divided three main groups as metals, ceramics and organic materials. These three groups have more&less advantages and disadvantages according to each other [1]. Beside these three groups, materials are non uniform solid consisting of two or more different materials that are mechanically or chemically bonded together, are called composite materials [6-7]. Each of the various components retains its identity in the composite and maintains its characteristic structure and properties [6]. Composite materials are combined with macro structural materials in order to create new features according to area where materials will be used. It can be also thought for composite materials as "ordered material". Materials combined in atomic or molecular dimensions are not classified as composite materials due to being homogenous in macroscopic dimensions. Advantage of composite material is gathering best features of ingredients. Nowadays, materials which are developed and still developing progressively, have been using for thousands of years, indeed [1]. It is seen the structure of a composite material in Fig. 1.

Today composite materials are used in many important and vital engineering applications due to having advantages and varieties. In some applications, polymers do not provide desired physical and chemical features by self. In these cases, these polymers are supported by various textile fibres in different ratios according to desired features. Nowadays, these kinds of production methods are very common to provide "ordered material". Suitability of engineering materials in terms of durability, flexibility, lightness, resistance to environment conditions (humidity, sun lights etc.) as main features and fatigue against period of time, impact, tensile, bending, compression and chemical resistance as assistive features, are investigated according to areas where materials will perform. It is quite rare to find a material having all these features only in itself. Composites which are launched to be manufactured since 1950's as an alternative material, started to solve suppling problem of materials including all different
kinds of features together. Interest and attention to polymeric composites reinforced with fibres, are increasing progressively by reason of high strength and module values [3].

The matrix forms a significant volume fraction of a polymer composite and it has a number of critical functions; it binds the reinforcements together, maintains the shape of a component and transfers the applied load to the reinforcing fibres. It protects the reinforcing fibres from degradation, due to abrasion or environmental attack. It contributes significantly to the mechanical properties of structural polymer composites, acting to resist delamination between plies of reinforcements and to inhibit fibre buckling during compression. Thermoplastics are used in certain applications but constitute a relatively small sector of the structural composites market. Matrices used for structural composites are mainly thermosetting plastics, such as polyester resins, epoxy resins, phenolic resins and vinyl-ester resins. Thermosetting plastic systems generally consist of liquid mixtures of relatively low molar mass reactants, such as monomers and/or prepolymers, which polymerise upon heating to form highly-cross linked, network polymers [8-16].

In the research on literature of composites consisted of natural fibres as a reinforcing component, it is observed that most of investigations were carried out to improve bonding of natural fibres to interface or searching mechanical features. Investigations in which natural fibres and synthetic fibres (linen/glass fibre, hemp/glass fibre, basalt/glass fibre, jute/glass fibre, felt/glass fibre) used together, are observed, as well [5]. Cross-sectional view of a composite blade consisted of different kinds of fibres and fabrics, is shown in Fig.2.

**II. MATERIAL AND METHOD**

The aim of this study is to create a difference than the other studies and produce low cost and high strength composites through a process which is not complex. Thus, polyester fibres which are used also in textile sector were chosen as a reinforcing material in our products. The most important reasons of choosing polyester fibre are cheapness and high strength values. Polyester fibre prices in market start from 3,5 TL/kg. Physical properties of some chemical fibres are indicated in table I.

Phenol-formaldehyde as shown in Fig. 4, is preferred as a bonder to generate composite materials due to having low thermal conductivity, strong bonding and high resistance against water and being cheap features. Phenol-formaldehyde prices in market are about 750 TL/ton.
Before producing of composite samples, polyester fibres being in floc cases as can be seen in Fig. 3, opened by hand. Then, phenol-formaldehyde is mixed in one-to-one ratio with water and sprayed on opened polyester fibres to provide bonding. It is required heat for phenol-formaldehyde to be activated and establish chemical bond with polyester fibres. Thus, in first step composite samples were produced by pressing the blend consisted of polyester fibres and sprayed bonder and then laid with hand in a pattern heated at 130 °C. Pattern is shown in Fig. 5. Polyester film was used for not adhering by the reason of heat effect to patterns.

Tensile tests are applied to samples produced in 2 different density and 4 different fibre/bonder rate to observe the performance of composite materials where they can be used. Tensile tests were carried out for samples in size of 50x50x0,35 cm according to ASTM D 638 standards. One of produced samples can be seen in Fig. 6 and codes of samples are shown in table II. Shimadzu AG-IS device with 1 mm/min tensioning speed, was used for tensile tests in standard atmosphere conditions. 5 measurements were carried out for each sample and average of results was evaluated.

III. RESULTS AND DISCUSSION

Tensile test results of samples were analysed in this session and comparisons and interpretations of results were also mentioned. First, test results were evaluated in terms of investigating the effect of changing density of samples having same fibre/bonder rate and then, it is remained in term of investigating the effect of fibre/bonder rate of samples having same density.
When test results of samples were analysed, it is seen that tensile strength values for samples produced in both density are decreasing together with increasing of fibre rates in Fig. 7. It is observed that together with increasing fibre rate in samples, gap between tensile strength values of samples having same fibre/bonder rate but in same density, is decreasing. This case indicates us that main structural material makes samples strength is phenol-formaldehyde used as bonder. This impression is more distinct and clear in samples having more density in Fig. 9. Highest tensile test value belongs to B1 sample and lowest tensile test value belongs to A4. When young modulus of samples is evaluated in Fig. 6, it is understood that all samples having higher density in same fibre/bonder rate performs higher young modulus values. Highest young modulus belongs to B1, lowest one belongs to A4. This shows that rigidity of materials is decreasing together with increasing of fibre rate.

As it is seen clear in fig. 8, if samples have same density, tensile strength is decreasing together with increasing of fibre rate. This decrease (slope) is moving slowly until a specific point and then getting rapid. It is thought that possibility of occurring non-parallel, tangled and nested fibre structure in sample will increase by the reason hand laying of fibres in pattern together with increasing fibre rate. So these tangled fibres structure causes lower tensile strengths to sample instead of causing higher tensile strength values. In other words, these tangled fibres take space in samples and do not contribute to tensile strength values. Together with decreasing of bonder rate and increasing of fibre rate causes rapid decrease in tensile strength values after a specific point. It is thought that decreasing in tensile strength values of B1, B2, B3, B4 is faster than A1, A2, A3, A4 is a proof this explanation.

IV. CONCLUSION

One of most important aim of this study is to produce samples at low cost as much as possible. So maximum price of one samples produced in size of 50x50x0,35 cm is 0,45 TL and minimum one is 0,16 TL. On the other side, tensile tests were applied to samples. Thus, tensile strength and young modulus values obtained from tensile test informed about performance of sample according to using areas. It is observed that together with density increase of all samples having same fibre/bonder rate, tensile strength values are also increasing. Highest strength value (83,44 MPa) belongs to B1, lowest one (50,12) belongs to A1. It is seen from figures that together with increasing fibre rate in samples having same density, tensile strength values are decreasing. Rate of decrease is getting faster with increasing of fibre rate in samples. It can be thought that tangled fibres structure in samples causes lower tensile strength instead of higher tensile strength values. From this point of view, in order to increase contribution of fibres to tensile strength, it is supposed pressed in patterns after spraying bonder to all fibres parallelised to each other in one direction. So vertically arranged fibres against force will increase the strength.

Karamanoglu Mehmetbey University,
Karaman, Turkey
stu_150851201@kmu.edu.tr

Abstract— Electrochemical studies on Poly(3,4-ethynylidioxythiophene) (PEDOT) electrode material as a conducting polymer and its potential application in electrochemical capacitor have been concentrated in this study. 3,4-ethynylidioxythiophene (EDOT) has been successfully electropolymerized in the presence of ionic liquid, 1-ethyl-3-methylimidazolium hydrogen sulphate (EMIMHSO4) and organic electrolyte medium, LiClO4/ACN electrolytes. Their capacitance performances were evaluated and compared with each other in the monomer free medium. The initial galvanostatic charge/discharge tests of PEDOT polymers were also investigated. The SEM studies show that the PEDOT films electropolymerized in EMIMHSO4 were highly porous and have a higher anion doping level than those electropolymerized in LiClO4/ACN electrolytes. Additionally, the symmetrical electrochemical capacitors based on two PEDOT electrodes were also constructed and characterized with electro-analytical methods. Furthermore results were compared with each other.

Keywords— electrochemical capacitor, PEDOT, ionic liquids, conducting polymers

I. INTRODUCTION

What would we do in case of power failure on emergency if we needed to electrical energy rapidly? Have you ever thought about it or how would we solve this problem? Certainly the most important subject that we can meet in this century is energy storage. As a solution to supply the all energy demands of in our modern world by considering ecological factors, new essential search are proceeding for low cost, and eco-friendly storage systems [1]. There are rapid developments of research in this field; such as rechargeable batteries, fuel cells and electrochemical capacitors, which could store energy with electrochemical methods, are the most important energy storage devices for these purposes.

The main difference between capacitors and electrochemical capacitors is about charge storage mechanism. Electrochemical capacitors store energy in the bulk with chemical reactants, whereas capacitor store energy directly with using dielectric sheet between conducting two plates [2].

Electrochemical capacitors also commonly known as “supercapacitors” or “ultracapacitor”, is a new class energy-storage devices whose specific performance characteristics fill the gap between capacitors and rechargeable batteries with the energy versus power density [3]. Batteries are low power devices compared to the capacitors but they have more energy densities. Supercapacitors can merge both these properties. Supercapacitors power density is also higher than the rechargeable batteries and its energy density is higher than conventional capacitors [4].

We can classify to supercapacitors into two types. These are electrochemical double layer capacitors (EDLCs) and pseudocapacitors. In EDLCs, the charge is stored electrostatically at the electrode-electrolyte interface in the form of double layers on either electrode which these double layers act as two serial capacitors on the electrical equivalent circuit, while in pseudocapacitors charge storage occurs via fast redox reactions [6]. Because of the pseudocapacitors charge storage mechanism is consisted of electroosorption, reduction-oxidation reactions, and intercalation processes, pseudocapacitors achieve more capacitances and energy densities than EDLCs [12]. The capacitance values of pseudocapacitors are 10-100 times higher than EDLC [13].

Structurally, a supercapacitor consist two electrodes which should be nonreactive porous plates and these electrodes are immersed in an electrolyte. Electrodes are separated by porous membrane [5]. The separator is soaked in electrolyte and prevents short circuits on device therefore; the separator should have a high electrical resistance and also need to be ion-permeable, to allow the ion transfer during charging/discharging [7]. The separator thickness is important in order to achieve the performance. The electrolyte potential range limits the working voltage of supercapacitor. This fact effect performance of supercapacitor due to capacitors charge storage capable is related to square of voltage (E=1/2CV2). Aqueous electrolytes typically have around 1 V adequate voltage, which is relativity lower than the organic electrolytes (around 3V), but the ionic conductivity of aqueous electrolytes is higher than organic electrolytes [8]. In generally, the
There are two types of intrinsically. Conductivity of conducting polymers delocalized π-E polymers have different band ga conjugated bond structure. Therefore it plays crucial role in determining the energy and power densities of supercapacitor. [9] If we want to design a high-performance super capacitor, the electroactive material on the electrode surface include high specific capacitance which this criteria may be gravimetric, volumetric or areal of active material, and large rate capability and also high cycle stability. At the same time active material should have low toxicity and low cost for economic and ecological in order to realize a high performance super capacitor [10].

Generally, electrode materials for EDLCs are carbon-based materials such as active carbon, carbon nanotubes and graphene. Likewise, redox active materials can be used for pseudocapacitor. These are transition metal oxides such as RuO$_2$, MnO$_2$, WO$_3$, NiO, Fe$_2$O$_3$ etc. and conducting polymers such as polypyrrole, polyaniline, polythiophene and its derivatives. All these materials have different properties, therefore its specific characters effect to the performance of super capacitor in different way [10]. For example, carbon-based materials provide high power density and high stability unlike have low specific capacitance, therefore, limits its application for high-energy density devices. Metal oxides have electroactive materials for pseudocapacitance and have wide charge-discharge potential range; however, their application is limited by surface area, low conductivity, high cost, toxicity, and poor stability [11]. The most capacitive performance of RuO$_2$ exhibits 720F/g values in metal oxides. But it has high cost and high toxicity in nature [6].

Another electroactive material for pseudocapacitors is conductive polymers (CP). CPs have the advantages with its unique properties such as, high specific capacitance, good conductivity, low cost, easy fabrication, good thermal and chemical stability and environmental friendless [11,14]. Conducting polymers store charge, not only in the polymer double layer, but also throughout the body of the polymer by rapid faradaic charge transfer by three-dimensional charge storage mechanism, therefore it has higher capacitances [12]. As an interesting property of CP, is also applicable for flexible application, due to their inherent flexible polymeric nature, which is a crucial requirement for the portable flexible electronics [11].

**A. Conducting Polymers**

Conducting polymers are electrically conducting polymers (ECPs) due to high mobility of electrons in conjugated bond structure. Because of the conducting polymers have different band gap between 1-3 eV conducting polymers may have metallic or semi-metallic properties [15]. Electrical energy conducted in conjugated polymers with delocalized π-electrons in its conjugated structure, intrinsically. Conductivity of conducting polymers enhance during delocalized π-electrons are accepted or released with chemical or electrochemical doping/un-doping processes [16]. There are two types of doping process below:

\[
\begin{align*}
\text{p-doping: } & \text{(CP) + nA} \leftrightarrow [(\text{CP})^+ n\text{A}^-] + ne^- \quad (1) \\
\text{n-doping: } & \text{(CP) + nC} \leftrightarrow [(\text{CP})^n n\text{C}^-] \quad (2)
\end{align*}
\]

Conducting polymers have intrinsic conductivity from a few S/cm to 500 S/cm in doped state [17].

Polymer based super capacitor devices have three configuration as per types of conducting polymers doping process. Type I or also known as symmetric, super capacitor using the same p-dopable polymer for both electrodes. Type II or also known as unsymmetric, super capacitor using two different p-dopable polymers have different potential ranges. Type III or also known as asymmetric, super capacitor using p-dopable polymer for positive electrode and also using n-dopable polymer for negative electrode [17,18].

Type III super capacitor device have theoretically highly capacitances because of the charge mechanism is observed the both electrodes, but n-doped polymers have high resistance and n doping process is difficult for conducting polymers [17].

For type I device, while one electrode fully p-doped in completely charged, another electrode becomes undoped state. When the device becomes completely discharged state, both electrodes become half p-doped state.

For type II device, while one electrode becomes fully p-doped in completely charged, another electrode becomes undoped state. When the device becomes completely discharged state, both electrodes become partially p-doped state. As the same way, for type III device, while both electrodes become undoped in discharged state, in completely charged state p-dopable polymer becomes p-doped, and n-dopable polymer becomes n-doped [19].

A lot of conducting polymers can be used for electrochemical capacitor. Specific capacitance in related to mass, of conducting polymers is an important selective way to choose all of these materials for electrochemical capacitors. PEDOT has a theoretical specific capacitance about 210 F/g, which is rather low in comparison to such (PANI) polyaniline (750 F/g), (PPY) polypyrrole (620 F/g) or (PT) polythiophene (485 F/g) [20].

PEDOT is one number of these conducting polymers of PT derivatives. It has a good thermal and chemical stability, fast electrochemical switching and a high electrical conductivity in the p-doped state (approximately 550 S/cm) [20]. Conducting polymers have low life cycles due to volumetric changes during the doping/de-doping processes. Volumetric changes occur during the insertion/de-insertion of counter ions and this changes result in swelling, shrinkage, cracks on polymer structure [21]. Therefore, PEDOT have attractive properties with regard to other ECPs for stability of device.

**B. Ionic Liquids**

Ionic liquids (ILs) are low-melting molten salts composed completely of anions and cations. In general, ionic liquids consists polyatomic organic cations and an inorganic or organic anions. It is also named as room temperature ionic
liquids (RTIL) because of its melt on near room temperature [22]. ILs have lots of advantages such as a wide liquid range, high ionic conductivity, a wide voltage window, non-volatility, and non-flammability [23,24]. ILs are salts in the liquid phase usually below 100 °C, and they dissolve both polar organic molecules. Mainly because of their low volatility, they are considered to be “eco-friendly solvents” [25]. Ionic liquids are resistant in a wide potential window (up to 4-6V) and provide a high cell voltage. [26]

The most commonly used ionic liquids consist imidazolium, pyridinium, pyrroldinium, phosphonium, piperidinium, pyrazolium, sulfonium, thiazolium, and ammonium cations and anions such as chloride, bromide, nitrate, acetate, hexafluorophosphate, tetrafluoroborate, alkylsulfate, alkylsulfonate and tosylate[27,28]. Among these systems, the physicochemical properties of 1-alkyl-3-methylimidazolium-based ionic liquids with various anions have been extensively investigated [29]. The alkyl imidazolium based ionic liquids have been investigated as possible electrolytes for their application as batteries and capacitors [30]. It is necessary to develop ILs with high conductivity and low viscosity. The viscosities of the ILs were increased with an alkyl spacer length. The potential reasons were increased Wan Der Walls interaction between the alkyl groups [32]. Environmentally friendly and electrochemically stable imidazolium cations with stable anions were used herein to synthesize ionic liquids [31]. Using an IL as device electrolyte allowed an extension of the voltage window of Type I ESCs by 60%, resulting in a 2.5-fold increase in the energy density obtained [32]. There are three main advantages of using ionic liquids for electrochemical capacitors. Firstly, the electrochemical activity of the polymer grown in ionic liquids is less affected by the nature of the cycling solvent than the polymer achieved in other solutions. Secondly, the porous structure of polymer offers a higher specific surface area that is convenient for dopant ions accessing into the polymer matrix and inducing higher charge to keep stable. And the last one, p type or n type polymer is more stable with using ionic liquids [33]. Recent studies have shown that ECPs can be electropolymerized using ILs as dopant and electrolyte and that polymers have shown improved cycling stability in ILs and gel electrolytes compared to organic electrolytes. This improved electrochemical performance and stability was mainly attributed to the lower volume changes observed for ECPs when using solvent-free electrolytes [34].

Although fluorinated ILs usually show better conductivity, non-fluorinated electrolytes are more attractive from a safety and environmental stand point. A non-fluorinated IL, 1-ethyl-3- methylimidazolium hydrogen sulfate (EMIMHSO₄), has been suggested as a proton conducting electrolyte for fuel cells [35]. In this work, EMIMHSO₄ was chosen as ionic liquid electrolyte.

In literature, a few study reported on type I electrochemical capacitors in related to combination with PEDOT polymer based electrode and ionic liquid electrolytes. Such as Pandey et al. have studied on PEDOT polymer with ionic liquid electrolyte to prepare electrochemical capacitor. They have characterized devices and have calculated the PEDOT electrodes specific capacitance of 154.5 F/g. Another study, Wei-Cheng Fu and al. have prepared PEDOT electrodes in combination with [BMI][BF₄] 1-butyl-3-methylimidazolium tetrafluoroborate and they have exhibited 191 F/g specific capacitance. As the same way Keke Liu and al. have studied electrochemical capacitors on PEDOT electrodes in [BMI][BF₄] ionic liquids and they have calculated the specific capacitance of device about 130 F/g.

II. Experimental Methods

3-4 Ethylenedioxythiophene (EDOT) and EMIMHSO₄ ionic liquid was purchased from Sigma Aldrich. In this work acetonitrile (ACN) and LiClO₄ were used as solvent and supporting electrolyte, respectively. EDOT monomer was polymerized with three electrode configurations using potentiostat in order to control electrode potential. Three main electroanalytical methods were used to investigate performance of electrochemical capacitor in this work. These are cyclic voltammetry, galvanostatic charge/discharge test and impedance spectroscopy analysis.

In this work we used Ag/AgCl electrode as a reference electrode and also Pt wire as counter electrode. Pt disc electrode was immersed into solution as working electrode. Its surface area was calculated as 0.02 cm². As a presence of monomer for electrochemical deposition, we prepared a solution which its concentration 0,1M EMIMHSO₄, 0,1M EDOT, 0,1M LiClO₄ in 3mL ACN solvent. Furthermore we prepared a monomer free solution with 0,1M LiClO₄ in 3 mL ACN solvent for all the electrochemical analysis. Electrodeposition method was realized in presence of ionic liquid and electroanalytical analysis was realized in monomer free medium.

III. Results and Discussion

The polymer film was grown potentiostatically at a DC potential of 1.7 V versus Ag/AgCl at 25°C. PEDOT was synthesized in an acetonitrile (ACN) based electrolyte containing 0.01 M EDOT monomer and 0.1 M LiClO₄. After deposition of PEDOT the substrates were washed in ACN solution. The FTIR spectroscopy analysis shows that the structure of the polymer film is consistent with that of the monomer. The peak one at 3120 cm⁻¹ is due to C–H stretching (–hydrogen) of external EDOT units disappear and other peaks still appear indicating that polymerization proceeds via C-2 and C-5 position of external EDOT units. The peak at about 1090 cm⁻¹ belongs to ClO₄⁻ dopant. The morphology of polymer film exhibits a densely packed structure morphology which comprises of uniform globular grains with size of about 80-150 nm. Thus, the electronic conductivity of the polymer may be improved due to more interconnected grains (densely packing) with uniformly distribution of globular grains.
Furthermore by incorporation of the ionic liquid, the P-150 CE exhibited more porous structure and larger active surface area in comparison to PEDOT without ionic liquid. Chronoamperometry method was used during electrodeposition of monomer on Pt disc electrode with constant potential. In this work we electrodeposited the EDOT monomer with a 1.7 V constant potential. Firstly, EDOT monomer was electrodeposited on Pt disc electrode the till 5 mC charge on electrode and scanned the polymer film using CV method with a 50 mVs⁻¹ scan rate in the potential range of 1.2 and -1.2 V. In Figure 1a, capacitive effect of polymer film on CV was adduced. Polymer film has a well defined and reversible doping process and a loop was seen on CV between -0.5 and 0.2 V potential ranges. This loop based on the pseudo-capacitive behaviour on electrode Figure 1(a).

Where E1 and E2 are the cutoff potentials in cyclic voltammetry, i(E)d(E) is the total voltametric charge obtained by integration of the positive and negative sweeps in the cyclic voltammograms, v is the scan rate and A is the area of the polymer film. Since the diffusion of supporting anion had same time to intercalate into the electrode at both low and scan rates, the specific capacitance values using equation 1 was found as approximately same value (32 mF cm⁻²). It can be observed that the measured capacitance value was constant as the scan rate increased.

\[ C_{sp} = \frac{\int_{E1}^{E2} i(E)d(E)}{2vA(E2 - E1)} \]  
(Equation 1)

Figure 1 (a) The capacitive effect of polymer film (potential range between 1.2 and -1.2 V with 50mVs⁻¹ scan rate) (b) CV characteriztion of polymer with different scan rates.

Secondly, the polymer film was scanned with different scan rates from 25 mVs⁻¹ to 200 mVs⁻¹ with an increment of 25 mVs⁻¹ (Figure 1(b)).It was found that the peak currents for the film increase linearly with increasing scan rate, indicating non-diffusional redox processes, and well-adhered electroactive polymer film on the working electrode surface (Figure 1(b)).

\[ C_{CV} = \frac{I}{v} \]  
(Equation 2)

The voltammetric capacitance \( C_{CV} \) of the polymer film can be obtained from the cyclic voltammograms based on the following equation where \( v \) is the voltage scan rate and \( i \) is the...
current. At a scan rate of 50 mVs$^{-1}$, a maximum $C_{\text{CV}}$ value of 55 mF cm$^{-2}$ was obtained. With reference to this figure, the most capacitive behaviour was seen on approximately 0.2 V potential value. Such a big capacitance value may be explained on the basis of charge saturation effect taking place at the end of the doping process [37]. (Figure 2(b)).

EDOT monomer was also electrodeposited on electrode with different charge value with chronocapamperometric method such as 5 mC, 10 mC, 15 mC and 20 mC respectively to estimate the doping level of PEDOT polymer film. CV characterization of these polymer films which have different charge values at a scan rate of 50 mVs$^{-1}$ were displayed in Figure 3(a).

![Figure 3(a)](image)

**Figure 3 (a)** The capacitive effect of polymer film (potential range between 1.2 and -1.2 V with 50 mVs$^{-1}$ scan rate). (b) The capacitive effect of polymer film (potential range between 1.2 and -1.2 V with 50 mVs$^{-1}$ scan rate).

The charge density $Q_d$ required for the formation and deposition of the oxidized PEDOT film from monomer can be determined experimentally. $Q_d$ corresponds to $(2+\gamma)$ electrons per EDOT where $\gamma$ is the number of electrons per EDOT required for switching. For doping level the maximal quantity of oxidized polymer ($Q_{\text{fmax}}$) is needed. $Q_{\text{fmax}}$ value was found from the integration of oxidized part of during cyclic voltameter. In this process doping level of polymer can be calculated to following formula:

$$Q_{f_{\text{max}}} = \left(\frac{\gamma}{\gamma + 2}\right)Q_d$$  \hspace{1cm} (Equation 3)

From equation 3, the $Q_{\text{fmax}}$ increase linearly with polymerization charge of polymer film with a slope of $\gamma / (2+\gamma)$. $\gamma$ value was found as 0.41 (Figure 2-b). This value agrees with those determined for polythiophene and its derivatives as reported in the literature value is higher than the reference value (0.33) [20]. This phenomenon is most probably related to ionic liquid medium. Ionic liquid increased the doping level of polymer film in our work.

Electrochemical impedance spectroscopy was also tested for the PEDOT electrode in this work. Nyquist plots of polymer film with different charges changes depending on the polymerization charges indicating ohmic resistance of polymeric films and ion transportation (Figure 4(a)). The low frequency capacitance $C_L$, which is related with frequency dependence of charging processes, can be calculated from the charge saturation region observed at low frequency. The capacitances value increase linearly with the polymerization charge of polymer film, as shown in Figure 4(b). In order to ascertain the performance of PEDOT electrode material for supercapacitor applications, galvanostatic charge discharge cycles were analysed for PEDOT film with various current densities. The specific capacitance ($C_{sp}$) of a material can be

![Figure 4(a) Nyquist plots of PEDOT films having different polymerization charges (b) Plots of low frequency capacitances from impedance spectroscopy versus polymerization charge at 0.4 V.](image)
estimated from charge discharge (CD) and as well as CV cycling. When charge-discharge method was used, the specific capacitance can be calculated according to Eq. 4

$$C_{sp} = \frac{It}{AV}$$  
(Equation 4)

where $I$ and $t$ are the discharge current and time, respectively. $V$ is the potential range and $A$ is the area of polymer on Pt electrode.

![Graph showing the effect of electrolyte on specific capacitance.](image)

Figure 5. Galvanostatic charge discharge characteristics of PEDOT electrode at different electrolytes at various current densities in 0.1 M LiClO$_4$ and ACN solvent.

Consistent with CD results, the specific capacitance decreased as the current density increased and the specific capacitance of the electrode at the current densities of 2, 3, 4 and 5 mA cm$^{-2}$ were 171, 79, 66, 68, respectively (Figure 5).

IV. Conclusion

Electrochemically synthesize PEDOT polymer film has good stability and reversible redox process. The specific capacitance value of PEDOT was found as 33 mF cm$^{-2}$ for a polymer film (5 mC).

Abstract— In this study, Silver (Ag) nanoparticle thin films were deposited on microscope slide glass substrate by Pulsed Laser Deposition (PLD) in Argon (Ar) background gas pressure. Vacuum chamber can be evacuated down to $3 \times 10^{-7}$ mbar and then experimental works can be carried out using an Ar ambient gas pressure. Atomic Force Microscopy (AFM) analyse has shown that the deposition rate was decreased due to the collisions of Ag particles in the shrinking plasma by filling of Ar gas into the vacuum chamber. According to the absorption spectra taken by UV-VIS spectrometer, the wavelength, where the Localized Surface Plasmon Resonance (LSPR) was observed, which was shifted towards to the lower wavelength region as Ar background gas pressure was increased. The obtained spectra for Ag thin film nanoparticles was theoretically analysed and figured out by using a BEM (Boundary Element Method) simulation programme. In this study, experimental spectrum and simulation data for metal nanoparticles were acquired and compared, both are in well agreement. As a result of the release of Ar gas into vacuum chamber, the interparticle distance was increased and the changes occurred on the shapes of Ag nanoparticles. This has shown that LSPR wavelength can be tuned by adjusting the size of metal nanoparticles depending on Ar ambient gas pressure.

Keywords — Nanoparticle, Gas Pressure, Thin Film, BEM, PLD

I. INTRODUCTION

Recent years, the nanoscale noble metal particles have attracted a great amount of interest due to their unique optical properties not found in their bulk counterparts or in molecules [1, 2]. When the noble metal nanoparticle is exposed to the light, the excited plasmons in nanoparticle that oscillate with the electromagnetic field of light. This phenomena is called as Localised Surface Plasmon Resonance (LSPR). If the wavelength of light is larger than the nanoparticle diameter, LSPR occurs [3-6]. The silver nanoparticles among the plasmonic metals which is in group 11 metal and leads to polarization of electrons line up in $d^{10}$ orbit [7]. It has many application fields such as catalysis, energy storage, photovoltaics, optical nanosensors, surface enhanced spectroscopy [8-11].

The plasmonic nanoparticles are used in the light trapping method to increase the efficiency of the thin film solar cells [12]. The metal nanoparticles embedded into the interface of p-n junction of the solar cells which lead to absorption of more photons in the active layer with the effect of LSPR and prevent the recombination of charge carriers in the active layer. LSPR depends significantly on the nanoparticle size, shape, height, particle density, inter-particle distance, surrounding medium and the dielectric constant of the substrate [1, 2, 13].

Thin film coating techniques have significantly effect on the morphology of the thin film nanoparticles. Particularly, PLD technique [14] has many parameters that can be easily controlled during the deposition process of the nanostructures [15-25]. The nanoparticle size, nanoparticle density and the inter-particle distance can be controlled by background gas pressure in PLD [21]. Therefore, LSPR peak is tunable over the desired region in the solar spectrum.

In this study, experimental and the simulation results were compared to prove the accuracy of the LSPR wavelength of Ag nanoparticle thin films that were grown depending on the Ar ambient gas pressure. LSPR properties of metallic nanoparticles were simulated by using a Boundary Element Method (BEM) [26].

II. EXPERIMENT

Ag nanoparticles were deposited on the microscope slide glass substrate by PLD at room temperature (RT). An Nd:YAG laser system was used to ablate and deposite thin films and laser system was operated to deliver laser pulses with 5 ns duration, 40 mJ energy per pulse at 1064 nm wavelength, 10 Hz repetition rate. A 99.95% pure Ag metallic target material (Kurt Lesker) in one inch in diameter was used in experiments. The distance between the target material and the substrate was set to 45 mm. The 40 cm focal length biconvex
lens was used to focus the laser beam onto the target material. To avoid damage the target, and to form a uniform and smooth thin film, the target material and the substrate holder were rotated at a certain-constant speed.

The microscope slide glasses were first cleaned with soap foam, subsequently was bath in acetone and isopropyl alcohol for fifteen minutes for each chemicals. The cleaning procedure was carried out in an ultrasonic bath, and then the substrates were dried in a N₂ flow.

The vacuum chamber was evacuated to 3×10⁻⁷ mbar before the experiment. Afterward, Ag nanoparticles were grown in Ar gas pressure of 1.0×10⁻³ mbar and 7.5×10⁻⁴ mbar, respectively.

The morphology of the Ag thin films deposited on a microscope glass substrate was analysed by AFM techniques. The optical absorption spectra of the Ag thin films were measured using an UV-VIS spectrophotometer (JASCO, V-670 Spectrophotometer, JAPAN).

III. RESULTS AND DISCUSSION

Ar used in the experiment as an inert gas which does not react with the ablated Ag particles. The ambience in the Ar gas pressure of 1.0×10⁻³ mbar that is close to vacuum conditions [20]. When the high-energy laser pulses focuses on the surface of target material, the ablated Ag particles form the plasma [22]. The plasma plume expands freely in the Ar gas ambient [17, 18, 25] of 1.0×10⁻³ mbar. Ag nanoparticles collide several times with the surrounding gas atoms at low density and their kinetic energy are not incurred a great loss [27]. So, the velocities of Ag nanoparticles are still high. Also, the mean free path of nanoparticles is long [11, 23, 24], and the deposition rate is high [11].

![Fig. 1 Plasma plume of Ag nanoparticles formed in Ar gas ambience of 1.0×10⁻³ mbar](image1)

![Fig. 2 AFM image of Ag nanoparticles formed in Ar gas ambience of 1.0×10⁻³ mbar in 5μm×5μm area](image2)

When Ar gas pressure is increased to 7.5×10⁻⁴ mbar, the ablated Ag particles collide strongly with surrounding dense Ar gas atoms, thus the kinetic energies of nanoparticles are decreased rapidly [27]. A portion of Ag nanoparticles scatters backward and escape to the vacuum environment or stops [22]. Therefore, the number of particles reaching on the substrate are reduced and the mean-free path of the ablated particles decreases [20]. It can be seen of the volume of the plasma plume is became smaller [15, 25] as presented in Fig.3.

![Fig. 1 Plasma plume of Ag nanoparticles formed in Ar gas ambience of 7.5×10⁻⁴ mbar](image3)

![Fig. 4 AFM image of Ag nanoparticles formed in Ar gas ambience of 7.5×10⁻⁴ mbar in 5μm×5μm area](image4)

Because of a small amount of particles reach on the substrate, the density of particles on the surface is reduced. Ag nanoparticles reaching on the surface that have no longer high kinetic energy. They move slowly as similar to moving particles in decreasing substrate temperature [16]. Since the diffusion length of the nanoparticles is low on the substrate surface [11, 19], the aggregation of Ag nanoparticles is limited and therefore, the size of particles are became smaller [11, 21]. Ag nanoparticles grown in the Ar gas pressure of 7.5×10⁻⁴ mbar that have smaller size as shown in the AFM image in Fig. 4. Also, inter-particle distance was increased.
When a plasmonic nanoparticle is subjected to light, due to the fact that the conduction electrons in the nanoparticles are confined in three dimensions, the electric field of the light induces a movement of the free electrons. The conduction electrons accumulate at the surface of nanoparticles a called the "plasmon".

Fig. 5 Oscillating motion of plasmons induced by the electric field of light

The plasmons are oscillates by the electric field of light at a certain frequency which lead to light to be confined into the nanoscale size of the metallic particle. The frequency where LSPR (inversely proportional to the oscillation wavelength) is strongly dependent on the morphology of nanoparticles [3-6]. The changes on the morphological parameters lead to the tuning of the wavelength of LSPR between UV to IR region [28].
According to the simulation results of the extinction spectra of Ag thin film nanoparticles, LSPR peaks for Ar gas pressure of 1.0 × 10⁻³ mbar and 7.5 × 10⁻³ mbar which were located on the 655 nm (purple solid line) and 555 nm wavelength (turquoise dashed line), respectively. Consequently, the simulation results are in agreement with experimental results.

IV. CONCLUSION

LSPR peaks of Ag nanoparticles grown in the Ar gas pressure which were located on the longer wavelength that can be attributed to the larger particle size. As the gas pressure is increased, the size of Ag particles were reduced and the wavelength where LSPR shifted to the shorter region. These experimental results are consistent with the results which was obtained by using BEM simulations. The Ag nanoparticles can be embedded into the active layer of the thin film solar cell by PLD. The absorption region of the active layer can be made to be tunable by controlling Ar gas pressure. Thus, it can be contributed to the efficiency of thin film solar cells by PLD technique.

Abstract—The progression in technology requires improved material performance to satisfy market necessities. One of the promising ways for the improvement of composite materials is the addition of some additives or fillers. Due to scientific and industrial relevance, the investigation of the effects of additives into material have become popular subject in the current decade. The current study presents the effects of nanoclay particles on the impact behavior of glass fiber reinforced composite laminates. Nanostructured composite laminates are fabricated by a vacuum bag molding after hand layup technique using different weight percentages of nanoclay. Charpy impact tests are performed to determine the impact behavior of fabricated laminates. The results show that the incorporation of nanoclay particles have significant effects on the Charpy impact behaviour.

Keywords—nanocomposite, nanoclay, glass fiber, epoxy, impact

I. INTRODUCTION

Fiber reinforced polymer composite materials have attracted significant interest in the past few decades due to their outstanding performance-to-weight ratio in relation to conventional engineering materials [1]. Fiber reinforced polymer composites also exhibit better damping characteristics, good fatigue resistance and high resistance to corrosion [2]. With these outstanding properties, fiber reinforced polymer composites have become promising materials for the application of aerospace, automotive, marine and defense industries. However, fiber reinforced polymer composites are susceptible to out-of-plane impact damage resistance which can cause significant reductions in strength and, in turn, leads to heavier designs to meet safety requirements [3]. One of the methods to improve the impact damage resistance of fiber reinforced polymer composites is the addition of small amount of nanoparticles into the matrix of composites [4].

The introduction of nanoparticles into the resin constituting the composites matrix is a relatively new advancement in the field of polymer composites. Over the last two decades, several researches have reported that the addition of small amounts of nanoparticles, such as carbon nanotubes, nanometal oxides, graphene and nanoclays, lead to remarkable improvements in mechanical, thermal, morphological, electrical and optical properties of polymer composite materials without compromising on toughness, density and manufacturing process [5]. Among different types of nanoparticles, nanoclays have received significant attention due to its low cost and easy availability [5]. Numerous researchers have investigated the various properties and characteristics of nanoclay reinforced polymer composites. The range of properties in which the introduction of nanoclay yields improvements over neat polymers used composite materials is much more than the expected. The advantages of nanoclay filled composites are generally demonstrated with the improvements in mechanical and thermal properties such as quasi-static tensile and flexural properties, fracture resistance, thermal degradation resistance. However, the mechanical properties of nanoparticle reinforced polymer composite are very low compared to fiber reinforced polymer composites [6]. In recent years, an increasing interest has emerged on the development of ternary hybrid composites in which continuous fibers and nanoparticles are simultaneously added to polymer matrix. In particular, some studies have focused on the improvement of mechanical properties of fiber reinforced polymer composites by introduction of nanoclay to the epoxy matrix. Haque et al. [7] investigated the influence of nanoclay content on fracture behavior, mechanical and thermal properties of glass fiber reinforced polymer matrix composites. Siddiqui et al. [8] analyzed the mechanical properties such as compact tensile, flexural, fracture and Izod impact behavior of carbon fiber reinforced nanoclay based polymer matrix composites. Chowdary and Kumar [9] prepared glass fiber reinforced polyester matrix composites with five different wt% of nanoclay in order to assess the effect of nanoclay content on tensile and flexural behavior. Chandradass et al. [10] outlined the effect of nanoclay dispersion on tensile, flexural, interlaminar shear strength, vibration, impact and thermal characteristics of glass fiber reinforced vinyl ester polymer composites. Sivasaravanan et al. [11] presented the tensile, impact and hardness characteristics of nanoclay added glass fiber reinforced polymer matrix composites. Iqbal et al. [4] revealed the impact damage resistance of carbon fiber reinforced composite based on nanoclay filled epoxy matrix. Reis et al. [12] explored the influence of nanoclay content on impact response of Kevlar fiber reinforced epoxy composites
to determine the ideal amount (wt.%) of nanoclay for the best impact response.

Despite the large number of publications on polymer-clay nanocomposites, there is very little literature about the effects of adding nanoclay to polymer on Charpy impact behavior of glass fiber reinforced polymer composites. Therefore, the aim of this work is to analyze the variation of Charpy impact behavior of glass fiber reinforced nanoclay based epoxy matrix composite with respect to the nanoclay weight fraction. A group of glass fiber reinforced nanoclay based epoxy matrix composites with clay concentration up to 3 wt% have been prepared using hand lay-up technique.

II. MATERIALS AND METHODS

A. Materials

Epoxy resin (MOMENTIVE-MGS L285) and hardener (MOMENTIVE-MGS H285) were supplied by DOST Chemical Industrial Raw Materials Industry, Turkey. Montmorillonite nanoclay with 35-45 wt% dimethyl dialky (C14-C18) amine was obtained from Grafen Chemical Industries, Turkey. Plain weave E-glass fabric (01266 0800 TF970) with areal density of 202 g/m² manufactured by Hexcel Corporation, Italy was used as the main reinforcement phase. Firstly, epoxy/nanoclay mixture with different clay contents (1, 2, 3 wt%) were prepared by adding the weighted epoxy and nanoclay in a suitable beaker and mixing with a mechanical stirrer. Then hardener was added to the mixture at an epoxy to hardener weight ratio of 100:40 and mixed thoroughly again. The density and thickness values of glass fiber fabric, nanoclay and matrix are presented in Table I.

B. Fabrication of Specimens

The preparation of nanoclay filled epoxy based glass fiber reinforced composites was carried out by hand layup method in Fig. 1. Twelve plies of glass fabric were cut into 300 mm × 250 mm. A thin release agent film was applied on the surface of mold plates. A layer of resin (epoxy/nanoclay/hardener) mixture was deposited on bottom mold surface. First ply was placed over mold and resin mixture was applied with the help of a brush until it was entirely wetted. Second ply was placed on the first one and resin mixture was applied until it became entirely wet. This operation was repeated until twelve plies were stacked. After completion of all plies, the top of entire fabric stack was covered with top mold plate and whole assembly was placed in a hot press. The laminate was cured at a temperature of 80°C and a pressure of 4 MPa for 3 hours. After the plate was cured, it was removed from the mold.

C. Mechanical Tests

Charpy impact tests were conducted following ISO 179/92 standard. A Köger 3/70 Charpy impact test machine, shown in Fig. 2, was employed for the tests. Both notched and unnotched specimens with a dimension of 55 mm × 10 mm were prepared and subjected to flatwise and edgewise impact loadings, respectively. For each laminate structure and test configuration (edgewise and flatwise), five specimens were tested. All tests were performed at standard weather conditions. The absorbed impact energy and impact toughness of specimens were determined according to following equations:

\[ E = E_a - E_b \]

where, \( E, E_a, E_b, \) and \( b \) represent the absorbed impact energy, potential energy of the weighted pendulum before and after impact (shown in Fig. 3), impact toughness, thickness and width of the test specimen, respectively. Average values and standard deviations for the absorbed impact energy and impact toughness were used to assess the effect of nanoclay.
III. RESULTS AND DISCUSSION

The Charpy impact test was used to measure the impact energy absorbed by the specimens. The impact energy values for notched (edgewise impacted) and unnotched (flatwise impacted) specimens were plotted against nanoclay contents in Fig. 4 and 5, respectively. Compared to impact energy of glass fiber reinforced epoxy composite, the achieved increase in absorbed impact energy of the notched specimens were 3%, 19% and 10% for 1 wt%, 2 wt% and 3% nanoclay filled glass fiber reinforced epoxy composites, respectively. The results showed that the addition of nanoclay into glass fiber reinforced epoxy became more significant at low contents and the 2 wt% clay content exhibited the highest impact energy absorption. At higher content, the addition of nanoclay was not so effective in improvement of impact energy absorption. Probably, it can be attributed to the agglomeration of nanoclay particles which resulted with a weak interfacial adhesion.

For the unnotched test specimens, the variation in absorbed impact energy of the notched specimens were 8%, 11% and -19% for 1 wt%, 2 wt% and 3% nanoclay filled glass fiber reinforced epoxy composites, respectively. The addition of nanoclay became more significant at low contents and the 2 wt% clay content exhibited the highest impact energy absorption by 11% improvement. At higher content, the addition of nanoclay was derogated the impact energy absorption. The agglomeration of nanoclay particles can be the reason of decrease. In the literature, several similar results were reported for effect of nanoparticles on mechanical properties of composite materials [13].

IV. CONCLUSIONS

The Charpy impact properties of nanoclay filled epoxy based glass fiber reinforced composites were studied. The impact properties were measured by the impact energy absorption of notched and unnotched specimens. For the notched specimens, addition of nanoclay provided an improvement in impact energy absorption regardless of clay content. The improvement in impact energy absorption was increased to a maximum by 19% at 2 wt% nanoclay content and showed diminishing improvement for further addition of nanoclay. For the unnotched specimens, the improvement in impact energy absorption was increased to a maximum by 11% at 2 wt% nanoclay content. However, further addition of nanoclay decreased the impact energy absorption. The results suggested that the impact energy absorption of glass fiber reinforced composites could be improved by the addition of small amounts of nanoclay.

Abstract—In this study, the effect of nanoclay particles on tensile and flexural properties of glass fiber reinforced polymeric composite laminates are investigated. The nano-structured composite laminates are fabricated by hand layup process using different weight percentages of nanoclay additive. The nanoclay particles are dispersed in epoxy resin using mechanical stirring. The tensile and flexural behavior of fabricated composite laminates are measured by performing uniaxial tensile and three-point bending tests. The present results show that the incorporation of nanoclay yields a substantial effect on the tensile and flexural properties of glass fiber reinforced composite laminates.

Keywords—nanocomposite, nanoclay, glass fiber, epoxy, impact

I. INTRODUCTION

The fiber reinforced polymeric composites have already proven their worth as weight-saving materials having high strength. Because of that, application areas of polymeric composites have extended day by day. Nowadays, polymeric composites have become one of the most popular materials in several engineering applications such as sporting goods, household appliances, automotive, aerospace, marine and defense industries. The desire to improve the performance, reliability and functionality of polymeric composite materials with increasing demand in the market necessities is directed to develop and implement new approaches in the fabrications of polymeric composite materials.

One of the ways to enhance the mechanical properties of polymeric composites is to improve the polymer matrix-dominated properties by incorporating some fillers or particles into the resin. The addition of particles, especially nanoparticles, into polymeric matrix is a newly developing area in the polymeric composite sector. Polymeric nanocomposites, where at least one of the dimensions of the particulate material is less than 100 nm, have shown significant improvements in mechanical, thermal, morphological, electrical and optical properties of polymeric composites [1]. Various types of nanoparticles, such as carbon nanotubes, nanometal oxides, graphene and nanoclays, are currently used as fillers in the polymeric composites. Due to substantial enhancement of mechanical properties with the addition of small amount of nanoclay and large natural abundance of nanoclay, nanoclay-polymer composites have engrossed great attention. Numerous researches have dealt with the effect of nanoclay on tensile, flexural, impact and fracture characteristics of polymer resins. In these investigations, variations of mechanical properties with respect to nanoclay loadings have been reported as increasing or decreasing.

However, the cited properties of nanoparticle reinforced polymer composite are so low that cannot be compared with the properties offered by fiber reinforced polymer composites [2]. In recent years, a new trend has developed toward the development of ternary hybrid composites by using continuous fibers and nanoparticles simultaneously in the same matrix system. Several studies have particularly dealt with the effect of nanoclay content on mechanical properties of fiber reinforced. Dorigato et al. [3] prepared glass fiber reinforced epoxy nanoclay composites and carried out a detailed investigation about the potential use of nanoclay-epoxy matrix for fiber reinforced composites. The quasi-static tensile and single edge notched bend tests were performed to determine effect of nanoclay on tensile and fracture toughness characteristics. Subramaniyan and Sun [4] sought the variation of compressive strength of glass fiber reinforced vinyl ester with the addition of nanoclay. Rahman et al. [5] explored the effect of nanoclay on thermal stability, tensile and flexural behavior of chopped glass fiber reinforced polypropylene composites. Mohan and Kanny [6] analyzed the effect of nanoclay content on short glass fiber reinforced polypropylene composites. Santiago et al. [7] revealed the changes of quasi-static tensile and dynamic compression properties with variations of nanoclay content. Chowdary and Kumar [8] studied the tensile properties of glass fiber reinforced polyester-nanoclay composites and reported the effect of nanoclay on tensile strength and modulus.

The present work focused on measurement of tensile and flexural properties of nanoclay filled epoxy based glass fiber reinforced composites and the investigation of effect of nanoclay content on tensile and flexural properties of glass fiber reinforced epoxy composites. Several glass fiber reinforced nanoclay filled epoxy based composite laminates with different clay concentrations have been prepared.
II. EXPERIMENTAL PROCEDURES

A. Materials

Epoxy resin (MOMENTIVE-MGS L285) and hardener (MOMENTIVE-MGS H285) provided by DOST Chemical Industrial Raw Materials Industry, Turkey were used to form matrix constituent. Montmorillonite nanoclay with 35-45 wt% dimethyl dialkyl (C14-C18) amine was obtained from Grafen Chemical Industries, Turkey. E-glass fabric (01266 0800 TF970) produced by Hexcel Corporation, Italy was employed as the main reinforcement of nanocomposite. The fabric was characterized by plain weave and areal weight of 202 g/m². The epoxy/nanoclay mixture with different clay contents (1, 2, 3 wt%) were prepared by stirring the weighted epoxy and nanoclay with a mechanical stirrer. After that the hardener was added to mixture of epoxy/nanoclay using epoxy-to-hardener weight ratio of 100:40 and mixed thoroughly again. The density and thickness values for epoxy resin, nanoclay and glass fabric were presented in Table I.

B. Fabrication of Specimens

Hand layup technique, shown in Fig. 1, was used for the fabrication of nanoclay filled epoxy based glass fiber reinforced composites. At first, a thin release agent film was deposited on the surface of mold plates. First fabric layer was put on mold and fully soaked with resin mixture (epoxy/nanoclay/hardener) using a brush. Second fabric layer was laid on the first one and resin mixture was applied until it became entirely wet. This operation was repeated until twelve layers were stacked. After stacking procedure, top mold plate was placed on fabric stack and the whole assembly was compacted in a hot press. The laminate was cured at a pressure of 4 MPa and a temperature of 80°C for 3 hours. Finally, composite laminate was demolded.

C. Mechanical Tests

In order to investigate the effect of nanoclay on mechanical properties of epoxy based glass fiber reinforced composites, three-point bending and uniaxial tensile tests were performed. Five specimens were prepared for each test of each composite configuration and averages of results were provided. The tests were exerted at standard humidity and room temperature conditions using a 50 kN Shimadzu AG-X series universal testing machine.

The uniaxial tensile tests were carried out in accordance to the ASTM D3039 standard specifications. The three-point bending tests were conducted according ASTM D790 standard. The span-to-depth ratio of specimens were used as 32:1 and specimen dimensions were 200 mm in length and 12.7 mm in width.

III. RESULTS AND DISCUSSIONS

The tensile strengths of the prepared composite samples were determined by conducting uniaxial tensile test. The variation of tensile strength values against nanoclay contents was presented in Fig. 2. Compared to tensile strength of glass fiber reinforced composite without nanoclay content, the increase in tensile strength were 8%, 4% and 1% for 1 wt%, 2 wt% and 3% nanoclay filled epoxy based glass fiber reinforced composites, respectively. As can be seen in figure, the enhancement of tensile strength at low nanoclay contents was more significant and the 1 wt% clay content yielded the highest tensile strength. At higher content, the introduction of nanoclay was not so effective in improvement of tensile strength. Probably, it can be attributed to the agglomeration of nanoclay particles which resulted with poor adhesion. Several similar results were reported in the literature [9].

Fig. 2: Variation of tensile strength according to nanoclay content

Flexural strength and modulus of nanoclay filled epoxy based glass fiber reinforced composite laminates were plotted against nanoclay contents in Fig. 3 and 4, respectively. As seen in the figure, all nanoclay filled composites showed lower flexural strength and modulus compared to the composites without nanoclay. The addition of nanoclay into glass fiber reinforced epoxy composites resulted with decreases in both flexural strength and modulus from 327 MPa to 280 MPa and 15 GPa to 13 Gpa, respectively. The declines in flexural strength and modulus with addition of nanoclay can be seemed as a result of debonding of nanoclay and epoxy, poor dispersion.
and the presence of multiple micro-sized voids due to excess stretching fibers. The increase in the rate of decline with respect to increase in nanoclay content can be attributed to agglomeration of nanoclay particles.

The enhancement in tensile strength was reached to a maximum by 8% at 1 wt% nanoclay content and showed diminishing improvement for further addition of nanoclay. The addition of nanoclay resulted in lower flexural modulus and strength compared to the composites without nanoclay content. The rate of decline in flexural modulus and strength were increased with respect to increase in nanoclay content. The maximum decrease in flexural modulus and strength were 17% and 14% for 3 wt% nanoclay content. The declines in flexural modulus and strength can be attributed to poor adhesion and the presence of multiple micro-sized voids due to excess stretching fibers. The results showed that the tensile strength of glass fiber reinforced composites could be improved by the addition of small amounts of nanoclay.

IV. CONCLUSIONS

Fiber reinforced hybrid nanocomposites were fabricated using glass fiber and nanoclay filled epoxy. The composites were prepared with the introduction of different weight percentage of nanoclay (1 wt%, 2 wt% and 3 wt% of weight of matrix). The uniaxial tensile and three-point bending tests were performed to investigate the effect of nanoclay on tensile and flexural properties of epoxy based glass fiber reinforced composites. The introduction nanoclay yielded an improvement in tensile strength regardless of nanoclay content.

Abstract—In the present work, Al₂O₃-Ni and Al₂O₃-Co powder mixtures were prepared with 3 vol. % metal ratios by the heterogeneous precipitation method. To increase the green strength, PPC was used as a binder while preparing green compacts. Specimens are pressureless sintered at 1550°C for 2h in reducing atmosphere condition. The structural and mechanical properties of the composites were characterized by XRD, SEM, Vickers Indentation technique and three-point bending test. The effects of 3 vol. % Ni and 3 vol. % Co to the microstructure and mechanical properties were investigated by comparison.

Keywords—Alumina, Composite, Microstructure, Hardness, Toughness, Strength.

I. INTRODUCTION

The structural applications of alumina ceramics (Al₂O₃) are restricted due to its brittle nature, low tensile strength and low thermal shock resistance [1]. Incorporation of ductile metal particles into the alumina matrix is an effective way to overcome these problems [2]. Especially, alumina/metal nanocomposites are of great interest because of the superior properties they have such as hardness improvement [3]. The particular case of Al₂O₃/nNi system has been widely studied up to the present [2,4,5]. It is shown that the fracture strength and hardness of the alumina clearly enhanced by incorporating Ni nano particles into matrix [5]. Al₂O₃/nCo system is another choice for this concept due to the attractive properties of cobalt like high melting temperature (1495°C) and better wetting ability with Al₂O₃ in comparison with Ni [6,7].

In ceramic processing, binders are often used to improve the strength of the green compacts and sometimes the relative density [8]. There are various organic binders which are either soluble in water or organic solvents, like PVA (polyvinylalcohol) and PEG (polyethylene glycol). In this work, polypropylene carbonate (PPC) was preferred as a binder because it burns out completely during the sintering cycle in reducing atmosphere conditions[9].

To prepare of the composite powders, the heterogeneous precipitation method was chosen as fabrication method that provides homogeneous metal particle dispersion [2,10]. The metal ratios of both Ni and Co were adjusted as 3 vol. % in the final composites and the specimens were conventional sintered at 1550°C. By comparing the effect of Ni and Co reinforcement on the alumina ceramic, densification, and mechanical properties were investigated.

II. EXPERIMENTAL PROCEDURE

In the present work, the starting materials were α-Al₂O₃ powder with average diameter of 0.60 µm (Almatis Calcined Alumina, Germany), nickel nitrate hexahydrate and cobalt nitrate hexahydrate, (Ni(NO₃)₂·6H₂O) (BDH Chemicals Ltd., Poole, England, 98% purity) (Co(NO₃)₂·6H₂O) (Sigma-Aldrich, 98% purity), ammonium bicarbonate (NH₄HCO₃) (Sigma Aldrich, 99% purity), polyacrylic acid as dispersant (Darvan 821A from MSE Tech Co. Ltd., Turkey) and finally PPC as binder (Qpac 40, Empower Materials, USA).

Al₂O₃, an appropriate amount of metal nitrate hexahydrate that provides 3 vol. % metal content in the final composite and 0.5wt% (equivalent to Al₂O₃ weight) polyacrylic acid were first mixed in distilled water and ball milled for 24 hours with alumina balls (ball: Al₂O₃ powder ratio of 10:1 by weight). 1.0 M aqueous solution of NH₄HCO₃ (the precipitation agent) was added dropwise into the 24h ball milled slurry under vigorous stirring on a magnetic stirrer. The reactions were given by the following equations [2,10,11]:

3Ni^{2+} + 6HCO_{3}^{-} + H_{2}O -→ NiCO_{3}•2Ni(OH)_{2}•2H_{2}O ↓ + 5CO_{2} ↑

3Co^{2+} + 6HCO_{3}^{-} + H_{2}O -→ CoCO_{3}•2Co(OH)_{2}•2H_{2}O ↓ + 5CO_{2} ↑

To guarantee the completion of above reactions during precipitation, an excess amount of NH₄HCO₃ was used and the pH value of the slurries was kept between 8-9. After precipitation, the slurries were filtered and washed with distilled water and ethanol. After the drying in air for a day, the dried powders were first calcined in air at 500°C for 2h and then reduced in a 90%Ar/10%H₂ atmosphere at 700°C/4h for Ni and at 950°C/2h for Co [9,11]. The reducing cycles were 5°C/min for both calcination and reduction treatment and then cooled down to room temperature in the furnace. Following these heat treatments nano metal coated Al₂O₃ composite powder can be obtained. Monolithic Al₂O₃ powder was prepared under the same conditions to compare the final properties with composites. The reduced powder mixtures and the monolithic alumina powder were sieved down to 90 µm and pressed in to a rectangular prism form in a 40x50 mm steel mold under the uniaxial pressure of 100 MPa. However, the pressed samples were cracked and broke up easily while removing from mold.
In order to increase the green strength, 3 wt. % and 2 wt. % PPC binder was added to the alumina and composite powders, respectively. For uniform mixing of PPC, a stoke solution was prepared with acetone and acetone was evaporated under vigorous stirring from PPC solution-powder mixture. The powders were dried and sieved again. The pressing procedure was repeated and the specimens in required form and strength were obtained. All the specimens were pressureless sintered in a vertical tube furnace at 1550°C for 2h in reducing (90%Ar/10%H₂) atmosphere. Binder burn out was carried out during sintering at 350°C. The prismatic bars were cut from the pieces after sintering with 3 mm width, 2 mm thickness, and 40 mm length.

X-ray diffraction (XRD) patterns were obtained at a scanning rate of 4°/min with a 2θ range from 5° to 70° by a Bruker® D8 Advance diffractometer. The Archimedes’ water replacement method was used to measure the bulk density of the sintered specimens. Scanning electron microscope (SEM) (Philips XL 30 SFEG) was employed to characterize the microstructure of the samples. The samples were grounded and polished down to 0.5 μm to see the grains and metal phases clearly in SEM analysis and to eliminate the effect of surface flaws on mechanical properties. The samples were thermally etched to reveal the grain boundaries at 1400°C/0.5h in the sintering conditions. Hardness was measured by an Instron® Wolpert Testor 2100 equipped with a diamond pyramid Vickers indenter. Loading time and load was selected as 10 s and 5 kg, respectively. Fracture toughness, Kc, was determined using the Vickers indentation technique using 10 s and 10 kg load. Flexural strength was measured by three-point bending test with a load span of 20 mm and a loading rate of 0.2 mm/s.

III. RESULTS AND DISCUSSION

As summarized in the experimental section, the powder mixture was calcined, reduced, and sintered. With calcination at 500°C/2h in air, the crystallization to discrete nano sized metal oxide phase occurred. By heat treatment at 700°C/4h and 950°C/2h in reducing atmosphere, metal oxide particles were all reduced to nano sized Ni and Co particles, respectively. The calcination and reduction parameters were determined according to Guo-Jun Li and his co-workers study [2]. Fig. 1 shows the XRD patterns of Al₂O₃/3 vol. % Ni composite after a) calcination, b) reducing, and c) sintering. In these figures, only Ni and NiO peaks are labelled for clarity, not labelled peaks are Al₂O₃’s. When the patterns are analysed, it can be seen that after reducing only Ni peaks are present and after sintering at 1550 °C, the peaks of Ni metal phase become more pronounced. This increase in peak intensity is attributed to the growth of metal phase from nano sizes (about 50 nm) to submicron sizes (from 100 nm to 500 nm). Fig. 2 shows the XRD patterns of Al₂O₃/3 vol. % Co composite after a) calcination, b) reducing, and c) sintering. Similar to Ni containing composites, CoO peaks were replaced by Co peaks after reducing and the intensities of Co peaks increase after sintering at 1550°C due to Co particle growth.

Fig. 3 shows SEM micrographs of thermally etched monolithic alumina and the composite specimens in backscattered electron mode. Metal particles and Al₂O₃ grains seem brighter and darker, respectively. For both composites, metal particles were spherical and dispersed homogeneously in the matrix. Also, it can be seen that metal particles were generally located at the triple junctions and at grain boundaries.

![Image](510x423 to 549x557)

![Image](510x423)

Table 1 shows the experimental results of the % relative density, Vickers hardness, toughness and flexural strength measurements of the specimens. The densities were first measured by Archimedes’ water replacement method and theoretical densities were calculated by the rule of mixtures before determining the relative densities. The highest relative density was obtained for the monolithic alumina, 98.9 %. For both Ni and Co composites, the relative density was 97.8 % which is lower than monolithic aluminas. The density difference can also be seen from SEM micrographs in Fig. 3. The decrease in density can be attributed to poor wetting of the metal phases, hence hindering the sintering of alumina [12]. It was reported that wetting ability of cobalt is better than nickel’s; still, it appears that their sintering behaviour is not different.

Vickers hardness measurements as presented in Table I show that alumina and metal reinforced composites have equal hardness values. The soft character of metal phases would expect to decrease the hardness of the composites by the rule of mixtures. Also, lower relative densities of metal reinforced composites should result in decreased hardness for these materials. On the other hand, the small size of metal particles increases the hardness and compensates for the decrease in hardness [10]. As a result, similar hardness values are obtained for monolithic alumina and the composite specimens.

Strength ($\sigma_f$) of ceramic materials is determined by their fracture toughness ($K_c$) and defect size ($a$) [13]:

$$\sigma_f = \frac{K_c}{\sqrt{\pi a}}$$

It is desired that a structural ceramic material would have a high fracture toughness and a small defect size so that it would have a high tensile or bending strength [13]. From Table 1, it is seen that the highest strength is achieved for monolithic alumina, 62.3±70 MPa, even tough, they had lower toughness 3.68±0.45 MPa·m$^{1/2}$, compared to the composites. Monolithic samples had the highest relative density; therefore, they had the smallest defects and the highest strength. On the other hand, metal reinforced composites have similar densities; i.e. similar defect size. Since the defect sizes are similar, the strength is determined by fracture toughness of the material. Co reinforced composites have higher fracture toughness, 4.67±0.96 MPa·m$^{1/2}$, compared to Ni reinforced composites, 4.42±0.67 MPa·m$^{1/2}$. The mechanism for increasing the fracture toughness is believed to be a combination of the plastic deformation of the ductile phase ahead of the crack tip and the crack bridging at the wake of the crack. It appears that Co is a more effective reinforcement in order to enhance the fracture toughness of the alumina by using heterogeneous precipitation method. SEM observations reveal that Co particles were larger compared to Ni particles and the enhanced fracture toughness is attributed to these larger ductile particles. As a result of its higher toughness, the strength of Co reinforced composites is higher than that of Ni reinforced composites; 588±82 MPa and 549±86 MPa, respectively. In other words, a 5% increase in fracture toughness while keeping the defect size similar resulted in a 5% increase in strength.

IV. CONCLUSIONS

Al$_2$O$_3$-Ni and Al$_2$O$_3$-Co powder mixtures with 3 vol. % metal ratios were prepared successfully by the heterogeneous precipitation method and sintered at 1550°C/2h in reducing atmosphere. When the densification and mechanical properties of alumina were compared to the composites, the highest density was observed for Al$_2$O$_3$. Still, the hardness measurements showed that 3 vol. % metal phase reinforcement did not cause a decrease in hardness. Metal phase, specifically Co, increased the toughness of the material; however, due to smaller defect size accompanied by better densification, maximum strength is achieved in monolithic alumina.

Department of Mechanical and Manufacturing Engineering, Bilecik Şeyh Edebiyat University, 11200 Bilecik, Turkey

Abstract— This study investigates the effect of Silicon (Si) and Manganese (Mn) on AS91 (9% Al, 1% Si) and AM90 (9% Al, 0.5% Mn) magnesium alloys that are among important magnesium alloys wear resistance and machinability. Hardness of intermetallic phases found in the microstructure of magnesium alloys was observed to affect wear resistance and machinability. Mg-Si found in the microstructure of AS91 alloy was established to reduce machinability while intermetallic phase increased hardness and wear resistance. It was found that intermetallic phases (Mg17Al12, Mg2Si and Al4Mn) of AS91 and AM90 magnesium alloys had an impact on cutting forces and machinability and mechanical properties.

Keywords— Machinability, cutting force, surface roughness, wear, AS91, AM90 series magnesium alloys

I. INTRODUCTION

Today, there are numerous areas of use for magnesium and its alloys due to their characteristics, and these areas of use grow in number every day. Especially due to being among the lightest structure metals for their low density and high resistance characteristics, magnesium alloys gain importance in many fields, predominantly in logistics, automotive, and aviation sectors [1,2,3]. Their use in vast fields continues depending on improving certain characteristics. Some of such characteristics to be improved are their mechanical features, hardness, wear, and machinability. A large number of studies carried out on magnesium alloys were about obtaining different alloys and investigating the mechanical characteristics of such alloys [4,5]. Studies conducted on alloy properties affecting the improvement of wear characteristics of magnesium alloys and their correlation with machinability are quite low in number and insufficient. It is quite important to investigate the use of magnesium alloys in engine, piston, and cylinders especially in automotive sector and also such characteristics as hardness, wear resistance, and machinability. It is known that wear resistance is closely related with tensile properties of the material. Wear can be defined as resistance of metal against friction in its most basic sense. Today, the most commonly used Mg-Al (magnesium-aluminium) alloys are AZ91, AM20, AM60, AS21, AS41, AJ62 etc. The most significant properties of these alloys are their well castability and improvable tensile properties.

This study investigates the effect of Si (Silicon) and Mn (Manganese) on wear resistance and machinability, and also the effects on hardness, wear resistance, strength, and machinability depending on microstructure of AS91 and AM90 containing 1% Si and 0.5% Mn.

II. EXPERIMENTAL PROCEDURE

The magnesium alloy used AS91(containing 9%Al, 1%Si) and AM90 (containing 9% Al, 0.5% Mn) in the experimental study were prepared by melting pure magnesium (Mg) and Aluminium (Al), Al-Si and Al-Mn master alloys in a graphite crucible under Argon gas (Ar) atmosphere at 750°C. Mg, Al, and Zn bullions (with a minimum purity of 99.90%) used in the casting and aluminium silicon (Al-Si 50%) and aluminium manganese (Al-Mn 10%) master alloys bullions were supplied from Bilginoglu Co. AS91 and AM90 magnesium alloys used in this experimental study were obtained by cast into a cast iron mould (preheated to 270°C) under protective SF₆ gas. Detailed information on the production methods of the magnesium alloys can be found in the work of Unal [6]. The produced magnesium alloys samples were 22 mm in diameter and 200 mm in length. The chemical compositions of the alloys were determined by a Spectrolab M8 Optical Emission Spectrometry (OES). After the casting process characterization of the alloys were made by microscopic examinations and tensile tests. Alloy compositions are listed in Table I.

| TABLE I: CHEMICAL COMPOSITION OF THE STUDIED AS91 AND AM90 ALLOYS |
|-----------------------------|---------|-------|-------|-------|-------|-------|
| Alloys | Al% | Mn% | Zn% | Si% | Fe% | Mg% |
| AS91 | 9.3 | 0.1 | 0.2 | 1.2 | 0.02 | Rest |
| AM90 | 9.41 | 0.5 | 0.26 | 0.1 | 0.02 | Rest |

Microstructural surveys were conducted on the metallographic samples by optical microscopy (LV150 Nikon Eclipse). The samples prepared 12 mm in diameter and 15 mm in length were machined, ground with grit emery papers (200, 400 600, 800 1000, and 1200 grits, respectively), and then polished with 6μm, 3μm and 1μm diamond paste using pure water. Lastly, the samples were etched in a solution of...
100ml ethanol, 5ml Acetic acid, 6g picric acid and 10ml water for use in microstructural evaluations. X-ray diffraction (XRD) analyses (Panalytical-Empyrean) were carried out under Cu Kα radiation with an incidence beam angle of 2°. The tensile tests (ASTM E 8 M-99 standards) were performed at a crosshead speed of 0.8 mm/min⁻¹ and at room temperature (Shimadzu Autograph AGS-J 10 kN Universal Tester). The hardness values of the samples were determined by the Vickers hardness test (HV) with a load of 10N by using microhardness tester (Shimadzu HVM-2). At least ten hardness measurements were carried out on each sample.

Wear tests of experimental samples were carried out on pin-on disk test device (Fig.1) At the end of wear experiment, sizes of marks left on sample surfaces were measured and thus wear resistances of samples were estimated. Wear tests were performed on a reciprocating wear tester (Tribotester TM, Clichy) under a load of 4 N. Al₂O₃ balls having a 6mm diameter rubbed on the surfaces of the samples with a sliding speed of 5mm/s. The stroke of the Al₂O₃ balls was 5mm for a total sliding distance of 25m. Wear test samples were 15mm in diameter and 10mm in length. The coefficient of friction and frictional force were continuously recorded throughout the wear tests. Contact surfaces of the samples were examined using a surface profilometer (Dektak TM 6 M).

Cutting forces were implemented to evaluate the usage of two experimental methodologies. The feed rate (f) and depth of cut (DoC) were held constant to maintain the cross-sectional area of the chips in millimetres per revolution (mm/rev). The feed (f; mm min⁻¹) was held constant for various revolutions. The machining parameters and conditions of the experimental studies are given in Table II. The cast magnesium alloy samples were subjected to a pre-cleaning operation (i.e. diameter reduced from 22 to 20mm) before the experiments.

**III. EXPERIMENTAL RESULTS AND DISCUSSION**

A. Microstructure and Mechanical Properties

Microstructure photographs and XRD patterns of AS91 and AM90 magnesium alloys used in the study are given in Fig.3 and Fig.4, respectively. Microstructure of magnesium alloys analysed in the study was generally observed to be made up of α-Mg matrix and intermetallic phases. It was observed that network formation of Mg₁₇Al₁₂ intermetallic phase in AS91 Mg alloys tended to surround α-Mg grains throughout the matrix[7]. The intermetallic phase could easily be distinguished from the matrix under the optical light microscopy (Fig.3a).

In AS91 alloy, Mg₃Si intermetallic phase was present along with Mg₁₇Al₁₂ intermetallic phase [8]. Previous studies reported the presence of Mg₁₇Al₁₂ intermetallic phase in AZ91 alloy [9,10]. The formation of Mg₁₇Al₁₂ phase was repeatedly reported due to changes of the solidification behaviours of the melt caused by Zn addition [9,10]. In AS91 magnesium alloy, the constitution of the matrix is α-Mg phase, Mg₁₇Al₁₂, and Mg₃Si phases as shown in Fig.3. The formation of Mg₃Si phases in AS91 alloy appeared as Chinese script form in accord with the published literature [5,8-13]. In AM90 magnesium alloy, the constitution of the matrix is α-Mg phase and Al₆Mn₅ intermetallic phases as shown in Fig.3.

![Fig.1 Schematic view of the reciprocating wear tester utilized in this study.](image1)

![Fig.2 Schematic representation of experimental set-up with strain](image2)
B. Mechanical Properties

Hardness and wear values of the analysed alloys are given in Table III. When checked the mean hardness values of alloys, these were estimated to be 61.45 HV 10 in AS91 alloy and 88.5 HV 10 in AM90 alloy. The fact that AM90 demonstrated a higher hardness property resulted from the Al₅Mn₅ phase found in the microstructure.

Based on the data obtained from wear tests, presence of Al₅Mn₅ intermetallic phase in AM90 alloy microstructure provided the demonstration of a higher wear resistance at a rate of 22% compared to AS91 alloy. According to this, it was observed that the Al₅Mn₅ intermetallic phase that occurred thanks to the effect/presence of Mn in AM90 alloy increased wear resistance compared to (Mg₅Si,Mg₁₇Al₁₂) intermetallic phase formed due to the effect/presence of Si in AS91 alloy. A significant difference was not found between the friction coefficients of these two alloys. The reason for AM90 alloy to demonstrate a higher hardness and wear resistance compared to AS91 alloy was due to Al₅Mn₅ intermetallic phase found in the microstructure. When analysed the correlation between wear resistance and hardness in the experimental study, wear resistance was observed to increase depending on hardness (Table III). From this point of view, Al₅Mn₅ intermetallic phase found in AM90 alloy was observed to have an impact on hardness and wear properties. Experimental test results obtained from AS91 and AM90 series magnesium alloys are given in Table III.

Table III shows the dependence of the ultimate tensile strength (UTS), yield strength (YS) and elongation (EL) of the alloys studied on their Si and Mn content. The results obtained for UTS, YS and EL values could entirely be attributed to the presence of intermetallic phases (Mg₅Si,Mg₁₇Al₁₂,Mg₂Si and Al₅Mn₅) occurred in the structure. The various morphologies of the intermetallics indicate that particles were formed under various conditions [6,9-19]. Deviations from the reported results [12,16,19] are caused probably because of the production conditions such as casting temperature, solidification condition and impurity of the alloy.

C. Machining Properties

In the turning processes of AS91 and AM90 experiment samples used in the experimental study, data obtained as a result of applications conducted by keeping chip sections fixed are given in Fig.5. The highest cutting force in AM90 alloy was obtained as 55.7N at a cutting speed of Vc:168m/min, and as 49.8N in AS91 alloy; the lowest cutting force value was 43.12N in AS91 and 48.8N in AM90 at a cutting speed of 56m/min. It was observed at three different cutting speed selected in the experiment that cutting forces occurred during machining AM90 alloy was higher compared to cutting forces occurred during machining AS91 alloy. An increase was observed in cutting forces (with chip section fixed) due to a rise in cutting speed in machining AS91 and AM90 alloys (Fig.5). When compared the cutting forces, the highest cutting force value was obtained from AM90 alloy (Fig.5). From this point of view, it may be noted that the increase in cutting forces depending on cutting speed could occur due to dislocation build-up with chips in cutting edge.
Values of surface roughness that occur by machining AS91 and AM90 magnesium alloys are given in Fig.6. Both alloys were observed to have an increase in surface roughness as the cutting speed rises. It was observed that the surface roughness values obtained from AS91 alloy were higher compared to surface roughness values from AM90 alloy. It may be noted that intermetallic phases that occurred due to Si effect/presence (Mg$_2$Si, Mg$_{17}$Al$_{12}$) in the alloy had an impact on the formation of surface roughness values.

![Fig.6 Relationship between surface roughness (Ra) and cutting speeds of AS91 and AM90 series magnesium alloys](image)

Wears occurring due to machining AS91 and AM90 alloys on the surface of cutting edge surface are observed in Fig.7. When analysed cutting edge surfaces used in the experiment, it was established that Flank Build-up (FBU) occurred due to dry friction [13-16] between the work piece and cutting tool surface during the machining of AS91 and AM90 alloys and that cutting edges were worn. The said wear was found to be deeper in the cutting edge from AM90 alloy; and when analysed the cutting tool surface with which AS91 alloy was machined, chips were observed to advance along chip angle on a vaster surface (Fig.7c). Intermetallic phases (Mg$_2$Si, Mg$_{17}$Al$_{12}$ and Al$_3$Mn$_5$) that occurred/found in alloy were effective in the increase of the cutting forces. From this point of view, it was observed that Al$_3$Mn$_5$ intermetallic phase formed due the effect/presence of Mn in AM90 alloy had a harder structure compared to Mg$_2$Si, Mg$_{17}$Al$_{12}$ intermetallic phase formed due to the effect/presence of Si in AS91 and that this wore the cutting tool much more [17-19].

Flank Build-up (FBU) increase in the cutting surface between the cutting edge and sample surface due to intermetallic phases also causes a rise in cutting forces (Fig. 5) Flank Build-up (FBU) formation increases with friction and temperature rise occurring on the cutting tool surface due to an increase in cutting speed [14], and this may be noted to raise cutting forces (Fig.5)

![Fig.7 SEM image of cutting tool tip used for machining of magnesium alloys](image)

Images of chips obtained from machining AS91 and AM90 magnesium alloys are given in Fig.8. When analysed the chip images, it was observed that while chips formed from AM90 alloy were smaller in length and more plaited, chips from AS91 alloy were longer and helical [13,17]. When compared chips from AS91 with chips from AM90, it was found that chip lengths reduced and had more brittle breaks, and that chips were in the form of sawtooth. It may be noted that chips from AM90 alloy were smaller in length and occurred as a result of brittle breaks due to the effect of Al$_3$Mn$_5$ intermetallic phase, and in AS91 alloy, chips were longer and formed as a result of ductile breaks due to the effect of Mg$_2$Si and Mg$_{17}$Al$_{12}$ intermetallic phase (Fig.7). In both alloys, chip formations may be noted to occur due to intermetallic phases thanks to Si and Mn effect/presence (Mg$_2$Si, Mg$_{17}$Al$_{12}$ and Al$_3$Mn$_5$) found in the alloy [13]. It was observed that chips obtained from AM90 alloy were harder and fragile compared to AS91.

![Fig.8 Chip Formation of Magnesium Alloys ($V_c$:168 m/min, DoC:1mm, f:0.10 mm/rev).](image)

IV. CONCLUSIONS

The below results were obtained from this experimental study:

- Si and Mn found in the AS91 and AM90 alloys that were investigated in this study were effective on the hardness, wear resistance, and machinability of alloy in addition to having an impact on formation and type of intermetallic phases formed in the microstructure.
- It was found that intermetallic phases (Mg$_{17}$Al$_{12}$, Mg$_2$Si and Al$_3$Mn$_5$) of AS91 and AM90 magnesium alloys had an impact on cutting forces and machinability.
- AS91 alloy had lower hardness and wear resistance compared to AM90 alloy. AM90 alloy had higher machinability. While it was observed that chips formed by machining AM90 alloy were smaller in length, chips from AS91 alloy were longer. It was established that intermetallic phases were effective in the formation of chips and cutting force.
- Intermetallic phases were found to be effective on surface roughness. Higher surface roughness were obtained from AS91 magnesium alloy compared to AM90.
- Hardness and wear resistance of AS91 alloy was lower compared to AM90 alloy.
- Wear resistance and hardness (at Al$_3$Mn$_5$ intermetallic phase) of AM90 alloy was higher compared to AS91.
alloy (in which Mg\(_{17}\)Al\(_{12}\) and Mg\(_2\)Si intermetallic phase occurred).

- Intermetallic phases occurred from AS91 and AM90 magnesium alloys were observed to have an effect on machinability.
- Si and Mn were observed to have an effect on the formation of intermetallic phases in AS91 and AM90 magnesium alloys.

Abstract- In this study, API 5L X80 steel which are used in natural gas and petroleum pipeline were welded by submerged arc welding method (SAW). The micro-macrostructure and mechanical properties (tensile and hardness tests) of welded samples were investigated. In the mechanical tests, it was observed with the tensile tests that the ruptures were occurred from the base material. Besides, when the hardness tests were examined, the highest hardness values were determined in the weld metal. In the microstructure investigations, it was observed that acicular ferrite phase formed and fine grain structure was obtained in the weld metal. According to all results obtained from tensile-hardness tests and microstructure analyses, the welding process exhibited expected local properties as mechanical.

Keywords- API 5L X80, Submerged Arc Welding, Pipeline, Microstructure, Weld Region.

I. INTRODUCTION

Oil and natural gas are of great importance in the lives of people and in international relations as the most important energy resources [1]. Having such economic and strategic importance, oil and natural gas should be extracted from their sources and transported to the areas where they will be used. The transportation process occurs at high pressure and carried out through large diameter steel pipes [2]. Pipeline transportation is commonly used for transporting the products such as gas, oil, water or steam. Potential occurrence of natural events that might cause plastic deformation (landslide, dent, etc.) brings the importance of pipeline design and material selection to the forefront. Pipeline materials and connection systems must have the mechanical properties that can resist the harmful external effects [3]-[10].

Most of today's pipelines are manufactured in accordance with the API (American Petroleum Institute) standards. API 5L X80 steel is one of the high strength and low alloy (HSLA) steels used in natural gas and oil transmission and distribution lines [11]-[14]. It is among the fine-grained steels manufactured through controlled thermomechanical rolling [15]-[17]. X80 steel is commonly used in pipeline transportation due to good mechanical properties, ease of fabrication and low-cost [2], [18].

The pipes used in pipelines are usually welded by submerged arc welding with a spiral or longitudinal seam. Submerged arc welding is an automatic welding method and the performance and success of the welding process totally depends on the preference of the welding parameters. In this study, X80 steel materials manufactured in accordance with the API 5L specification were welded by submerged arc welding. The samples of the welded joints were subject to micro-macrostructural examinations as well as tensile and hardness testing. The study examined the effect of the welding process on the microstructure and mechanical properties.

II. MATERIAL AND METHOD

In the experimental phase of the study, 19.45 mm API 5L X80 steel pipes were used. Table 1 shows the chemical composition and mechanical properties of the material. Table 2 and 3 show the chemical composition of the welding wire and flux used in the welded joints.

Welding was performed by employing a total of 4 runs (2 runs on the inside and outside). Fig. 1a and 1b show the geometry of welding groove and a list of weld runs. The welding process was carried out at Emek Pipe Company, by automatic spiral submerged arc welding. 4 different welding heads were used in the submerged arc welding unit. The weld runs no. 1.1 and 2.1 were performed using direct current (DC+), while the ones no. 1.2 and 2.2 were performed using alternating current (AC). Table 4 shows the welding parameters used in the process. Before the welding process, the materials were preheated at 80 °C and the temperature between the runs was kept at a maximum of 200 °C.

To determine the mechanical properties of the welded joints, 5 samples were taken from the joints in accordance with ASTM E8 to be subject to tensile test. Tensile tests were performed using the Instron testing machine with 600 kN capacity. Micrographs and macrographs of the joints were obtained from the microstructure samples. The hardness distribution of the welded joints was determined as macro hardness using Vickers (HV10) hardness test. Tensile and hardness tests were carried out in the laboratories of Emek Pipe Company. Micro-macrostructural examinations were performed in the laboratories of Gazi University Faculty of Technology Metallurgical and Materials Engineering Department.

The samples were ground and polished in accordance with the metallographic methods for the micro-macrostructural examinations and macro hardness measurements. The samples were then etched using 3% HNO₃ (Nital). Optical microscope was used for the microstructural examinations of the samples.

### III. RESULTS AND DISCUSSION

Fig. 2 shows the image of the macrograph of the samples taken from the welded joint. The macrograph shows no weld defects (undercut, crack, porosity etc.). The base metal, heat-affected zone (HAZ) and weld metal were clearly separated. Engagement of the weld runs were clearly seen on the inside and outside. The macrograph also shows that grains of the weld metal grew in the opposite direction to heat flow (towards the weld center), the penetration is good and the materials were welded perfectly.

Fig. 2 Macrograph of the X80 steel welded by submerged arc welding

Fig. 3 shows the micrographs of the welded joint. The base metal, HAZ and weld metal were shown in a single micrograph in Fig. 3. Fig. 3b-d shows the microstructures of the base metal, HAZ and weld metal, respectively.

Fig. 3a shows that the base metal has an equiaxed grain structure, while the HAZ has a grain structure getting coarser towards the joint line, and the weld metal has fine and rather needle-like grains. The phase with a white needle-like shape observed on the weld metal can be said to be acicular ferrite [17]. The formation of acicular ferrite which increased the toughness and strength of the weld metal could be said to occur due to the slow cooling rate that resulted from the preheating process (at 80 °C) [18].

Fig. 3 Micrograph of the a) Base metal (A) – HAZ (B) – Weld metal (C),

<td>20</td>
</tr>
</tbody>
</table>

Table 5 shows the results of the tensile test. The findings show that the welded joints and the base metal have almost the same strength and percent elongation values. This indicates that the ruptures during the tensile test actually occurred on the base metal (Fig. 4). This could be interpreted as that the weld metal exhibited better strength than the base metal under mechanical loads. The reasons could be the lack of weld defects on the joints and the acicular ferrite formation which increased the toughness and strength of the weld metal [19-23].

Hardness measurements were performed at the points shown schematically in Fig. 5. Hardness was measured horizontally at 15 different points in order to determine the hardness of different microstructures (base metal, HAZ, weld metal) at the end of the welding process. Fig. 6 shows the results of the hardness test.
The results of the hardness test show that the highest hardness values were measured at the weld metal, while the lowest values were measured at the base metal (Fig. 5). The highest hardness values observed in the weld metal are thought to be caused by fusion-solidification thermal cycling, additional wire-weld powders and the formation of acicular ferrite.

IV. CONCLUSION

The findings of this study can be summarized as follows:

- In this study, API 5L X80 steel materials were welded by submerged arc welding, forming a “X groove”.
- Macrographs show that grains of the weld metal grew in the opposite direction to heat flow (towards the weld center), the penetration is good and the materials were welded perfectly.
- The ruptures observed during the tensile test were found to be occurred on the base metal.
- The weld metal was found to have high hardness. The lowest hardness values were measured at the base material.

Abstract—In this study, pure Ti powders and Ni-rich NiTi shape memory alloy powders were prepared using the method of mechanical alloying and the effects of the addition of pure Ti powders were investigated. For this purpose, different Ti powder (10µm) ratios (respectively 2%, 4%, 6%) were mixed for mechanical alloying with Ni-rich prealloyed NiTi (30 µm) powders. 1:10 powder/ball ratio was used for mechanical alloying experiments. The samples were characterized by X-ray diffractometry (XRD), element distribution spectrometer (EDS), scanning electron microscopy (SEM) techniques. As a result of experiments, mechanical alloying technique is effective the Ti addition in NiTi alloy system.

Keywords—Prealloyed NiTi Powders, Shape Memory Alloys, Powder Metallurgy

I. INTRODUCTION

NiTi shape memory alloys, also known as Nitinol, have gained technical importance equally in biomedical and aerospace industries due to their excellent mechanical and shape memory properties.

NiTi shape memory alloys (SMA) obtain Ni and Ti alloys, also known Nitinol. This alloys having inimitable shape memory effect, good biocompatibility, excellent wear corrosion resistance effects, damping effect, have been using in many industrial and medical service application areas[1-3].

In general, NiTi SMA produce via casting technology. But using this technique, couldn’t obtain significant fracture resistance, super elasticity and ductility [4-5]. During production process and environmental conditions increase hydrogen amount which give rise to negative effects on mechanical properties. Better production technique is very important in this area [6-9]. Therefore, NiTi SMA could be fabricated by powder metallurgy (PM) technique recently. The best known and mostly used powder production techniques are gas atomization, pulverisation, hot isostatic pressing, sparcplasma and mechanical alloying [10-18]. Mechanical alloying technique was used in this area with change Ni and Ti content for NiTi alloy systems and the new alloy systems were synthesized [19-26].

In this study, pure Ti alloy (respectively 2, 4 and 6 %) was milled with prealloyed NiTi powders (55% wt.) by mechanical alloying technique. Scanning electron microscopy (SEM), element dispersion spectrum (EDS) and X-Ray analyses were applied on milled NiTi + Ti alloys system for determine to structure and properties.

II. EXPERIMENTAL RESULTS AND DISCUSSION

In general, NiTi alloys produce via conventional mass production technique. But this type of powders produced as the commercial and experimental couldn’t find. For this purpose, NiTi powders used in experimental studies were obtained by NANOVAL (NANOVAL GmbH&Co.KG Kienhorststraße 61-65 D-13403 Berlin) firm as prealloyed. Used prealloyed NiTi powders were produced by gas atomization technique. Figure 1.a shows pure surface quality and spherical powder morphology of prealloyed NiTi powders. Fig 1-b shows the irregular shaped powder structure of pure Ti powders.

Figure 1. SEM images; a) 30 µm sized prealloyed NiTipowders, b) 5 µm sized pure Ti powders
The average particle size distributions of prealloyed NiTi powders and pure Ti powders were respectively measured as 30 µm and 20 µm (Table 1).

Table 2. Weight and atomic Ti – Ni % of prealloyed NiTi powders

Figure 2 shows general EDS analyses of prealloyed NiTi powders (30 µm) used in experimental studies. In general only Ni and Ti elements could be confirmed. Different alloy elements were analyzed. However, the presence of only Ni and Ti elements in the alloy were identified. The particle morphology in all PM methods is now among the primary considerations. In this case, the spherical, flat and homogeneous particles are preferable in order to gain the appropriate parameters in the press ability and production stage of powders. This situation could be achieved with gas atomization and carbonyl methods [27]. Hence, the preference of gas atomization method to fabricate used powders shows the suitability of production parameter.

Figure 2. General EDS analysis of prealloyed NiTi powders

SEM image and EDS analyses of the pure Ti powders added prealloyed NiTi powders in mechanical alloying process are shown in Fig 3. It could be seen from Fig. 3-d (EDS analysis) that likely to be C and O elements in the structure were not determined depending on the production technology. This result shows the conformity of production parameter of NiTi powders.

Figure 3. SEM and EDS images of pure Ti powders
NiTi + Ti powders after 60 minutes milling by mechanical alloying technique are shown in Figure 4. When SEM images (Fig 4) of the pure Ti powders (respectively; 2, 4 and 6 % ratio) added prealloyed NiTi were investigated, the changes in the microstructure (Figure 4.a – b – c) with increasing of Ti content in alloying system were determined. However, the high hardness value of NiTi alloy and the lower hardness of the alloy element from NiTi alloy revealed the Ti powders coating on NiTi powders surface with increasing Ti content.

Figure 4. SEM images of NiTi + Ti powders after 60 minutes milling; a) 2% Ti, b) 4% Ti and c) 6% Ti

Figure 5 shows the SEM images and EDS analysis after 60 minutes milling. NiTi –2%Ti powders. When SEM image (Figure 5) was investigated, it was determined that Ti powders began to coating on NiTi powders surface after 60 minutes milling. With increasing of the Ti content such as 4% (Figure 6), it was determined to be more apparent of structural differences. The increasing of Ti content in alloyed powders was supported the EDS analysis (Figure 6.b). Also free Ti powders could be seen in EDS analysis (Figure 6.c). With increasing of Ti content (6% ratio) in milled alloy, increasing Ti coating ratio on NiTi powders is shown in SEM image (Figure 7.a). EDS analysis support to increasing Ti element ratios in NiTi powders (Figure 7. b and c).

Figure 5. NiTi + 2%Ti powders after 60 minutes milling; a) SEM image, b) EDS analysis of 1. point, c) EDS analysis of 2. point
Figure 6. NiTi + 4%Ti powders after 60 minutes milling; a) SEM image, b) EDS analysis of 1. point, c) EDS analysis of 2. point

Figure 7. NiTi + 6%Ti powders a) SEM image, b) EDS analysis of 1. point, c) EDS analysis of 2. Point

Figure 8 shows the XRD patterns of the mechanical alloyed powders after 60 minutes milling. In Figure 8, XRD analysis of the prealloyed NiTi powders was shown as the first sample. The highest intensity obtained after reflection by the NiTi powder belongs to NiTi peak with general 111 plane [28]. With mechanical alloying process in NiTi alloy system, amorphous structure could be achieved [19, 24]. In XRD results could be determined the structural differences on XRD intensity reflection ratio. The decrease of NiTi phase intensity was observed after 60 minutes milling. Also, with increasing the Ti content, the differentiation of peak intensities and the formation of different peaks were determined by XRD analysis (Figure 8. 2 – 3 – 4). In different experimental studies, XRD analysis of alloying elements added to NiTi alloy show to occur of differences [29].

Figure 8. XRD analysis of samples:
III. CONCLUSIONS

- Gas atomization technique used to fabricate prealloyed NiTi powders likely to occur oxide and carbon structures prevents and also directly effective in the formation of homogeneous, smooth and spherical powders.
- The structural differences of increasing of Ti content in NiTi alloy were determined with SEM images and also increased Ti ratio after EDS analysis were identified.
- The formation of amorphous structure, the differentiation of peak intensity and width were determined by XRD analysis depending on increased of Ti content after 60 minutes milling. Increasing with the covered ratio of Ti contents on NiTi powders was identified by mechanical alloying processing. This situation would be very effective for sintering period.

Abstract—Agava Americana L. plant is known as century plant in Turkey belongs to Amaryllidaceae family. Commonly, the plant is cultivated in West Mediterranean Region and lingo-cellulosic fibers are obtained from the plant. Enzymes are defined as bio-catalysers consisted of the metabolic products of living organism. Trametes versicolor and Coriolus versicolor produce laccase enzymes. In this study, the fibers obtained from Agava Americana L. plant was treated with laccase enzyme at different concentrations (0.5, 1, 1.5, 2 and 2.5 %) in order to remove oils, waxes and other contaminations according to conventional and ultrasonic methods. After the enzymatic treatment, whiteness index, hydrophility and mechanical properties of samples were analysed in terms of concentration and treatment methods.

Keywords—Agava Americana L. fibers, laccase enzyme, ultrasonic method.

I. INTRODUCTION

In Turkey, textile industry, which is a leading sector of imports and exports, employs for 3 million people. However, textile industry in Turkey is going to different problems by the reason of making cheap production of Far East countries. For this reason, as a solution, use of innovative production methods and raw materials should be considered. In Turkey, cotton is the most produced fiber plants as well as linen and hemp are produced. In order to compete Far East countries, adaptation of different fiber plants should be carried out in Turkey. In this context, Agava Americana L. plants have fibrous structure and the plants are usually thrived in semi-arid region such as Mexico, Australia and Africa [1].

Agava Americana L. plant is known as century plant in Turkey belongs to Amaryllidaceae family [2]. Commonly, the plant which is an endemic plant in Turkey is cultivated in West Mediterranean Region and lingo-cellulosic fibers are obtained from the plant. Agava Americana L. plants and fibers are given in Fig. 1.

Fig. 1. Agava Americana L. plants and fibers.

Agava Americana L. plants are characterized with fleshy, hard-surface and lanceolate leaves. The length of leaves is 1 ranging from 1.5 m [3]. The leaves consist of numerous fibers which are high resisting and lingo-cellulosic structure. The fibers are obtained from leaves with mechanically, chemically or retting in seawater [3].

Agave Americana L. fibers are usually used in paper industry [4]–[6], technical textiles especially automotive industry because of having high mechanical properties [7]–[9]. Furthermore, the fibers can absorb metal ions such as Cd (II) and Pb (II) in aqueous solution [10], [11]. Agave Americana L. fibers are indicated that the fibers can be used as bioenergy...
source due to sustainable properties. In textile industry, in order to use Agave Americana L. fibers, oils, waxes and lignin should be removed from the fiber structure and the process can be carried out with enzymes, alkali, acetylation or chemicals [12], [13]. In textile industry, enzymatic hydrophilicity is an alternative method to conventional hydrophilicity methods. Studies have been showed that cellulases, pectinases, proteases, xylanases and lipases are the most common enzymes used in textile industry [14].

In this study, Agava Americana L. fibers were treated with laccase enzyme at different concentrations (0.5, 1.0, 1.5, 2.0, 2.5 and 3% concentration at 55 °C and pH 5.5 for 1 hour via conventional and ultrasonic methods. After the enzymatic treatment, whiteness index, hydrophility and mechanical properties of samples were analysed in terms of concentration and treatment methods.

II. MATERIALS AND METHODS

A. Materials

In this study, Agava Americana L. fibers were used. Agava Americana fibers were obtained from Agava Americana L. plant with carding process. The process of fibers obtained was given in Fig. 2.

![Fig. 2. The process of fibers obtained (a. Agave Americana L. plants , b. The cutaway view of plant leaves, c. The leaves waiting in water, f. The fibers obtained from water waiting process, g. Fiber separating machine).](image)

B. Methods

After the obtaining of fibers, fibers were treated with laccase enzyme (Denolite II S (Novozymes)) at 0.5, 1.0, 1.5, 2.0, 2.5 and 3% concentration at 55 °C and pH 5.5 for 1 hour via conventional and ultrasonic methods at the liquor ratio of 1:50. After the enzymatic treatment, whiteness index, tensile strength and hydrophilic properties of samples were analysed. The method of used on this study is given in Fig. 3.

![Fig. 3. The method of study.](image)

In order to analyse the hydrophilic properties of samples, 0.4 ml colored solution was dropped on the stretched position fibers. The duration of diffusion of the colorful drop to the surface with the length of 50 mm was measured.

Whiteness index of samples was determined by using Konica Minolta Spectrophotometer CM-3600d according to Stendsby Method and whiteness values were calculated using illuminant D65 and 10°standard observer values.

The tensile strength of samples was analysed with use Instron 4410 instrument, according to the ASTM D 3822 standard.

III. RESULTS AND DISCUSSION

A. Results of Hydrophilic Properties Measurements

The hydrophilic properties of samples were measured the duration of diffusion of colorful drop on the fibers surfaces. The results of hydrophilic properties measurement were given in Fig. 4.

![Fig. 4. The hydrophilic properties of samples.](image)
Fig. 4 shows the hydrophilic properties of samples. The results show that enzymatic pre-treatment raises hydrophilicity of samples. The increase of enzyme concentration causes to increase hyrophilicity of samples. The reason of these results was considered that the amount of reduced oils, waxes and other contaminants increases with increase of enzyme concentration.

B. Results of Whiteness Index Measurement
After the measurements of whiteness index of samples, the whiteness index properties of samples were calculated with Equation 1.

\[ W(CIE) = Y + 800(0.3138 - x) + 1700(0.3310 - y) \] (1)

The whiteness index results of samples were given in Fig. 5.

Fig. 5. The whiteness index results of samples.

Fig. 5 shows the whiteness index results of samples. According to the results, the enzymatic pre-treatment causes to increase whiteness index of samples. The reason of results was deemed that the enzymatic pre-treatment removes oils, waxes and other contaminants which are colorful components in the fibers. Furthermore, compared with conventional and ultrasonic method, ultrasonic method causes to increase whiteness index more than conventional method. Sonication energy removes oils, waxes and other contaminations more than heat energy. In addition, sonicatation energy cause to save of time and energy compared with conventional method.

C. Results of Tensile Strength Measurements
The tensile strength measurement results were given in Fig. 6.

Fig. 6. Tensile strength measurement of samples.

Fig. 6 shows the tensile strength measurements of samples. According to the Fig. 6, tensile strength of samples decreases with the enzymatic pre-treatment. In addition, the increase of enzyme concentration causes to increase in tensile strength of samples. Enzymatic pre-treatment removes some competent in the fibers. The tensile strength properties of samples were compared with regards to methods, conventional method causes more decrease. The duration of ultrasonic procedure is low than the duration of conventional procedure. Because of low duration procedure, amount of deformation is low.

IV. CONCLUSION
In this study, the usability of Agava Americana L. fibers in textile industry was investigated. In this context, Agava Americana L. fibers were obtained with fiber separating machine. After, the fibers were treated with enzymatic process with conventional and ultrasonic methods in order to reduce oils, waxes and other contaminates on the surfaces. Following enzymatic pre-treatment, hydrophilic, whiteness index and tensile strength properties of fibers were investigated. According to the results, enzymatic pre-treatment causes to increase hydrophobility and whiteness index. After the enzymatic pre-treatment, the tensile strength properties of fibers decrease. Compared with ultrasonic and conventional method, ultrasonic method causes to save of time energy. In addition, enzymatic pre-treatment is an ecological method due to being biologic materials. Furthermore, Agava Americana L. fibers can be used in textile industry after pre-treatment.

Department of Mechanical Engineering, Bartın University
Bartın, Turkey

Abstract— Developments of material science constitutes the basis of technological development. Composite materials with superior properties are produced with combining materials whose physical and chemical properties are different. Thanks to the superior performance of metal composites meet the needs in aviation, aerospace industry, military applications and automotive industry, technology is developing rapidly. They are preferred because of their superior mechanical properties. In this study, we investigate the corrosion behavior of traditional and waste reinforced metal matrix composites. Al1014 (Al10O3) which is alloy, were used as a matrix material, the reinforcing members are SiC and MgO particles with a grain size of 10 μm - 25 μm and 50 μm micrometer, heater solid waste as the waste material (coal slag) were used. There will be an inferences with production of composite materials. SEM analysis and examining mechanical abrasion tests.

Keywords— Materials, Composite, Wear, Manufacturing, Alloy

I. INTRODUCTION

The importance of materials in many applications today come have The low cost of production and the intensive use of aluminum alloys in the industry has advantages over other materials. Together with the developments in technology as well as develop specific properties of materials, material development and the attractiveness of studies on the number of shows a day by day now. physical of traditional materials such as metals, due to the insufficient against the needs of today's technology of mechanical and thermal properties, is rapidly increasing interest in composite materials. In the production of composite materials, virtually all engineering materials are used. Composite materials are known to gather together the best features of the material is obtained by combining the macro level of at least two materials with different methods. Metal matrix composites, matrix and reinforcement to consist of two phases. Matrix materials can protect reinforcing members together while holding the reinforcing member transshipment reinforcing members against wear and corrosion. Prevent the spread of brittle cracks in the reinforcement member. The task of the reinforcement element to increase the strength of the matrix carrying the load. because of their low densities and production cost, aluminum and its alloys are at the forefront of metals and alloys commonly used in the industrial field. These alloys are mainly in the automotive sector, food showing a great improvement in recent years, are widely used in the aerospace industry. In this study we Al1014 as matrix material (Al10O3) alloy, the reinforcing member is 10 μm - with a grain size of 25μm and 50μm SiC and MgO particles are used. Heating disposed of as solid waste material (coal slag) were used. Particles, as the ratio of volume reinforcement to matrix material indicating the volume ratio of 5% - 10% and 15% values are selected. as composite manufacturing method, hot molding process is selected. In the crucible cast specially prepared by heating to 7800 C + particulate materials and test samples poured into the mold is prepared by mixing. In this way we aimed to investigate the corrosion behavior of the composite material is improved in the mechanical properties to some extent

II. COMPOSITE MATERIALS

A. Definition of Composite Materials

The most common meaning composite material; polycrystalline and multiple and diverse, is expressed as a collection of metal and non-metal compounds together [1]. Again according to yet another characterization; a composite material physically and / or chemically distinct, material containing suitably lined or dispersed phase [2]. A material must have certain characteristics to be considered composites. These characteristic;

- Different components together with chemically different from each other should be a combination of at least two materials.
- Materials forming the composite material should be combined in three dimensions.
- Composite formed by the combination of different materials must have better properties that can not have the features of the constituent components [1].

Classification of composite material is generally made according to the shape and structure of the structural matrix.
Composite materials are classified as follows according to the structural component. (I) Fiber Composites: reinforced with fibers composites, (II) Levasal Composites: derived by combining the flat plate composites (III) Particle Composites: reinforced with particulate composites (IV.) Impregnated (or a frame) Composites: Filling a second matrix material of a continuous skeleton, (V) laminated composites

Composites are divided into three according to the formed component layers of different matrix materials. (1) Ceramic matrix composites (II) Polymer matrix composites (III) metal matrix composites [1]

B. Metal Matrix Composites

The metal matrix composite are called that consisting of a variety of metal or metal alloy matrix composites. Metal matrix composites; generally continuous fiber as a reinforcement material, particles and whiskers are used [3]. Some of the advantages and disadvantages of metal matrix composite materials are

Advantages;

• High strength (abrasion, tensile and compressive) shows properties.
• Increased elasticity modulus (E)
• Increased yield and tensile strength
• Improved creep resistance
• Decreased coefficient of thermal expansion (CTE)
• Low density
• Increased elevated temperature strength
• Improved wear resistance

Disadvantages;

• Low fatigue strength.
• Low toughness and ductility.
• More complex and expensive production methods [6].

1) Materials Matrix Materials in MMK: Main function in matrix composite systems, to transmit the load applied to the composite reinforcement. matrix in the production of metal matrix composites. Aluminum alloy MMCs, which are also known as Aluminum Matrix Composites (or AMCs) or Discontinuously Reinforced Aluminum (DRA), have been the focus of the majority of research and development programs and indeed commercial applications. However, non-aluminum composites have also been produced using a wide range of matrix metals and alloys which also include copper alloys, iron and steel alloys, magnesium alloys, nickel-base superalloys, titanium alloys, and zinc alloys[3]. The popularity of aluminum as a matrix material is attributed mainly to: (i) its low cost ($1.5/kg) relative to other light structural metals, (ii) its current dominance of the aerospace structural application market, (iii) its introduction and acceptance in the automotive engine market, and (iv) its versatility in terms of properties and ease of fabrication. [4].

The matrices generally employed include 1000, 2000, 5000, 6000, 7000, and 8000 series aluminum alloys. Table 2.1 lists the typical compositions and applications of these alloys [5] As the material generally, Al, Mg, Cu, Zn, Ti, Pb, Fe, Ag, Sn and Si alloys are used [7]. Aluminum matrix in commercial applications and scientific research programs recently composites have been used widely [5]. Because the Al alloy used as a matrix material with good mechanical properties, low electrical conductivity, have low density and high corrosion resistance. This is cheaper than the other metals besides the features of ($1.5 / kg), easy to produce, its dominance in space applications in the automotive market and the other attractive features [6]. The metal matrix generally employed include 1000, 2000, 5000, 6000, 7000, and 8000 series aluminum alloys.

2xxx (alcunmg), 5xxx (AlMg), 6xxx (almeuc), the 7xxx (alznmgc) and 8xxx (Al-Li) aluminum alloys are used very widely in composite production [6,8]. In general, as the matrix alloy, with good strength values (2xxx) and (7xxx) alloys have found using one in commercial applications. (6xxx) alloys other than alloys, and provide convenience in production because it has a higher corrosion resistance is preferred as the matrix alloy. Aluminum-Lithium (8xxx) ensure a good ability to be welded of the alloy increased work on these alloys. Mg, and Al alloys containing alloying elements such as Li reinforcement phase as it forms a good bonding aluminum alloys containing these alloying elements are used as the matrix material [8].

2) Reinforcement material in MMK: Reinforcing materials used in the production of MMCs according to the structural shape is divided to as continuous and discontinuous [6-8]. Reinforcements are typically added to the strength of the composite matrix, may change the high temperature mechanical properties and hardness arttirnkrk density. The main task of reinforcing material is to carry the load applied to the composite. Reinforcement materials are divided into five according to their shapes. (i) continuous fibers, (ii) short fibers, (iii) whiskers, (iv) particles, (v) metallic wires [6,8]. The reinforcement materials are divided into four groups according to their chemical structure: (i) Oxides, (ii) Carbides, (iii) nitride (iv) Other (stainless steel, C, etc.) [9]. Fibers (f): continuous fibers rather high length / diameter ratio has. diameter of this type of reinforcement is about 100 μm. Final MMK exhibits high anisotropic property. The average price of a continuous fiber $ 1,000 / kg [6].

Whiskers are mono crystalline materials with high aspect ratios of 50 to 100. Their small size lends them to a variety of MMC production methods, although powder metallurgy (P/M) is the most popular. The typical cost of whisker reinforcements are $20-40/kg Whisker-reinforced MMCs are mainly used in the form of extrusions, forgings, and rolled sheet. The properties of the finished MMCs range from isotropic to slightly anisotropic, and costs range from moderate to high, according to the mechanical and physical properties. Particle average price of $ 10 / kg [6].

C. Production Method of MMC Material

Many methods are used in the production of metal matrix composites. While the classification of the composite manufacturing method is possible in many different ways, using the matrix form; liquid phase, the solid phase and two (solid + liquid) phase can be in the form of a classification method [9].

1) Liquid Phase Production Methods: Liquid phase production methods are methods that composite production occurs in the liquid phase. In liquid phase processes, the ceramic particles in the matrix by using different and appropriate techniques are added. These methods include methods by mixing ceramic particles in liquid metal, compression molding, pressure and non-pressure infiltration, xD method [9].

2) Liquid Metal-Ceramic Particles Mixing Methods: Addition of the liquid matrix alloy and
particles of a reinforcing material in the form of methods are used to obtain the uniformly dispersed in the liquid matrix reinforcement. Techniques used for mixing liquid particles to metal [9].

- using an injection gun; Injecting ceramic particles in the liquid with an inert gas.
- Into liquid metal (composed of matrix alloy and particles shaped reinforcing material) Adding and mixing of small pellets.
- liquid obtained by mixing ceramic particles with the help of vortex molten metal is mechanically joined to the metal.
- The addition of the liquid metal inside of the mold with molten metal filling the ceramic particles.
- ceramic particles to be pushed into the liquid using reciprocates rods.
- Central-liquid particles with few effects to be distributed into the metal.
- continuous vibrating liquid metal with ultrasound, to reinforce the liquid metal into the ceramic particles [9,12].

Particle-reinforced composite material production conditions in the foundry most efficient and economical method to use, vortex method. In this method, consists a mechanical stirrer (propeller) and consists of a furnace. The matrix alloy is melted in a crucible. When the desired vortex is obtained, a vortex of the particulate reinforcing material is mechanically mixed with a certain given propeller in the center and the liquid feed rate to be deployed in a homogeneous manner in the metal. It is necessary for the uniform control of the following parameters; (I) the liquid metal composition and temperature, (ii) mixer depth, speed and pitch, (iii) stirring time, (iv) the time elapsed between the end of mixing and casting, (v) characteristics of the molding material [13]. The biggest drawback of mixing; It is the porosity of the products. Porosity was a lot of work on minimizing be. Stirring of the control was made in a vacuum atmosphere and the crucible surface is said to reduce the amount of porosity of the blown gas, such as argon-nitrogen. Porosity rate depends on heat treatment applied to the particles prior to mixing speeds and production. The moisture layer on the particles to cause the liquid to prevent the porosity of the metal particles is necessary to maintain the heat-treated before being added to the matrix. Another important disadvantage of vortex method; (I) gluing together of the ceramic particles during mechanical mixing, (ii) collapsing particles of the crucible bottom, and (iii) segregation of the reinforcing material in the matrix, (iv) large interfacial reaction, (v) cleavage of the ceramic particles [9]

3) Compression Cast: In this method the liquid alloy, comprising reinforcement preforms are impregnated with the pressure provided by the hydraulic press, as shown in Figure 2. mold to avoid solidification of the liquid alloy, and the preform is subjected to preheating staples. Reinforcement particles comprising the preform is heated to a temperature exceeding the melting temperature of the matrix alloy. Preform metal exceeds the melting temperature of the preheat temperature of the fluid penetration to be completed, but under high pressure in the liquid leaking from the gap between the punch and the mold. Important parameters affecting the quality of compression molding composites; (I) the mold preheat temperature, (ii) the applied pressure, (iii) is the density of the preform or bed tucked [13,14].

On the other hand penetration rate spaces between and particles are the factors that affect the quality of the composite. In fiber reinforced composites of the staple of the damage to the preform moving very fast and fibers causes poor infiltration. In this method, Acritical pressure requires for allowing fullfluid flow top reform [11].

4) Pressureless Infiltration: Liquid metal, including reinforcement preform spontaneously developed by this patented method is infiltrating Lanxiu. In this method, the pressing, the preforms produced by techniques such as injection molding allows the infiltration of pressure during Al-Mg alloy in a nitrogen atmosphere. Including pressureless infiltration method with 55 to 60 vol% Al2O3 or SiC composite materials can be produced [9,10]. Alloy-ceramic system is heated to 800-1000 °C.

\[
\text{reaction that infiltration of development,} \quad N_2 + 3 \text{ Mg} \rightarrow \text{ Mg}_3\text{N}_2 \quad (2.1)
\]

\[
\text{reaction during infiltration;} \quad \text{Mg}_3\text{N}_2 + 2 \text{ Al} \rightarrow 2\text{AlN} + 3\text{Mg} \quad (2.2)
\]

During heating the infiltration temperature evaporates magnesium and magnesium supplements covering surface reacts with nitrogen to form nitrides. Magnesium supplements nitrite pressure or vacuum application of the alloy is a compound that allows the excess infiltration. System is schematically shown in Figure 2.2. immersed
into the liquid within the heated preform is provided of the same method it is also a variant of self infiltration [12]. aluminum nitride composite material produced in the microstructure, increases the hardness of the composite and reduces the thermal expansion coefficient [7].

Fig. 2 Pressureless infiltration schematic representation of the process

Done at high temperature makes the reaction occurring in the production of composite preform interfaces. The oxidation of the reaction of the preform interface, causing a matrix material containing oxide and unreacted. And complex-shaped composites can be produced with high density is the most important advantages of the pressureless infiltration technique [7].

5) Pressure Infiltration: In many cases it is weak Islatabilirig external pressure is needed to infiltrate into the liquid metal preform. widely used in the production of metal matrix composite pressure infiltration method. This method consists of porous metal gas pressure infiltration of fluid into the preform [9]. Preforms, particles, whiskers or a compact version of the supplements in the form of fibers or been agglomerate. Other casting methods for producing composite reinforcement can be admixed with up to 30%, the composite can be produced containing high proportions of up to 70% reinforcing element in this method [6]. The advantages of the pressure infiltration method include; (I) it is quicker and simpler than other methods, (ii) has a low production cost, and (iii) can be obtained composite piece having the shape of the desired end product [4,6,14]. The disadvantages of this method; (Ii) non-homogeneous microstructure, (ii) the porosity due to very close together reinforcements structure, (iii) coarse grain size, (iv) adverse interfacial reactions, (vi) failure of the reinforcement [6,9]. Pressure infiltration method is described in Section 3.1

6) XD Method: Martin Marietta XD method developed by the company, is a patented production method. XD methods, chemical compounds are added to form the reinforcing member for the production of the composite material into the matrix material in liquid form reinforcement particles of the present production method, the chemical compounds are obtained by reacting in the liquid matrix alloy. These supplements obtained most of the particles are produced TiB_2 and TiC according to the following reaction [10].

\[
2B + Ti + Al \rightarrow TiB_2 + Al \quad (2.3)
\]

\[
C + Ti + Al \rightarrow Al TiC \quad (2.4)
\]

Matrix particles are formed by the reaction, in a single crystalline, it has clean and unoxidized interface. Although it varies between 0.25-1.5 micron particle size by altering production parameters such as the reaction temperature is between 0.2-10 um particles of varying size can be obtained [10].

7) Solid Phase Production Methods: Powder Metallurgy, Ceramic particles due to the difficulty in the production of composite developed first wetted by the liquid alloy is a powder metallurgy method [9]. In this method, whisker or particulate reinforcement material in the form of metal or alloy powders are mixed with sieved. The mixture is then molded by cold or hot pressing. cold pressing after the molding, is sintered in order to increase the particle strength and matrix interface. After sintering, to provide an intermediate product having a density of 75-85%. This intermediate product is beaten after the degassing process is rolled or extruded [8-10]. Metal powders are usually atomized powder in 20-40 um size [7,10]. Because supplements significantly affect the distribution in the matrix of the powder mix is an important step in powder metallurgy method. Metal or alloy powd the oxide layer can be formed on the particles, matrix-reinforcement interface reduces the strength and leads to cavities. To avoid the removal of water molecules from the gas space it must be carried out under vacuum or hot and cold pressing [10]. After sintering the final product is about 20: 1 and higher rates are obtained by extrusion. High extrusion rate; provide a link between the development of dust, to distribute the oxide film between the metal powder particles, and therefore particles to prevent agglomeration of particles is required to ensure homogeneous distribution. The advantages of powder metallurgy method include: (i) the matrix as most metals and metal alloys can be used, (ii) supplemented with can be minimized the reaction between the matrix, a variety of reinforcement can be used, (iii) high reinforcement enables one to composite production volume ratio [10 ]. Powder metallurgy method also has some disadvantages. These are: (i) highly reactive, processing of explosive powder, (ii) to have a complex production processes, and (iii) is not limited to producing shapes the initial product obtained [10]

8) High Speed Method: Successfully used methods for bringing together the metal powder containing fine
ceramic particle distribution, "high speed-high energy methods are known as. In this method, the reinforcing metal-ceramic mixture is obtained by periodically applying high energy in a short time. As well as high mechanical energy to electrical energy sources are expressed can be used successfully in the production of metal matrix composites. High energy and high speed, provides rapid heating of the conductive powder in the mold. short-term operation at a given temperature, phase transformations and provides control of the grain coarsening. successfully used in the production of high energy-high-speed method of Al-SiC composites [15].

9) Diffusion Linking: In this method is carried out using supplements or block between Flemma single metal or alloy foils. the bonding surfaces are made of metal or reinforced in metallurgical polishing level. After polishing SiC and Al, ultrasonically cleaned in acetone or ethanol. Surface cleaning is very important in connecting the diffusion, working to provide high cleanliness required in various chemicals. below the melting temperature hold at 50 MPa pressure for 2 hours, afterwards cooling in the furnace operation is carried out [12].

10) Dual Phase Production Methods: Dual phase production methods, the matrix alloy dual phase (solid + liquid) at temperatures that are contained comprises the reinforcing particles added to the matrix. Dual phase production methods; osprey method and semi-solid mixing method [9,12].

11) Osprey Method: In this method, under an atmosphere of inert gas to make up a composite material atomized liquid matrix alloy is converted into molten metal while the spray flow. Ceramic particles introduced into the spray and metal matrix composite material consisting of the mixture to be deposited on a substrate [9]. The size of the metallic particle is approximately 20 to 40 μm. reinforced metal matrix ratio is limited and this rate is around 30%. The interaction of the liquid matrix and ceramic reinforcement phase is limited. limited reaction occurs at the interface and in this case the better mechanical properties of the composite effects [10]. It is a homogeneous dispersion in the matrix of reinforcing particles. Is porosity of the produced composite and has a higher cost compared to other methods, this method has disadvantages. [8]

12) Semi-solid mixing: The method, also called the Compocasting and Rheocasting made by mixing semi-solid with a solid between the solidus liquidus technical supplement is added. The temperature of the alloy is removed liquidus temperature of 30-50 °C on violent way is allowed to cool by mixing the semi-solid range. This ongoing activity, breaking dendrite is solidified into fine spherical particles and prevents the rise in semi-fluid viscosity. Supplements added while stirring is performed. Relatively low viscosity pourable mixture with the form of direct index. In this case the method "rheocasting" takes its name. It is removed on a continuous stirring liquidus temperature "compocasting" is called [12].

D. Uses of Aluminum Matrix Composites

MMC materials tend to be more expensive than the matrix alloy is typically used in applications where high costs outweigh the benefits of strength and elastic modulus. With advancing technology in recent years it has increased the expected properties of the materials used and, therefore, has expanded the usage of MMCs. Lately need space and aviation, as well as resistant to high temperatures in the automotive industry, high-strength, high wear resistance and the use of MMCs can protect high temperature these properties and production has greatly increased [5].

NASA and the US Department of Defense in the 1960s and 1970s, the continuous carbon and boron fibers with development and production, research and development activities on a continuous boron fiber-reinforced composite Al-B began to play [4].

The most important increase in the use of MMCs in 1982 was realized with the use of short fiber reinforced aluminum composite Al₂O₃ Toyota's piston rings [16]. To reduce operating and fuel costs in technological applications, thereby reducing the weight and strength of the material / It is important to increase the intensity ratio [5].

Al major use of the metal matrix composite aerospace / military applications and the automotive industry. In recent years, also in the electronics industry in the manufacture of superconducting cables and sporting goods MMCs are used.

1) Aerospace / Military Applications: Characteristic of aerospace applications, is the production of small quantities. Those obtained from the embodiments save weight, allowing improvement in fuel economy. Spacecraft in the benefits of weight saving $ 2000 / kg and more in civil aircraft 100-1000 $ / kg. Continuous fiber reinforced metal matrix composites that require high strength and temperature resistance, but the cost of aviation is important in aerospace and military applications with more applications. Continuous fiber reinforced MMCs are Al missiles systems, compressor rotors, are used in warheads system.

When the fan and compressor blades, in addition to material creep properties of lightness, high modulus of elasticity and strength are important, boron fiber reinforced aluminum alloy to carry the body of a spaceship matrix composites were produced. Fiber reinforced composites of different composition is used in jet engine fan blades. Due to the good high temperature properties of aluminum alloys reinforced with continuous graphite fiber has attracted attention in various military applications [4,5]. Al graphite fiber reinforced metal matrix composite materials in rocket and helicopter parts, Al₂O₃ fiber reinforced Al metal matrix composite materials are used in the construction
of helicopter gears [17]. Short fiber or whisker-reinforced composites are usually found in areas of the conveyor system and telescope. Particle reinforced composites in the wing panels, etc. In satellite solar reflective it is used. The cause of particulate reinforced composites industry compared to other supplements in uzayhavacılık more preferred, is isotropic properties and is providing more save weight [5].

2) Automotive Applications: In the automotive industry, it is desirable that the weight gain and high wear characteristics, the use of metal matrix composites lately has become quite prevalent [4,5,16]. The advantages of using metal matrix composites for automobile parts include: (i) weight saving especially engine parts, (ii) high attrition resistance, (iii) improved material properties, (iv) low coefficient of thermal expansion [16]. fuel savings with the reduction of the weight of the car is increasing. In cars and large vehicles, saving weight and $ 0.5-2 / kg may be [5]. Instead of cars in the steel shaft 20% Al2O3 fiber reinforced Al with the use of metal matrix composites, in addition to weight savings, the reduction of vibration and rotation speed of the shaft is provided critical grow [17]. Graphite Al2O3 particles reinforced Al engine block, cylinder liners made from metal matrix composites increased heat transfer, thermal expansion coefficient of the composite that minimize the dimensional tolerances between the liner and the piston is low and thus the motor efficiency is saving fuel increasing. Automobile Al SiCp the use of composite materials in the piston-weight gain, provided wear resistance and thus increase life of the piston [11].

III. EXPERIMENTAL STUDIES

AL 1014 as the matrix mateiral in the study (AL2O3) alloy, the reinforcing member is 10 microns with a grain size of 25 microns and 50 microns SiC and MgO particles arae used. Heating the solid waste in the waste materrial (coal slag) were used

Abstract-Aluminum, one of the five most widely used metal in metal based industries, has 8 different series and over 30 different alloys. Each alloy has different mechanical and chemical properties. It can meet the requirements of many applications with various needs thanks to this variety. However, the variety of choice also comes with the complexity of choice of the most suitable aluminum alloy. Hence, the choice of optimal aluminum alloy has become an area that requires special expertise.

In this study, an expert system that can select the most suitable aluminum alloy using the input of a user was developed. The expert system that is called Al_expert was built up an expert system shell program, Kappa PC. Kappa PC is preferred for some advantages that have inference engine tools and rule base, and programming with C++. The system uses multi-criteria weighted average method. Al_expert has a friendly user interface that is designed visual objects. More than 100 rules are written for Al_expert. The system asks a few simple questions to user about Al alloy. And, Al_expert can make a decision by using forward chaining method. Finally, Thus, Al_expert system can select an ideal Al alloy automatically.

As a result show that Al_expert makes easy to select ideal Al alloy for any application area without any expert. In this way, the system helps any user select the most suitable alloy and reduces faults and unnecessary choices.

Keywords - Aluminum Selection, Alloy, Expert System, Kappa PC, Data Mining, MCDM Methods

1. INTRODUCTION

Materials of Aluminum are widely in many industries on the world. Aluminum is not used in its pure form in manufacturing industry [1]. Hence, different alloys are produced with various chemical, physical or mechanical properties [2]. Aluminum has 8 different series and over 30 different alloys. Due to this variety, it is very difficult to choose the most suitable alloy that has many different properties. Choosing the most suitable aluminum has become an area of expertise.

Expert systems are basically computer algorithms that are used for decision making and problem solving [3]. Expert systems are built by knowledge engineers and experts over many years of experience. The expert systems use their own databases and rules to reach a intermediate decision. Each decision is then used as an input of another stage until the final decision is made.

Expert systems provide improvement in quality and reliability in manufacturing industry [4]. For this particular reason that various studies exist regarding the use of expert systems to help users choose correctly. The studies are explained below.

İpek et al. has developed an expert system to choose materials used in car parts in automobile industry [5]. The developed system chooses among a pre-defined number of metals, composites and polymer materials. Strength, weight, formability, corrosion durability and price are the main criteria of decision making process. Zanandi et al. proposes an expert system that chooses the most environmentally friendly, ecological and sustainable materials by their social, economic and environmental factors [6]. Another expert system proposed by Blundell and Gennway classifies materials according to their static load resistance, torque transmission, operation temperature and corrosion durability [7]. Kayir, et al. [8] were built up an expert system by using Leonardo shell program for selection optimal cutting tools and operation for drilling holes. Poyrazoglu, et al. [9] were implemented an expert program to choose right operation from non-traditional machining methods.

In this study, we address the problem of aluminum alloy selection as opposed to other studies. An expert system that was developed by using KAPPA-PC expert shell program, is used to determine the most suitable aluminum alloy using the most basic requirements as an input. The system is called Al-Expert. The system comprises of rule base, user interface,
inference module and help module. The most widely used 16 types of aluminum alloys are determined in Al-Expert. The most suitable aluminum alloy is selected by AI_Expert. The expert system uses multi-criteria decision making (MCDM) method [10] and the method allows the user to change the importance factor of any parameter. This allows the expert system to sort the alloys by scores calculated from user input and relative weights.

II. ALUMINUM ALLOY

Aluminum is the third most frequent element found in the nature. In spite of this fact, it can’t be used in its pure form. An advanced manufacturing process is required to make the aluminum usable. For this very reason aluminum is widely utilized in the late 1800s. Advances in industrial methods and the advances in material science motivated by two world wars emerged different alloys of aluminum. Aluminum alloys are basically categorized in 6 different series in Al_expert program. The basic properties of the alloys are as such:

Aluminum 7075, indispensable raw materials of aerospace industry, was developed during 1940s by Japanese. During 1960s, aluminum was utilized in manufacturing process of engine blocks in automobile industry. Aluminum is a widely recognized raw material in various industries such as pressure vessels, chemical industry, and ship industry. Aluminum owes this wide recognition to having many alloys that have very different mechanical, chemical and physical properties. Choosing the most suitable alloy among these alloys are very critical in quality and production time of the end-product.

Choosing among 16 different aluminum alloys based on 6 different aluminum series is a difficult task. The user is be able to choose the most suitable aluminum type using the proposed expert system.

III. OVERALL SYSTEM DEVELOPMENT

The flowchart below shows the structure of the developed expert system. The expert system consists of inference module, database, help module and user interface.

Fig 1. Al_Expert flow chart

A. Al_Expert Selection System and Database

The expert system analyzes the input using inference module. The evaluation of user input is based on the pre-defined inputs by experts, catalogs and literature surveys. All physical, chemical and mechanical properties of aluminum alloys are pre-defined in the developed expert system. To improve user-friendliness, some sections of the developed system includes symbolic statements instead of numerical counterparts. The current system includes 16 different aluminum alloys and 9 different parameters. The parameters are listed in Table 2

B. Al_Expert Selection Module

All properties of aluminum alloys are defined in a database. We built an expert system called “Inference Module” that chooses aluminum alloy using the input from the user. The decision tree of the expert system consists of three elements: objects, classes and slots.

Objects are part of the main program and are used to group basic events in the program. The developed aluminum alloy expert system consists of 4 objects (Fig. 2). These are Aluminiun, userinput, calculation and constant.

Classes are parameters of objects.

The figure below shows classes of objects that are connected to objects with dashed lines. For instance, there are different classes for 9 different properties of the material connected to the object that holds the input from the user.

Slots are the part that holds data belonging to a class.

The system comprises of functions and rules. The system has 21 function that define button events. In kappa-pc, rules are created with IF – THEN structures (Fig.3). The core algorithm of the developed expert system is rule based, and it simply follows rules to reach a result. The expression in “THEN” part gives the result, which is then used as an input to another condition to reach the desired solution.

The expert system algorithm is run until the desired slot value of a class of an object is calculated. Hierarchical structure between rules can be viewed by Fig. 4. In Al_expert rule base was designed by writing around 81 rules. Moreover, Al_expert system is capability of use forward chaining method to solve problems.

```
IF
    ( Calculation:H1000 > Calculation:H1050 ) And
    (Calculation:H1000 > Calculation:H2014 ) And
    (Calculation :H1000 > Calculation:H7075 ) And
    (( Userinput:Form == Rod ) And
      ( Userinput:Form == Sheet ) Or
      ( Userinput:Form == Bar ) Or
      ( Userinput:Form == Wire ) Or
    );
THEN
    SetValue( Aluminum:AluminumTypes, 1000 );
```

Fig 3. Al_Expert system sample rule structure

Aluminum alloy expert system is developed using multi-criteria decision making (MCDM) method [10]. The parameters of this method and the weights of the parameter are defined by user. The score of an alloy is calculated by first evaluating all inputs and multiplying each with their respective weights. The scores of alloys are evaluated using MCDM, and then sorted from highest to lowest to recommend the most suitable alloy to the user.
C. Help Module

Help module give some details and information to user about decision support system parameters. With the help of the module user will get the information about solution. In addition to this mechanical parameter calculation method is sharing with user in help module.

D. User Interface

A user interface was designed between Al_expert program and user. Many pages were created for the user interface. The user can learn about the program by using these pages. The user manual page is shown in Fig. 6.

The expert system is able to choose according to user's priorities as it scores user inputs by their importance level as weights. As of now, the system is capable of assessing 16 different most used alloys of 6 different aluminum series. As can be seen in figure 7, the system firstly assesses alloys depending on the material form. For instance, wire will only be chosen among 1050, 6061 and 6063 series. Hence, the user is offered to the right aluminum series and forms that are easily

IV. CONCLUSION

In this study, an expert system was developed for selection aluminum alloy. Thus, Al_Expert system can solve problems about selection right aluminum alloys unnecessary an expert. Al_expert is good stable program to detect an optimal aluminum alloy. Because, Al_expert decide based on 9 different parameters for aluminum alloys. This system can provide a lot of advantages to user. The planning time and costs can decrease for selection aluminum alloys in many industries.

If desired to improve system some different parameter can describe system database. Shearing strength, elongation percent and termal parameters are some of those. Existing system don't interest cost of alloy. According to user requirements cost parameter will be added. New module can developed for Al_expert which is identify new aluminum alloy to knowledge database of system about based on user input. One of the capability and expertise of Al_expert system is to become a useful assistant for user in aluminum and metal based area.

Mechanical and Thermo-Mechanical Buckling Analyses of Composite Cylindrical Shells

Eyüp YETER*

*Asst. Prof. Dr.
Gaziantep University, Aeronautics and Aerospace Faculty, Aircraft and Aerospace Engineering Department, Gaziantep / TURKEY, eyeter@gantep.edu.tr

Abstract— In this study, Mechanical and Thermo-Mechanical Buckling characteristics of thin-walled fiber reinforced composite cylindrical shells have been investigated. Glass/Epoxy and Carbon/Epoxy composite materials are used and mechanical and thermo-mechanical buckling loads are determined for these material types. The composite plies are laid up to form eight-ply laminates having [0|90]s, [15|75], [30|60] and [45|45]. Comparisons of effects of different fiber orientations on buckling loads with different temperatures are discussed. These analyses are performed using commercial finite element analysis program ANSYS. Effects of temperature, material types and aspect ratio (diameter / length) on mechanical and thermo-mechanical loads are analyzed.

Keywords— Composite, Mechanical buckling, Thermo-mechanical buckling, cylindrical shells.

I. INTRODUCTION

Composite materials are an important part of the material science and these materials are used in the design of many engineering structures. These structures are many times used in the form of cylindrical Shells. These structures are used in areas such as aerospace, automotive, civil engineering and marine. Since thickness of composite cylindrical shell structures are small compared to the other dimensions, design of these structures needs to be controlled to the buckling loads. The load-carrying capability of cylindrical shells without occurring buckling is important and has been considered and investigated by many researchers [1-7].

Shiau et al. [12] studied thermal buckling behavior of composite laminated plates by making the use of finite element method. Barton [13] presented an approximate closed-form solution to compute the thermal buckling response of a symmetric angle-ply laminates that are clamped in one edge and free along the other edge. Results are compared with Rayleigh-Ritz method solutions.

Engineering structures can expose high temperatures and mechanical loads. So designing these structures only with mechanical buckling cases is insufficient. In this study, Mechanical and Thermo-Mechanical Buckling characteristics of composite cylindrical shells have been investigated. Glass/Epoxy and Carbon/Epoxy composite materials are used during the study. Comparisons of buckling loads with different temperatures, different fiber angles, and with different aspect ratios (length/diameter) have been performed.

II. NUMERICAL STUDY

Equivalent buckling analysis is performed by using finite element analysis program ANSYS. Thermo-mechanical, and mechanical buckling loads are determined for composite cylindrical shells. Glass/Epoxy and Carbon/Epoxy composite materials are used during the study and their mechanical properties are given in Table 1.

Used fiber orientations are given in Table 2. As seen in this Table, 4 different orientation are used. 0, 15, 30, and 45 are stand for [0|90|0|90], [15|75|15|75], [30|60|30|60], and [45|45|45|45], respectively. In the study, both sides of the cylindrical shells are fixed and lateral (external) unit pressure is applied as shown in Fig. 1.

Fig. 1. Boundary conditions and loading

III. ANALYSIS RESULTS

1) Mechanical Buckling

Mechanical buckling loads are determined for Glass/Epoxy and Carbon/Epoxy composite cylindrical shells with different fiber orientations. Diameter (D) of cylinder and thickness (t) are taken as 100 mm, and 2 mm, respectively.

External (lateral) unit pressure load is applied then critical buckling loads are determined. Fig. 3 shows that Both Glass/Epoxy and Carbon/Epoxy, 0° has minimum buckling load and 45° has maximum buckling load. When Glass/Epoxy and Carbon Epoxy are compared, it is seen that Carbon/Epoxy has higher buckling load as expected. Buckled shapes of the composite cylindrical shell is given in Fig. 2.

Fig. 2. Buckled shape of composite cylindrical shell

Fig. 3. Variation of buckling loads with fiber angle a) Glass/Epoxy, b) Carbon/Epoxy

Fig. 4a. shows the mechanical buckling loads for Glass/Epoxy with aspect ratios (length / diameter) (L/D) varying from 1 to 5. As can be seen from fig., Mechanical buckling load is decreased by changing L/D from 1 to 5 up to 40.1% for 30°, 25.2% for 15°, 9.2% for 0°, and 3.7% for 45°.
Fig. 4b. shows the mechanical buckling loads for Carbon/Epoxy with aspect ratios (length / diameter) (L/D) varying from 1 to 5. As can be seen from fig., Mechanical buckling load is decreased by changing L/D from 1 to 5 up to 54.3% for 30°, 25.1% for 15°, 1% for 0°, and 8.9% for 45°.

As can be seen from Fig. 5., Mechanical Buckling load is decreased by increasing temperature from 25 °C to 150 °C up to nearly 80% for both Glass/Epoxy and Carbon/Epoxy.

![Graph of buckling load vs L/D for Carbon/Epoxy](image)

![Graph of buckling load vs Temperature for Glass/Epoxy](image)

![Graph of buckling load vs Temperature for Carbon/Epoxy](image)

2) Thermo-Mechanical Buckling

Effects of temperature for the different materials are important and cause the decrease of performance of the materials during the operation conditions. Hence in this section, mechanical buckling loads are determined with varying temperature. The cylinder of length (L), diameter (D) and thickness (t) are taken as 250 mm, 100 mm, and 2 mm, respectively.

Fig. 6 shows the mechanical buckling loads for Glass/Epoxy with aspect ratios (length / diameter) (L/D) varying from 1 to 5 and temperature changes from 25 °C to 150 °C. At different L/D ratios, there is not huge difference at buckling load.
summarized as:

Mechanical buckling loads for Glass/Epoxy with aspect ratios (length/diameter) varying from 1 to 5 is decreased to 54.3% for 3°, 25.1% for 15°, 1% for 0°, and 8.9% for 45°.

Mechanical Buckling load is decreased by increasing temperature from 25 °C to 150 °C up to nearly 80% for both Glass/Epoxy and Carbon/Epoxy.

The mechanical buckling loads for Glass/Epoxy with aspect ratios (length / diameter) (L/D) varying from 1 to 5 and temperature changes from 25 °C to 150 °C. At different L/D ratios, there is not huge difference at buckling load.

IV. CONCLUSIONS

Thermo-mechanical and mechanical buckling characteristics of the composite cylindrical shells have been investigated in this study. Glass/Epoxy and Carbon/Epoxy are used as material types. Effects of temperature, material types, fiber orientations and aspect ratios on buckling load have been searched. From the present study, the conclusions can be summarized as:

- Both Glass/Epoxy and Carbon/Epoxy, 0° has minimum buckling load and 45° has maximum buckling load. When Glass/Epoxy and Carbon Epoxy are compared, it is seen that Carbon/Epoxy has higher buckling load.
- Mechanical buckling loads for Glass/Epoxy with aspect ratios (length / diameter) (L/D) varying from 1 to 5 is decreased to 40.1% for 30°, 25.2% for 15°, 9.2% for 0°, and 3.7% for 45°.
- Mechanical buckling loads for Carbon/Epoxy with aspect ratios (length / diameter) (L/D) varying from 1 to 5 is decreased to 54.3% for 30°, 25.1% for 15°, 1% for 0°, and 8.9% for 45°.
- Mechanical Buckling load is decreased by increasing temperature from 25 °C to 150 °C up to nearly 80% for both Glass/Epoxy and Carbon/Epoxy.
- The mechanical buckling loads for Glass/Epoxy with aspect ratios (length / diameter) (L/D) varying from 1 to 5 and temperature changes from 25 °C to 150 °C. At different L/D ratios, there is not huge difference at buckling load.

Termo-Mechanical Vibration of Functionally Graded Nano Plates and Beams Based on Couple Stress Theory

Şeref Doğuşcan AKBAŞ
Department of Civil Engineering, Bursa Technical University, Bursa, Turkey
serefda@yahoo.com

Abstract — This paper presents free vibration behavior of nano plates and beams made of functionally graded material subjected to thermal loading based on the modified couple stress theory. Material properties of the plates and the beams are dependent both the thickness direction and temperature. The material distribution is modelled in power-law in the thickness direction. The inclusion of an additional material parameter enables the new plate and beam model to capture the size effect. The new non-classical plate and beam model reduces to the classical plate and beam model when the length scale parameter is set to zero. In the solution of the problem, the Navier type solution is used for simply-supported boundary conditions. In the numerical results, the effects of the different material distributions, material length scale parameter, temperature rising on the fundamental frequencies of functionally graded nano plates and beams are investigated in both classical theory and modified couple stress theory in detail. Also, the effect of the temperature dependent physical properties is discussed for free vibration characteristics of nano FG structures.

Keywords — Nano Structures; Functionally Graded Material; Vibration; Couple Stress Theory

I. INTRODUCTION

With the increasing in technology, nano structures have found many applications. micro Carbon nanotubes and micro tubes are widely used in micro- and nano electromechanical systems (MEMS and NEMS) such as sensors (Zook et al. [1], Pei et al. [2]), actuators (Senturia [3], Rezazadeh et al. [4]). In the mechanical behavior of the nano structures, the classical mechanics is not capable of investigation of the size-dependent behaviors. Classical continuum mechanics does not contain the size effect, because of its scale-free character. So, nonclassical continuum theories such as higher order gradient theories and the couple stress theory are capable of explanation of the size dependent behaviors which occur in nano structures.

Functionally graded materials (FGMs) are a new generation of composites where the volume fraction of the FGM constituents vary gradually, giving a non-uniform microstructure with continuously graded macro properties such as elasticity modulus, density, heat conductivity, etc.. Typically, in a FGM, one face of a structural component is ceramic that can resist severe thermal loading and the other face is metal which has excellent structural strength. FGMs consisting of heat-resisting ceramic and fracture-resisting metal can improve the properties of thermal barrier systems because cracking and delamination, which are often observed in conventional layered composites, are reduced by proper smooth transition of material properties. Since the concept of FGMs has been introduced in 1980s, these new kinds of materials have been employed in many engineering application fields, such as aircrafts, space vehicles, defense industries, electronics and biomedical sectors, to eliminate stress concentrations, to relax residual stresses, and to enhance bonding strength. With the advance of the material science, micro–electro-mechanical systems are the new field in which FGMs have been utilized to achieve the desired performance. With the development of technology, FGMs are initialized to be used in micro/nano structural systems.

The nonlocal continuum theory initiated by Eringen [5] which has been widely used to mechanical behavior of nano-micro structures. The size effect plays an important role on the mechanical behavior of microstructures at the micrometer scale that the classic theory has failed to consider when the size reduces from macro to nano ((Toupin [6], Mindlin [7], Mindlin [8], Fleck and Hutchinson [9], Yang et al [10], Lam et al. [11]). Therefore, higher-order theories modified couple stress theory and modified strain gradient are used in the mechanical model of the nano-micro structures (Yang et al [10], Lam et al. [11]) proposed the modified couple stress theory (MCST) in which the strain energy has been shown to be a quadratic function of the strain tensor and the symmetric part of the curvature tensor, and only one length scale parameter is included. After this, the modified couple stress and the strain gradient elasticity theories have been widely applied to dynamic analysis of FG plates ([12-22]) and FG beams ([23-37]).

In this paper, the free vibration responses of FG nano simple supported beam and plate subjected to thermal loading are studied based on the MCST. Material properties of the plates and the beams are dependent both the thickness direction and temperature. The material distribution is modelled in power-law in the thickness direction. The considered problem is solved by using the Navier type solution for simply-supported boundary conditions. In the numerical study, the effects of the different material distributions, material length scale parameter, temperature...
rising on the fundamental frequencies of the functionally graded nano plates and beams are investigated in both classical theory (CT) and MCST. Also, the effect of the temperature dependent physical properties on the vibration behaviour of nano FG structures is investigated.

II. THEORY AND FORMULATIONS

The material properties are both temperature-dependent and position-dependent. The effective material properties of the functionally graded beam, \( P \), i.e., Young’s modulus \( E \), and mass density \( \rho \) vary continuously in the height direction \( (Y \) axis) and a function of temperature \( T \) (see Touloukian [38]) as follows;

\[
P(T) = P_{T}(P_{T}T^{-1} + 1 + P_{B}T + P_{T}T^{2} + P_{T}T^{3})
\]  

where \( P_{T} \) and \( P_{B} \) are the material properties of the top and the bottom surfaces of the micro beam. It is clear from Eq. (1) that when \( Y = -h/2, P = P_{B} \) (\( P_{B} \) is the material properties of the bottom) and when \( Y = h/2, P = P_{T} \) (\( P_{T} \) is the material properties of the top). Where \( n \) is the non-negative power-law exponent which dictates the material variation profile through the thickness of the micro structure.

Material properties of the FG beam are temperature-dependent and change in the thickness direction \((Y \) axis) according to a power-law form.

\[
P(Y, T) = (P_{T}(T) - P_{B}(T))\left(\frac{Y}{h}\right)^{n} + P_{B}(T)
\]  

where \( P_{T} \) and \( P_{B} \) are the material properties of the top and the bottom surfaces of the micro beam. It is clear from Eq. (1) that when \( Y = -h/2, P = P_{B} \) (\( P_{B} \) is the material properties of the bottom) and when \( Y = h/2, P = P_{T} \) (\( P_{T} \) is the material properties of the top). Where \( n \) is the non-negative power-law exponent which dictates the material variation profile through the thickness of the micro structure.

The beams considered in numerical examples are made of Zirconia and Aluminum Oxide. The bottom surface of the functionally graded beam is Zirconia and the top surface of the functionally graded beam is Aluminum Oxide. The coefficients of temperature \( T \) for Zirconia and Aluminum Oxide are listed in Reddy and Chin [39].

In the modified couple stress theory, the strain energy density for a linear elastic material which is a function of both strain tensor and curvature tensor is introduced for the modified couple stress theory Yang et al. [10];

\[
U_{i} = \int_{V} (\sigma : \varepsilon + m : \chi) \, dV
\]

where \( \sigma \) is the stress tensor, \( \varepsilon \) is the strain tensor, \( m \) is the deviatoric part of the couple stress tensor, \( \chi \) is the symmetric curvature tensor, defined by

\[
\sigma = \lambda \, \text{tr}(\varepsilon)I + 2\mu \varepsilon
\]

\[
\varepsilon = \frac{1}{2}[\nabla \mathbf{u} + (\nabla \mathbf{u})^{T}]
\]

\[
m = 2l^{2} \mu \chi
\]

\[
\chi = \frac{1}{2}[\nabla \theta + (\nabla \theta)^{T}]
\]

where \( \lambda \) and \( \mu \) are Lamé’s constants, \( l \) is a material length scale parameter which is regarded as a material property characterizing the effect of couple stress, \( \mathbf{u} \) is the displacement vector and \( \theta \) is the rotation vector, given by

\[
\theta = \frac{1}{2} \text{curl} \, \mathbf{u}
\]

The parameters \( \lambda \) and \( \mu \) in the constitutive equation are given by

\[
\lambda(Y) = -\frac{E(Y) \nu(Y)}{(1 + 2\nu(Y))(1 - \nu(Y))}, \quad \mu(Y) = \frac{E(Y)}{2(1 + \nu(Y))}
\]

where \( E \) is the modulus of elasticity and \( \nu \) is the Poisson ratio and their dependence on \( Y \) coordinate are given by Eq. (1).

2. Governing equations of FG nano beams

Based on Euler-Bernoulli beam theory, the strain of the beam and the curvature tensor \( \chi \) are expressed as

\[
\varepsilon_{xx} = \frac{\partial u_{0}(X, T)}{\partial X}, \quad Y = \frac{\partial^{2} v_{0}(X, T)}{\partial X^{2}}
\]

\[
\chi_{xx} = \frac{1}{2} \frac{\partial^{2} v_{0}(X, T)}{\partial X^{2}}
\]

where \( u_{0} \) and \( v_{0} \) components of the displacements. The constitutive relations is expressed as

\[
\sigma_{xx} = E(Y, T) \varepsilon_{xx}
\]

\[
m = 2l^{2} \mu(Y, T) \chi
\]

The elastic strain energy \((U)\) and the kinetic energy \((T)\) are expressed as

\[
U_{i} = \frac{1}{2} \int_{0}^{L} \left[ A_{11} \left(\frac{\partial u_{0}}{\partial X}\right)^{2} - 2B_{11} \left(\frac{\partial u_{0}}{\partial X}\right) \left(\frac{\partial^{2} v_{0}}{\partial X^{2}}\right) + A_{55} \left(\frac{\partial^{2} v_{0}}{\partial X^{2}}\right)^{2} \right] \, dX
\]

\[
T = \frac{1}{2} \int_{0}^{L} \left[ I_{1} \left(\frac{\partial u_{0}}{\partial X}\right)^{2} - 2I_{2} \left(\frac{\partial u_{0}}{\partial X}\right) \left(\frac{\partial^{2} v_{0}}{\partial X^{2}}\right) + I_{3} \left(\frac{\partial^{2} v_{0}}{\partial X^{2}}\right)^{2} \right] \, dX
\]

where

\[
(A_{11}, B_{11}, D_{11}) = \int_{A} E(Y, T)(1, Y, Y^{2}) \, dA,
\]

\[
A_{55} = \int_{A} \mu(Y, T) \, dA,
\]

\[
(A_{11}, B_{11}, D_{11}) = \int_{A} E(Y, T)\alpha(Y, T)(1, Y) \, dA
\]

\[
(I_{1}, I_{2}, I_{3}) = \int_{A} \rho(Y)(1, Y, Y^{2}) \, dA
\]

In deriving the governing equations of the FG nano beam, the Hamilton’s principle is used;

\[
\delta \int_{0}^{L} [T - U_{i}] \, dt = 0
\]
After using the Hamilton’s principle, the governing equations of the FG nano beam can be obtained as follows:

\[
\frac{\partial N}{\partial x} = I_3 \frac{\partial^3 u_0}{\partial x^2} - I_2 \frac{\partial^3 w}{\partial x^2} \tag{15a}
\]

\[
\frac{\partial^2 M}{\partial x^2} + \frac{\partial^2 P}{\partial x^2} - N_1 \frac{\partial^3 w}{\partial x^2} = I_3 \frac{\partial^2 u_0}{\partial x^2} + I_2 \frac{\partial^3 u_0}{\partial x^2} - I_3 \frac{\partial^3 w}{\partial x^2} \tag{15b}
\]

where \(N, M, P, \) and \(N_1\) are stress resultants, and expressed as follows:

\[
(N, M, P) = \int_A \left( \sigma_{x\gamma}, Y \sigma_{x\gamma}, m_{xy} \right) \, dA \tag{16a}
\]

\[
(N_T) = \int_{-0.5h}^{0.5h} (E(Y, T)) \, d\tau \tag{16b}
\]

In the solution of the governing equations, Navier method is used for free vibration of a simply-supported FG nano beam. In the Navier solution, the displacement fields are expressed as follows:

\[
u(x, t) = \sum_{n=1}^{N} A_n e^{i\beta_n t} \cos(kx) \tag{17a}
\]

\[
w(x, t) = \sum_{n=1}^{N} B_n e^{i\beta_n t} \sin(kx) \tag{17b}
\]

where \(\beta_n\) is the natural frequency, \((A_n, B_n)\) are the unknown constants, \(k = \pi n / L\) and \(i = \sqrt{-1}\). Substituting eq. (17) into eq. (15), and then using matrix procedure the governing equations of the problem can be solved.

### 2.2 Governing equations of FG nano plates

According to the Kirchhoff-Love plate theory, the strain-displacement relation and the curvature tensor \(\chi\) are expressed as

\[
\varepsilon_{x_1} = \frac{\partial u_0}{\partial x_2} - X_3 \frac{\partial^2 w}{\partial x_2^2} \tag{18a}
\]

\[
\varepsilon_{x_2} = \frac{\partial u_0}{\partial x_1} - X_3 \frac{\partial^2 w}{\partial x_1^2} \tag{18b}
\]

\[
\varepsilon_{x_1x_2} = \frac{1}{2} \left( \frac{\partial^2 w}{\partial x_1^2} + \frac{\partial^2 w}{\partial x_2^2} - 2X_3 \frac{\partial^2 w}{\partial x_1 \partial x_2} \right) \tag{18c}
\]

\[
\chi_{x_1x_1} = \frac{\partial^2 w}{\partial x_2^2} \tag{18d}
\]

\[
\chi_{x_1x_2} = -2X_3 \frac{\partial^2 w}{\partial x_1 \partial x_2} \tag{18e}
\]

\[
\chi_{x_2x_2} = -2X_3 \frac{\partial^2 w}{\partial x_1 \partial x_2} \tag{18f}
\]

\[
\chi_{x_1x_2} = \frac{\partial^2 w}{\partial x_1^2} \tag{18g}
\]

\[
\chi_{x_2x_2} = \frac{\partial^2 w}{\partial x_2^2} \tag{18h}
\]

The constitutive equations of the nano plate are as follows:

\[
\sigma_{ij} = \frac{E(Y, T)}{1 - \nu^2} \left[ \varepsilon_{x_1} \delta_{ij} + (1 - \nu) \varepsilon_{x_2} \right] \tag{19a}
\]

\[
m_{ij} = 2 \mu(Y, T)^2 \chi_{x_i} \tag{19b}
\]

The elastic strain energy \((U_i)\) and the kinetic energy \((T)\) of the nano FG plate are expressed as follows:

\[
U_i = \frac{1}{2} \int_A \left( \sigma_{ij} \varepsilon_{ij} + m_{ij} \chi_{ij} \right) \, dA \, dX \tag{20a}
\]

\[
T = \frac{1}{2} \int_0^L \int_A \rho(Y, T) \left[ \frac{\partial u_0}{\partial t} \right]^2 + \left( \frac{\partial w}{\partial t} \right)^2 + \left( \frac{\partial w}{\partial x} \right)^2 \right] \, dA \, dX \tag{20b}
\]

The Hamilton’s principle of the problem:

\[
\delta \int_0^L [T - U_i] \, dt = 0 \tag{21}
\]

After using the Hamilton’s principle, the governing equations of the FG nano plate can be obtained;

In the solution of the governing equations, Navier method is used for free vibration of a simply-supported FG plate. In the Navier solution, the displacement fields are expressed as follows:

\[
u(x, y, t) = \sum_{m=1}^{\infty} \sum_{n=1}^{\infty} A_{mn} \cos(kx) \sin(py) e^{i\beta_n t} \tag{22a}
\]

\[
w(x, y, t) = \sum_{m=1}^{\infty} \sum_{n=1}^{\infty} B_{mn} \sin(kx) \cos(py) e^{i\beta_n t} \tag{22b}
\]

\[
w(x, y, t) = \sum_{m=1}^{\infty} \sum_{n=1}^{\infty} C_{mn} \sin(kx) \sin(py) e^{i\beta_n t} \tag{22c}
\]

where \(\beta_n\) is the natural frequency, \((A_{mn}, B_{mn}, C_{mn})\) are the unknown constants, \(k = m\pi / a, \, p = n\pi / b\) and \(i = \sqrt{-1}\).}

### III. NUMERICAL RESULTS

In the numerical study, the effects of the different material distributions and temperature rising on the fundamental frequencies of the functionally graded nano plates and beams are investigated in both classical theory (CT) and MCST in figures. The structural elements considered in numerical examples are made of Zirconia and Aluminum Oxide. The bottom surface of the functionally graded beam is Zirconia and the top surface of the functionally graded beam is Aluminum Oxide. The material properties and coefficients of temperature \(T\) for Zirconia and Aluminum Oxide are listed in Reddy and Chin [39]. The reader can found the material properties in Reddy and Chin [39]. In numerical examples, the initial temperature (installation temperature) of the beam is assumed to be \(T_{i}=300\) K.

#### 3.1 The results of FG nano beam

In figure 1, the effect of material distribution (the power-law exponent) and the aspect ratio \((L/h)\) on the dimensionless fundamental frequency \((\beta = \omega h^2 \frac{L}{\sqrt{E A^3}})\) of the FG nano beam for \(AT=300\) K, the width of the beam is \(b=1\) mm for CT and MCST.

It is seen from Fig.1 that increase in the aspect ratio leads to a decline on effects of size effect and difference between the results of MCST and CT. Also, as seen from Fig.1 that with increase in the power-law exponent \((n)\), the dimensionless fundamental frequency decreases. This is as expected, due to the fact that an increase in the ratio of the \(n\) can decrease the
elasticity modulus and bending rigidity of the FG nano beam according to equation (2). As a result, the strength of the material increases.

Figure 2 shows that the effect of temperature rising (ΔT) and the aspect ratio (L/h) on the dimensionless fundamental frequency of the FG nano beam for n=2, the width of the beam is h=1 nm, the height of the beam is h=1 nm, the length of the beam is L=200 nm for CT and MCST.

It is seen from Fig. 2 that increase in the temperature, the fundamental frequency decreases because of the temperature dependent physical properties. Also it is seen from Fig. 2 that the results of the CT are always larger than those of the MCST.

3.2 The results of FG nano plate

In figure 3, the effect of material distribution (the power-law exponent) and the dimensionless material length scale parameter (l/t) on the dimensionless fundamental frequency (β = ωL / √(E_A h^3)) of the FG nano plate for ΔT=500 K for the height of the beam h=1 nm for the widths of the plate a=b=30h for CT and MCST.

It is seen from fig.3, with increase in the power-law exponent (n) the dimensionless fundamental frequency decreases like the results of the FG nano beam. Another result from Fig. 3 that increase in the ratio of l/t the difference between of CT and MCST increase significantly. It shows that the material parameter and material distribution has a very important role on the vibration responses of the nano structures.

Figure 4 shows that the effect of temperature rising (ΔT) and the aspect ratio (l/t) on the dimensionless fundamental frequency of the FG nano plate for n=2 for the height of the beam h=1 nm for the widths of the plate a=b=30h for MCST.

As seen from Fig.4 that increase in the temperature, the fundamental frequency decreases as expected. In the temperature-dependent physical properties, with the temperature increase, the intermolecular distances of the material increase and intermolecular forces decrease. As a result, the strength of the material decreases. Hence, the structure becomes more flexible with rising in temperature.

IV. CONCLUSIONS

In this study, free vibration characters of FG nano simple supported beam and plate investigated with temperature-dependent physical properties in both MCST and CT. The
Navier type method is used for the solution of the problem. In the numerical results, the effects of the different material distributions, material length scale parameter, temperature rising on the fundamental frequencies of the functionally graded nano plates and beams are investigated in both classical CT and MCST. It is observed from the numerical results that the material parameter and material distribution play important role on the vibration responses of the nano structures. Also, the thermal effect leads to change significantly the thermo-mechanical of beam and plates with considering the temperature-dependent physical properties.

Üniversite Bulvarı 27310 Gaziantep/TURKEY
mehmetmumbucoglu@gmail.com

Abstract— Automotive industry focused on reduction in weight to reduce fuel consumption and carbon footprint. This causes new studies on looking for materials has high specific strength. One of the current studies is concentrated on magnesium alloys. Its high specific strength is one of the most important reasons that make it popular. However, the low formability of magnesium alloys due to its hexagonal close packed crystal structure at room temperature limits their usage in automotive industry. In this study, bending of AZ91B sheet was investigated experimentally. The minimum permissible bend angle and localized thickness change were measured for cold and locally heated specimens. The effects of local heating are presented.

Keywords—Bending, Locally heating, Cracking, AZ91B, Springback

I. INTRODUCTION

The most important characteristic of magnesium is its low density, 1.74 g/cm3, which is only 1/4 of steel and 2/3 of Al. Magnesium has a higher specific strength and stiffness than many other engineering materials, including aluminum, steel and polymer-based composites. This low density and high specific strength makes it attractive for academic studies and industries. Aerospace, information and communication technology, medical and automotive are industrial areas increase the usage of magnesium or magnesium alloys. Although Mg alloys have low density and high specific strength, they have low formability at room temperature due to hexagonal close-packed (HCP) crystal structure. The main reason of restricted formability of Mg alloys is limited slip system at room temperature. Texture effect on plastic deformation of Mg alloy at room temperature was studied as in [1]. It was observed that Magnesium alloys has limited ductility and poor formability at room temperature due to insufficient number of operative slip and twinning systems. According to Von Mises slip system theory, as in [2], a polycrystalline must have least 5 independent slip systems to deform uniformly and without failure at the grain boundaries. However, Mg alloys have less number of independent basal slip systems than required at low temperature. To improve formability of magnesium and its alloys, non-basal slips system must be activated or deformation occurs by twinning. It is clear that the activity of a non-basal slip system, i.e., the critical resolved shear stress (CRSS) for non-basal slip, depends on solute atoms, precipitates as well as on temperature. The CRSS for prismatic slip at room temperature is about 100 times higher than that of basal slip, whereas at 300° C it is only four times higher [3]. Important effect of temperature on formability of magnesium alloy were discussed a lot of studies. Ebrahimi et al.[4] studied on flow behavior and microstructure evolution of AZ91 magnesium alloy during a thermo-mechanical process. The specimens were hot compressed at range from 350° C and 425° C at different strain rates and recrystallized grains nucleate along the pre-existing grain boundaries was investigated. Trojanová et al.[5] worked on plastic deformation of AZ91 in temperature range between 360° C and 420 °C at different strain rates. The maximum elongation of 584% was obtained at 420 °C and 1 × 10−4 s−1 for the sample aged at 380 °C with a corresponding value of the strain rate sensitivity m = 0.68. The tensile elongations of all samples exceeded 200%, which represents a substantial improvement over the poor room-temperature ductility, typical for magnesium alloys. Mabuchi et al.[6] worked on low temperature superplasticity in an AZ91 magnesium alloy processed by ECAE (Equal Channel Angular Extrusion). An AZ91 alloy with very small grain size of about 1µm was processed by ECAE. The alloy showed a large elongation of 661% at a low temperature of 473 K (0.57nm). Raghunath et al.[7] studied on flow stress modeling of AZ91 magnesium alloy at elevated temperature. The flow curve is constructed by flow stress data obtained from compression test conducted at different temperature and strain rate. Accurate flow stress model is crucial for investigating magnesium alloys deformation behavior at the elevated temperatures. An analytical method, which reflects temperature, strain and strain rate effect by introducing temperature-compensated strain rate (Zener–Holloman Parameter), is proposed in the study. This model has been applied on the experimental data and predicted flow stress curve match well with those measurements.

Taleghani et al.[8] studied on hot deformation behavior and workability characteristics of AZ91 Mg alloy powder compacts by performing hot compression tests. The true stress–true strain curves peaked at low strains, after which the
flow stress increased slightly or remained constant. The work hardening rate decreased with increasing deformation temperature or strain rate. According to the developed processing maps and the microstructures of the hot-compressed specimens, the optimum hot working window for AZ91 Mg alloy powder compacts was determined to lie between 275–325°C and 0.001–0.01 s⁻¹.

In this study, bending of AZ91B sheet was investigated experimentally. The minimum permissible bend angle and localized thickness change were measured for cold and locally heated specimens. The effects of local heating are presented.

II. EXPERIMENTAL STUDY

A. Material

As-rolled AZ91 (wt. % of Al-9%, Zn-1%, Cu-0.3%, Mn-0.13%, Mg-remainder) magnesium alloy sheet with thickness of 1.5 ± 0.05 mm was investigated in this study. Magnesium alloys are designated according to ASTM B275 (Practice for Codification of Certain Nonferrous Metals and Alloys, Cast and Wrought) which indicates chemical components by weight. The first letter refers to the principal alloying element. The second letter refers to the second most significant alloying element. The first number refers to the nominal content of principal alloying element. The second number refers to the nominal content of the second most significant alloying element, as shown in Fig. 1. The last letter, A or B, differentiates between alloys of similar composition [9].

![Fig. 1 Designation of magnesium alloys](image)

Its crystal structure is one of the important causes to choose AZ91B as material. Magnesium alloys have low formability at room temperature because of the hexagonal closed packed crystal structure. This limitation restricts using of magnesium alloys at low temperature, but the search [10] shows that magnesium alloy exhibits high formability at high temperatures. Enhancement of formability of a material at elevated temperatures can be seen clearly in HCP. So choosing of material that has HCP crystal structure would be proper. Magnesium nearly ideal axial ratio is other cause to choose as a study material. The ideal axial ratio is 1.633 for Hexagonal Closed Packed crystal structure [11]. This value is 1.623 for magnesium (at 150° C) [12], This ideality would be provide advantages in theoretically calculations. The deviations in calculations will be 0.7% for magnesium. This value is 13.5% for cadmium. HCP crystal structure consists of three layers and totally 6 atoms in per unit cell. This compacted structure brings high atomic packing factor. Hexagonal closed packed atomic ratio is 74% (26% voids in unit cell). This ratio is 68% for Body Centered Cubic. Planes and directions are indicated by using 4 coordinate axes (a1, a2, a3 and c). This coordinate system is consist of 3 vectors that has 120° between themselves on a plane and one vector perpendicular to the plane as shown in Fig. 2 [12].

![Fig 2 HCP Crystal Structure Slipping Planes and Coordinate Axes](image)

Hexagonal Closed Packed crystal structure has 3 three slip planes which are basal slip plane, prismatic slip plane and pyramidal slip plane. HCP structure has less number of independent slip systems at room temperature so Mg and its alloy have poor ductility at room temperature. Ratio of Critical Resolved Shear Stress (CRSS) of basal plane to CRSS of non-basal plane is between 1:40-1:80 for single crystal models [13]. This low CRSS value is attributed low Schmid Factor. On the basal plane Schmid factor is too small due to orientation, so CRSS value on the basal plane is too small compared with non-basal plane. Slipping on the pyramidal slip plane is not expected at room temperature because to activate slipping in the c-axis direction high temperature is required.

B. Bending Die Set Up

Specimen was cut in same dimensions (60x225x1.5mm) perpendicular to rolling direction to observe cracking clearly. Bending was investigated as cold bending and locally heated bending by bending apparatus in Fig 3 and Fig. 4.
C. Experimental Procedure

Cold and locally heated bending was compared in terms of bendability as shown in Fig. 5. In cold bending specimens were bent at room temperature at angles of 60°, 65°, 67.5°, 75° and 90° for all specimens. In second step of experiment, pin has 13.5 mm diameter- which contact during bending process was heated up to 330°C by induction heating using RETERM RT-380M50 induction machine. Heated pin was placed on the apparatus. It was waited until to obtain regular temperature distribution on bending area of specimen. When regular temperature distribution observed at certain temperature level (this temperature level is about 150°C for this study). When pin and specimen reached to heat equilibrium at 150°C bending process was executed.

III. RESULTS AND DISCUSSION

In first step of experiment, specimens cut in same dimensions bent 60° at room temperature, small cracking was observed. When bent angle was increased to 65°, deepen in cracking can be observed explicitly on edge of the bending area. Cracking was regulated along bending line at 67.5°. Cracking was observed clearly at 75° along bending line. Fracture was observed at 90°. As a result cracking was observed on the specimens that were bent at room temperature.

In second step of experiment, specimens were locally heated and bent at same angles. Locally heated was executed by sheet metal with heat transfer. When specimens were locally heated up to about 150 °C and bent in same angles. Almost there was no cracking at 60°. Surface cracks initiated at 65°. They were obvious at 75° and deepened at 90°.

Thinning of specified points (as shown in Fig. 6) on bending line of sheet metals after bending was measured with ultrasonic thickness gauge. This thinning was illustrated in Fig 7 and Fig 8. In Fig. 9, thinning at 60° and 90° was compared for cold and locally heated bending. Locally heating has advantages in terms of formability but thinning on bending line observed.
Effect of locally heating on bending process at elevated temperature was investigated experimentally. The main conclusions derived from this study are as follows:

1) The locally heating is a successive method to prevent cracking in bending of AZ91B alloy. There is no cracking on bending area of locally heated specimen up to 75º bending, although all specimens were cracked at room temperature for cold bending.

2) Maximum thinning was observed at 90º for locally heated bending. The amount of thinning is about 9.1%. Therefore, thinning must take into consideration for locally bending process.

3) Commonly thinning increases directly proportional to the bending angle.

Drying of ionic hydrogels using fluorescence technique

Demet Kaya AKTAŞ

Istanbul Technical University Department of Physics, Maslak, 34469 Istanbul, Turkey
demet@itu.edu.tr

Abstract—Steady-state fluorescence (SSF) technique was employed for studying drying of poly(acrylamide-co-acrylic acid) (P(AAm-co-AAc)) composite gels for low and high pH. Disc shaped composite gels were prepared by free-radical crosslinking copolymerization of P(AAm-co-AAc). N, N'-methylenbis (acrylamide) (BIS) and ammonium persulfate (APS) were used as cross-linker and initiator, respectively. Pyranine 4 (4sPy) was introduced as a fluorescence probe. It was also observed that fluorescence intensity values increased as drying is proceeded. A phenomenological equation was introduced to determine the desorption coefficient, D of water molecules from drying hydrogels for various pH contents. Gravimetrical experiments for drying process were also performed. It was shown that diffusion coefficients for drying process D decreased as the pH values are increased.

Keywords—Hydrogels, pH, drying, fluorescence, diffusion

I. INTRODUCTION

Progress in material science stimulates the economy and greatly influences the living standards of a society. Intelligent materials are based on a new concept where the information science is introduced to the material. Today it is a challenging task to manufacture new multifunctional materials which possess intelligence at the material level. Intelligent materials can be referred in terms of three main functions: sensing changes in environmental conditions, processing the sensed information and finally making judgement (actuating) by moving away from or to the stimulus [1]. The innovative functions of these new materials are in many respects similar to those of living organisms. Biological systems continuously adapt to a dynamically evolving environment, while developing innate properties of homeostasis. The intelligent materials should also display these characteristics while maintaining harmony with the environment. The current generation of intelligent materials can be divided into two main parts.

1) Hard and dry materials, such as metals, ceramics and plastics. Intensive research is currently being devoted to compound semiconductors, dielectric ceramics, thin ferroelectric films and photovoltaic energy converters.

2) Soft and wet materials, such as electrorheological fluids, magnetic fluids and polymer gels.

In the last few years it is observed that a migration of interest and activity from the traditional hard materials towards soft materials, such as biomaterials, self-assembly materials, complex fluids and polymer gels. It is aware that soft materials will probably never replace hard ones, but their study has led to significant advances in areas such as artificial tissues, controlled drug delivery, molecular recognition, chemical valves, artificial muscles and chemomechanical energy conversion.

Polymer gels are unique materials in the sense that no other class of materials can be made to respond to so many different stimuli as polymer gels. The stimuli that have been demonstrated to induce abrupt changes in physical properties are diverse and include temperature, pH, solvent or ionic composition, electric field, light intensity as well as the introduction of specific ions [2-5]. In the last few years, these gels have become of major interest as novel intelligent materials. Many kinds of such gels have been developed and studied with regard to their application to several biomedical and industrial fields, for example, controlled drug delivery systems, muscle-like soft linear actuators, biomimetic energy-transducing devices and separation techniques.

In general, hydrogels were first described in the last century as networks that contain small fractions of polymers and large fractions of water; hydrogels maintain their shapes while they imbibe fluids or are dried [6]. The swelling and drying kinetics of hydrogels are very important in the pharmaceutical industry, in designing slow-release devices for drugs, in the agricultural industry for producing storable foods, and in medical industry in developing artificial organs. Hydrogel properties depend strongly on the degree of cross-linking, the chemical composition of the polymer chains, and the interactions of network and surrounding liquid. Especially, on the basis of their dramatic swelling and deswelling behaviours, pH-sensitive hydrogels are being utilized for new potential applications. Hydrogel properties depend strongly on the degree of cross-linking, the chemical composition of the polymer chains, and the interactions of network and surrounding liquid. Especially, on the basis of their dramatic swelling and deswelling behaviours, pH-sensitive hydrogels are being utilized for new potential applications. Hydrogels exhibiting pH-sensitive swelling behaviour have been usually swollen from ionic networks that can contain acidic or basic pendant groups. When these groups are ionized, a swelling osmotic pressure inside the material is built up, and fixed charges are trapped in the gel. As a result of the electrostatic repulsion, the uptake of solvent in the network is increased
In case of anionic polymeric networks, ionization takes place as the pH of the external medium rises above the pKa of the ionizable moiety [9]. The polymeric network becomes more hydrophilic as the degree of ionization increases and the polymer swells. One of the important types of anionic hydrogel is Poly(AAm-co-AAc), owing to the existence of hydrophilic –COOH and –NH2 groups, has the capacity to absorb large amounts of water. Poly(AAm) hydrogels can absorb relatively high amount of water; however, their swelling capacity is not sensitive to pH or electrolytes [10]. Also, due to the presence of hydrophilic carboxylic acid side groups, the swelling behaviour of these hydrogels is highly dependent on the pH of the surrounding medium [11]. Hence, poly(AAm-co-AAc) hydrogels have been investigated for use as adsorvents in water purification [12,13], insulin release [14], osteoblast adhesion [16] and drug delivery systems etc. [15,16].

The understanding of the phenomena occurring in the drying of these hydrogels is necessary for the designing of the entire process. Drying of hygroscopic solids is generally known to be a complex process because of simultaneous heat and mass transfer and variable physical properties of the materials [17]. Special polymers and hydrogels are highly hygroscopic and shrinking colloidal materials and the drying of these encompass many fields of technology. The quantity of bound water associated with polymer varies as per the internal structure of the macromolecule. Monomer and cross-linking agent proportions are responsible for both the porous structure and the pore size of the gel. An acrylamide derived hydrogel is a cross-linked network of polymer whose molecular weight is fairly high; it can absorb solvent (water), but is itself insoluble. During the water migration in drying process, shrinkage corresponds simply to the compacting of solid mass.

Using the fluorescence technique, a pyrene derivative was employed as a fluorescence probe to monitor the polymerization, aging and drying of aluminosilicate gels [18], where peak ratios in emission spectra were monitored during these process. Recently, we performed drying [19,20] kinetics in disc shape non-ionic PAAm hydrogels at various temperatures and cross-linker contents using by steady-state fluorescence technique. In this study we investigated the effect of pH during drying processes in poly(acrylamide-co-acrylic acid) P(AAm-co-AAc) ionic composite hydrogel by using fluorescence technique. Here 4sPy was chosen as an aromatic molecule since its emission spectra does not depend on pH. Change in fluorescence intensity of 4sPy was monitored during in situ drying processes of composite gels. It was shown that diffusion coefficient for drying process, DG decreased as pH values are increased. The gravimetric measurements for drying process were also performed to compare results found from fluorescence technique. It is expected that diffusion coefficient, D values measured by using fluorescence technique are at least order of magnitude much larger than the values measured by gravimetric technique, which may present the different behaviours of the gel. Segmental motion of the gel network can be monitored by using fluorescence intensity and monitors the swelling at a molecular level. According to the above argument, one may suggest that chain segments move much faster than the bulk polymeric material during volume phase transition process.

II. EXPERIMENTAL

Disc shaped ionic composite gels were prepared by free-radical crosslinking copolymerization of P(AAm-co-AAc). BIS (Merck) and tetramethylethylenediamine (TEMED, Merck) were added as a cross-linker and an accelerator, respectively. The initiator, ammonium persulfate (APS, Merck), was recrystallized twice from methanol. The initiator and pyranine 4 concentrations were kept constant at 7x10\(^{-3}\) M and 4x10\(^{-4}\) M, respectively, for all experiments. Composite gel prepared by using % 70 AAm (Merck) and % 30 AAc by dissolving them in 25 cm\(^3\) of water in which 10µl of TEMED were added as an accelerator.

The fluorescence intensity measurements were carried out using the Model LS-50 spectrometer of Perkin-Elmer, equipped with temperature controller. All measurements were made at 90° position and slit widths were kept at 5 nm. A disc-shaped gel samples were placed on the wall of 1x1 quartz cell.

III. RESULTS AND DISCUSSION

During drying process of PAAm hydrogel in air, as water release is increased, fluorescence intensity, \(I_0\) increases and the scattered light intensity, \(I_s\) decreases. Here the decrease in \(I_s\) corresponds to the decrease in turbidity of the drying hydrogel, so the corrected fluorescence intensity, \(I\) was defined as \(I_{corr}/I_s\). Figure 1a and 1b present the variation of \(I\) versus drying time, \(t_d\) during hydrogel drying for pH=4 and pH=10, respectively. It can be seen that as drying time, \(t_d\), is increased, quenching of excited pyranines decrease due to increasing of water release from drying hydrogel. In order to quantify these results, the collisional type of quenching mechanism may be proposed for the fluorescence intensity, \(I\) from the hydrogel sample during drying process, where the following relation can be used [18].

\[
I^{-1} = I_0^{-1} + k_q\tau_\alpha [Q]
\]  

Here, \(k_q\) is quenching rate constant, \(\tau_\alpha\) is the lifetime of fluorescence probe and \(Q\) is the quencher. For low quenching efficiency, \((\tau_\alpha k_q[Q]<1)\), Eq. (1) becomes

\[
I = I_0(1 - k_q\tau_\alpha [Q])
\]
If one integrates Eq. (2) over the differential volume \((dV)\) of the hydrogel from the initial, \(a_0\) to final \(a_\infty\) thickness and then, reorganization of the relation produces the following useful equation.

\[
W = \left(1 - \frac{I}{I_0} \right) \frac{V}{k_q \tau_0} \tag{3}
\]

Here, amount of water release, \(W\) is calculated over differential volume by replacing \(Q\) with \(W\) as

\[
W = \int_{a_0}^{a_\infty} [W] dV \tag{4}
\]

Where \(V\) is the volume of the hydrogel at the equilibrium drying state, which can be measured experimentally. \(k_q\) was obtained from separate measurements by using Eq. (3) where the infinity equilibrium value of water release, \(W\) was used at each temperature. Since \(\tau_0\) \((5\text{ns})\) is already known from the dry hydrogel, then \(W\) can be calculated from the measured \(I\) values at each drying step. The plots of the water release, \(W\) for the hydrogels dried for pH=4 and pH=10 are shown in Fig. 2a and 2b, respectively.

Here it has to be noted that drying phenomena in gels has not yet been completely modeled, because drying process is not as simple as swelling, at least in water. In this work drying process is tried to be simplified, but still it is not modeled by considering elastic forces of the gel. During drying, it is assumed that there are two regions exist in the gel, i.e. less concentrated region near the surface separates itself from the high concentrated region by a boundary which moves during drying towards the center of the gel and as the boundary moves, water molecules evaporates from the surface of the gel into air. Then, the behavior of \(W\) against \(t_d\) can be explained by considering a model in which diffusion occurs in two regions separated by moving interface \([21]\). The moving interface can be marked by a discontinuous change in concentration as in the absorption by a liquid of a single component from a mixture of gases or by a discontinuity in the gradient of concentration as in the progressive freezing of a liquid. Discontinuities have been observed in several practical systems, for instance when two metals interdiffuse \([21]\). The sharp advancing boundary is well known in many polymer–solvent systems, which are considered as a discontinuity for some purposes. When the diffusion coefficient is discontinuous at a concentration \(c\); i.e. the diffusion coefficient is zero below \(c\) and constant and finite above \(c\); then the total amount, \(M_t\) of diffusing substance desorbed from unit area of a plane sheet of thickness \(a\) at time \(t\), is given by the following relation.
\[ \frac{M_t}{M_\infty} = 2 \left( \frac{D}{\pi a^2} \right)^{1/2} t^{1/2} \]  
(5)

where \( D \) is constant diffusion coefficient at concentration \( c_1 \). Here \( M_\infty = a c_1 \) is the equilibrium value of \( M_t \). If one assumes that the diffusion coefficient of polymer segments in the gel is negligible compared to the desorption coefficient, \( D \) of vapor of water into air, then Eq. (5) can be written to employ our data in Fig. 2 as follows

\[ \frac{W}{W_\infty} = 2 \left( \frac{D}{\pi a^2} \right)^{1/2} t_d^{1/2} \]  
(6)

Here it is assumed that \( M_t \) is proportional to the amount of water molecules released, \( W \) at time, \( t_d \). Figure 3a and b give the plots of \( W \) versus \( t_d^{1/2} \) for pH=4 and pH=10, respectively where the fit of the data produced desorption coefficient, \( D_F \) which are listed in Table 1. It is seen that as pH is decreased \( D_F \) values present increase by predicting faster desorption of water molecules from drying PAAm hydrogels at lower pH.

On the other hand, by using gravimetric technique (Gravimetical experiments were performed at the same condition of fluorescence experiment), water desorption was also measured from the drying PAAm hydrogel. Measured \( D_G \) values are listed in Table 1, where it is observed that desorption coefficient increase as the pH is decreased. This result is expected since hydrogel segments and water molecules move much faster in gels swollen at low pH, which cause faster evaporation of water from the hydrogel.

Here it is seen in Table 1 that \( D \) values measured by using fluorescence technique are at least twice much larger than the values measured by gravimetric technique, which interested different behaviours of the gel. It is obvious that the fluorescence technique measures the behaviour of the microstructure of the gel, i.e. segmental motion can be measured by fluorescence because pyranine molecules are bounded to the polymer chains. However, volumetric and gravimetric measurements may provide us with the behaviour of the macroscopic environment. According to above argument, one may suggest that chain segments move much faster than the bulk polymeric material during swelling process.

IV. CONCLUSION

These results have shown that the steady-state fluorescence technique, which is quite powerful and inexpensive, can be used for real-time monitoring of hydrogel drying process. The empirical model was derived and used to determine the desorption coefficients for the drying process. It is observed that diffusion coefficients for drying process \( D \) decreased as the pH values are increased.

Weight Reduction Study on BIW by Using Boron Alloyed Hot Stamping Solution of Front Frame Rail Instead Conventional HSS or AHSS Applications

Levent AKSEL¹, Şaziye EFENDIOGLU¹, Harun YENI¹, Çiğdem BİLGE¹
ITOFAŞ, Turkish Automotive Company R&D Center, Bursa, Turkey

Abstract—With the increase of the performance requirements and homologative restrictions the correct way of choosing the right material on the related area is an inevitable manner for weight reduction of the vehicles. A hot stamped front frame rail which have roughly same performance with conventional cold stamped one was designed by using tailor welded and patch reinforcement. The part was optimized with full sized frontal crash (EUNCAP), full sized rear crash (Trias33) and fatigue simulations. Critic interferences-accelerations into the passenger cabin was considered for acceptance criteria of frontal crash, deformations on fuel system for acceptance criteria of rear crash and plastic deformations on the part, especially suspension fixing points, for acceptance criteria of fatigue test. At the end of all optimization the thicknesses of the system was designed as; first tailor welded part: 1.2mm, second tailor welded part: 2.5mm and patch reinforcement: 1mm. Also some design critics (such as laser cut holes and trims, seal and barrier application for eliminating water infiltration into the bare surfaces of the hot stamped part) was clarified to guarantee the performance of the part during lifecycle of the vehicle. With final condition new hot stamped system was weighted 5 kg and gained a 2 kg weight reduction.

Keywords—Front Frame Rail, Hot Stamping, Boron Alloyed Steel, Body Light Weighting, Frontal Crash, Suspension Fixing

I. INTRODUCTION

This document represents a weight reduction study and its application on the vehicle body to reduce total weight of the vehicle, energy consumption of the required material and finally CO2 emissions.

There are several type of materials and method to reduce total body weight. But the multi material concept and the selection of the correct material in correct places is very important for cost effective solutions. [1] Steel has every time widest usage area on body structure during material selection in multi material concept. Beside steel grades is increasing thicknesses there can need to use different processes like tailor welding. Using this type of processes to get more rigid structure like laser tailor welding and patch welding. With this type of processes is aimed to eliminate negative effects of the weight-thickness reduction of component. New front rail design verified with all aspect of performance requirements of the vehicle like crashworthiness and fatigue life of the vehicle.

Fig. 1 Steel grades in BIW design [3]

II. EXPERIMENTAL PROCEDURE

Front frame rail (Fig. 2) is a structural component on the underbody structure and has important performance requirements such as safety cage protection during frontal crash, fuel tank protection during rear crash, fatigue life during driving with the aspect of energy absorption which is coming the from the road through the front suspension. Thanks to process advantages of hot stamping process sheet metal mechanical properties increase highly and can be reached at 1500Mpa without any crack, wrinkles or spring back, with good microstructure well dispersed hardness. [4], [6]

A. Tailor Laser Welding & Patch Welding

To reach the high performance targets when optimising the thicknesses there can need to use different processes like tailor welded steel solutions and patch welding. Using this type of processes the thickness of the component can be adjusted with
different mechanical properties during the component section. [5]

For having lightweight body structure new front frame rail is designed by using hot forming material with tailor laser welded two different thickness 1.2 and 2.5mm. This rail is reinforced by patch welding with 1mm FEE 340 material. The section of the rail is optimised considering the crash performances and fatigue life of the vehicle. Especially suspension fixing point is reinforced with patch welding. The distance between the sheet metal parts on the patch welding area is 0mm as a process necessity. This situation decrease the inertia on this point but local rigidity across the fatigue load of the suspension fixing will increase.

Tailor laser welding of the sheet metals with the thicknesses 1.2mm and 2.5mm brings the advantage of optimisation of the component for the crashworthiness. With this process additional ~60g weight reduction is gained and also cycle time of the process is decreased. Basic weight reduction is provided with the elimination of matching surface which is using for spot welding area. Laser welding is designed for butt welding and there is no need for matching of the surfaces. Fig. 4 shows the comparison of the zones used for spot welding versus laser butt welding.

B. Cutting and Blanking of the Hot Stamped Part

One of the most important production problem of the hot stamped parts is cutting. At the end of the process hot stamped part has a yield strength between 950 – 1250 MPa and this value make the cutting operation almost impossible with conventional cutting tools or punch. Even if the using cutting operation with blanking tools or punch the tool life will be very short. In this case producers has to put up with high repair costs. These additional repairing cost is important but rather than the cost, repairing time of the tools cannot be accepted for serial production cases. To eliminate this problem can be used warm forming process for cutting or blanking operations. [7] Or directly, like this example, can be used laser cutting operation both for trim cutting and hole blanking. Laser cutting operation has a cost disadvantage respect to blanking operation. Also with laser cutting operations trim tolerances are higher than blanking. On trim lines part has to at least ±1mm tolerances. So the mating parts also can need to be redesigned with the tolerances of hot stamped parts not to have misaligning the holes or mismatching the periphery edges.

C. Forming of the Part

During the hot stamping process the heating temperature reaches to 900 °C and for an ideal martensit structure formation approximately it has to be cooled 30 °C/s till to 250 °C. Thanks to heating effect of the material part under the press condition can be formed easily. Steel part formability limits enhances drastically. This situation gives to designer an opportunity to design the parts with small radii and sharp corners. At the end of the process there is no expectation like spring back or wrinkles of the part geometry. Small radii and completely matching of the patch part on the front rail can
used to get final geometry of the part which guarantee performance requirements. As shown in Fig. 6 hot stamping part can be stamped within the acceptable limits of wrinkle and thinning. The deepest zone of the part has no any crack problem or excessive thinning problem. Without any form modification or radii relaxation on the geometry, same geometry cannot be stamped with cold stamping die without crack or wrinkle.

**D. Vehicle Virtual Validations**

Structure and mechanical characteristics of front frame rail is crucial for the safety performance of the vehicle. To be protected safety cage front rail has to good energy absorption characteristics and high mechanical properties. Generally these characteristics are obtained by using functionally graded strength (FGS). FGS structures are found by optimizing all of the crashworthiness and its deviation by the time of the crash impact (peak forces, max-min acceleration of the deformation, max displacement of the related zone in safety cage etc.) [8]

**Front Crash:** For the evaluation of the vehicle in Europe Market; within the Euro NCAP - European New Car Assessment Programme the vehicle crashes to a static barrier with 64 km/h velocity. Fig 8 shows schematically the regulation.

At the end of the test the deformations on the vehicle is controlled for validation of the vehicle. Basically there musn’t be interferences creating high risk for driver & passenger safety into the safety cage and the vehicle after crashing must let the passengers going out easily.

In the Table 1 can be found the interferences into the vehicle categorized according to critic areas for the driver.

New front rail is rigid enough to protect safety cage and limits the interferences. Buckling of the rail is located on the left of the vehicle because of the barrier impact side. On the right side the front rail seems with very few plastic deformations.

The interference values and other front crash results are positive, in the following Fig. 9 is shown the crash simulation.
Rear Crash: For the evaluation of the rear crash performance of the vehicle TRIAS 33 has been executed. TRIAS 33 basically controls the deformations on the fuel pipes and fuel tank. Within the TRIAS 33 a rigid barrier has been impacted with 52 km/h to the vehicle from the rear side. Following Fig 10 shows schematically the test condition.

The vehicle which contains hot stamped front frame rail is crashed by moving rigid barrier and controlled elastic and plastic deformation. The test is resulted as positive. Deformations on the body structure is shown in Fig 11 and 12.

Fatigue Performance: Vehicle with the hot stamped front rail part has been verified also with respect of fatigue life of the vehicle. For the fatigue life of the part the most critical effect comes from front suspension fixing points. On these points fixing element selection is very important and they must carry the force coming from road to the vehicle body structure without any structure fail. Fixing nuts are welded on the front rail by projection welding.

With these condition vehicle is analysed and investigated a good fatigue life conforming to vehicle targets.

Fig. 13 Fatigue life analysis
E. Treatment of the Part and Corrosion Behaviour

Hot stamping part (or blank) is heated till to 900 °C to obtain austenite formation. The blank sheet needs to be transformed quickly to the forming die. If blank is selected without any protective coating there can be abrasive iron oxide layer on blank sheet. [9] There are two solution to eliminate this problem; 1- heating must be done in a protected zone from atmosphere, 2- selecting an appropriate coating on blank sheet. Within this study blank sheet selected with hot-dip aluminized coating.

III. CONCLUSIONS

In the present study within the BIW light weighting trials a new front frame rail is designed. It is inspected that functional graded strength structure formation is inevitable during the optimisation between thickness decrease and structural performance targets. For creating FGS alternative type of welding and reinforcing can be used. The virtual analysis showed that the new structure with new front frame rail reinforcement succeeded all safety and structural tests with 2kg decreased weight per vehicle.

The producers still has to use additional coating to protect abrasive oxide layer and the necessity needs further studies to optimize or completely eliminate this requisite.

Abstract—Recently, as a result of the development of new commercial steel sheets for applications in car body manufacturing, high manganese twinning-induced plasticity (TWIP) steel sheets are gaining popularity in automotive body structure applications. The use of steel sheets in the automotive industry inevitably involves welding, particularly after the cold forming. Resistance spot welding (RSW) is the most widely used joining process for steel sheets in car body manufacturing. The application of cold formed TWIP steels may require a more complete understanding of some issues associated with the resistance spot welding. So, in this study, the effect of weld current on the tensile shear strength of cold rolled TWIP980 steel joints welded by resistance spot welding was investigated. Prior to welding, TWIP980 sheets were cold rolled to 15% reduction in thickness. The welding processes were carried out using MFDC (Mid-Frequency Direct Current) resistance spot-welding machine connected to ABB robotic arm. Weld currents were chosen as 6, 7, 8, 9 and 10 kA and the other welding parameters were kept constant. Microstructural study and tensile shear tests of the joints were conducted. From the examinations, the post weld properties, such as the nugget size, indentation depth and tensile shear strength of the joints, were determined depending on the weld current.

Keywords—TWIP980 Steel; Cold rolling, Resistance Spot Welding; Weld Current; Tensile Shear Strength

I. INTRODUCTION

TWinning-Induced Plasticity (TWIP) steel is one of the candidate materials for the car body manufacturing because of its superior balance of ductility and strength. The TWIP steels contain a high amount of manganese, which stabilizes the austenitic microstructure at room temperature and decreases the stacking fault energy (SFE). In lower SFEs, mechanical twinning is highly promoted [1-5]. This mechanical twinning acts as strong barriers to dislocation motion [6]. There are numerous studies about microstructural and mechanical properties, effect of alloying elements, strain hardening mechanism, heat treatments etc. of TWIP steels [7-14].

Automotive sheet components inevitably involve welding, particularly after the cold forming. Resistance Spot Welding (RSW) is the primary sheet metal welding process in automotive body construction because of its low cost, easy automation, minimum skill requirements, and robustness to part tolerance variations [15,16]. However, because of the thermal cycle during the RSW process, the designed microstructure of sheet steels is destroyed. These microstructural deteriorations in the weld zone are highly dependent on the initial microstructure of the base metal and the welding parameters.

Saha and Park [17] have studied on optimization of double pulse schedule of cold rolled TWIP steel sheets by means of compact tension test (CTT). They reported that an increase in nugget size around 15% was observed compared to ISO standard schedule and conventional single pulse schedule. Spena et al. [18] have studied on the effects of welding parameters of RSWed TWIP steel sheets using Taguchi approach. They reported that the most effective welding parameter was weld current on tensile shear test. Saha et al. [19] reported the microstructure, mechanical properties and fracture morphology of RSWed TWIP steels. Yu et al. [20] identified the RSW characteristics of 1 GPa grade TWIP steel.

Recently, as a result of the development of new commercial steel sheets for applications in car body manufacturing, high manganese TWIP steel sheets are gaining popularity in automotive body structure applications. So, performing RSW of TWIP steel sheets after cold forming is an inevitable demand in the automotive industry. Therefore, it is important to study the welding behaviour of the resistance spot-welded joints of cold formed TWIP sheet steels. In the best of authors’ knowledge, quite a few investigations have been carried out concerning the effect of RSW process on the microstructure and mechanical behaviour of cold rolled TWIP steel sheets. The present investigation was aimed at studying the effect of weld current on the tensile shear strength of cold rolled TWIP980 steel joints. Microstructural study and tensile shear tests of the joints were conducted. From the examinations, the post weld properties, such as the nugget size, indentation depth and tensile shear strength of the joints, were determined depending on the weld current.
II. MATERIAL AND METHOD

In this study, as-received (1.3 mm) TWIP steel sheets were cold rolled around 15% reduction in thickness (around 1.1 mm) using cold rolling. All tests were conducted on cold rolled TWIP steel sheets. The chemical composition of the sheets used in this study is shown in Table 1. Tensile properties of as-received and 15% cold rolled steel sheets were also presented in Table 2. The ultimate tensile strength of TWIP sheet steel increased roughly 24% with 15% cold rolling and the total elongation value decreased around 57% with 15% cold rolling.

The sheets were cut into the samples for the welding process with the dimensions 50 mm x 20 mm. Welding was performed by overlapping the samples using MFDC resistance spot-welding machine connected to ABB robot arm. The welding configuration can be seen in Fig.1. Copper alloy electrodes having the face diameter of 6 mm were used in the welding processes. The spot welds were performed with the weld current of 6 kA, 7 kA, 8 kA, 9 kA and 10 kA while keeping the welding time and electrode force constant at 250 ms and 2.25 kN, respectively.

In order to describe the microstructural characterization of the joints, the spot welded joints were cross sectioned through the weld nugget center using an electrical-discharge cutting machine. The microstructure was revealed using both Nital (3%) and Na₂S₂O₃ solution (10 g Na₂S₂O₃ in 100 ml H₂O), respectively. The optical microscopic studies were carried out by a Nikon DIC microscope under polarized light with a Clemex image analysis system. The tensile shear tests were performed with a fully computerized UTEST-7014 tensile testing machine in laboratory conditions using a constant strain rate of 3.33x10⁻³ s⁻¹. The nugget size of the welds was measured through the fractured specimens using Mitutoyo digital caliper. A ball ended Mitutoyo micrometer was used to measure the indentation on the spot welds. In addition, a scanning electron microscope (SEM) was used to describe the failure modes of the joints.

III. RESULTS AND DISCUSSION

RSWed joints exhibited three different microstructural zones: the fusion zone (FZ), heat-affected zone (HAZ), and base metal (BM) (Fig.2). BM microstructure consists of fine grained austenite including mechanical twins, with evident bands in the rolling directions. The HAZ has fairly coarse grained austenite including annealing twins. On the other hand, a typical coarse columnar dendritic structure existed in the FZ.

TABLE 2
THE TENSILE PROPERTIES OF AS-RECEIVED AND 15% COLD ROLLED TWIP STEEL SHEETS USED IN THIS INVESTIGATION.

TABLE 3
THE WELD PROPERTIES OF THE RESISTANCE SPOT WELDS FABRICATED WITH DIFFERENT WELD CURRENTS (AVERAGE VALUES). (NS: NUGGET SIZE; SD: STANDARD DEVIATION)
The weld properties, such as nugget size (NS), indentation depth and tensile shear load, are shown in Table 3. The relationship between the weld properties and weld current can also be seen in Fig. 3. The NS is one of the most important factors that determine the quality and the strength of the spot weld [21-24]. As shown in Fig.3a, the weld current is one of the main controlling parameters for the NS. With an increase in the weld current from 6 kA to 10 kA, the NS was increased from 5.54 mm to 6.43 mm owing to the increased heat input. Fig.3a shows that there is a strong linear correlation between the NS and the weld current; the NS increases almost linearly with increasing weld current. The spot weld that meets the requirements of the appropriate specifications should have a minimum nugget diameter of 3.5–4 times the thickness of the thinnest outside part of the joint [25]. The measured NSs for all weld current values was found to be acceptable, i.e. over five times the thickness of the outside part of the joint. An indentation has also a vital importance for weld strength and external appearance in automotive industry. With an increase in the weld current from 6 kA to 10 kA, the indentation percent was increased from 11.16% to 42.21%. Especially, it should be noted that 42.21% can be considered as high indentation for automotive industry. Similarly to the relationship between NS and weld current, the indentation depth increases almost linearly with increasing weld current owing to the enhanced expulsion phenomenon during RSW process with higher heat input. However, a decrease in weld strength should be expected with further increase in indentation depth over 42.21%.

The weld current affected the tensile shear load of the resistance spot-welded joints (Table 3 and Fig.3c). The tensile shear loads of the joints increased almost linearly with increasing weld current (Fig.3c). The tensile shear load of the spot-welded joints increased approximately 18% when the weld current was increased from 6 kA to 10 kA. This increase in tensile shear load of the spot welds can be attributed to the enlargement of the NS. On the other hand, as shown in Fig.3d, the tensile shear loads of the joints increased almost linearly with increasing NS. In the tensile shear tests, spot welded joints with lower weld current (6 kA and 7 kA) exhibited an interfacial failure mode, in which the fracture propagates through the weld nugget (Fig. 4a). The failure mode of the spot welded joint with 8 kA was partial interfacial, in which the fracture initially propagates through the weld nugget and then redirects through the thickness direction (Fig.4b). On the other hand, the spot welded joints with higher weld current (9kA and 10 kA) exhibited a full button pull-out failure mode referring to higher deformation energy, in which fracture occurs in the HAZ at the around of the spot weld (Fig.4b).
IV. CONCLUSIONS

The conclusions derived from this study can be given as follows:

- The weld zone of the cold rolled TWIP980 spot welds has three different microstructural regions: the fusion zone, heat-affected zone, and base metal. The grain structure in HAZ is quite coarser than that of base metal. In addition, HAZ includes only annealing twins, whereas the base metal has only mechanical twins. On the other hand, fusion zone has a typical coarse columnar dendritic structure.
- The nugget size, indentation depth and tensile strength of the cold rolled TWIP980 spot welds increase almost linearly with increasing weld current. The peak indentation and tensile shear load was obtained with 10 kA. However,
a decrease in weld strength should be expected with further increase in weld current depending on the increase in the indentation depth.

- There is a direct relationship between the nugget size and the tensile strength of the spot welded joints: The tensile strength of the spot welded joints increases with increasing nugget size.
- The spot welded joints with higher weld current (over 9 kA) exhibited a full button pull-out failure mode, providing high weld strength.

ACKNOWLEDGMENT

The authors are grateful to the Scientific and Technological Research Council of Turkey (TUBITAK) for its financial support to this research (*Project number: MAG 213M597*). The authors are also grateful to Ermetal Inc. for providing facilities for the resistance spot-welding processes.

Abstract— In this study, the effect of Al-powder (up to 30% by weight) on the phase composition and microstructure for the clinoptilolite based porous ceramics is studied. The mixture was dry ground in a ball mill; it was shaped by uniaxial pressing at 50 MPa and later sintered at the temperatures of 1200°C for 1 hour under air atmosphere. The clinoptilolite is composed from silica and alumina, the silica with Al-powder being reaction sintering which leads to corundum and silicon product and their amount has been increased with the amount of aluminium additive in the composition. The amount of metal powder in ceramic matrix is strongly determined the microstructure of samples where the material being either glassy foam nature or open-cell microstructure. The significant open porosities (~30-37%) could be obtained with the high aluminium content (10-30% by weight). As the sample contained 10% by weight, corundum crystallization with some cristobalite and silicone is determined. At higher aluminium content the samples being corundum with silicon. The high stable phases indicated uniform porosities and with smooth pore wall surfaces could be obtained.

I. INTRODUCTION

There have been great attentions to enhance the producing of alumina based engineering ceramics whose are high strength and hardness with high chemical stabilities. The attention is also focused on the fabricating the materials with more precisely and cheaply. The advanced structural and functional ceramics from the mixtures of Al-metal and ceramic powders is achieved by the reaction bonding and the reaction sintering processes. The powder processing of the metal-ceramic powder mixture greatly determined the type of reactions as well as the furthermore the properties of the final product.

During the milling, the metal component is more reactive to the aqueous and solid media when oxidation, hydrolysis or amorphization is occurred as well as being the mechanical alloying. The size of the metal particles significantly affects the microstructural homogeneity where difficulty in the oxidation during sintering leads to microstructural failures. On the other hand, the fine size of aluminium powder is very dangerous because of its high activity. The size of the metal oxide has greatly determined the microstructure since the newly formed alumina from oxidation of the Al-particles appeared at grain junctions in large particles and showed porous microstructure. It is necessary to use of good enough aluminium additive to achieve the structural and functional properties such as high green strength (strong Al/Al contact bridges) and low shrinkage (due to volume expansion when Al is oxidized to form Al2O3). Thermal treatment of the green bodies in air leads to the formation of alumina/high alumina-containing ceramics, the atmosphere used as reducing/vacuum leads to produce of alumina-aluminate alloys. The significant advantages of the processing lie in the low-cost starting materials, easy green machining, good wear resistance, improved fracture toughness as well as in a broad microstructural and compositional variability of the sintered compacts [1-3].

Mullite type refractory ceramic was produced through the reaction bonding of aluminium oxide process by an attrition-milled mixture of kyanite (Al2O3·SiO3) and sintering of the sample after compaction. Attrition milling creates significant particle size reduction and develops homogeneity of the kyanite-aluminium powder mixture. Nearly half of the aluminium powder was oxidized during milling. The sample is slowly heated to 1100°C in air, and after rapidly heated to 1600°C and held for 1 h. In the course of the oxidation-sintering process, the aluminium oxidizes to alumina through both solid-state and liquid-state oxidation of the milled aluminium metal. This highly reactive alumina combines with the silica that is expelled during the decomposition of the kyanite. A dense, equated fine-grain-size mullite was produced [4]. The addition of 5 wt% of metallic aluminium powder to a refractory composition (designed kaolin clay, andalusite-rich schist, red clay, miocene clayey maly and silica sand) has increased the technological quality of the refractory which increased the resistance to 59.9 MPa where relatively coarse particle size of andalusite rich schist has been used in the composition [5].

The effects of mechanical activation on the sintering of mullite produced from kaolin and aluminium metal powder was investigated with respect to porosities of the ceramic samples. It is found that the open porosities of the samples for 1 h (~20%) of milling are higher than those with 40 h (~1%) of milling [6]. The natural ceramic powder such as kaolin was used for the fabrication of ceramic membrane support by using Al-powder up to 16% weight percent. The mixture was pressed and sintered at 1250°C under air atmosphere. The porosities (28.5%), pore sizes (multi-modal, mean diameter: 2000 nm) and hydrophilic nature (contact angle: 50°) was found to increase with increasing percentage of aluminium. The high metal content in the kaolin matrix has enhanced the mechanical strength of the sample [7].
The synthesis of pure and porous mullite has been investigated from kaolinitic clay with aluminium powder (10.5 wt. %) by sintering in oxidizing atmosphere. The bodies obtained by reactive sintering at 1550°C have a high open porosity initiated during the oxidation of aluminium powder. This porosity increases when a small amount of magnesium powder (3 wt. %) is added. In spite of this high porosity the sintered bodies have a good mechanical cohesion [8]. A highly porous mullite–zirconia composite was investigated from the mixture of zircon and aluminium powders sintered at 1600°C in oxidizing atmosphere. The major oxidation reaction of Al proceeds with a liquid–gas mechanism that is suitable for producing low dense ceramics. TiO₂ addition accelerates the oxidation reaction of aluminium and obtained the high porosities (47%) [9].

The zeolitic ceramic powders have high potential to use for advanced ceramics by the reaction sintering processes. Since wetting of melted aluminium through the silicate matrix is strongly influenced by the presence of impurities. The natural zeolites such as clinoptilolite are high potential for use in ceramic-metal composites where the composition is contained high alkaline and alkaline earth metal cations such as Na⁺, K⁺, Ca²⁺ and Mg²⁺ [10][12], so as the oxides should be decreased the melting temperature more than the kyanite and kaolinite and facilitated fusibility that leading to high liquid phase sintering. By this way, glassy pore wall production is expected.

In this study, high alumina containing porous ceramic is investigated from the reaction-sintering of natural zeolite (clinoptilolite)-aluminium metal powder mixture through applied relatively low firing temperature (at 1200°C) is investigated with respect to the amount of Al-powder contaminations (up to 30 wt.%).

II. EXPERIMENTAL

The starting materials of this study were clinoptilolite-type natural zeolite (Manisa, Gördes, Turkey) and commercial pure aluminium (99% purity). The compositions of the clinoptilolite was analyzed by X-ray fluorescence and obtained as: 75.28% SiO₂, 11.85% Al₂O₃, 3.97% CaO, 2.71% Na₂O, 2.46% K₂O, 1.74% MgO, 1.63%Fe₂O₃, 0.14% TiO₂, 0.09% SO₃, 0.06% P₂O₅, 0.04% MnO. A laser size analyser (Malvern) was used for the particle size distribution determinations and the results are shown in Figure 1. The maximum size of the ceramic and metal powder was similar as 150 µm in size. The aluminium powder has narrow size (average size ~ 3 µm) and the zeolite has finer up to 170 nm in size.

The clinoptilolite and aluminium, mixed in the ratio of 9.5:0.5 to 7:3 by weight, was dry mixing in a ball mill for 5 min. The mixture powder was formed into a green body by uniaxial pressing into a cylindrical steel mould φ 30 mm under a pressure of 50 MPa. Later the samples sintered at the temperatures of 1200°C for 1 hour in an air furnace. The heating and cooling rates of the furnace was 10°C/min.

The crystalline phases of all the sintered samples were identified by X-ray diffraction (XRD) analysis using Rigaku Miniflex powder diffractometer. The measuring rate was of 2°/min. and the interval was of 20°-60°. The microstructure of the samples were investigated by SUPRA 40VP scanning electron microscope (SEM). Apparent porosity and bulk density were measured by water immersion technique according to Archimedes’ principle. Total shrinkage was how much the samples shrinks from its plastic state to its fired state and can be calculated using the following equation:

\[ \%TS = \frac{L_1 - L_2}{L_1} \times 100 \]

where, TS: Total shrinkage, L₁: Length of sample directly after pressing (mm), L₂: Length of fired sample at the temperatures of 1200°C (mm).

III. RESULT AND DISCUSSION

Figure 2 shows firing shrinkage of the clinoptilolite sample without and with AI-powder up to 30% by weight for the sintering temperature at 1200°C. The clinoptilolite without aluminium has the firing shrinkage of about 16.3%. As the sample contained 10% by weight of aluminium, it is observed that significant decrease in the shrinkage which is 6.4%, and after the shrinkage changed is no more with the increase of the aluminium content. The aluminium content between 20-30% by weight, the shrinkage is relatively low and remained constant; it is determined as 3.8%.

Figure 3 shows XRD patterns of the clinoptilolite sample without and with Al-powder. The clinoptilolite without Al-powder shows mainly two major crystalline phases: cristobalite and quartz. The clinoptilolite contained 5% by weight of Al-powder indicates a very small quantity of corundum and Si formation. The corundum and Si peak height increase as the Al-powder increased to 10% by weight. The high Al-powder mixture (20-30% by weight) indicated the crystallization occurred without cristobalite. The mixture with high aluminium content can be considered a corundum material with Si contamination. It may have a potential for use in the ceramic
industry because of its expected high thermal stability as well as high chemical resistance. A low firing shrinkage is observed with the high percentage of Al-powder contained material (see Fig. 2), it consist formation of the high stable phase structure such as corundum (see Fig. 3).

![Figure 2. Total shrinkage of the clinoptilolite sintered without and with Al-powder.](image)

![Figure 3. Phase compositions of the clinoptilolite sintered without (a) and with Al-powder for 5% by wt. (b), 10% by wt. (c), 15% by wt. (d), 20% by wt. (e), 25% by wt. (f), 30% by wt. (g), C: corundum, Cr: cristobalite, S: silicon, Q: quartz](image)

Figure 4a-f show the SEM micrograph of the fracture surface of the samples without and with aluminium for varied amount of metal powder additives. Without the aluminium, the vitrified zeolite phase is shown where some gas evaluation makes the material having some closed porosities. The SEM micrographs of the ceramic bodies reveal the better microstructural features of the ceramic body produced from the aluminium additives at 10% by wt. where it was observed a homogenous pore distribution and less local, massive vitrification of zeolite. As the increase of the amount of aluminium makes the material as high open porosities where the local mass parts changed to fine size of porosity containing parts (see Fig. 4c-g and Fig. 5). The high open porosities observed with the high aluminium contents may be the finer pores appeared between the large size pore connection points. It is found that the samples containing aluminium powder between 10-30% by wt. of aluminium are good enough for the sample to use as a porous filtering material.

![Figure 4. SEM Analysis of the samples from fracture surface where without and with different amount of aluminium additives; without aluminium (a), 5 % wt.(b), 10%wt.(c), 15%wt.(d), 20%wt.(e), 25%wt.(f), 30%wt.(g).](image)

Figure 6 shows the bulk densities of sintered samples without and with varied content of Al-powder. Low content of aluminium up to 10% by weight decreased the densities and after the densities slightly increased by the metal powder contents. The decrease of the densities is attributed that the formed porosities (see Fig. 4c-f and Fig 5). On the other hand, the slightly increase of the densities may be due to the high crystallization of the samples as corundum (see Fig. 3).
samples with high content of aluminium (15-30 % by wt.) show the ceramic material having more stable phase (corundum) with uniform porosities and with smooth pore wall surfaces.

REFERENCES

CONCLUSIONS

The addition of metallic Al-powder up to 30 wt.% on the phase composition and microstructure of clinoptilolite has have investigated for the sintering temperature applied at 1200°C in an oxygen atmosphere. The clinoptilolite without metal powder indicated glassy foam ceramics with less porosities as well as small pore sizes (~10-50 micron). As the metal powder addition with sufficiently amounts (10% by wt.) it makes the material with opened porosities with large sizes (~50 micron). The opened porosity of the sample is measured as 29.7%. The pore wall of the porous structure that is formed is uniform and smooth structure. The increase of the amount of Al-metal powders increased the fine size porosities where the massive vitrification of zeolite is disappeared and the finer pores being appeared. Increasing of the aluminium content leads to increase of the number of fine pores in the ceramic structure. The current results show that the clinoptilolite requires at least %10 by wt. of Al-powder to obtained the samples as capillary porous material where these are significant founding’s: (i) well spreading and wetting, (ii) good enough opened porosities and (iii) sufficiently crystallization of the samples with corundum phases. The milling of the clinoptilolite with Al-powder and the applied sintering temperature are the main factors whose will be further studies to optimization of the capillary porous formation.
Improving Die Filling Utilizing Bi-Directional Forging Process

Abstract—Precision forging (net or near net shape) process is preferred in manufacturing automobile components due to high productivity, closer dimensional tolerances and minimal material waste. The basic drawback of the process is the requirement of higher forging load and encountered tool stresses. This limits the parts size and shape complexity. In this study, uni-directional and bi-directional forging processes are compared in terms of the forging load and die filling for U-shape axisymmetric part. The finite element analysis package (DEFORM) were used to simulate the process, and an experimental work was carried out for verification of the simulation model. A double acting servo press was used for the bi-directional forging. The movement of the top and the bottom punches of the press can be accurately controlled by the servo drive units. The results show that the forging load asymptotically increases at the final corner filling stage. The required forging load is considerably reduced by using bi-directional step loading. The unfilled area at the corner of the U-shape axisymmetric forging is minimized with lower punch load.

Keywords— Precision forging, die filling, finite element method, bi-directional forging, servo-drive press.

I. INTRODUCTION

Enclosed die forging has been developed since the 1970s, which uses one-ram or multi-ram as punches to press the billet in a pre-enclosed die to form a complicated shape forging without flashes [1,2]. As compared with the conventional flashless die forging, in which the billet is compressed between the upper and lower dies, the die cavity can be filled under a lower forming load owing to the reduction of the contract area between the loading punch and the billet material. But as the billet material fills the die cavity, the forming pressure increases sharply. Therefore, it is very important to reduce the forming pressure at the final stage of the process [3-5].

Moreover, the material flow in the case of fully-enclosed die forging is more complicated and difficult to predict. The forging defects (laps, folds, non-filling of dies, etc.) tend to appear. This result in the production of forgings with defects these are unsuitable for subsequent machining.

With recent advancements in software development and the availability of more powerful computers, numerical methods, especially finite element method has been developed. The finite element analysis (FEA) packages have enabled this entire forging process to be simulated, while simultaneously predicting all the necessary stress–strain states in both die and workpiece [6]. Recently, there has been a growing demand for developing enclosed die forging using the servo-press for the forging industry across the world. The development of servo-press realizes the complex and flexible press motion [7-10].

Kawamoto et al [11] focused on utilizing servo die cushion as a back pressure load generator to determine its effect on shape accuracy of the formed part and total forming load in cold forging. They have shown that the back pressure enabled better die filling with lower load. Yetkin et al [12] have shown that the forging load can be reduced and the metal flow can be improved by using bi-directional loading for H-shape axisymmetric part.

In this study, uni-directional (top punch movement), bi-directional (bottom punch movement together with the top punch) and bi-directional step (bottom punch and top punch movement, subsequently) forgings were compared in terms of forging load and die filling under various friction conditions. The initial work was done by using plasticine and the finite element (FE) model was verified. The U-shape axisymmetric forgings of Aluminum 1100 were simulated by using the FEA model and the results were presented.

II. FINITE ELEMENT MODELING

Although, many commercial finite element software packages are available, Deform was used in the study, because it is especially designed for simulation of metal forming processes. Using the rotational symmetry of the U-shape forging, axisymmetric analyses were performed. The die was considered as rigid and the workpiece was modeled as elasto-plastic materials. The dimensions of the preform and the final shape of the forged product are shown in Fig. 1 and Fig. 2, respectively. Three loading conditions were performed as they called uni-directional, bi-directional and bi-directional step loading. The dimensions of the billet were calculated from the final forging using the volume constancy. For the models 5196 elements were formed by using automatic mesh generation. Lagrangian incremental type and the Newton-Raphson Method were used for the solver and the iteration method, respectively. DEFORM uses the AMG (Automatic Mesh Generator) to solve problems of large deformation and to automatically provide an optimized re-meshing capability.
The speeds of the top and bottom dies were chosen as 0 and 1 mm/s according to aforementioned three loading conditions. Because of symmetry, only right one side of the model was used for the FEM simulation to reduce the calculation time.

![Fig. 1 Cylindrical billet for U-Shape Forging](image1)

![Fig. 2 Final geometry of U-shape forging](image2)

**III. EXPERIMENTAL STUDY**

**A. Plasticine specimen preparation**

For the verification of the finite element simulations, a physical modeling technique was used. Due to the capacity limitation (20 kN) of the servo-press used in the study, plasticine was chosen as a modeling material. The true stress-true strain diagram of the plasticine [12] is given in Fig. 3.

In order to make plasticine softer, it was heated to 50°C. Then it was subjected to repeated rolling and folding processes to remove any cavities formed.

A steel tube having 49 mm internal diameter and 50 mm length was completely filled with plasticine dough. Before filling, the internal surface of the tube was dusted with talcum powder in order to prevent sticking. Then the plasticine was pushed out from the steel tube and cut out to pieces having 12.8 mm height.

![Fig. 3 The true-stress true-strain diagram of the plasticine.](image3)

**B. Forging Press and Die Set**

The servo-press shown in the Fig. 4 has two movable punches (top and bottom) driven by two separate servo motors. The maximum capacity of the servo-press is 20 kN. Load cells and linear encoders are attached to the servo-press to plot load-stroke diagram. The die is fixed on the press bed.

The U-shape forging die set (see Fig. 5) consist of four main parts; a container, a bottom punch and two top punches. The parts are made of plexiglass and the dimensions are same as the components used in finite element model.

![Fig. 4 Photograph of the servo-press.](image4)

**C. U-Shape Forging**

By using the servo-press and the plexiglass die set, the plasticine preforms were forged to U-shape. In the forging processes talcum powder was used as the lubricant. Three loading conditions are schematically shown in Fig 6. The speed of the punches (top and bottom) was chosen as 1mm/s for all loading conditions.
IV. RESULTS AND DISCUSSION

A. Plasticine Simulations and Experimental Verification

The experimental and finite element results of load-stroke diagram are shown in Fig 7. The experimental measurements are given by symbols on the diagram. The results revealed that the finite element results and the experimental ones are in a very close agreement. This is verifying the finite element simulations where the friction factor was taken as 0.01.

The maximum forging loads for uni-directional and bi-directional forging conditions are very close to each other as 580 N and 520 N, respectively. The load in bi-directional step loading is considerably lower than the others. The maximum load in step 1 is 300 N and the maximum load in step 2 is 360 N.

B. Al-1100 Simulations

In order to show the effect of loading conditions (uni-directional, bi-directional and bi-directional step) in forging processes, finite element simulations were carried out for aluminum 1100. The material data for aluminum 1100 was taken from the Deform database. The load-stroke diagram of U-shape forgings for friction factor \( m = 0.4 \) is given in Fig 8.
The maximum forging loads for uni-directional and bi-directional forging conditions are very close to each other as 1020 kN and 990 kN, respectively. The load in bi-directional step loading is considerably lower than the others. The maximum load in step 1 is 274 kN and the maximum load in step 2 is 562 kN. The Fe results are summarized in Table I for all loading conditions.

### Table I
FE results for U-shape forgings of Al-1100

</table>

For various friction factors (m), the maximum forging load is given in Fig 9. It can be seen from the figure that the maximum load in uni-directional and bi-directional forgings were higher than the bi-directional step forgings for all friction conditions. This is because of the material flow characteristics during forging. In uni-directional and bi-directional loading conditions, all mass of the body is forced to move in order to fill the die, but in bi-directional step condition a small portion of the mass is subjected to move to fill the die. The corresponding material flows for aforementioned loading conditions are shown in Fig 10.

![Fig 9 Maximum forging load versus friction factor, m.](image)

![Fig 10 Material flow during a) Uni-directional loading b) Bi-directional loading and c) Step Loading](image)

The die filling characteristics of the three loading condition is also given in Table I. The unfilled areas (see Fig 11) for all conditions were determined from the FE model and the unfilled area and corresponding forging load is presented in Fig 12. The improvement in die filling and the reduction in forging load in bi-directional step loading are obvious.

![Fig 11 The die filling and the unfilled area.](image)
V. CONCLUSIONS

The followings can be concluded from the experimental studies and FE simulations:

- As the FE model is verified, the plasticine can be used as a physical modeling material for forging.
- The forging load asymptotically increases at the final corner filling stage.
- The forging loads for all loading conditions are increasing with friction.
- The required forging load is considerably reduced by using bi-directional step loading. The unfilled area at the corner of the U-shape axisymmetric forging is also minimized with lower punch load.

Abstract— Filament winding process commonly is applied for high pressure containers, gas and liquid transfer line, mobile bridging components and military applications. In this production methods, glass fiber generally used in but, mechanical properties of glass fibers are lower than Kevlar, basalt and carbon fibers. Although carbon and kevlar fibers have high mechanical properties, their costs are so high. Therefore, basalt fibers, having high mechanical properties than glass fibers and low cost are preferred and gotten by gaining the significant for the polymer composites as reinforcement material. To improve the mechanical properties of composites especially for polymer matrix, the matrix polymers have been modified with nanoparticle addition. SiO₂ nanoparticles have low cost and ensuring fine mechanical properties. In this present study, the static internal pressure tests were carried out to 4%wt SiO₂ nanoparticle added [±55]₆ BFR and pure [±55]₆ BFR ±6 layers filament wound epoxy composite pipes under open ended conditions. To find possion ratio and young modules of composite pipes strain gauges were used. At the end of experiments, strength and failures of SiO₂ nanoparticle added BFR and pure BFR composite pipes were investigated. It was observed that SiO₂ nanoparticle improved the hoop tensile strength of BFR composite pipes by 29% increase and affected the damage mechanisms.

Keywords— Basalt fiber, SiO₂ nanoparticle, composite, filament wound, mechanical properties.

I. INTRODUCTION

Basalt fiber reinforcement for polymer composites is increasingly used in the industry and plays a significant role in engineering polymer composites for many industrial applications. These reinforcement materials are generally used in high pressure containers which gas and liquid gas such as natural gas, hydrogen gas are deposited, gas transfer pipes, mobile bridging components, trusses, bridge piers and other applications etc. These reinforced composites have high strength-to-weight ratio and fine corrosion resistance [1-3]. However, it still need to widely usage for many application like automotive, aircraft and marine parts and excluded the high pressure application as reinforcement materials. Composite applications for gas cylinders are widely available on industry and they have many advantages and disadvantages. The weight of metal cylinders is an important disadvantage. The weight of a cylinder is reduced by using the reinforced polymers instead of metals. These cylinders maintain their durability due to their high strength and light weight epoxy matrix impregnated carbon fibers used. However, high price and current shortage of carbon fiber cause to high manufacturing cost. Basalt fiber has higher mechanical properties than E-glass fiber and cheaper than carbon fiber[1, 3-4]. These advantages could be a good alternative for gas storage vessels and pipes. Basalt fiber is readily available natural materials and produced from volcanic rocks that are found worldwide. Basalt fiber is environmental and nonhazardous materials. For high pressurized pipes, the filament winding method commonly used to produce the composite pipes to provide the high strength. The filament winding process allows a thermost resin-impregnated glass, carbon and basalt reinforcement to be wrapped around a suitable mandrel. The resin-impregnated fiber bundles wrap over the rotating mandrel and orientated according to ± lay-up angle to form the designed reinforced pipes. After that winding process, the component is cured under the defined temperature. Mechanical properties of the filament wound parts do not just depend from composition of component material. In addition, process parameters like winding angle, fiber tension, resin type and curing cycle effects the mechanical properties of filament wound parts [4-6]. The usage of the nanoparticles to improve the mechanical properties of polymer composite, is widely increased and gotten important for scientific people and industry. And so, many studies have been executed about the nanoparticles applications on polymer composites. In the polymer composite studies, carbon nanotubes, SiO₂, Al₂O₃ nanoparticles and nano clay are the best preference for researchers [7-8, 10]. Deng et al. (2007) studied on the fracture toughness of 0, 2, 4, 6, 8wt% SiO₂/Epoxy nanocomposites. They founded that silane modification provide the easy dispersion in the epoxy matrix material. They determined that the fine fracture toughness are attained at 4wt% SiO₂/Epoxy nanocomposites. They proved this definition with TEM analysis [8]. Sadej-Bajerlain et al. (2011) conducted to 0, 2, 4, 5, 10%wt Aerosil7200 and AerosilR711 silane surface modified SiO₂/Epoxy nanocomposites. The defined that 4%wt SiO₂ nanoparticle addition to epoxy matrix shows the best dispersion than other additions with AFM tests and TEM analysis [9].

In this study, we aimed to investigate experimentally burst failure of 4wt% SiO₂ nanoparticle added and pure [±55]₆ Basalt/Epoxy filament wound pipes under internal pressure at
open ended condition. Whitening and final bust failures of 4wt% SiO\textsubscript{2} nanoparticle added and pure BFR pipes have been observed.

II. MATERIAL AND METHOD

Basalt fiber with 400 Tex (BFR) and 11-13µm diameter is used as reinforcement and Ciba Geigy Bisphenol-A Epoxy CY225 resin system is used as matrix. As nanoparticle, SiO\textsubscript{2} nanoparticle which is 650g/m\textsuperscript{2} SSA and 15 nm mean diameters particle size has been used. 4wt% SiO\textsubscript{2} nanoparticle was added to epoxy matrix of BFR composite. After adding SiO\textsubscript{2} nanoparticle to matrix, the mixture have been stirred by sonicator during 20 min, and then, 40wt% curing agent added to the mixture and mechanically stirred by mechanic mixer during 5 min(Fig.1). End of the mixture processes, SiO\textsubscript{2} nanoparticle added mixture was placed into the filament winding machine resin chamber. 4wt% SiO\textsubscript{2} nanoparticle added and pure [±55\textdegree] Basalt/Epoxy filament wound pipes are produced at the filament winding facilities of commercial filament winding company. The wet winding method used for the production of the composite pipes with ±55 lay-up. For the geometry of composite specimen, ±6 layers of reinforcement, 2.63mm of thickness, 72mm inner diameter and 300mm length of specimen [10].

III. RESULTS AND DISCUSSION

Burst failure and damage formation of 4wt% SiO\textsubscript{2} nanoparticle added and pure [±55\textdegree] Basalt/Epoxy filament wound composite pipes were investigated with internal pressure experiments. End of the internal pressure hoop tensile strength of 4wt% SiO\textsubscript{2} nanoparticle added and pure [±55\textdegree] Basalt/Epoxy composite pipes are give in Fig. 2.

Fig. 1 a) SiO\textsubscript{2} nanoparticle mixing processes b) internal pressure test apparatus [10].

Open ended internal pressure test apparatus are given in Fig. 1b. According to ASTM D2992 standard. To determine other mechanical properties, axial and tangential LY13 type strain gages were placed on midpoint of composite pipes[10].

From the observation of during the experiment, the first failure sign was the formation of whiting line which stem from debonding failure along the basalt fiber oriented direction on ±55\textdegree filament wound BFR pipes. This failure occurred and progressed as thin white lines parallel to fiber direction due to the departure of fiber from matrix all along fiber bundle. As increasing internal pressure, debonding failure have been concentrated on fiber bundle by increasing and end of critical accumulation of debonding failure on same bundle, layer separation as called the delamination have been occurred. More and more increasing pressure increased swelling of pipe at center zone and so diameter of pipe especially at center zone extended. In addition the pipe length got short by increasing pressure. The whiting failure firstly were seen about 375-410 MPa stress values. End of step, basalt fibers were exposed the last failure by tearing as fiber breakage with burst at 595 MPa. These failure mechanisms are indicated on BFR composite pipe in Fig. 3. [10].

When Samanci’s study were investigated, whiting failure and burst failure were observed about 100 MPa and 405 MPa stress values respectively and elasticity modules were found to be about 23.17 GPa[11]. Our experimental results show that the whiting and burst failure of BFR pipes has higher than GFR pipes as well as elasticity of BFR pipes. Burst failure of BFR pipes are presented in Fig. 3. When Internal pressure tests were applied 4wt% SiO$_2$ nanoparticle added [±55]$_6$ Basalt/Epoxy composite pipe, similar observations just as failure mechanism of [±55]$_6$, Basalt/Epoxy composite pipe have been seen as near as 733 MPa hoop tensile strength. After this strength, SiO$_2$ nanoparticle added BFR composite pipe have been started to bend like three point bending test. This bending of SiO$_2$ nanoparticle added BFR composite pipe have been continued as about 769.2 MPa hoop tensile strength [10]. In this strength of composite pipes, fluid jets failure end of the forming pin holes into layers were occurred on different regions caused by accumulation of debonding, delamination and fiber breakage failures. Fluid jets occurred on composite pipes is matrix failure. When the debonding and delamination failures defined as matrix failures concentrate on fiber bundle, layer and interlaminar layer by accumulating, and reach the critical levels, pin hole matrix damages form into the layer and then fluid jet occurs as final failure given in Fig. 4[5, 10,12].

![Fig. 3 The final failure of [±55], filament wound Basalt/Epoxy composite pipes.](image1)

![Fig. 4 The final failure of 4wt% SiO$_2$ nanoparticle added [±55], Basalt/Epoxy composite pipes.](image2)

When compared 4wt% SiO$_2$ nanoparticle added and pure [±55]$_6$, Basalt/Epoxy composite pipes each other by considering hoop tensile strengths and final failure of composite pipes, SiO$_2$ nanoparticle addition increased the hoop tensile strength of composite pipe and fluid jets failure occurred instead of burst failure which occurred on pure [±55]$_6$, Basalt/Epoxy composite pipes. It was commented from this results that SiO$_2$ nanoparticle retarded the forming nano, micro and macro scale matrix cracks by providing fracture mechanism of SiO$_2$ nanoparticles like crack pinning, crack tip blinding, crack bowling and branching, retarding of crack occurrence and propagation, local plastic deformation and increasing the interface area[10-13].

IV. CONCLUSION

As results of experiments of open ended internal pressure, the mechanical properties of 4wt% SiO$_2$ nanoparticle added and pure [±55]$_6$ Basalt/Epoxy composite pipes were determined and compared eachother. Obtained inferences from experiments can be itemized below.

- The increasing internal pressure increase the debonding and delamination matrix failure and the first whiting failure which sign of debonding and delamination were seen about 375-390 MPa for pure [±55]$_6$, Basalt/Epoxy composite pipes. For 4wt% SiO$_2$ nanoparticle added [±55]$_6$, Basalt/Epoxy composite, accumulated whiting failures along the basalt fiber bundles were seen about 733MPa.
- The final failure occurred with burst of composite pipes of pure [±55]$_6$, Basalt/Epoxy composite pipes were observed at about 595 MPa the hoop tensile stress value and for the final failure as fluid jets of SiO$_2$ nanoparticle added [±55]$_6$ Basalt/Epoxy composite, the average hoop tensile strength have been seen at 769 MPa. And so, it’s the average increase was 29%
higher than \([±55]_6\) Basalt/Epoxy composite. SiO\(_2\) nanoparticle addition provided \(±18\) increase to \([±55]_6\) Basalt/Epoxy composite.

The usage of SiO\(_2\) nanoparticle for BFR pipes is very alternative application according to provided their mechanical properties which given above. The cost of BFR composite pipes by adding nanoparticles are lower than CFR (Carbon Fiber Reinforced) composite pipes and can ensure higher mechanical properties than CFR composite pipes. For gas transport line and liquid gas storage SiO\(_2\) nanoparticle added BFR composite pipes and vessels can be applied as safely.

Abstract—Concrete is irreplaceable material in civil engineering world owing to its superior characteristics like strength, moldable, cost-effective and available components that result in widespread utilization. Growing concerns for carbon dioxide (CO₂) emission manipulate concrete designs for more environment-friendly mixtures bearing in mind that cement is responsible for 7% of overall (CO₂) emission. Production of large amount of cement can be limited by designing long-lasting concrete applications that directly contributes to sustainable development. Recent developments in nanotechnology have led to exploitation of nano-scale products for cementitious composites that exhibit high performance and durable properties. Among nano-scale products, nanosilica materials present unique benefits in cementitious-based systems compared to conventional additives. The purpose of using ultra-fine nanosilica particles in cementitious composites is to improve fresh and hardened properties of composites. Taking into account that there is a link between the micro-scale structure and bulk structure of material, it is quite important to unite both scale in engineering manner. For this reason, researchers study to understand fundamental science of nanosilica on pozzolanic reaction kinetics, morphology and hydration structure in order to control properties at nano-scale that can make radical changes in bulk properties. In this paper, utilization of nanosilica powder in cementitious composites was extensively reviewed considering the wide range of research that were undertaken to enhance performance of cement-based materials. In addition to general approaches in nanosilica applications, some issues that are required to be addressed were summarized in order to take full benefits of nanotechnology. Future challenges in the use of nanosilica in civil engineering applications were considered and potential alternative applications were also discussed within the scope of this paper.

Keywords—Civil engineering, Material science, Sustainable materials, Cementitious composites, Nanosilica

A. Introduction

Civilization in parallel with economic development has always been close relationship with the civil engineering. It is known that concrete is a dominating material in civil engineering compared to other construction material in terms of its production amount and vital importance on structures. Over a century, huge amount of Portland cement and aggregates are required in order to develop infrastructures in the forms of airports, dams, bridges, buildings, etc. which play essential roles in the human life. In last few decades, attention was drawn by production of cement particles which cause detrimental effects to atmosphere. Also, raw materials such as lime, clay and coal that is used in cement kiln trigger reduction of productive soil and forest lands. In cement market today, production of cement has reached to 4 billion ton causing 7% of all CO₂ emissions in the world [1]. Construction industry has also some initiatives to barrier CO₂ emissions and control the production of cement along with the other industries [2]. However, considering the increase of cement production, concrete applications should serve within its designed lifespan beside other environmental efforts.

In European design codes, lifespan of reinforced concrete structures is accepted as 75 years [3]. However, a great deal of structures are become out of service even before their half of lifespan due to mechanical loads and environmental effects. Short lifespan of structures, rehabilitation and reconstruction of damaged structures and detrimental effects of these activities cause great expenses for economy. It is obvious that beneficial elements are required to create sustainable construction industry. For this reason, concrete, the most important composite material in construction world, should exhibit longer durability properties as well as providing energy efficiency. Deterioration of concrete is attributed to mechanical, physical and chemical interactions that can occur in different ages of concrete. Cracks can critically damage the concrete due to brittle property of concrete. Damages consist of durability problems such as corrosion that leads to rigidity reduction of concrete, freeze-thaw cycles, alkaline-aggregate reactions, sulfate attack, aggressive water attacks, acidic attacks etc. Only few studies, deal with all of the abovementioned issues, exploit the advanced materials technology. In these studies, scientists take advantage of nanotechnology products that contain many novelties. Nanotechnology means the controlling, producing and understanding of materials at nano scale (below 100 nm, 1 cm = 10⁻⁹ nm) in order to create new functionalities and properties for materials [4]. Nanomaterials draw interest in construction materials world and many studies are carried out because of superior functional characteristics of nano products. In civil engineering, nanotechnology refers to use of materials at nanoscale in order to engineer bulk properties of that material. Therefore, nano-engineered concrete provides many benefits such as strength, performance and durability at once compared to conventional
concrete. Progress of high performance concrete was illustrated in Figure 1.

B. Influence of nanosilica in cement based composites

Micro and nano-scale silica particles fill between cement particles and act as filler effect. Strength of materials can be improved by designing accurate composition and concrete mixtures can be produced with low water/cement ratio. Besides physical effect, nano silica particles have much more pozzolonic reaction effect compared to silica fume. For this reason, high performance concrete can be designed by tailoring of beneficial effects [5, 6, 7]. However, primary requirement of this production is to disperse nano silica homogeneously into cementitious composites. In the opposite case, inhomogeneous particles can lead to voids and weak zones [8].

In last decade, numerous studies are undertaken by taking advantage of the nano silica, carbon nanotubes, nano titanium, nano alumina etc. Among nano products, nano-silica (SiO2) has been one of the most used nano material in advanced concrete studies since hydration mechanism of nano silica is still complex process and understanding of its mechanism is required to be focused on. Nowadays scientists study on the mechanical and durability properties of cementitious composites incorporating nano silica in order to enhance impermeability. Investigations comprise hydration kinetics of nano silica, micro structure healing, and fresh/hardened properties of cementitious composites.

The reason of producing high performance concrete with nano silica admixtures is reaction mechanism of cement hydration in the presence of nano silica. Cement hydration can be accelerated by nano silica admixture. In the case of nano-silica inclusion into cement particles, H2SiO4 occurs and react with Ca2+ so that additional C-S-H (calcium-silica-hydrate) which improves the strength and durability of concrete is formed. By this way, additional C-S-H products disperse in water and fill the spaces between cement particles. Additional products induce more compact C-S-H phases and seeding effect takes place in cement hydration. C-S-H phase not only takes place in cement particles but also acts in other voids thus many seeding products accelerate the early hydration of cement. In literature, acceleration of cement paste hydration and earlier occurrence of calcium hydroxide have been investigated extensively in many studies [9, 10, 11, 12, 13, 14]. In these studies, setting time of nano silica incorporated cement pastes is reduced and early hydration time is achieved as soon as possible in order to generate calcium hydroxide in shorter time. In similar studies, it was found that, in the presence of nano silica, C3S decomposed faster than normal cement hydration14. Micro analysis of these studies support the findings of abovementioned issues so far[15] (Figure 2).

It is known that nano-silica inclusion increase the C-S-H and C-A-H (calcium-alumina-hydrate) products in cement paste[16]. In addition to that, utilization of nano silica based activators triggers fly ash to assist more dense and less porous structure for composite production. For this reason, nano silica particles provide mineral admixture containing composites to perform better properties in an economic way [17]. Furthermore, nano silica additive contributes the thermal stability of cementitious material systems. For example, compared to silica fume incorporation into specimens, nano silica incorporated specimens have exhibited less strength loss at 500 C after the gradually increased temperatures [18]. It was also revealed that cement mixtures containing nano silica and
fly ash exhibited adequate strength performance up to 700 C and residual strength was not so different from the virgin ones. This is because after dehydration of C-S-H products, residual calcium silicate act as a new binder so that composite still perform its strength [19]. Nano silica incorporated composites have also low permeability characteristics and penetration of water is limited by nano silica presence. Therefore, healing of porous zones can be helpful to durable utilization of cementitious composites [20, 21, 22, 23, 24]. Studies mentioned at present can give point of view for the innovative research in civil engineering. Applications of nanotechnology have breakthrough potential in material technology. In the future, utilization of nano materials will contribute to many innovative materials owing to material design based on performance. As one of the most preferred nano product, importance of nano silica has been understood for a decade. In the light of mentioned issues, benefits of nano silica can be summarized as; enhancement of strength, blocking of porous structures, Acceleration of cement hydration and improvement of durability properties of concrete. Typical advantages of nano silica were also summarized in Figure 3.

It is obvious that, different properties of materials used in the investigations are the reason of this variability. Therefore, there is a necessity for novel method exhibiting the all functional improvements rather than mineral additive. Compared to other ingredients of concrete, additive of nano silica into concrete is more time-consuming. In addition to that there is a contradiction for each type of process that specify the optimum homogenous dispersion. Generally nano silica is added into mixtures by using sonication, homogenization or physical mixing process. Duration of this process, solution/nano silica ratio and variation of inclusions trigger different results since over mixing can change the texture of nano materials. In the same manner, shorter duration of mixing can lead to agglomeration of nano particles due to nano materials bonds. Beside these problems, usage of high range water reducer admixture can also have significant effect because of addition process [25]. It can be said that such details are not effective way to design cementitious composites in the real applications. For this reason novel, innovative and effective nano silica application is required to develop. One way of realizing this is to develop nano silica based solutions that can heal the cracks of cementitious composites or improve the durability and mechanical properties of composites. To practice it, the most effective curing solution and effective way of producing this method need to be studied. By this way significant savings of cement can be achieved and lifespan of structures can be extended. As it is mentioned in the earlier parts of this review, environmental problems of cement production can be limited by means of nano silica solution. The main purpose of this research should meet the strength loss of cementitious composites owing to superior pozzolonic reactivity of nano silica. Investigations that exploit the nanotechnology products can enable the designing of high performance concrete so that maintenance and rehabilitation cost of reinforced concrete buildings can be lowered. The main target of these studies need to address the following issues;

1) Observation of nano silica effect pervasively on the all surface of specimens
2) Determination of penetration tendency on the cementitious composites.
3) To specify the pozzolanic reactions to what extent in order to use these products for the enhancement of Durability properties.
4) Investigation of additional C-S-H on the virgin and damaged cementitious composites.

Novel findings are required to meet the summarized outputs as given in Figure 4.

C. Potential investigations and discussion

Utilization of nano silica is beneficial for improving the properties of cementitious composites. At the present time, no nanomaterial exists except nano silica that can improve both parameter, strength and durability for cementitious composites. However numerous studies exist that contradicts between themselves. Although contradictions for other ingredients ratio in the cementitious composites can be accepted, it is not the same for nano materials additives. In the conducted studies, it is normal to expect more accurate findings for nano silica material since economic aspect of nano materials is crucial. In this review, it can be said that ratio of nano silica in the use of cementitious composites has not been clearly determined in the surveyed studies.
Homogenously dispersion problem, variable results, high dosage of usage (%5-6 by weight of cement), high cost, increase of water demand at given workability are the drawbacks of nano silica utilization in the cementitious composites. Although nano silica additive has many advantages, abovementioned problems are needed to be resolved. 1 kg of micro silica correspond to 4 kg of cement in concrete mixtures. By taking advantage of nano silica more cement savings can be achieved. Cost of nano materials have decreased dramatically over decade however nano materials have still high cost compared to other ingredients of materials used in concrete. It is vital that functional nano silica applications should be improved by taking the account of cost parameter. Such investigations can assist to develop high amount of mineral admixture incorporated specimens by means of additional C-S-H so contribution to preservation of natural resources and energy efficient studies can also be realized.

It can be said that many researchers have studied the effects of nano silica on the cement paste or cement mortar although nano silica incorporated concrete investigations are less studied. Effects of nano silica on the absorption and mechanical properties of the cementitious composites are required to be focused on more extensively. Innovative studies can be beneficial especially for developing applicable and effective repairment material. Dispersion process and physical state of nano silica in concrete are still contradictory issues. Although dispersive agents are used in the process of dispersion, these kind of methods still leave questions marks over minds. The more innovative nano silica studies are conducted the easier and more effective applications can be achieved for civil engineering.

D. Conclusions

Comparison of Optical and Electrical Conductance and Refractive Index Values of the PTCDI-C5 Small Molecule for Various Relations and Conditions

Bayram Gündüz*

*Department of Science Education, Faculty of Education, Muş Alparslan University, Muş 49250, Turkey
bgunduz83@hotmail.com

Abstract—The optical and electrical conductance of the PTCDI-C5 small molecule for different molarities and solvents were compared and the refractive index values of the PTCDI-C5 for various relations (experimental, Moss, Ravindra, Herve-Vandamme, Reddy and Kumar-Singh), different molarities, solvents and types of the optical band transitions were obtained. Effects of molarities and solvents on optical and electrical conductance of the PTCDI-C5 were investigated. Also, effects of various relations, molarities, solvents and types of the optical band transitions on refractive index of the PTCDI-C5 were investigated in detail. The refractive index values were controlled.

Keywords—Optical and electrical conductance, PTCDI-C5 small molecule, refractive index, molarity, solvent.

I. INTRODUCTION

Organic materials (OMs) such as organic polymers (OPs), organic conjugated polymers (OCPs), organic semiconductors (OSC) and organic nanomaterials (ONMs) have received substantial attention for many applications [1] such as diodes, solar cells (SCs), switches, displays, lasers, transistors, photovoltaics, sensors, generators, conversions, detectors [2-9]. To fabricate such devices, the fundamental properties of the materials are significant to determine suitable device or devices. OSCs such as N,N'-bis(2-((5-(dimethylamino)methyl)furan-2-yl)methylthio)ethyl) perylene-3,4,9,10-tetracarboxylic imide) PTCDI can be used in fabrication of the optoelectronic devices. PTCDIs have high photosensitivity, highly versatile molecules, high fluorescent quantum yield and low HOMO-positions [10].

Furthermore, many scientists made many researches on various materials for many applications. Lopez et al. [11] showed that the refractive index decreased with increasing flow ratio (Ro). Ali et al. [12] reported a Y_{0.225}Sn_{0.775}CoO_3 thin film for MgO (111) single crystal substrate with a dispersion energy value of 10.0 eV, a single-oscillator energy value of 3.76 eV, a M,1 moment value of 2.66 and a M,3 moment value of 0.19 eV⁻². Lalova and Todorov [13] varied the n value of the films from 1.78 to 2.42 at 1550 nm. Purniawan et al. [14] found the refractive index ratio (1.8) for ethanol and isopropyl alcohol (IPA). Manera et al. [15] reported that the refractive index (n) and reflectance values increased with increasing incident angle.

In this study, the aim is to compare the optical and electrical conductance of the PTCDI-C5 small molecule for different molarities and solvents and is to obtain the refractive index values of the PTCDI-C5 for various relations (experimental, Moss, Ravindra, Herve-Vandamme, Reddy and Kumar-Singh), different molarities, solvents and types of the optical band transitions.

II. EXPERIMENTAL DETAILS

PTCDI-C5 small molecule, chloroform, chlorobenzene and toluene solvents were used in this study (bought from Sigma–Aldrich Co.). The solutions of the PTCDI-C5 for different molarities and solvents were prepared. Then, the UV measurements for these materials were recorded.

II.A. THE SOLUTIONS FOR DIFFERENT MOLARITIES AND SOLVENTS

The molecular weight and formula of the PTCDI-C5 molecule are 530.61 g/mol and C_{30}H_{26}N_{2}O_{5} respectively. To prepare the solutions, The PTCDI-C5 material was weighed with a AND-GR-200 Series Analytical Balance (United States) for 6.618 and 0.654 mM molarities and for 0.436 mM of the chloroform, toluene and chlorobenzene solvents. After that, these PTCDI-C5 materials weighed for different molarities and solvents were dissolved homogeneously in related solvents.

II.B. THE UV MEASUREMENTS FOR DIFFERENT MOLARITIES AND SOLVENTS

The UV measurements for different molarities and solvents were performed by solution technique. For this, the cylindrical cuvettes (Hellma QS-100), whose optical path length and volume are 10 mm and 3.5 mL, respectively. The UV measurements of the PTCDI-C5 material for different molarities and solvents were recorded with a Shimadzu model UV-1800 Spectrophotometer at room temperature.

III. RESULTS AND DISCUSSION

III.A. COMPARISON OF OPTICAL AND ELECTRICAL CONDUCTANCE OF THE PTCDI-C5 FOR DIFFERENT MOLARITIES AND SOLVENTS
Conductance is an important parameter for optoelectronic devices. The optical conductance ($\sigma_{\text{op}}$) and electrical conductance ($\sigma_{\text{elec}}$) of the OMs can be obtained from [16],

$$\sigma_{\text{op}} = \frac{\alpha n c}{4\pi}$$

(1)

and

$$\sigma_{\text{elec}} = \frac{2\lambda\sigma_{\text{op}}}{\alpha}$$

(2)

where $\alpha$ is the absorption coefficient, $n$ is the refractive index, $c$ and $\lambda$ are the velocity and wavelength of light, respectively. The optical and electrical conductance values of the PTCDI-C5 molecule for different molarities and solvents were obtained from Eq. (1) and (2), respectively. Fig. 1(a,b) shows the $\sigma_{\text{op}}$ and $\sigma_{\text{elec}}$ plot vs. E of the PTCDI-C5 for 6.618 and 0.654 mM. As seen in Fig. 1(a,b), molarity has a significant effect on $\sigma_{\text{op}}$ and $\sigma_{\text{elec}}$ values of the PTCDI-C5. As seen in Fig. 1(a,b), the optical and electrical conductance of the PTCDI-C5 increase significantly with increasing molarity and the form of the $\sigma_{\text{op}}$ and $\sigma_{\text{elec}}$ curves varies due to high absorption coefficient with molarity. Also, the $\sigma_{\text{op}}$ values of the PTCDI-C5 for 6.618 and 0.654 mM are higher than the $\sigma_{\text{elec}}$ values of the PTCDI-C5 as seen in Fig. 1(a,b). These results indicate that the optical and electrical conductance of the PTCDI-C5 can be increased with increasing molarity and molarity affects the form of the optical and electrical conductance curves.

Fig. 2(a,b) indicates the $\sigma_{\text{op}}$ and $\sigma_{\text{elec}}$ plot vs. E of the PTCDI-C5 for chloroform, toluene and chlorobenzene solvents. As seen in Fig. 2(a,b), the forms of the $\sigma_{\text{op}}$ and $\sigma_{\text{elec}}$ curves of the PTCDI-C5 are close to each other, but the average $\sigma_{\text{op}}$ and $\sigma_{\text{elec}}$ values for toluene are the highest. As seen in Fig. 2(a,b), the $\sigma_{\text{op}}$ and $\sigma_{\text{elec}}$ of the PTCDI-C5 exhibit the maximum peaks between about 2.3 and 2.65 eV. The $\sigma_{\text{op}}$ values of the PTCDI-C5 for chloroform, toluene and chlorobenzene solvents are higher than the $\sigma_{\text{elec}}$ values of the PTCDI-C5 as seen in Fig. 2(a,b). Obtained results show that for higher optical and electrical conductance values of the PTCDI-C5, toluene can be preferred according to chloroform and chlorobenzene solvents and the optical and electrical conductance can be varied with solvents.

**Fig. 2.** The (a) optical conductance ($\sigma_{\text{op}}$) and (b) electrical conductance ($\sigma_{\text{elec}}$) plot vs. E of the PTCDI-C5 for chloroform, toluene and chlorobenzene solvents.

### III.B. REFRACTIVE INDEX VALUES OF THE PTCDI-C5 FOR VARIOUS RELATIONS, DIFFERENT MOLARITIES, SOLVENTS AND TYPES OF THE OPTICAL BAND TRANSITIONS

The refractive index ($n$) is an important parameter for optoelectronic applications and technologies. The $n$ is known to decrease with energy gap. The $n$ can be calculated by [17,18],

$$n = \left[ \frac{4R}{(R-1)^2 - k^2} \right]^{1/2} - \frac{R+1}{R-1}$$

(3)
The n values of the PTCDI-C5 molecule for different molarities and solvents were calculated from Eq. (3). Obtained n values are given in Tables I(a) and II(a), respectively. As seen in Table I(a), the n value (3.118) of the PTCDI-C5 for 0.654 mM is lower than the n value (3.337) of the PTCDI-C5 for 6.618 mM. As seen in Table II(a), the n value (3.096) of the PTCDI-C5 for chloroform solvent is the lowest, while the n value (3.129) of the PTCDI-C5 for toluene solvent is the highest. Obtained results suggest that the refractive index of the PTCDI-C5 can be increased with increasing molarity and can be controlled by solvents.

There are many relations such as experimental, Moss, Ravindra, Herve-Vandamme, Reddy and Kumar-Singh between the energy gap and refractive index of semiconductors [19] and these relations are extensively used to determine the refractive index. In our previous study [1], we obtained the direct ($E_{gd}$) and indirect optical band gap ($E_{g}$) values of the PTCDI-C5 semiconductor for 6.618 and 0.654 mM. These $E_{gd}$ and $E_{g}$ values are as given in Table I(a,b). Similarly, in our another previous study [10], we obtained the $E_{gd}$ and $E_{g}$ values of the PTCDI-C5 semiconductor for chloroform, toluene and chlorobenzene solvents. These $E_{gd}$ and $E_{g}$ values are as seen in Table II(a,b).

Moss relation is given by

$$n = \left( \frac{95 \text{eV}}{E_g} \right)^{1/4}$$

(4)

For different molarities and Moss relation, the n values of the PTCDI-C5 molecule at the related $E_{gd}$ and $E_{g}$ values were obtained from Eq. (4) and are given in Table I(a,b). As seen in Table I(a,b), the n values (2.537 and 2.557, respectively) for 0.654 and 6.618 mM at the $E_{gd}$ values are lower than the n values (2.547 and 2.584, respectively) for 0.654 and 6.618 mM at the $E_{g}$ values. Similarly, for different solvents and Moss relation, the n values of the PTCDI-C5 molecule at the related $E_{gd}$ and $E_{g}$ values were obtained from Eq. (4) and are given in Table II(a,b). As seen in Table II(a,b), the n values (2.542, 2.565 and 2.545, respectively) for chloroform, toluene and chlorobenzene solvents at the $E_{gd}$ values are lower than the n values (2.555, 2.578 and 2.562, respectively) at the $E_{g}$ values.

Ravindra relation is given by

$$n = 4.084 - 0.62E_g$$

(5)

For different molarities and Ravindra relation, the n values of the PTCDI-C5 molecule at the related $E_{gd}$ and $E_{g}$ values were obtained from Eq. (5) and are given in Table I(a,b). As seen in Table I(a,b), the n values (2.663 and 2.707, respectively) for 0.654 and 6.618 mM at the $E_{gd}$ values are lower than the n values (2.685 and 2.763, respectively) for 0.654 and 6.618 mM at the $E_{g}$ values. Similarly, for different solvents and Ravindra relation, the n values of the PTCDI-C5 at the related $E_{gd}$ and $E_{g}$ values were obtained from Eq. (5) and are given in Table II(a,b). As seen in Table II(a,b), the n values (2.672, 2.724 and 2.681, respectively) for chloroform, toluene and chlorobenzene solvents at the $E_{gd}$ values are lower than the n values (2.702, 2.750 and 2.718, respectively) at the $E_{g}$ values.

Herve-Vandamme relation is given by

$$n = \left( 1 + \frac{4}{E_{gd}B} \right)^{1/2}$$

(6)

where A is the hydrogen ionization energy 13.6 eV and B = 3.47 eV is a constant assumed to be the difference between the band gap energy and UV resonance energy. For different molarities and Herve-Vandamme relation, the n values of the PTCDI-C5 molecule at the related $E_{gd}$ and $E_{g}$ values were obtained from Eq. (6) and are given in Table I(a,b). As seen in Table I(a,b), the n values (2.563 and 2.591, respectively) for 0.654 and 6.618 mM at the $E_{gd}$ values are lower than the n values (2.577 and 2.626, respectively) for 0.654 and 6.618 mM at the $E_{g}$ values. Similarly, for different solvents and Herve-Vandamme relation, the n values of the PTCDI-C5 at the related $E_{gd}$ and $E_{g}$ values were obtained from Eq. (6) and are given in Table II(a,b). As seen in Table II(a,b), the n values (2.569, 2.601 and 2.574, respectively) for chloroform, toluene and chlorobenzene solvents at the $E_{gd}$ values are lower than the n values (2.587, 2.618 and 2.597, respectively) at the $E_{g}$ values.

Reddy relation is given by

$$n = \left( \frac{154}{(E_{gd}-0.365)} \right)^{1/4}$$

(7)

For different molarities and Reddy relation, the n values of the PTCDI-C5 molecule at the related $E_{gd}$ and $E_{g}$ values were obtained from Eq. (7) and are given in Table I(a,b). As seen in Table I(a,b), the n values (2.990 and 3.018, respectively) for 0.654 and 6.618 mM at the $E_{gd}$ values are lower than the n values (3.004 and 3.056, respectively) for 0.654 and 6.618 mM at the $E_{g}$ values. Similarly, for different solvents and Reddy relation, the n values of the PTCDI-C5 at the related $E_{gd}$ and $E_{g}$ values were obtained from Eq. (7) and are given in Table II(a,b). As seen in Table II(a,b), the n values (2.996, 3.029 and 3.001, respectively) for chloroform, toluene and chlorobenzene solvents at the $E_{gd}$ values are lower than the n values (3.015, 3.047 and 3.025, respectively) at the $E_{g}$ values.

Kumar-Singh relation is given by

$$n = 3.366E_{gd}^{-0.32234}$$

(8)

For different molarities and Kumar-Singh relation, the n values of the PTCDI-C5 molecule at the related $E_{gd}$ and $E_{g}$ values were obtained from Eq. (8) and are given in Table I(a,b). As seen in Table I(a,b), the n values (2.577 and 2.603, respectively) for 0.654 and 6.618 mM at the $E_{gd}$ values are lower than the n values (2.590 and 2.639, respectively) for 0.654 and 6.618 mM at the $E_{g}$ values. Similarly, for different solvents and Kumar-Singh relation, the n values of the PTCDI-C5 at the related $E_{gd}$ and $E_{g}$ values were obtained from Eq. (8) and are given in Table II(a,b). As seen in Table II(a,b), the n values (2.582, 2.614 and 2.588, respectively) for chloroform, toluene and chlorobenzene solvents at the $E_{gd}$ values are lower than the n values (2.600, 2.630 and 2.610, respectively) at the $E_{g}$ values. These results indicate that the refractive index for experimental, Moss, Ravindra, Herve-Vandamme, Reddy and Kumar and Singh relations increases with increasing molarity and the n values of the $E_{gd}$ are higher than the n values of the $E_{g}$ values. Also, the refractive index for experimental, Moss, Ravindra, Herve-Vandamme, Reddy
and Kumar and Singh relations can be controlled with various solvents.

Thus, the refractive index values of the PTCDI-C5 for different molarities at the related E_{gd} and E_{gid} values were obtained from experimental, Moss, Ravindra, Herve-Vandamme, Reddy and Kumar and Singh relations (see Fig. 3(a,b)). Similarly, the refractive index values of the PTCDI-C5 for different solvents at the related E_{gd} and E_{gid} values were obtained from experimental, Moss, Ravindra, Herve-Vandamme, Reddy and Kumar and Singh relations (see Fig. 4(a,b)). As seen in Figs. 3(a,b) and 4(a,b), the refractive index values obtained from experimental data are the highest, while the refractive index values obtained from Moss relation are the lowest.

Fig. 4. The refractive index values of the PTCDI-C5 for different solvents obtained from various relations at the related (a) E_{gd} and (b) E_{gid} values.

IV. CONCLUSIONS

The optical and electrical conductance of the PTCDI-C5 semiconductor for different molarities and solvents were compared. Then, the refractive index values of the PTCDI-C5 for various relations, different molarities, solvents and types of the optical band transitions were obtained. The optical/electrical conductance and refractive index values of the PTCDI-C5 increase with increasing molarity. For higher optical and electrical conductance values of the PTCDI-C5, toluene can be preferred according to chloroform and chlorobenzene solvents. The refractive index (n) for
experimental, Moss, Ravindra, Herve-Vandamme, Reddy and Kumar and Singh relations increases with increasing molarity and the n values of the indirect optical band gap ($E_{\text{gid}}$) are higher than the n values of the direct optical band gap ($E_{\text{gd}}$) values. Also, the refractive index for experimental, Moss, Ravindra, Herve-Vandamme, Reddy and Kumar and Singh relations can be controlled with various solvents. The refractive index values obtained from experimental data are the highest, while the refractive index values obtained from Moss relation are the lowest.

Analysis of Refractive Index Dispersion and Relation between Optical Band Gaps and Indexes of Refraction of PPTTPP Nanofiber

Bayram Gündüz*

*Department of Science Education, Faculty of Education, Muş Alparslan University, Muş 49250, Turkey
b.gunduz@alparslan.edu.tr; bgunduz83@hotmail.com

Abstract—The refractive index dispersion of the PPTTPP crystal nanofiber for different solvents was analyzed. The relation between optical band gaps and indexes of refraction of PPTTPP crystal nanofiber for different solvents was investigated. Effects of solvents on refractive index dispersion and indexes of refraction were investigated in detail. Finally, the surface morphology properties of the PPTTPP film were investigated by a Park System, XE100 atomic force microscope (AFM).

Keywords—Refractive index dispersion, PPTTPP crystal nanofiber, refractive index, solvents, AFM.

I. INTRODUCTION

Organic single crystal materials (OSCMs) have many advantages such as their lower cost, high chemical purity, high order molecular packing, excellent optoelectronic properties and easier processability [1-4]. OSCMs are widely used in the photonic and optoelectronic devices such as transistors, cells, electroluminescence (EL) devices, diodes and lasers[2,3]. 5,5′-di-4-biphenyl-2,2′-bithiophene (PPTTPP) crystal nanofiber, which is organic fluorescence material is known as BP2T [5]. The fundamental properties of the PPTTPP crystal nanofiber are significant for materials science, organic materials, p-type small molecules, printed electronics and p-type organic semiconductors.

The aim of this study is to analyze the refractive index dispersion of the PPTTPP crystal nanofiber for different solvents and is to investigate the relation between optical band gaps and indexes of refraction of PPTTPP crystal nanofiber for different solvents. The optical measurements were conducted on a Shimadzu model UV-1800 Spectrophotometer at room temperature. Finally, the surface morphology properties of the PPTTPP film were investigated by a Park System, XE100 atomic force microscope (AFM).

II. EXPERIMENTAL

5,5′-Di(4-biphenyl)-2,2′-bithiophene (PPTTPP) nanofiber (Sigma–Aldrich), N,N-dimethylformamide (DMF), chloroform, and toluene solvents (Merck Co.) were used in this study.

II.A. THE SOLUTIONS OF THE PPTTPP NANOFIBER FOR DIFFERENT SOLVENTS

The molecular formula and weight of the PPTTPP are C_{32}H_{22}S_{2} and 470.65 g/mol, respectively. The PPTTPP materials were weighed to prepare the solutions with a AND-GR-200 Series Analytical Balance for 0.611 mM and were dissolved homogeneously in 10 mL volume of DMF, chloroform and toluene solvents. To obtain the best results of the optical measurements, the prepared solutions of the PPTTPP were filtered through PTFE membrane filter.

II.B. THE OPTICAL MEASUREMENTS

The optical measurements of the PPTTPP crystal nanofiber for different solvents were performed by solution technique. For this, we used the cylindrical cuvettes (Hellma QS-100), which have 10 mm optical path length and 3.5 mL volume. The optical measurements of the solutions of the PPTTPP for different solvents were taken by a Shimadzu model UV-1800 Spectrophotometer at room temperature.

II.C. PPTTPP NANOFIBER FILM

The prepared and filtered solution of the PPTTPP nanofiber was deposited on cleaned microscopy glass at 3000 rpm for 20 s by the spin coating method. After that, the film was dried at 60 °C for 5 min to remove organic residuals and evaporate the solvent. Surface morphology properties of the PPTTPP film were investigated by a Park System, XE100 atomic force microscope (AFM).

III. RESULTS AND DISCUSSION

III.A. ANALYSIS OF REFRACTIVE INDEX DISPERSION OF THE PPTTPP CRYSTAL NANOFIBER

The refractive index (n) is an important parameter for photonic and optoelectronic applications. The n can be calculated by [6,7],

\[ n = \left( \frac{4R}{(R-1)^2-k^2} \right)^{1/2} \frac{R+1}{R-1} \]  

The n values of the PPTTPP crystal nanofiber for DMF, chloroform and toluene solvents were obtained from Eq. (1). Fig. 1 shows the plot of n vs. \( \lambda \) of the PPTTPP nanofiber for DMF, chloroform and toluene solvents. As seen in Fig. 1, the refractive index values of the PPTTPP for toluene solvent are the highest, while the refractive index values of the PPTTPP for DMF solvent are the lowest. This result suggests that the refractive index of the PPTTPP crystal nanofiber can be varied by various solvents and solvents play a significant role on refractive index of the PPTTPP nanofiber.
The given in Table I. As seen in Table I, the \( E_0 \) values of the PPTTPP nanofiber for DMF, chloroform and toluene solvents were obtained from [11]:
\[
E_0' = \frac{M_1}{M_3}
\]
and
\[
E_3' = \frac{M_1'}{M_3'}
\]
The \( M_1 \) and \( M_3 \) moments of the PPTTPP nanofiber for DMF, chloroform and toluene solvents were found and given in Table I. As seen in Table I, the \( M_1 \) value varies from 2.249 to 5.688 and the \( M_3 \) value shifts from 0.945 to 2.194 eV\(^2\) with changing solvent.

The optical oscillator strength \( f \) is an important parameter and it is given the following equation [10]:
\[
f = \frac{E_0E_d}{E_0 + E_3'}
\]
The optical oscillator strength of the PPTTPP nanofiber for DMF, chloroform and toluene solvents were obtained and given in Table I. As seen in Table I, the \( f \) value shifts from 5.352 to 14.743 eV\(^2\). This result suggests that the optical oscillator strength can be varied with various solvents.

#### III.B. RELATION BETWEEN OPTICAL BAND GAPS AND INDEXES OF REFRACTION OF PPTTPP CRYSTAL NANOFIBER

The \( \sigma \) values of the PPTTPP nanofiber for DMF, chloroform and toluene solvents were calculated from Eq. (1). Obtained \( \sigma \) values are given in Tables II. As seen in Table II, the \( \sigma \) value (2.558) of the PPTTPP for DMF solvent is the lowest, while the \( \sigma \) value (2.627) of the PPTTPP for toluene solvent is the highest. Obtained results suggest that the refractive index of the PPTTPP can be controlled by solvents.

There are many relations such as experimental, Moss, Ravindra, Herve-Vandamme, Reddy and Kumar-Singh between the energy gap and refractive index of semiconductors [9]. In our previous study [4], we obtained the optical band gap \( E_g \) values of the PPTTPP nanofiber for DMF, chloroform and toluene solvents. These \( E_g \) values are also given in Table II.

Moss relation is given by
\[
\sigma = \left( \frac{95 eV}{E_g} \right)^{1/4}
\]
For different solvents and Moss relation, the \( \sigma \) values of the PPTTPP were obtained from Eq. (6) and are given in Table II. As seen in Table II, the \( \sigma \) value (2.575) of the PPTTPP for DMF solvent and Moss relation is the lowest, while the \( \sigma \) value (2.629) of the PPTTPP for toluene solvent is the highest.

Ravindra relation is given by
\[
\sigma = 4.084 - 0.62E_g
\]
For different solvents and Ravindra relation, the n values of the PPTTPP were obtained from Eq. (7) and are given in Table II. As seen in Table II, the n value (2.744) of the PPTTPP for DMF solvent and Ravindra relation is the lowest, while the n value (2.851) of the PPTTPP for toluene solvent is the highest.

Herve-Vandamme relation is given by

\[ n = \left( 1 + \left( \frac{A}{E_g + B} \right)^2 \right)^{1/2} \]  

\[ (8) \]

where A is the hydrogen ionization energy 13.6 eV and B = 3.47 eV is a constant assumed to be the difference between the band gap energy and UV resonance energy. For different solvents and Herve-Vandamme relation, the n values of the PPTTPP were obtained from Eq. (8) and are given in Table II. As seen in Table II, the n value (2.614) of the PPTTPP for DMF solvent and Herve-Vandamme relation is the lowest, while the n value (2.685) of the PPTTPP for toluene solvent is the highest.

Reddy relation is given by

\[ n = \left( 1 + \left( \frac{A}{E_g - 0.365} \right)^2 \right)^{1/4} \]  

\[ (9) \]

For different solvents and Reddy relation, the n values of the PPTTPP were obtained from Eq. (9) and are given in Table II. As seen in Table II, the n value (3.043) of the PPTTPP for DMF solvent and Reddy relation is the lowest, while the n value (3.121) of the PPTTPP for toluene solvent is the highest.

Kumar-Singh relation is given by

\[ n = 3.3668(E_g - 0.3223)^{-0.3223} \]  

\[ (10) \]

For different solvents and Kumar-Singh relation, the n values of the PPTTPP were obtained from Eq. (10) and are given in Table II. As seen in Table II, the n value (2.626) of the PPTTPP for DMF solvent and Kumar-Singh relation is the lowest, while the n value (2.698) of the PPTTPP for toluene solvent is the highest. These results indicate that the refractive index for experimental, Moss, Ravindra, Herve-Vandamme, Reddy and Kumar and Singh relations can be controlled with various solvents and the highest refractive index values of the PPTTPP can be obtained with toluene solvent.

**Table II.** The optical parameters of the PPTTPP nanofiber for DMF, chloroform and toluene solvents.

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

Thus, the refractive index values of the PPTTPP nanofiber for DMF, chloroform and toluene solvents were obtained from experimental, Moss, Ravindra, Herve-Vandamme, Reddy and Kumar and Singh relations as seen in Fig. 3. As seen in Fig. 3, the refractive index values obtained from Reddy relation are the highest, while the refractive index values obtained from experimental data are the lowest.

**III.C. Surface morphology properties of the PPTTPP film**

The surface morphology properties of the PPTTPP nanofiber film deposited on cleaned microscopy glass were investigated using an AFM. The scan area was chosen as 10x10 µm². Fig. 4 indicates one (1D) topography image of the PPTTPP film. As seen in Fig. 4, PPTTPP film consists of different crystal grains, which are different shapes and sizes.

**Fig. 3.** The refractive index values of the PPTTPP nanofiber obtained from various relations for DMF, chloroform and toluene solvents.

**Fig. 4** The one (1D) topography image of the PPTTPP film.

Abstract—Changing the size and distribution of the eutectic silisium particles by the addition of alkali metals such as Na, Sr, K, Rb, Cs, Li, Ca, Ba, Mg, La, P, Bi, Cd, Mn, Ni, Pb to Al-Si alloy is called modification. Modification process can be done in different ways such as the addition of elements, rapid solidification, vibration applied during solidification, high pressure and spheroidizing by heat treatment. The modification of casting structure can be described as to be converted from lamellar eutectic Si structure to fiberims structure. During modification process the growth of silicon crystals slows down in the eutectic, the growth of silica-matrix is stabilized and fine lamellar structure is formed in this way. The most practical and widespread application for the modified process is the modification process by the addition of element and the most effective modification can be made by using Na, Sr and Sb. However, there are only strong implications using Na and Sr for industrial applications in a low concentration. Percent elongation and castability of strontium-modified alloy are higher than those modified with sodium. Also the initial effect of Na and Sr is very good, due to the loosening of oxidation and vapor pressure for sodium this effect is temporary. Alternatively, when processing features of Al-Si alloy with eutectoid composition is important it is known to supply significant advantages for the modification with CuSn5 alloys. In this study to examine the effect of the modification of eutectic Al-Si alloy casting experiments will be done. Casting experiments will be done in four ways by no addition, adding Al10Sr, adding CuSn5 and adding Al10Sr+CuSn5 master alloy. The microstructures of the cast samples will be analyzed and the effect of the modification will be determined depending on the master alloy.

Keywords—Aluminum Casting, Modification, Eutectic Solidification, Al10Sr, CuSn5.

I. INTRODUCTION

Aluminum-silicon alloys are used in the casting of automotive parts and in aerospace applications due to their mechanical properties, light weight, high thermal conductivity and low thermal expansion. They have also high viscosity during casting due to containing high amount silicon. Therefore it is necessary to continuously improve the quality of the castings made from these alloys and mechanical properties [1]. Mechanical properties are affected by the microstructure. Al-Si alloys have ductile aluminium phase and hard and brittle silicon phase which is needle shape [1, 2].

Eutectic modification is a process in which mechanical properties, especially strain and ductility, are developed by modifying of eutectic silicon phase in Al-Si eutectic alloys [3]. The process is carried out adding the alkaline elements such as Na, Sr, K, Rb, Cs, Li, Ca, Ba, Mg, La, P, Bi, Cd, Mn, Ni, Pb. The modification also can be achieved by heat treatment, rapid solidification and high pressure effects. Aim of this process is to transform from lamellar eutectic Si phase to fiber structure [4-7]. Adding of Na, Sr and Sb is the most effective method for the modification [4,6]. The microstructure modified with Sr and Sb is given in Figure 1.

Fig 1. The microstructure photographs of Al-Si eutectic alloy a) unmodified, b) modified with Sr and c) modified with Sb [8].

However, there are strong effects of Na and Sr in the industrial application [6-8]. The initial effects of Na and Sr are strong. However, the effects of Na is temporary due to oxidation [6]. In the literature, there are a lot of study about modified Al12Si [9-16]. While some of them is related to the microstructure, another is on mechanical properties.
In this study, the microstructure and mechanical properties of eutectic Al-Si alloy modified with CuSn5, Al10Sr, CuSn5+Al10Sr and unmodified alloy were investigated. Microstructure and chemical analyses and hardness measurement were carried out to characterization of the alloys. According to the experimental results, effects of alloying elements and modification are determined.

II. EXPERIMENTAL STUDIES

In this study, Al12Si master alloys with different modifications were investigated. Al12Si alloy was used as master alloy containing 12%Si. Al10Sr and CuSn5 master alloys were used as modifying alloys to determine effect of the alloys. The chemical composition of the alloys used in the study can be seen in Table 1.

The alloys were melted by electric resistance furnace in SiC curicible. For all of the test parameters, sufficient amount of aluminum ingot was placed in the furnace and the temperature increased to 700°C. After melting was completed, degassing and deslagging were done. Then the molten was poured into permanent mould in which temperature was 150°C, shown in Figure 2. The test samples were removed from the permanent mould after solidification and cooling and obtained 20 mm in diameter and 100 mm in height.

The samples for microstructural analysis were initially polished with 80, 400, 600, 800 and 1000 grit SiC emery papers and finally were polished with 1 μm diamond paste. Microstructural examination of all samples was performed by using a Nikon MA 100 Eclipse optical microscope. Hardness measurement was carried out under 10 kg preload and 60 kg major load with steel ball in 3.175 mm diameter.

III. EXPERIMENTAL RESULTS

Figure 3 shows the microstructure of the unmodified Al12Si, Al12Si+CuSn5, Al12Si+Al10Sr and Al12Si+Al10Sr+CuSn5 alloys after casting. The unmodified Al12Si eutectic alloy has Si phases which are needle, long and coarse shape. Unmodified eutectic Si alloys have generally coarse grains and when compared modified Al12Si alloys, the needle and coarse structure cause to decrease tensile strength and ductility [5, 11].

CuSn5 alloy has finer Si phases. Therefore, it can be said that copper affects to the microstructure and causes to increase the hardness. When copper and phosphor are added to Al-Si alloys, AlP forms and lamellar grains transform to block form [15]. In this work, it was observed that lamellar structure formed in Si phases and increased the hardness.

Uludag et al. [17] reported that in the alloys with Sr, when cooling rate increased primary Si phases become smaller and secondary Si phases become smaller as well and partially segregate. When Al10Sr alloy analyzed that strontium caused to be the finest fibrous structure in all alloys. Effect of Sr modifier on hardness having very little was observed. Strontium as a modifier in Al-Si eutectic alloys, morphology of eutectic transforms from coarse and needle structure to the fibrous structure, which leads to good mechanical properties [18].

When Al10Sr+CuSn5 master alloy was investigated it was observed that the morphology of Si phases changed to fibrous structure from coarse needle compared to the unmodified alloy. The morphology transformation leads to increase on hardness. Also, in Al10Sr+CuSn5 master alloy, Si phases coarser than that of Al10Sr master alloy due to decreasing of modification effect. Therefore in modification process, the metals having least phosphorus are used [19].

Figure 4 shows hardness results of the alloys. The unmodified Al12Si alloy has the lowest hardness. Tasha et al. [20] reported that copper and magnesium increase the hardness and surface quality. The alloy modified with CuSn5 has better hardness compared to the unmodified alloy and the alloy modified with Sr due to effect of copper on mechanical properties. Copper increases yield and tensile strength and hardness via precipitation hardening [2]. The alloy modified with Al10Sr has higher hardness to the unmodified alloy. However, the alloy modified with CuSn5 has higher hardness than the alloy modified with Al10Sr. Therefore it can be said that CuSn5 master alloy increase the mechanical properties to Al10Sr. Strontium modifies the microstructure of aluminium silicon eutectic rather than to improve the mechanical properties. The best amount of modification elements is between 0.008% and 0.04% [5].

Barzani et al. [21] reported that antimony and strontium affect only hard Si phase. When Al10Sr and CuSn5 master alloys added the Al12Si alloy, the highest hardness values were obtained. It was also observed that, Al10Sr + CuSn5
master alloy has more effect to improve the mechanical properties to the Al10Sr alloy.

### IV. CONCLUSIONS

In this study, Al12Si alloy was modified with Al10Sr, CuSn5 and Al10Sr+CuSn5 master alloys. The results obtained in studies are given in summary below:

- It was obtained that Si phases are lamellar, long and coarse morphology in main Al12Si alloy whereas lamellar structure is finer morphology in CuSn5 master alloy. When Al10Sr and CuSn5 master alloys are used together, Si phases change to fiberous structure from lamellar. In Al10Sr master alloy, strontium is more effective in grain refinement.
- According to the positive changes in the microstructure of the master alloys, it was observed that modification effect can be ranged such as Al10Sr, Al10Sr+CuSn5, CuSn5.
- The highest hardness was obtained in the Al10Sr + CuSn5 master alloy. Also in the other alloys, hardness values are almost same.
Al10Sr master alloy has strong modification effect on the microstructure rather than hardness. However, CuSn5 master alloy increased the hardness rather than modification the microstructure.

Abstract—In this paper, an automatic cell counting method under microscopy is proposed. The cell counting process can be performed in two ways: The manual counting in which a specialist counts the cells with naked eye, and the automatic counting that utilizes the computer-based techniques. In manual counting, there are several techniques for dying the cells to turn them visible with naked eye. However, if the concentration is more than normal the cells can overlap. Overlap and incorrect adjusted microscopy parameters are the main factors that cause inaccurate counting results. Furthermore, in manual counting inter-observer variability is high. Even though the same cell image is taken into account by the different specialist, different counting results can be obtained. Because of the above mentioned problems, the cell counting process must be performed automatically.

The proposed automatic stem cell counting process is based on image processing techniques that appropriate the frame of method. At first, stem cell sections were obtained under the fluorescence microscopy. In the following pre-processing step Gaussian filtering and background extraction are performed. Before applying watershed algorithm histogram of the image is partitioned in to four parts and the best combination is determined to obtain the most exact counting results. The aim of using watershed algorithm is to make the boundaries and maximum points of the cells more clear. Finally, spherical contours corresponding to the stem cells are counted.

The effectiveness of the proposed method is evaluated by performing numerous computer simulations. It is shown that the proposed method gives promising results and can eliminate the subjectivity originated from the manual counting. The method is tested on a database contains two image groups at different noise levels validated by the specialists.

Keywords—cell counting, cell detection, pre-processing, embryonic stem cell, watershed algorithm.

I. INTRODUCTION

In recent years, cell researchers are interested in counting, sorting and tracking the cells. The specialists at clinics and hospitals use cell counting in determining the health condition of a patient. Cell counting is a valuable process used for different investigations. For example, in molecular biology and biochemistry, finding the concentration of cells is important during some experiments. This value is essential for calculating the volume of a particular chemical substance or reagent that should be applied to the concentration of cells in order to obtain reliable results. Cell counting is also used in measuring cell viability. This is the calculation of the number of dead and living cells in a cell culture and useful for determining the life expectancy of a cancerous cell, the effectiveness of insecticides and pesticides or the environmental harmfulness of poisons and toxins.

Stem cells have a special importance in clinical researches and they provide a promising cell source especially for developing new diagnosis and treatment techniques. Stem cells can turn into many different cell types in the body during early life and growth. They can serve as a sort of internal repair system, dividing essentially without limit to replenish other cells as long as the person is still alive. Stem cell research is still one of the most challenging areas in biology.

Embryonic stem cells (ESC) are denominated as “super cells” with their self-renewing elements and properties of generating all endoderm, ectoderm and mesoderm layers. ESC are derived from human pre-implantation embryos. Their differentiation process can be managed by culturing them in non-adherent plates. Counting ESC is an important task that has numerous applications afterwards [1, 2].

There are a lot of ways to count human cells. Medical research has found various methodologies that does not only count the cells but also determine other aspects such as cell shape and other properties. Todays, with the advent of dreadful diseases such as tumors, cancers, and other deadly diseases, cell counting has become even more important in the field of medicine and science. Through this medical procedure, cancer cells and other harmful diseases can be determined and treated accordingly. The cell counting process can be performed in two ways: The manual counting in which a specialist counts the cells with naked eye, and the automatic counting that utilizes the computer-based techniques. In manual counting, there are several techniques for dying the cells to turn them visible with naked eye. However, if the concentration is more than normal the cells can overlap. Overlap and incorrect adjusted microscopy parameters are the main factors that cause inaccurate counting results. Furthermore, in manual counting inter-observer variability is high. Even though the same cell image is taken into account.
by the different specialist, different counting results can be obtained. Because of the above mentioned problems, the cell counting process must be performed automatically. There exist various studies in the literature applying different image processing algorithms to the cell image [3-10]. Advanced digital image processing methods and pattern recognition techniques are used in various applications, too [11-13].

In this study we propose an automatic ESC detection and counting method for fluorescence microscopy images based on commonly used image processing techniques. In the pre-processing red-green-blue (RGB) channel image split in to the individual R, G and B channels, respectively. Next, Gaussian filtering and background extraction have been performed for green channel which gives the best counting results according to the experiments. Before applying watershed algorithm, the histogram of pre-processed image is calculated. Then, histogram of the image is partitioned into four equal intervals and best combination of these intervals is determined with various trials. By using watershed algorithm, we separate the overlapped cells from each other. Finally, spherical contours corresponding to the stem cells are counted.

The study is organized as follows: in Section II, the pre-processing step including background extraction and filtering is discussed. In Section III, watershed algorithm for cell counting is explained. Experimental results and comparisons are given in Section IV. Finally, Section V concludes the paper.

II. PRE-PROCESSING STEP

In this section, pre-processing step including background extraction and filtering is explained. Because of the distortions in cell images, this step is necessary before counting the cells. For this study, embryoid bodies’ images are given by Geisa Martins Faustino. Database contains 92 different cell images. Acquisition of cell images is described in reference [2]. In Figure 1, captured images distorted by low noise and high noise are illustrated as an example.

The necessity of applying pre-processing step arises from the following reasons. At first, it is important to adjust the focus of microscope properly. Wrong adjusted microscopy parameters cause wrong counting results. At this case manual counting with naked eye is becomes impossible. Second, to make cells more visible in microscopy images there are various dying techniques. The concentration level of dying is crucial. For example, if the concentration is high cell overlap occurs. Overlap is one of the main reasons of erroneous counting results. At last, the presence of fluorescence image noise may also cause the inaccurate counting.

In conclusion, the pre-processing step is needed to make cell images more clear and convenient for counting. Now, we describe the procedures, respectively.

A. Filtering

When the cell images are taken with fluorescence microscope, the luminance of pixel in the center of cell is lighter than the boundaries of the cell. By exploiting this property, cell counting with maximum brightness analysis becomes possible. In this study, the Gaussian blur filter is used to smooth the surface and put forward the maximum points of cell images. In Figure 2, surface of a cell image before and after Gaussian filtering is illustrated.

From the figure, we can say that using Gaussian filter makes the maximum points of the image more explicit than normal.

B. Background Extraction

Segmentation is one of the influential process in digital image analysis. It is known that, the performance of the segmentation turns the scale of whole counting procedure [14, 15]. Thresholding is a commonly used simple technique to perform background segmentation. In this study, segmentation is implemented with thresholding. Threshold value is determined with mean μ and standard deviation δ of the cell images. We set the threshold value to t = μ + x.δ according to the trials [17]. The pixel intensities under t is set to zero for R, G and B channels. The results are given in Figure 3. As clearly seen from the figure, for green channel, overlapping is less than other channels and cell boundaries are more explicit. Pre-processing step for green channel is illustrated in Figure 4. Furthermore, a background segmentation example under low and high-level noise is shown in Figure 5 and 6, respectively.
III. WATERSHED ALGORITHM FOR COUNTING

Before using watershed algorithm, histogram partitioning is applied to the cell images. The aim of histogram partitioning is to identify connected cells. At first, we obtain the histogram of pre-processed cell image. As discussed before, it is calculated for green channel. The histogram of the green channel is split into four equal interval of size 64. Because of the luminance difference between the center and edges of the cells, histogram partitioning provides useful information for counting. The partitions of green channel histogram are demonstrated in Figure 7. Then, each interval is checked from top-to-bottom and left-to-right two times and detected connected components are labelled. The components that have similar luminance take higher labels [16, 17].
In this section, we give and discuss the simulation results performed on the database obtained by communicating with the author Geisa Martins Faustino as given in reference [2]. In the database there are two groups containing 69 and 23 ESC images, respectively. For the second group the noise level is stronger than that of the first group. Gaussian radius values for Group 1 and 2 are 2 and 3, respectively. To determine the threshold value as given in Section II, is chosen as 0.3, the mean value and is the standard deviation of green channel input image.

In Figure 9 and 10, watershed applied low-noise (from Group 1) and high-noise (from Group 2) ESC images are illustrated. As it is clear from the figures, counting with naked eye will be exhausting and time consuming. Furthermore, counting results will not be reliable in these cases. Thus, the proposed automatic counting algorithm implemented for different images which are chosen randomly from Groups 1 and 2. Experimental results are given in Table 1 in comparison with the author’s before work given in [17] and with reference [2]. Because of the lack of fluorescence microscopy and experts, we are not able to measure the accuracy of the proposed method for all practical cases. However, to show the good performance of our method we compare our results with accepted studies.
Table 1. The counting results of the proposed method in comparison with reference [2] and [17].

V. CONCLUSION

In this study, an automatic ESC counting method based on watershed algorithm is proposed. The main steps of the proposed method are explained in the corresponding sections of the study. In the first step that referred as pre-processing step, Gaussian filtering and background extraction are applied to the ESC images. Then, before performing watershed algorithm image histogram is partitioned into four parts and the best combination is determined for watershed algorithm to obtain the reliable counting results. By means of these processes, the over-segmentation problem of the watershed algorithm is also eliminated. At last, spherical contours corresponding to the stem cells are counted. Experimental results are given in comparison with the author’s before study and with one of the accepted popular paper given in reference [2]. According to the results, proposed algorithm provides consistent and promising results for automatic cell counting task. Thus, the proposed method can be used for different blood cell counting processes to provide useful result for task. Thus, the proposed method can be used for different consistent and promising results for automatic cell counting and with one of the accepted results corresponding to the stem cells are counted. Experimental processes, the over obtain the best combination is determined for watershed algorithm to algorithm image histogram is partitioned into four parts and to the ESC images step, Gaussian filtering and background extraction are applied of the study. In the first step that referred as pre- processing

I. INTRODUCTION

In the current search an attempt has been made to fabricate two groups of biological system (polymer Nano composites), consists from binary polymer blend (Polyetheretherketone (PEEK) - 7.5% polyvinylidene fluoride (PVDF)) reinforced with different Nano powders which are Nano Hydroxyapatite (HAp) and hybrid nanoparticle (ZrO$_2$+ 3%Y$_2$O$_3$) with selected weight percentage ratios of (0, 2.5, 5 and 7.5%), by melt blending with internal mixer. In the development of biomaterial, both mechanical (tensile, impact, and fracture toughness) and biological characteristics must be considered. These biological systems have characterized by using SEM, X-ray. A comparison have been done between these two groups of polymer blend Nano composites, and results clarify that by increasing the weight percentage of nanoparticle (ZrO$_2$ and, HAp) in polymer Nano composites, that the tensile strength, impact strength and flexural modulus were increased in both groups of Nano composites. Moreover it was found that the polymer hybrid Nano composites ((PEEK: 7.5%PVDF): (X%ZrO$_2$ +3%Y$_2$O$_3$)) gave higher values of mechanical characteristics as compared with their counterpart of the other group polymer Nano composites ((PEEK: 7.5%PVDF): X% hydroxyapatite). SEM results show uniform distribution of Nano powder ZrO$_2$, Y$_2$O$_3$, and fair dispersion of Nano-HA In vitro biological evaluations of the samples were done by carrying out cytotoxicity (3-[4,5-dimethylthiazol-2-yl]-2,5-phenyltetrazolium bromide) using MTT assay. Cell-material interaction with the surface of the composite was examined through inverted microscope for both developed biological system, cell viability, cell proliferation has been found to increase with increasing culture time (2,3,7) days. Moreover it was found that the polymer Nano composites((PEEK: 7.5%PVDF): (X%ZrO$_2$ +3%Y$_2$O$_3$)) revealed higher cell viability ,cell proliferation than the ((PEEK: 7.5%PVDF): (X%HA) polymer hybrid Nano composites.

Keywords- Polymer Blend, internal fixation ,biological system, Fracture Toughness, Biocompatibility.

Replacement of tooth and bone with metal implants and plates is one of the most frequently used and successful surgical procedures. The introduction of modern implants started with the work of Branemark, who in 1969 observed that a piece of titanium embedded in rabbit bone became firmly attached and difficult to remove. Current hybrid organic/inorganic composites have significant problems related mostly to their mechanical performance and their degradation in vivo [1].

However, PEEK is biologically inert which has limited its potential applications. Therefore, improving the bioactivity of PEEK is a significant challenge that must be solved to fully realize the potential benefits[2].

The concept of bioactive particulate reinforced polymer composite as bone analogue was introduced in the early 1980s by Bonfield et al.. The bone analogue material developed mimics the composition of natural bone, a natural composite material comprising mainly of collagen as the organic matrix and mineral apatite as the inorganic reinforcement. Polyetheretherketone (PEEK) Being one of the highest performance engineering thermoplastic currently available, it has received extensive applications for structural and load-bearing functions in the aerospace and marine industries. For biomedical applications, PEEK offers additional benefits including its ability to be repeatedly sterilized and shaped readily by machining and heat contouring [3].

Hydroxyapatite (HA)-reinforced polymer bioocomposites offer a robust system to engineer synthetic bone substitutes with tailored mechanical, biological, and surgical functions. The basic design rationale has been to reinforce a tough, biocompatible polymer matrix with a bioactive
HA filler. Hydroxyapatite-reinforced polymers offer the ability to tailor the composite’s elastic modulus, presumably to meet performance criteria for a particular application or implant, by varying the HA-reinforcement content[4].

Zirconia is a transition metal oxide with current applications to orthopedic implants. It has been shown to up-regulate specific genes involved in bio-integration and injury repair[5]. Rui Ma et al., incorporated 40 wt% nano-hydroxyapatite (nHA) into polyetheretherketone (PEEK) through a process of compounding, injection, and molding. The mechanical and surface properties of the nHA/PEEK composite were characterized, and the in vitro osteoblast functions in the composite were investigated [6]. Bablu Mordina et al. have prepared by melt mixing in a co-rotating twin screw extruder poly(ether ether ketone) micro/nanocomposite reinforced with N-(2-aminoethyl)-3-aminopropyl triethoxy silane treated micro- and nano-sized nickel and zirconia (0.5, 1, and 3 wt%) mechanical properties and thermal stability were characterized and the resulting nanocomposites with 3 wt% Ni and ZrO2 nanoparticles exhibit the maximum improvement in tensile and flexural strength as well as the modulus with respect to neat poly(ether ether ketone) [7]. Peng Chunzheng prepared by using the twin-screw extrusion Polyetheretherketone (PEEK) and carbon fiber (CF) composites reinforced with nano-ZrO2 particles. The results showed that the incorporation of nano-ZrO2 particles effectively enhanced the tensile properties of the composites. The tensile strength and Young’s modulus of the composites increased with content of nano-ZrO2. The incorporation of nano-ZrO2 effectively inhibited the failure of carbon fiber by reducing the stress concentration on the interface of carbon fibers. [8].

Francisco José Correa Bragaahave reported the preparation and characterization of polyvinylidenefluoride (PVDF) and hydroxyapatite (HAP) composites, analyzing the incorporation of HAP in PVDF and investigating their mechanical properties and cytotoxicity (biocompatibility) for use in bone restoration and filling[9].

The philosophy of blending two polymers is to produce a material which has properties that are tailored to a certain performance level. Since the morphology and resultant physical properties are controlled to a large extent by the miscibility and phase behavior, it is quite easy to understand why there is so much interest in controlling the phase structure in blends. The extremely high specific surface area of nanoparticles facilitates the creation of a strong interaction between the filler and matrix. Thus, nanocomposites always have unique properties resulting from the nanoscale structure [10].

To the best of our knowledge, no previous studies have reported the in vitro fibrosteoblast responses (such as cell attachment, spreading, proliferation, cell viability of L-929 cells to the PEEK+7.5%PVDF reinforced Nano Hydroxyapatite (HAP) and hybrid nanoparticle (ZrO2+3%Y2O3) composite.

So our objective is to develop two groups of biological system (polymer Nano composites), consists from binary polymer blend (Polyetheretherketone (PEEK) -7.5% polyvinylidene fluoride( PVDF )) reinforced with different Nano powders which are Nano Hydroxyapatite (HAP) and hybrid nanoparticle (ZrO2+3%Y2O3) with selected weight percentage ratios of (0, 2.5, 5 and 7.5%), by melt blending with internal mixer, and evaluate. The mechanical properties, surface morphology, chemical composition, were characterized. The in vitro fibrosteoblast functions of the composite were studied by detecting cell attachment, spreading, proliferation, and cell viability of L-929 cells.

II. Preparation of Nanocomposites

The Polyetheretherketone (PEEK) and polyvinylidenefluoride (PVDF) are desired in the granule form and were purchased from China PEEK (KLC607), the PVDF granule used in this study with particle Size (16μm). The nano particles were also supplied from china HAp (44.04nm), ZrO2(36.05-50nm) and Y2O3 (46-50nm).Polymer blend (PEEK: 7.5 wt.% PVDF) reinforced with mixture of hybrid Nano (X% ZrO2 +3%Y2O3) with selected weight percentage of Nano ZrO2 (0, 2.5, 5 and 7.5%) and Nano HAP with desired weight percentage (0, 2.5, 5 and 7.5%), were fabricated via a series of processes; as follow:- mixing, compounding, compression molding. Compounding was achieved in an internal mixer (Haake) at temperature of 365°C and mixing speed at 70 rpm. The time needed for compounding was about 5 min, depending on the amount of ZrO2, and HAp incorporated, compression molding carried out at temperature (380-400)°C using a compression molding machine.

III. Mechanical and physical tests

Tensile test samples were cut according to ASTM D 638-03 [2, 11]. Tensile test was performed with an Instron 5567 tester, carried out at ambient temperature at a cross head speed of (5mm/min); and gauge-length, 50 mm. Izod impact strength was achieved according to ASTM D256-Type 3 [12]. Using impact testing machine at the striking rate of 3.2 m/s, capacity of the pendulum: 2 joule at room temperature, a notch of 2.5 mm width with an angle of 45° was created on the sample have dimensions (3.3 mm thickness, 12.5mm width and 63.5 mm length) [12]. Three specimens for each composition were tested and the average value reported.

A. Physical Characterization

XRD pattern of the Polymer blend (PEEK: 7.5 % PVDF), blend reinforced with mixture of hybrid Nano powders (X% ZrO2 +3%Y2O3) and Nano Hap, nanocomposites were obtained using XRD, SIEMENS, D5000 (GERMANY) Theta/2Theta; XRD data were evaluated.
was achieved according to different culture time for (2,3 viability is measured as follow this test is done with microplate reader (STAT FAX 2100, USA) absorbance was measured isopropanol were incubated for further 24h, then add of sterilized MTT solution was added and the specimens serum well plate and 95% air for 24 h incubated at 37°C 250μm) rectangular specimens 929 cell suspension containing 5×10⁴ composite [(PEEK+7.5% PVDF): 7.5% HAp)]. 100 μL L polymer blend hybrid Nano composite [(PEEK+7.5% PVDF) polymer blend and polymer blend Nano composite (X%ZrO2 +3%Y2O3))]. This test is repeated four times, therefore four specimens were used for each sample test, and final results represent the average for the four specimens it was tested After finish of cell culture time, which is fixed time is (24 and 48) hours, of in vitro cell culture, morphology and cell attachment were evaluated under inverted microscope .

IV. RESULTS AND DISCUSSION

A. Structural Analysis

Figure 1 and 2 shows the XRD patterns of (PEEK, and (PEEK+7.5% PVDF) polymer blend and polymer blend hybrid Nano composite [(PEEK+7.5% PVDF): (X%ZrO2 +3%Y2O3)] as a first group and (PEEK, (PEEK+7.5% PVDF) polymer blend and polymer blend Nano composite[(PEEK+7.5% PVDF): (7.5wt X% HAp)] as second group nanocomposites respectively. Neat PEEK and (PEEK+7.5% PVDF) matrix component of the nanocomposites crystallized primarily in orthorhombic structure having diffraction peaks at about 18.7°, 20.8°, 22.9° and 28.9°, these are an agreement with other workers results [15,16]. And these corresponded to the diffraction planes of (110), (111), (200) and (211) [14,15]. No structural change was induced in (PEEK+7.5% PVDF) matrix by adding nHA, and hybrid (ZrO2%+3%Y2O3) Nano powders at different ratios contents.

Where

\[ \text{Viab. } \% = \frac{100 \times OD_{570e}^e}{OD_{570b}^e} \]
The SEM Figure 4 shown different morphologies with various contents of polymers blend composite. The fracture surface of ((PEEK: 7.5%PVDF): (X%HA) nanocomposites. shown in Figure (4 a, b and c) showed a heterogeneous morphology A co-continuous two phase structure that could be broken down into a spherical droplet structure, homogeneous micro structure, and with small regions have smoother fracture surface, which seems to indicate better interfacial adhesion between the components of composite sample.

During mixing process, the interactions between nHA and polymer blende mainly occurred through melting of PEEK and PVDF molecules, followed by wetting of molten molecules with nHAp. Figs. 4 (d), (e) and (f) show the morphologies in larger magnification (5000 ×). After mixing, polymer blend (PEEK+7.5%PVDF) molecule melt encapsulated the surface of HA nanoparticles and intimate interfacial bondings were formed in nanocomposites as observed from the dense and solid surface [16, 17].

It can be observed different sizes of spherical and oval shaped of PVDF phase were dispersed randomly in PEEK matrix it is shown through shares, moreover incompatible immiscible blends can be characterized by the domains of one phase pulling away from the domains of the other phase resulting in a droplet-in-matrix morphology (figs. d, e and f). So, PVDF particles will play as a center of energy dissipating in the PEEK matrix, and as a result, PVDF particles would respond to the triaxial stresses near the crack tip and make the localized shear yielding occurs, followed by bridging mechanism of PVDF at the crack tip zone in the PEEK matrix and plastic void growth initiated by cavitation or deboning of the PVDF particles from the surface [18].

Figs. 5(a, b, c, d, e and f), show the representative cryo-fracture surface morphology of ((PEEK: 7.5%PVDF): (X%ZrO2 +3%Y2O3)) nanocomposites which reveals that with the incorporation of hybrid nano (X%ZrO2 +3%Y2O3) there is uniform dispersion of the nano filler (ZrO2 and Y2O3) and the rough surface of the nanozirconia produces effective physical interaction and reduces the slippage of nanozirconia particulates. The SEM morphology exhibited a homogenous morphology (figure 5 (a, b and c), as co-continuous two phase structure, the SEM photos show very few of micro-cavities structure, this indicates a fairly weak interaction between the components of of hybrid nano composite especially at high ratio of ZrO2 as show in SEM photo (figure 5 (f), It was reported that the present a spherical and oval droplet particles will act as energy dissipating center in the PVDF[ 19]. Therefore from the morphological evolutions of the modified PEEK network by blending with PVDF, which were examined by scanning electron microscope and the toughening mechanism were determined to be due to spherical and oval droplet particles, followed by plastic deformation of the matrix resin as reported in [20].
It is conceivable that, with further improvement of nanoparticles clustering via particle surface modification, though more expensive, the mechanical properties can be further upgraded. Figs. 5 (b, d and f) show the morphologies in larger magnification (5000 ×) as illustrated in Figs. 5 (b, d and f) where the distribution of (X%ZrO2 +3%Y2O3) particles is quite homogeneous with some agglomeration which can be seen on the fracture surfaces at a higher magnification [21].

Fig. 5: SEM photos of the fracture surfaces of ((PEEK: 7.5%PVDF): (X%ZrO2 +3%Y2O3)) nano hybrid composites as a function of ZrO2 content (where a and d (2.5% ZrO2), b and e (5% ZrO2) and c and f (7.5% ZrO2) at different magnification (a), (b) and (c) at (1000×); (d), (e) and (f) at (5000).

B. Mechanical properties

The variations on the tensile strength, tensile modulus & elongation at break, as a function of hybrid nano (ZrO2%+3%Y2O3) and nHAp particles content have been shown in Figs. (6, 7 and 8) respectively. The tensile parameters of the nanocomposites and human cortical bone are listed in Table (1). Figs. (6, 7 and 8) suggesting that the tensile properties of nHAp/(PEEK+7.5%PVDF) and nano
Hydroxyapatite material and the compatibility of each filler. The hardness of zirconia is higher than hardness of polymeric materials, as well as has higher hardness values and higher strength properties as compared to their counterparts of the other group (nano hydroxyapatite polymer blends composites). Comparison between various loadings this hybrid as shown in Fig. 5 and 6 it was noticed that the tensile strength and tensile modulus respectively of nHAp/PEEK+7.5%PVDF) composite increases with increased nano fillers content from 0–7.5%, and this result exhibited an ultimate tensile strength of 93.502 MPa and 172.836 MPa for ((PEEK+7.5%PVDF): 7.5%nHAp) and ((PEEK+7.5%PVDF): (7.5%ZrO2%+3%Y2O3)) composites respectively, which as shown in Table 1 within the range of tensile strength of human cortical bone [17]. Most importantly the study suggests that there is no debonding occurring between the well-dispersed of nanoparticles (nHAp and nano hybrid (ZrO2%+3%Y2O3)) and polymers blend matrix (PEEK+7.5%PVDF) as shown previously by SEM, so, these results which provides a promising way to overcome the debonding issue of the PEEK-nHAp and PEEK-Nano hybrid (ZrO2%+3%Y2O3) composites [22]. The present work exhibits the increase of the tensile strength and tensile modulus of the composites with HAp nanoparticles content in a certain range, which is consistent with the results of PEEK nanocomposites with SiO2 and Al2O3 nanofillers [23, 24, 25]. According to the previous studies [26], the increase in tensile strength of the composites may be because the local stress in composites materials under load can be more easily transferred into rigid particles with the addition of nHAp and nano hybrid (ZrO2%+3%Y2O3) fillers, resulting in a higher mechanical strength, when the particles are in intimate contact with the polymer blend matrix. Moreover, these nanoparticles fillers (nHAp and nano hybrid (ZrO2%+3%Y2O3)) in composites can interrupt and delay the propagation of micro-cracks or even stop their growth via stress distribution, which is also attributed to improve tensile strength [27]. Furthermore, it was noticed that ((PEEK+7.5%PVDF): (x%ZrO2%+3%Y2O3)) composites have the higher values of tensile strength at break and young modulus as compared with their counterparts of the other group samples (nano hydroxyapatite polymer blends composites). This related to nature of both hydroxyapatite and zirconia, which have higher hardness values and higher strength properties as compared with polymeric materials, as well as the hardness of zirconia is higher than hardness of hydroxyapatite material and the compatibility of each filler with matrix especially when incorporate 3%Y2O3 nanoparticle with zirconia nanoparticle, which play an important role in the behavior and load transfer.

Generally, from Fig. (7) The tensile modulus of the polymer blend has been found to be (3.327 GPa) whereas when polymers blend matrix (PEEK+7.5%PVDF) incorporate with nano hybrid ratios of (7.5%ZrO2+3%Y2O3) the tensile modulus value reach to (7.002 GPa), this value is higher than the lower limit for the stiffness of cortical bone, i.e. 7 GPa, [28] therefore, these result in that ((PEEK+7.5%PVDF): (7.5%ZrO2+3%Y2O3)) nanocomposite is considered to be suitable for load-bearing application in orthopedics and these values fall within the lower range of the modulus of cortical bone [29].

Obviously, there is a synergistic effect of hybrid nano (ZrO2%+3%Y2O3) on the enhancement of the mechanical properties of composites. This can be seen from the graphs of tensile strength and Young’s modulus versus (ZrO2%+3%Y2O3) content for polymer blend composites with various loadings this hybrid as shown in Fig. (6,7). As is evident, the increasing trend is sharper as the ZrO2 content grows from 0 to 7.5%. The reinforcing effect of nano ZrO2 particles is more effective at a higher content of ZrO2.
Moreover, the modulus was seen to increase with nHAp content in the PEEK composite by about 19% higher than the polymer blend about 4 GPa which was closely match the lower limit of human cortical bone. This is expected, considering that the modulus of nHAp and PEEK are 85 and 3 GPa, respectively in accordance with [29]. The reinforcing effect of the nHAp particulate was evident even with the slightest inclusion of nHAp [29].

While the tensile elongation at break decreased with increasing nano hybrid (ZrO2%+3%Y2O3) and nHAp particles content in composite as shown in Fig. (8), however the decrease in tensile elongation at break of nHAp composite is lower than that of polymer blend reinforced with hybrid nano(ZrO2%+3%Y2O3) and this relate to the aforementioned reasons.

Fig. 8: Elongation at break for polymer blend (PEEK: 7.5%PVDF) as a function of nanoparticles content in polymer blends Nano-composites

Figures (9), Fig.(10) show the effect of weight ratio of hydroxyapatite and zirconia nano powders content on impact strength and fracture toughness respectively for (PEEK: 7.5%PVDF) polymer blends. It can be observed from this figure, that impact property of polymer blend has been increased with the addition of nHAp and nano hybrid (X%ZrO2 +3%Y2O3) and reaching to almost (17.54 kJ/m²) and (19.4 kJ/m²) at 7.5% nHAp and 7.5% ZrO2 respectively.

Results of the impact test of these materials is given in Table 1. Remarkable difference in the impact strength of the material can be seen with the addition of selected weight percentage of nano powders The value of impact strength has increased by more than 22% for ((PEEK: 7.5%PVDF): (X%ZrO2 +3%Y2O3)) and 20.8% for((PEEK: 7.5%PVDF): (X%HAn)). Polymer based composite materials when subjected to impact type of loading conditions, energy is absorbed in the process of plastic deformation of matrix material, debonding at matrix/reinforcement interface influence the fracture of reinforcing material. So, these composites material may be absorbs least amount of energy for its occurrence becomes prominent and that leads to fracture.

The increase in the impact strength and fracture toughness could be due to the high interfacial shear strength between nanofiller and matrix resulted from the formation of cross-links or supra molecular bonding which cover or shield the Nano fillers which in turn prevent propagation of cracks. Also the crack propagation may be changed by good bonding between nanofiller and resin matrix [30]. The small size and high surface area and relatively low concentration may helped in a good distribution of these fillers that may cause a restricted motion of macromolecule chains and enhance mechanical properties [31]. Moreover if the compatibility of the filler particles with the matrix material is not good, the crack blunting at the filler particle location will play an important role and again leads to the same conclusion that the nanofiller prevent the propagation of cracks which lead to increase fracture toughness as shown in Fig.10 [29]. In case of reinforced nano particles nHAp, compatibility with the matrix resin seems to be fair through scanning electron microscopic observation (Figure 4) While the compatibility of the hybrid (X%ZrO2 +3%Y2O3) with polymer blend ((PEEK: 7.5%PVDF) is better than counterpart group as shown in (Fig. 5) which may be resulted from the addition of small amount of nano yeteria which lead to enhanced compatibility of nano zirconia with polymer blend. For that reason the impact strength and fracture toughness of ((PEEK: 7.5%PVDF): (X%ZrO2 +3%Y2O3)) is higher than the counterparts of the other group ((PEEK: 7.5%PVDF): (X%HAn)). Beside that the increase in impact strength may be due to low loading of filler which is less than 10% as compared with microfiller[32].
the difference compared to 
(7.5%ZrO2 +3%Y2O3)) show higher absorbance as
compared to polymer blend and control due to the
formation of apatite on((PEEK: 7.5%PVDF): 7.5%
hydroxyapatite) and the ability of nHAp to increase the
growth of apatite as reported in [35].

Figure 11 and 12 show the MTT-assay results for the
polymer blend (PEEK: 7.5%PVDF) ((PEEK: 7.5%PVDF):
7.5% hydroxyapatite) and ((PEEK: 7.5%PVDF):
(7.5%ZrO2 +3%Y2O3)) nanocomposites up to 7 days
incubation compared with control. In the process, the
Yellow water-soluble MTT (3-(4,5-dimethylthiazol-2-yl)-
2,5 diphenyltetrazoliumbromid) is metabolically reduced in
viable cells to a blue-violet insoluble formazan. The
number of viable cells correlates to the colour intensity
determined by photometric measurements after dissolving
the formazan in alcohol. Fig.10 revealed that there is a
gradual increase in the light absorbance with culture time
for the polymer blend (PEEK: 7.5%PVDF), (PEEK: 7.5%
hydroxyapatite) and (PEEK: 7.5%PVDF): (7.5%ZrO2 +3%Y2O3)) nanocomposites seeded with the mouse fibroblasts. Compared with polymer blend and control, all of the nanocomposites show higher absorbance values. This indicates that the nanocomposites provide favorable surface sites for cell proliferation. More importantly, the nanocomposites with (7.5%ZrO2 +3%Y2O3)) show higher absorbance as compared to the nanocomposites with nHAp contents after 3day and after 7 days but, at the same time the difference between the two groups are not very significance. Thus, the((PEEK: 7.5%PVDF): (7.5%ZrO2 +3%Y2O3)) nanocomposites has higher cell activity or biocompatibility which revealed that the nanohybrid(7.5%ZrO2+3%Y2O3) have no cytotoxic effect as reported in[33,34], and competing with the ((PEEK: 7.5%PVDF): 7.5%
hydroxyapatite) which has good biocompatibility as
compared to polymer blend and control due to the
formation of apatite on((PEEK: 7.5%PVDF): 7.5%
hydroxyapatite) and the ability of nHAp to increase the
growth of apatite as reported in [35].

To obtain further information on cellular adhesion, optical
microscopy was used to observe the distribution of L-929
cells next to the extraction of Nano composite samples after various times of incubation period, points days incubations a. control sample, b. polymer blend ((PEEK+7.5wt%PVDF) sample, c. Nano composite(Blend+7.5%nHAp) and d. Nano hybrid composite( Blend+7.5%ZrO2 +3%Y2O3) sample.
ZrO$_2$+3%Y$_2$O$_3$), nHAp powder does not show any sign of cytotoxicity. Fig. 13(a,b,c,d) shows images of L-929 fibroblast cells on nanocomposites which show that after 24 hours the spread of cells was found in control as well as in polymer blend (PEEK: 7.5%PVDF), ((PEEK: 7.5%PVDF): 7.5% hydroxyapatite) and ((PEEK: 7.5%PVDF): (X%ZrO$_2$+3%Y$_2$O$_3$)) nanocomposites. After 48 hour the cell spread was found to be higher as compared to 24 hour which indicates that nanopowders hybrid(7.5% ZrO$_2$+3%Y$_2$O$_3$) and nHAp did not cause any toxic effect on cells. Moreover, cells attached well to these materials, proliferated, and formed a dense cell layer with numerous cell–cell contacts (Fig. 3.12,a,b,c,d). No significant differences were observed among cells with nano hybrid(7.5% ZrO$_2$+3%Y$_2$O$_3$) [Fig. 13(a,d)], and control cells in terms of the morphological characteristics of the fibroblasts which agreed with [36]. Fig.13 shows a regular pattern of cell growth of fibroblast cells which is characteristic of a test conducted on nanopowders hybrid(7.5% ZrO$_2$+3%Y$_2$O$_3$) and nHAp. The in vitro study conducted on cytotoxicity of ((PEEK: 7.5%PVDF): (X%ZrO$_2$+3%Y$_2$O$_3$)) nanocomposites, shows higher biocompatibility as compared to counterpart group of and ((PEEK: 7.5%PVDF): 7.5% hydroxyapatite) nanocomposite produced. Also, as appeared in Fig.12 (a,b,c,d) the numbers of living cells on ((PEEK: 7.5%PVDF): (X%ZrO$_2$+3%Y$_2$O$_3$)) were found to be increased and larger in size which as compared to polymer blend (PEEK: 7.5%PVDF), and((PEEK: 7.5%PVDF): 7.5% hydroxyapatite) as well as controls (Fig.13(a,b,c,d) after seeding cells for 24 hour and 48 hour.

(b)The cell morphologies of polymer blend (PEEK+7.5%PVDF) cell growth B1 after 24 hour and B2 after 48 hour

(c)The cell morphologies of ((PEEK: 7.5%PVDF): 7.5% hydroxyapatite) cell growth C1 after 24 hour and C2 after 48 hour

(d)The cell morphologies of ((PEEK: 7.5%PVDF): (X%ZrO$_2$+3%Y$_2$O$_3$)) cell growth D1 after 24 hour and D2 after 48 hour

(a)The cell morphologies of control cell growth A1 after 24 hour and A2 after 48 hour

(b)The cell morphologies of polymer blend (PEEK+7.5%PVDF) cell growth B1 after 24 hour and B2 after 48 hour

(c)The cell morphologies of ((PEEK: 7.5%PVDF): 7.5% hydroxyapatite) cell growth C1 after 24 hour and C2 after 48 hour

(d)The cell morphologies of ((PEEK: 7.5%PVDF): (X%ZrO$_2$+3%Y$_2$O$_3$)) cell growth D1 after 24 hour and D2 after 48 hour
V. Conclusion

Experimental investigation was conducted to evaluate and compare the effect of addition of different nanoparticles on characterization of prepared nanocomposites using in internal fixation of bone fracture. The following conclusions were drawn based on the present work:

1. The tensile strength of hybrid nanocomposites ((PEEK: 7.5%PVDF): (X%ZrO₂ +3%Y₂O₃)) value was increased from 85.1527 to 172.836 MPa while tensile strength of ((PEEK: 7.5%PVDF): (X%HA)) increased from 85.1527 to 93.5028 MPa when addition nanoparticle powder to prepared polymer blend.

2. The increase in tensile strength and elastic modulus in ((PEEK: 7.5%PVDF): (X%ZrO₂ +3%Y₂O₃)) was higher than in the counterpart group((PEEK: 7.5%PVDF): (X%HA)), however both prepared nanocomposite have tensile properties that closely match the tensile strength of cortical bone.

3. Impact strength of ((PEEK: 7.5%PVDF): (X%ZrO₂ +3%Y₂O₃)) increase by about 23% which was higher than in ((PEEK: 7.5%PVDF): (X%HA)), however the impact strength of this group increased by about 21%.

4. The results of mechanical test show a promising developed biomaterial that can be used in internal fixation of bone fracture, represented by ((PEEK: 7.5%PVDF): (X%ZrO₂ +3%Y₂O₃)), ((PEEK: 7.5%PVDF): (X%HA)) using low loading nano filler less than 10%.

5. SEM micrographs of cryo-fracture surface morphology of both prepared nanocomposite showed homogeneous micro structure, and with small regions have smoother fracture surface, which seems to indicate better interfacial adhesion between the components of composite sample. As well as uniform dispersion of the filler and the rough surface of the nano zirconia produces effective physical interaction and reduces the slippage of nano zirconia particulates.

6. The XRD patterns of polymer blend, polymer blend, hybrid Nano composite [(PEEK+7.5% PVDF): (X%ZrO₂ +3%Y₂O₃)] and Nano composite[(PEEK+7.5% PVDF): 7.5wt.% HAp)] nanocomposites indicated No structural change was induced in PEEK by adding nHA, and hybrid(ZrO₂+3%Y₂O₃) of different contents.

7. The developed nano composites exhibited excellent biocompatibility, bioactivity and on the basis of MTT assay. The cell viability was found to get promoted with increasing incubation time for toughened polymer blend with different nanopowdered and the neat blend, however it can be noticed that the Nano composite[(PEEK+7.5% PVDF): (7.5%ZrO₂+3%Y₂O₃)] show higher cell proliferation, cell attachment, and non-cytotoxic effect of the hybrid(7.5%ZrO₂+3%Y₂O₃). Moreover[(PEEK+7.5% PVDF): 7.5wt.% HAp)] also provide higher surface activity as compared to polymer blend as well as control. which means the nano hybrid (7.5%ZrO₂+3%Y₂O₃) and nHAp, exhibited active biological responses to physiological environment and promotes fibroblasts activities more effectively when compared to other nano materials.

8. From optical micrographs showing the cell morphologies in different states of cell growth on PS sample including division and flattening after 24 hour we can noticed that cell is well attached to the surface of nanocomposites. Moreover the polymer blend (PEEK: 7.5%PVDF incorporated with nano hybrid(7.5%ZrO₂+3%Y₂O₃) show best cell attachment next to control as compared the counterpart polymer hybrid Nano composites ((PEEK: 7.5%PVDF): 7.5% HAp) which make this new developed biopolymer blend a promising material for load bearing biomaterial.

ACKNOWLEDGMENT

The authors would like to express thanks to Materials Engineering Department/University of Technology for providing me this opportunity to complete my study. Great thanks are due for Iran polymer and Petrochemical institute Tehran – Iran for helping in fabrication of samples, mechanical properties test labs and for providing SEM and X-ray facilities and In vitro labs for cell culture.

Abstract— In this article, a study was carried on ultrasound (US) images for the automatic diagnosis of the disease of the developmental hip dysplasia (DDH). It was aimed with this study at minimizing the errors of the experts in DDH diagnosis. As a first step in the study; commonly known as the images and reduce noise in the US image, image filter are applied to improve the quality. In the second stage; by using Active Contour Model method it was determined acetabular roof and labrum areas. In the third stage; alpha and beta angles that is necessary to be applied Graf method and used DDH diagnosis are determined by using various morphological image algorithms on the image. In the last stage, the classification of Graf method was made and the performance of the system was measured by comparing expert data and the results. According to type conditions of Graf method, in the images of 40 out of 50 it was found the same due to software which was designed with expert data. In the remaining 10 images, expert result and program result are rather close especially for alpha angle. As a result, the success rate of the system for the 50 image is 80%. When considered the parameters such as the difficulty of physical examination of DDH diagnosis, decreasing quality of life in the people suffered from this disease, limb shortening, limping, functional disability, treatment costs, based on expert data and relativism of applying of Graf method on US images, the importance of DDH diagnosis system supported computer is seen.

Keywords— Developmental Hip Dysplasia, Ultrasound, Active Contour Model, Image Processing

I. INTRODUCTION

Developmental dysplasia of the hip (DDH) is structural dysfunctionality resulted from or dislocation of the hip, femur (thigh) head and acetabulum (cup). The incidence of this disease prevalence (of which the risk of) in the world identified as 1/3000 higher than in Japan and the Mediterranean Basin [1]. DDH can be treated successfully with early diagnosis. Delays in diagnosis and treatment of extremity (limb) brevity can cause restricted movement disorders such as claudication and functional disability. Diagnosed in the newborn period and successful in 96% of infants who were treated as anatomical and radiological can be obtained in normal development [2]. There is no chance of conservative treatment in the children that are in toddler age. To get successful results in all cases with surgical treatments is also impossible. Even if surgical treatment is successful, negativities is too large to be ignored [3].

To determine DDH incidence, differences in the definition of this abnormal situation in the hips, method differences in examining of hip, knowledge level of the person carrying out the examination vary depending on the characteristics of the studied communities. The incidence of approximately 1 in 1000 births, birth is stated to range between 100 3-4 [4]. Physical examination and ultrasonography (US) seen with higher frequency are determined by imaging [4].

Scanning hip US widely used in the world. The reason is that cheap sonography extremely common and safe. It is estimated that by introducing the world every four base units [5]. Furthermore, US usage is to diagnose the possibility of eliminating the risk of radiation intake in newborn infants.

US findings and hip development disorder can be defined, and treatment can be planned. Technically, Graf, Mortar, Harcke, and Terjesen methods are used [5]. Graf method is easy to learn compared to other methods is a simple method and is the most popular method worldwide hip US [6]. Europe has long been used in the study of newborn hip [7].

Fig. 1. US image for the diagnosis of DDH: a) raw image, b) manually determined α and β angles, c) diagnosis of DDH

Graf method is typing of hip morphology of hip angles that was measured on sonogram, and this was carried on tilted baby, and this is imagined on trochanter major in the standard plan of specific anatomical points with parallel placed the transducer to the body axis. Then the image shown in the standard plan
and as seen in Figure 1, the hip joint angles ($\alpha$ and $\beta$) is determined by the value morphology [8]. However, overall poor image quality makes it difficult to determine the angle of the hip joint radiologist.

Roof angle alpha bone, cartilage roof gives information about the beta angle. There is a relationship between decrease in the value of the acetabular angle alpha and dysplasia, and in clinical studies, alpha angle lower thighs is seen as the hip that can be dislocated [9].

The Graf method is examined four groups in hip ultrasound identification. Alpha angle values are used in the original grouping. Beta angle values are secondary typing (type 1a-1b and type 2c-D in differentiation), the baby several months by type 2a-2b distinction, such as whether the labral degeneration 3a-3b distinction and perichondrium morphology types used in 3-4 divisions (Figure 2) [10].

There are very few studies in the literature related to computer-aided diagnosis of DDH. The first study in the literature that was tried to recognize automatically is seen in 1998. Overhoff et al. [11] undertook a study on femoral automatically detect over 10 different images. not found any information about the performance of the system. Luis-Garcia and Lopez-Alberola have done several studies on the diagnosis of DDH. In their study, they tried to determine femur and acetabulum areas by segmenting US images. In their first study based on dividing of muscle area that are nonlinear and in this study, Dynamic Shape Priors method was used. Dynamic way of priority was also used in these studies, they suggested automatic creating in segmentation flow as well as anatomical knowledge. In their studies, they reported that the first impressions on real images showed promising results [12]. In 2006, they presented segmentation method for hip joint from 3D ultrasound data. Kullback-Leibler distance measurement is used as the actual difference measure; energy minimization is performed by estimating the optimal parameters of sphere and parabolic so that the femoral head and the acetabulum easier segmentation. Experimental results for a number of data set in this study; this approach has shown that the success of using simple geometric approach to the anatomy of the hip joint [13].

In 2007, ultrasound images of based on the Rayleigh distribution parameter which'n local estimate of for analyzing the ultrasound signal to have a new technique adopted as a model, the local estimator, the original ultrasound image conversion, it has been observed that the hip ultrasound images of increasing the feasibility allocated between different regions on [14]. Han-Yang et al., tried to implement a computer-aided design system for the treatment of DDH. Firstly, they used classic segmentation method in their studies, but they reported that these methods were giving unreliable results because of the difficulty of processing the images of US. Then they used a mixture of images-based algorithm for partial-volume segmentation and stated that they have achieved remarkable results [15].

In the dividing of US images used in diagnosis of DDH disease is seen not fully achieved results. By this study, this operation to be made independent from the DDH experts fault diagnosis it is provided with a high success rate.

II. MATERIAL

In the study, it was benefited from the US images used to diagnose DDH. Images are taken from Selcuk University Faculty of Medicine, Radiology Department. The US device used to collect the images is Toshiba Apio 400. Image set, each image section has been created under the supervision of specialist doctors radiologists examined individually. It was provided to be labeled correctly by using radiology report depending on the images taken in the standard form of sonogram. Besides the raw images obtained, there are also images that have been diagnosed by the experts according to Graf method.

The raw hip US images is gray level and the JPEG format. Images are irrelevant background areas in 800x600 pixels. US raw images obtained for use in this study and a sample image is diagnosed by the expert according to the state of the Graf method is given in Figure 3. A total of 25 patients, including 50 from the right and left hip image were obtained. Patients’ ages ranged from 0-3 months.

![Fig. 2 Types of hip according to Graf classification](image)

![Fig. 3 The ultrasound images used in the study a) raw image b) diagnosed image](image)
III. METHOD

In this study, a software was performed by using image processing techniques to provide the computer-aided diagnosis of DDH disease. Figure 4 shows a block diagram of the study.

Overall poor image quality makes it difficult to determine the angle of the hip joint for radiologist. Therefore, as the first; commonly known as the images and reduce noise in the US image, image filters have been applied to improve the quality (Mean, Median, Gaussian, Wiener, Perona & Malik Lee, and Frost). The most effective one (wiener) was applied to all images by measuring the effect on the image [16].

B. Active Contour Model

In recent years, ACM has been commonly used for medical image segmentation. ACM is known as basic idea of the overall development curve fitting method curves converge to object called [18-22]. It is selected a curve segments around the object and then according to effects of internal and external forces converge process is performed. When representation of the curve, ACM is divided two as open [20, 23] and close [19, 24, 25]. Snake model that made open demonstration of growing curve can be shown as an example for open ACM [20, 23]. Level sets modal that change the curve as parametric with a certain distance function can be shown as an example for close ACM [21, 26, 27]. Generally, close ACM’s can cope with topological deformation more than open ACM’s.

Unlimited ACM presented by Chan and Vese is a successful segmentation study that were used in many studies on various subjects [19]. It is based on Curve distribution, Mumford-Shah method and level set techniques [27]. It is known as Chan-Vese (CV model) region-based segmentation algorithm. This method is less sensitive to noise than other contour method. This model includes a function similar to the values of our energy to other mini-contour model. While determining the interior lines, it moves without depending on initial value. This feature is separated from the snake model. Zero level set of the surface image is a moving curve and this curve detected the object. The changes such as splitting and merging can be detected automatically. According to this method, an image is divided into homogeneous regions using this level function. This region is composed of image parts containing closed area value [28].

C-V algorithm divided by C is off limits u_0 official F(c_1, c_2, C) describes the energy function. This function is shown in Equation 1.

\[ F(c_1, c_2, C) = \mu.\text{Length}(C) + v.\text{Region}(\text{inner}(C)) + \lambda_1 \int_{\text{inner}(C)} |u_0(x, y) - c_1|^2 \text{d}x\text{d}y + \lambda_2 \int_{\text{outer}(C)} |u_0(x, y) - c_2|^2 \text{d}x\text{d}y \]  

(1)

In equation 1, \( \mu \geq 0, \lambda_1, \lambda_2 > 0 \) are fixed parameters, \( c_1 \) and \( c_2 \) are changing parameters, also they are average value respectively remaining areas outside and inside of C contour. The first term is regularization term that prevents contour merging with a small area. The last two terms are fitting terms [29].

IV. IMPLEMENTATION

A software that uses computer-aided Graf methods to put the diagnosis of DDH study was carried out on Matlab 8.3. Received by experts from US device 50 DDH image taken is processed by software designed and Graf method may be practiced alpha and beta angles were determined. Classifications in Graf method are carried out with these determined (alpha and beta) values. In the final stage, the outputs of software and the classifications which were applied by the radiologist were compared.
In the first stage of our study, in the phase of our work, in order to facilitate the processing of US images; when the applied filter on the effect of quality improvement as measured DDH images; observer sensitivity, resulting image quality measurements and images made with segmentation of tests, wiener filter the ilium, acetabular segmentation of the roof and the labrum is determined to be more successful than other filter [16]. Consequently, all obtained images were passed through wiener filter in pre-process stage.

In the second stage, wiener filter applied by applying the method improves the quality of images ACM estimated ilium region have been identified on the image. C-V ACM is used for segmentation of the ilium. As a result of estimated segmentation, the most-right and left areas were determined (Figure 5).

In the third step of our study, alpha and beta angles required to be applied Graf method provided to be determined used for DDH diagnosis. There must be a reference point drawn on ilium area and from base line to determine alpha and beta angles. The feature of this reference point in the negotiations with radiology specialists; the ilium area is divided. For the clarification of the estimated ilium identified in the previous section ACM method was once repeated between R-E, L-E and C.

Various morphological operations are applied to the resulting image in certain provinces. Thinning of the algorithm was first segment (thinning) has been converted into a pixel line subjected to the process (frame extraction). In this way, our image has taken a structure consisting of branches. After the thinning process is performed, the branch, and pruning was found that formation of unwanted images for the screening of the faulty branch (pruning) subjected to the process. Finding knot point to determine the latest stage in the branchpoint process is performed (Figure 6).

Fig. 6 Morphological processing for detecting the reference point: a) Ilium identified in the region of estimated ilium, b) Segmentation results, c) thinning results, d) as a result of pruning, e) branch points process results.

After determining the correct reference point, there are two areas that need to be find. These are the acetabular roof and labrum. The line that was drawn between acetabular roof and reference point is "Roof Line" and is used to determine alpha angles. The line between labrum and reference point is "Inclination Line" and is used to determine beta angles. In the determination of these two areas, it was taken estimated areas and segmentation process was performed. It was benefited C-V ACM algorithm for this segmentation process (Figure 7).

Fig. 7 Labrum and acetabular roof segmentation: a) segmentation results, b) determining the intersection point.

In the final stage of the study, reference, labrum and acetabular roof points were determined (Base Line, Roof Line, Inclination Line), and it was drawn lines between in these points, and beta and alpha angles were measured (Figure 8). The classification of Graf method was made in terms of these angles values.
In the study, a computer-aided system was designed in order to make diagnosis of DDH. Through a pre-process stage, the acetabular roof and labrum areas were determined, alpha and beta angles were also determined, and the diagnosis was made utilizing the Graf method. In evaluation stage, Graf alpha and beta angles, from the designed software alpha and beta angles diagnosis were compared (Table 1). In Table 1, the computer results which don’t match with expert evaluation is indicated as red. On the other hand, the missing result according to the beta angle is marked as green in Table 1.

V. RESULTS

Upon analyzing Table 1; when we look at only Type I, in 40 out 50 images were matched with expert evaluation, on the other hand, in 38 out 50 images were matched with expert evaluation by looking Type I and Type II together. As a result, the success rate is 80% based on only Type I, 76% based on Type I and Type II together.

VI. DISCUSSION

In the expert assessment of the results that calculated in the study; It was stated that the alpha value was near 60 degree had been an obstacle for the performance of the system. Because Type I Type 2 separation depends on keeping the value of alpha is 60 degrees or higher. For this reason experts; specifically stated that the results of the exit near the equivalent of close to 60 degrees of angle alpha. The shifting for 1-2 degrees completely change the diagnosis. These changes directly affect the performance of the system. For these reasons, with the recommendation of a system to alternative Graf method system success may increase. This system may be determined by Artificial Intelligence Applications used very often today.

Abstract—The articular cartilage overlying the bone consists of a network of collagen fibres. This network is essential to cartilage integrity, usually suffering damage in degenerative joint diseases such as osteoarthritis. We have been applying a number of techniques to study the bone–cartilage interface and of changes occurring in this with disease. The bone-cartilage samples with disease were investigated for their structural, elemental and molecular properties. The bone-cartilage samples with disease were characterized by scanning electron microscopy-energy dispersive X-ray spectroscopy (SEM-EDX) and Fourier Transform infrared spectroscopy (FTIR) and Fourier transform (FT) Raman spectroscopy. The energy dispersive X-ray (EDX) analysis confirmed nearly stoichiometric samples. The Raman spectra made it possible to monitor the changes in the main bone constituents: the mineral component with the apatite band at 960 cm⁻¹, the organic component with the collagen amide III band at 1268 cm⁻¹. Present results have been obtained on sections of bone not displaying evidence of an osteoarthritic lesion and can be used as a baseline against which diseased bone can be compared.

Keywords—Bone-cartilage, Raman, SEM-EDX, FTIR.

I. INTRODUCTION

Bone is a complex tissue which integrates two basic components, organic (matrix) and inorganic (mineral) material [1]. Its high strength and fracture toughness is achieved by a unique architecture of organic and inorganic phases [2–4]. It contains nano sized mineral platelets (essentially carbonated hydroxyapatite) [5], protein (mainly collagen type I), and water [3, 6]. The matrix makes up 30–40% of the total bone material and consists of collagen and other non-collagenous protein sand lipids [6]. Around 85–90% of the total protein content is made up by collagen fibrils. The mineral substance is mainly a carbonated form of crystalline calcium phosphate with a total percentage in bone material of 60–70% [7]. Therefore, because of the structural complexity of bone, its healing is an extremely complex process which has been under extensive investigation for many years [8]. Articular cartilage has an extracellular matrix composed primarily of water, type II collagen fibrils and proteoglycans [9]. Histologically, articular cartilage has unique variations in its morphological structure and molecular composition across its tissue depth, which is commonly considered to comprise three sub-tissue zones based on local fibril orientation [10]. These three zones are (a) the superficial zone (SZ) where the collagen is oriented parallel to the articular surface, (b) the transitional zone (TZ) where the collagen is oriented rather randomly, and (c) the radial zone (RZ) where the collagen is oriented mainly perpendicular to the articular surface. The critical role of the collagen matrix in cartilage is to preserve the tissue integrity where any alteration of the collagen microstructure due to tissue lesions will inevitably disrupt the molecular environment, consequently modifying the mechanical properties of the tissue.

Several microscopic imaging techniques have been used to study the load-induced deformation of the collagen matrix in articular cartilage. For example, microscopic MRI (mMRI) has been successfully used to image the modification of the tissue morphology in intact tissue blocks based on the proton...
signals in water molecules [11]. Scanning electron microscopy can directly visualize the effect of mechanical loading on the organization of the collagen fibrils in cartilage matrix [12]. The technique of Fourier transform infrared (FT-IR) spectroscopy is a powerful tool to study the previously described changes in degenerative cartilage at the molecular level. Raman analysis is sensitive to molecular orientation, and discerning between orientation and compositional contribution is crucial as bone is comprised of mineralized collagen fibres with alternating orientation within successive lamellae. The capability of Raman microspectroscopic analysis to distinguish between structural and chemical changes in bone were reported [13], by exploiting the dual influence of composition and structure with in the sample on the Raman signal [14].

Two human femoral head cartilage specimens from the autopsy of humans are reported in this paper. While one of the samples is of a osteoarthritic cartilage the other is a healthy cartilage. The healthy cartilage was due to a femoral head fracture. Prior to the sample analysis, there were no fixations, embedding or surface processing. This work is an effort to characterize the healthy and diseased bone-cartilage by using a combination of techniques such as scanning electron microscopy- energy dispersive X-ray spectroscopy (SEM-EDX), FT-IR and Raman spectroscopy. The aim of this study is to make comparison of structural, elemental and molecular properties of healthy and diseased bone-cartilage samples.

II. MATERIALS AND METHODS

Human femoral heads from total hip replacement procedures were used, due to surgical intervention in response to a degenerative joint disease. The femoral heads were sourced from the department of Orthopedics and Traumatology at Kocaeli University (Turkey). Using a water-cooled diamond saw (Isomet 1000 Precision) several sections at certain thicknesses were cut perpendicular to the articular surface from the superior aspect of the femoral head, the sections being of different diameters (15–20 mm), with thicknesses ranging from 200 μm to 300 μm. These sections were subsequently soaked in distilled water to remove any bone marrow and loose particulate matter. Morphological and elemental investigations were conducted on a scanning electron microscopy (Zeiss Supra 50 VP model SEM-EDX) with an acceleration voltage of 25 kV. Absorbance FT-IR spectra were obtained using a Thermo Scientific spectrometer in the range of 4000–400 cm⁻¹ using KBr pellets at room temperature. The resolution was 2 cm⁻¹, and the number of scans was 30.

An inViaReflex™ and an inViaQontor Raman microscope (Renishaw plc, Wotton-under-Edge, UK) were used. The spectrometers were configured with a diode laser excitation (785 nm) with the laser power of 300 mW, a 600 g mm⁻¹ grating (Reflex) / a 1200 g mm⁻¹ grating (Qontor), a motorized XY stage and a charge coupled device (CCD) detector. A line-shaped laser output was focused onto the sample through a microscope using a ×20 microscope objective.

III. RESULT AND DISCUSSION

The surface morphology and elemental analysis of the healthy and diseased femoral heads were characterised by scanning electron microscopy and energy dispersive X-Ray spectrometer. Fig. 1 shows the SEM images of the osteoarthritic femoral head cartilage sample and healthy cartilage (femoral head fracture) sample.

Fig. 1. SEM images of healthy and diseased cartilage samples.

Fig. 1 shows that femoral head fracture cartilage have a smooth surface structure. The cartilage surface contains the
presence of lacuna, chondrocytes and the chondroblasts structures. For the osteoarthritic femoral head cartilage, the level of surface deformation increased. Because of deterioration cartilage surface has occurred as the disease progresses. Consequently, the surface properties significantly, changed due to with cause deformation and diseases.

Fig. 2 shows the EDX data of the osteoarthritic femoral head cartilage sample and healthy cartilage (femoral head fracture) sample.

Fig. 2. EDX data a) healthy and b) diseased cartilage samples.

Fig. 2 shows that healthy and diseased cartilage samples have elements such as Ca, P, S, C, etc. It is evident that healthy bone cartilage sample has more amount of elements such as calcium, phosphate, etc., than the diseased cartilage.

Fig. 3 shows the RAMAN spectra of the osteoarthritic femoral head cartilage sample and healthy cartilage (femoral head fracture). Surface StreamLine images were obtained in an area of 773.9µm x 248.5 µm, using 90 mW laser power, 4 seconds/line acquisition time, and a 7.1 µm step size.

The human osteoarthritic cartilage tissue section is shown in Fig. 4. The data collection points are indicated by stars and numbered as: 1-) the cartilage, 2-) bone-cartilage interface, 3-) bone section, close to the interface and 4-) bone middle section.

Fig. 4. White light image of a healthy cartilage section. The stars indicate where point spectra were acquired.

Fig. 5 shows the Raman spectra from the four different regions that are indicated in Figure 4. The prominent bands are labeled. The $\nu_1$ phosphate stretching vibration at 960 cm$^{-1}$ is the strongest marker for bone mineral. The broader bands are assigned to amide III ($\sim 1239$ and 1268 cm$^{-1}$), the C–H bending mode ($\sim 1450$ cm$^{-1}$), and amide I ($\sim 1668$ cm$^{-1}$). The amide I at $\sim 1668$ cm$^{-1}$, and amide III $\sim 1239$ and 1268 cm$^{-1}$ peaks are mainly due to the presence of collagen, while the C–H bending band at $\sim 1450$ cm$^{-1}$ is present in both collaginous and noncollagenous organic moietyes. When the spectra are compared Number 1 through Number 4, from the
interface to the bone middle section, the relative intensity of the phosphate stretching vibration is increased as a result of increase in the mineral content. Whereas, the relative intensity of the band vibrations that are responsible from organic content of the tissue section is decreased.

Fig. 5. Raman spectra acquired from the locations marked by the stars in Figure 4.

The osteoarthritic femoral head cartilage sample was analyzed by Live Track StreamLine and the image of the sample illustrated in Figures 6 and 7.

Fig. 6. White light image of the osteoarthritic femoral head cartilage sample, as seen in Fig 3. The white box indicates the Surface Stream Line analysed area. At the cross hair position a single spectrum is acquired.

Fig. 7. An example spectrum from the cross hair position shown in Fig 6.

The spectrum displays mainly signals that are coming from the protein content, such as tryptophan, C-C protein, proline, hydroxyproline (874 cm\(^{-1}\)), phenylalanine (1003 cm\(^{-1}\) and 1030 cm\(^{-1}\)), amide III (collagen type I, 1239 cm\(^{-1}\) and 1268 cm\(^{-1}\)), CH from protein (1450 cm\(^{-1}\)) and amide I (collagen type I, 1668 cm\(^{-1}\)). Besides protein signals, the glycosaminoglycan and hydroxyapatite (PO\(_4^{3-}\)) vibrations are also evident in the spectrum. The hydroxyapatite signal scores are relatively low values compared with the bone tissue sections.

Fig. 8-9 shows FT-IR absorbance spectra of the samples. Two samples were characterized by use of FTIR spectrometry (Thermo Scientific, Erzincan, Turkey) as described. Data were collected in the absorption mode between 4000 and 400 cm\(^{-1}\), with resolution 4 cm\(^{-1}\). We used previous assignments of absorption bands. For healthy cartilage regarding carbonated apatite [\(\text{CA} : \text{Ca}_{10}(\text{PO}_4)_6(\text{OH})_x(\text{CO}_3)_y\)], the \(\nu_1\) and \(\nu_3\) P-O stretching vibration modes were measured at 723 cm\(^{-1}\) and 1163 cm\(^{-1}\) respectively, and the O-P-O \(\nu_4\) bending mode corresponded to the doublet at 531 cm\(^{-1}\). Regarding m-CPPD, O-P-O bending was recorded at 514 and 500 cm\(^{-1}\). Amid I, Amid II and Amid III infrared bands were measured at 1740 cm\(^{-1}\), 1464-1377 cm\(^{-1}\) and 1201 cm\(^{-1}\) respectively. These values change for diseased cartilage. For healthy cartilage regarding carbonated apatite [\(\text{CA} : \text{Ca}_{10}(\text{PO}_4)_6(\text{OH})_x(\text{CO}_3)_y\)], \(\nu_3\) P-O stretching vibration mode was measured at 1026 cm\(^{-1}\), and the O-P-O \(\nu_4\) bending mode corresponded to the doublet at 517 cm\(^{-1}\). Amid I, Amid II and Amid III infrared bands
were measured at 1747-1646 cm\(^{-1}\), 1540-1457 cm\(^{-1}\) and 1338-1200 cm\(^{-1}\) respectively.

Fig. 8. FT-IR spectra of healthy cartilage samples.

Fig. 9. FT-IR spectra of diseased cartilage samples.

IV. CONCLUSIONS

We used SEM-EDX, FT-IR and RAMAN spectroscopy to characterize the healthy and diseased bone-cartilage samples. SEM results show that the surface properties changed significantly due to deformation and diseases. It was found quantity of basic elements of the diseased bone-cartilage sample decreased. RAMAN spectrum displays mainly signals that are coming from the protein content, such as tryptophan, C-C protein, proline, hydroxyproline. The results obtained FT-IR analysis through also suggests disruption of bone cartilage structure. The results reveal that there are structural, elemental and molecular differences in healthy and diseased cartilages.

Abstract—While a healthy human walks, his or her legs mutually perform good repeatability with high accuracy. This provides an esthetical movement and balance. People with above knee prosthesis want to perform walking as esthetical as a healthy human. Therefore, to achieve a healthy walking, the above knee prosthesis must provide a good stiffness performance. Especially stiffness values are required when adding a second axis movement to the ankle for eversion and inversion. In this paper, stiffness analysis of above-knee prosthesis is presented. The translational displacement of above knee prosthesis are obtained when the prosthesis is subjected to the external forces. Knowing stiffness values of the above knee prosthesis, designers can compute prostheses parameters such as ergonomic structure, height, and weight and energy consumption.

Keywords—Stiffness analysis, above knee prosthesis, joint stiffness, prosthesis, accuracy

I. INTRODUCTION

It is required that serial robots have to make their tasks with a high accuracy, high precision and high stiffness [1]. The stiffness of robot manipulators generally provides to obtain the desired position and force commands with high accuracy [2, 3]. If the stiffness at the end point of robot manipulator is modified and identified accurately, it would be possible to compensate coupling and posing errors caused by the external forces [4].

Dumas et al. [1] introduced a method for the identification of the joint stiffness values of an industrial 6-DOF serial robot. In this method, it is aimed to evaluate joint stiffness values of any 6R serial robot using the model based on the Conservative Congruence Transformation (CCT). Pham et al. [5] proposed a method for identification of the joint stiffness values using band pass filtering. This method requires closed-loop control based on the robot’s dynamic model.

Alici and Shirinzadeh [4] presented the enhanced stiffness modeling, identification, and characterization of robot manipulators using experimental data obtained from sensors. Enhanced stiffness model is different from the conventional stiffness model which is derived firstly by Mason and Salisbury [4, 6]. While inherent stiffness of system is used in the conventional model, enhanced model contains the stiffness component due to the change in the manipulator configuration and the external forces acting on the manipulator in addition to inherent stiffness of system. The conventional stiffness model is valid only when the manipulator is in quasi-static configuration with no loading, or when it has a constant Jacobian matrix throughout its workspace [4].

Chen and Kao [7] reported that the conventional stiffness model derived by Mason and Salisbury [6] is not valid. According to them, a model based on the CCT must be used as the generalized relationship between the joint stiffness matrices and Cartesian stiffness matrices due to preserving fundamental properties of the stiffness matrices [4].

Ang and Andeen [8] presented variable passive compliance generated by means of topology of robot manipulators. As a conclusion they reported that a non-diagonal matrix is effective to prevent jamming and vibrations [4].

Abele et al. [9] presented two methods to obtain the Cartesian stiffness matrix of a 5R robot. They reported that second method is better than first because of considering the both joint and link stiffness. When load is applied, all deformations are considered such as links deformations and joint stiffness values.

This paper presents the stiffness analysis of above-knee prosthesis. The translational displacement of above knee prosthesis are obtained when the prosthesis is subjected to the external forces. Small displacements along x, y and z axes of the robot’s end-effector are illustrated by figures. Knowing stiffness values of the above knee prosthesis, researches can design prosthesis as optimal structure, height, and weight and energy consumption.

II. KINEMATIC ANALYSIS AND JACOBIAN MATRIX

A. Design of the Prosthesis

The solid model of proposed above knee prosthesis is illustrated on Figure 1. It has three joints. The first one is knee joint which is capable of one-axis movement and the second
and third one compose of ankle joint which is capable of two-axis movement.

Fig. 1. Proposed above knee prosthesis and its structure (a) knee joint (b) the entire prosthesis (c) ankle joint

B. Kinematic Model of Above Knee Prosthesis

This section deals with kinematic model of above knee prosthesis. The coordinate systems attached to the each joint of above knee prosthesis is presented in Fig. 1. The D-H parameters of the above knee prosthesis is illustrated in Table 1.

Fig. 2. The coordinate systems attached to the joint

The proposed above knee prosthesis has 3 rotational joints. The first one is knee joint which composes of one-axis movement. The second and third joints compose of ankle joint which performs two-axis movement. Ankle joint provides plantar flexion, dorsiflexion eversion and inversion movements.

The overall transformation matrix of above knee prosthesis can be written as

\[
^0T_4 = ^0T_1^1T_2^2T_3^3T_4^4
\]  

(1)

After determining D-H parameters, transformation matrices are obtained as follows.

\[
^0T_4 = \begin{bmatrix}
    c\theta_1 & -s\theta_1 & 0 & 0 \\
    s\theta_1 & c\theta_1 & 0 & 0 \\
    0 & 0 & 1 & 0 \\
    0 & 0 & 0 & 1
\end{bmatrix}
\]

(2)

The multiplication of overall transformation matrices is obtained as

\[
^0T_4 = \begin{bmatrix}
    r_{11} & r_{12} & r_{13} & p_x \\
    r_{21} & r_{22} & r_{23} & p_y \\
    r_{31} & r_{32} & r_{33} & p_z \\
    0 & 0 & 0 & 1
\end{bmatrix}
\]

(3)

where

\[
\begin{align*}
    r_{11} &= c\theta_3(c\theta_1c\theta_2 - s\theta_1s\theta_2) \\
    r_{12} &= -s\theta_3(c\theta_1c\theta_2 - s\theta_1s\theta_2) \\
    r_{13} &= c\theta_1s\theta_3 + c\theta_2s\theta_1 \\
    p_x &= l_2(c\theta_1c\theta_2 - s\theta_1s\theta_2) + l_1(c\theta_1s\theta_2 + c\theta_2s\theta_1) \\
    r_{21} &= c\theta_3(c\theta_1s\theta_2 + c\theta_2s\theta_1) \\
    r_{22} &= -s\theta_3(c\theta_1s\theta_2 + c\theta_2s\theta_1) \\
    r_{23} &= s\theta_1s\theta_2 - c\theta_1c\theta_2 \\
    p_y &= l_2(c\theta_1s\theta_2 + c\theta_2s\theta_1) - l_1(c\theta_1c\theta_2 - s\theta_1s\theta_2) \\
    r_{31} &= s\theta_3 \\
    r_{32} &= c\theta_3 \\
    r_{33} &= 0 \\
    p_z &= 0
\end{align*}
\]

(4)

The Jacobian matrix of prosthesis is obtained as follows

\[
J = \begin{bmatrix}
    -l_1s\theta_1 - l_2s(\theta_1 + \theta_2) + l_4c(\theta_1 + \theta_2) \\
    l_1c\theta_1 + l_2c(\theta_1 + \theta_2) + l_4s(\theta_1 + \theta_2) \\
    -l_2s(\theta_1 + \theta_2) + l_4c(\theta_1 + \theta_2) \\
    ... \\
    l_2c(\theta_1 + \theta_2) + l_4s(\theta_1 + \theta_2) \\
    0 \\
    0 \\
    1
\end{bmatrix}
\]

(5)
III. STIFFNESS MODELLING

The following relationship can be stated between actuated torques and the corresponding external forces and moments exerted on end-effector of the prosthesis can be expressed as:

\[ \Gamma = J^T \omega_0 \]  

(6)

where \( \Gamma \) and \( F \) are the 3x1 vectors and \( \Gamma = [\tau_1, \tau_2, \tau_3]^T \) is the actuator forces/torques needed to balance the external forces and \( \omega_0 = [f_x, f_y, f_z, f_{x0}, f_{y0}, f_{z0}]^T \) represents the corresponding external forces & moments exerted on end-effector of the prosthesis. There are two major changes happens in the manipulator because of its motion. First change happens angular position of the joints due to the torques/forges applied to the joints.

\[ \Delta = K_0 \Delta_0 \]  

(7)

where \( K_0 = \text{diag} [K_{\theta_1}, K_{\theta_2}, K_{\theta_3}] \) denotes joint stiffness matrix and \( \Delta_0 = [\Delta_{\theta_1}, \Delta_{\theta_2}, \Delta_{\theta_3}]^T \) represents change in the positions of the joints. Second change happens on the end-effector of the manipulator due to the external force and moment applied to the end-effector of the manipulator.

\[ \omega = K_\delta \Delta \]  

(8)

where \( K_\delta \) illustrates the Cartesian stiffness matrix of the manipulator and \( \Delta_0 = [\Delta_{\theta_1}, \Delta_{\theta_2}, \Delta_{\theta_3}]^T \) denotes change in the end-effector of the manipulator.

The following important identity is obtained by applying partial diffraction to the equation 1 with respect to \( \theta \).

\[ \frac{\partial \Gamma}{\partial \theta} = (J^T \partial \omega_0 + J \delta \partial X) \frac{\partial \theta}{\partial \theta} \]  

(9)

Equation 9 can be written as follows:

\[ K_\theta = K_c + J^T K_\delta J \]  

(10)

where \( K_c \) is the complementary stiffness matrix can be written for a 3DOF robotic manipulator as follows

\[ K_c = \begin{bmatrix} \frac{\partial J^T}{\partial \theta_1} & \frac{\partial J^T}{\partial \theta_2} & \frac{\partial J^T}{\partial \theta_3} \end{bmatrix} \]  

(11)

The stiffness matrix seen at the end-effector of the manipulator can be illustrated as

\[ K_\delta = J^T (K_\theta - K_c) J \]  

(12)

In order to find joint stiffness matrix, the Cartesian stiffness matrix can be simplified by ignoring \( K_c \) as follows:

\[ K_\delta = J^T K_\delta J \]  

(13)

Equation 8 can be rewritten by substituting equation 12 in equation 8 as follows.

\[ \omega = J^T K_\delta J \Delta \]  

(14)

Equation 14 can be rearranged as

\[ \Delta = K_\delta J \omega_0 \]  

(15)

Equation 15 can be rewritten as follows

\[ \Delta = \Delta_x \]  

(16)

where \( x \) and \( \Lambda \) include 6x1 vector of joint compliances and 6x6 matrix having external forces/moments and elements of Jacobian matrices.

\[ x = [1/k_{\theta_1}, 1/k_{\theta_2}, 1/k_{\theta_3}]^T \]  

(17)

IV. STIFFNESS ANALYSIS

Cartesian stiffness matrix can be obtained by using equation 11 as follows

\[ K_c = \begin{bmatrix} (-l_1 c_{\theta_1} - d_3 s_{\theta_1}) f_x + (-l_3 s_{\theta_1} + d_3 c_{\theta_1}) f_y & \cdots & c_{\theta_1} f_x + s_{\theta_1} f_y \\ 0 & \cdots & 0 \\ \vdots & \ddots & \vdots \end{bmatrix} \]  

(18)

A prosthesis end effector is forced to track a trajectory from its zero position (\( \theta_1 = \theta_2 = \theta_3 = 0 \)) to final position (\( \theta_1 = 150, \theta_2 = 15, \theta_3 = 10 \)) to identify joint stiffness values. The travel time of robot trajectory is planned as 3 seconds at 100Hz frequency. The joint stiffness values (\( K_{\theta_1}, K_{\theta_2} \) and \( K_{\theta_3} \)) along the trajectory are identified. Since trajectory frequency 100 Hz, 300 sample of joint stiffness values are obtained. The arithmetic averages of these sample values gives joint stiffness values. In this manipulator

Equation 16 can be written for prosthesis to find joint compliance values

\[ \Delta_x = \begin{bmatrix} j_{11} & j_{12} & 0 \\ j_{21} & j_{22} & 0 \\ 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} 1/k_{\theta_2} & 0 & 0 \\ 0 & 1/k_{\theta_2} & 0 \\ 1 & 0 & 1/k_{\theta_3} \end{bmatrix} \]  

(19)

where \( j_{11} = -l_1 s_{\theta_1} - l_2 s_{\theta_1 + \theta_2} - l_4 c_{\theta_1 + \theta_2}, j_{12} = -l_2 c_{\theta_1 + \theta_2} - l_4 c_{\theta_1 + \theta_2}, j_{21} = l_1 s_{\theta_1} + l_2 c_{\theta_1 + \theta_2} + l_4 s_{\theta_1 + \theta_2} \) and \( j_{22} = l_4 c_{\theta_1 + \theta_2} - l_3 s_{\theta_1 + \theta_2} \). This equation is reorganized to obtain 16 equality

\[ \begin{bmatrix} \delta_{\theta_1} \\ \delta_{\theta_2} \\ \delta_{\theta_3} \end{bmatrix} = \begin{bmatrix} j_{11} f_x + j_{12} f_y \\ j_{21} f_y + j_{22} f_x \\ 0 \end{bmatrix} \begin{bmatrix} f_x \\ \cdots \end{bmatrix} \begin{bmatrix} 1/k_{\theta_2} \\ 1/k_{\theta_2} \\ 1/k_{\theta_3} \end{bmatrix} \]  

(20)

V. STIFFNESS VERIFICATION

In order to compute the end effector displacements of proposed above knee prosthesis, the external forces are acted on anatomical position of human. Anatomical position is the erect position of the body with the face directed forward, the arms at the side, and the palms of the hands facing forward. It was used as a reference position for describing the relation of body parts to one another [10].

Cartesian stiffness matrix is calculated by using 12. Typical stiffness values of \( K_\theta = \text{diag} [10^5, 10^5, 10^5] \) N.mm/rad are chosen for initial values. \( K_\theta \) is constant, because it lets to the same joint stiffness values for it’s different initial values [4].
In this study, in order to have displacement values of the end-effector, an experimental study is performed. The magnitudes of force vector is implemented from 0 Newton to 200 Newton with a step size of 10 Newton as shown in Table II.

Fig. 3 represents the deflection values along the x, y and z-exes of prosthesis end-effector under the forces exerted on the prosthesis as shown in Table 2.

VI. CONCLUSION

In this study, the stiffness analysis of the proposed above-knee prosthesis is presented. The translational displacement of above knee prosthesis are obtained when the prosthesis is subjected to the external forces from 0 Newton to 200 Newton with a step size 10 Newton. The computed displacements along x, y and z axes of the prosthesis’s end-effector are illustrated by a table and figures. These results can be used to design and
manufacture an above knee prosthesis. Results can also help researchers to choose the material which will be used.

A Visual Stimulus Module for P300 Based Brain Computer Interfaces

Eda AKMAN AYDIN, Inan GÜLER
Gazi University
Faculty of Technical Education, 06500 Teknikokullar, Ankara, Turkey
{edaakman, iguler}@gazi.edu.tr

Abstract—Brain Computer Interfaces (BCIs) are the systems that provide a direct communication channel between human brain and environment. P300 potentials are involuntary brain responses which are used to control BCI systems. In order to elicit P300 responses, stimulus presentation must be provided to the users. However, there are not a common paradigm or optimal parameters for all BCI users, or all BCI applications. Using the most convenient method and parameters for each user individually will improve system performance. This study proposes a visual stimulus module for P300 based BCIs. The module offers to design stimulus interfaces based on three different stimulus interfaces, including row/column, single character and region based paradigms. The module also provides customization of the stimulus interface by setting optimal parameters for individuals practically. Furthermore, in this study, we also explained synchronization between stimulus interface and data acquisition module in detailed. In order to test the stimulus module, stimulus interfaces based on three visual stimulus paradigms were designed. All the paradigms were tested by three subjects. P300 responses yielded with three paradigms were compared by using one-way statistical analysis of variance (ANOVA) method. Preliminary results revealed that average amplitude and latency of P300 potentials that were elicited by the different paradigms may differ.

Keywords—Brain Computer Interface (BCI), P300 Potentials, Visual Stimulus Module, Row/Column Paradigm, Single Character Paradigm, Region Based Paradigm

I. INTRODUCTION

Neuromuscular diseases, such as amyotrophic lateral sclerosis, brainstem stroke, brain or spinal cord injuries, cerebral palsy, muscular dystrophy, multiple sclerosis etc. cause damage on the muscles or nerves that control the muscles, and lead to loss of voluntary muscle movements. Over 100 million people worldwide are affected by these diseases. Brain Computer Interfaces (BCIs) are systems that enable people with neuromuscular diseases to interact with external world without using neuromuscular activity. In other words, BCIs detect the signal activity in the brain and translate the changes in the brain activity into the control commands directly [1-3].

P300 potentials of event-related potentials (ERPs) is one of the electrophysiological signals used in BCI studies. P300 potentials are involuntary brain responses appeared in approximately 300 ms after an infrequent and task relevant stimulus is presented to the subject [4]. In order to elicit P300 potentials in EEG signal, stimulus presentation must be provided. According to user’s preferences and level of the disease, the stimulus presentation can be visual [4], auditory [5] or tactile [6]. However, superior performances were yielded by studies that use visual stimulus. [5].

Stimulus presentation in P300 based BCIs is based on oddball paradigm principle [7]. In oddball paradigm, during the stimulus presentation, all the stimuli intensify randomly. Meanwhile, users are asked to distinguish the two stimuli categories: target stimulus (task relevant infrequent stimulus) and non-target (irrelevant) stimulus, i.e. to focus on the target stimulus, and to count intensifications of each target stimulus silently. Intensification of target stimulus elicits P300 potential in EEG signal. Oddball paradigm is firstly adapted to the BCI studies as row/column paradigm for spelling applications [4]. Then, several visual stimulus paradigms based on oddball principle are proposed [8-10]. All these paradigms have their own advantages and disadvantages (Table 1).

Features of P300 potentials and performance of P300 based BCI systems vary according to the stimulus paradigm [11] and parameters of the stimulus interface [12-18], as well as individual characteristics of subjects, such as gender and age [19-20]. Stimulus and background colors, stimulation type, number of sequences, and stimulus timing can be listed as stimulus interface based factors. Colors of the stimulus interface are one of the factors that affects on system performance. Ikegami et.al. [12], revealed that character and background colors of visual stimulus interface affect the target prediction accuracy of the BCI system on both healthy and disabled subjects. Besides, Takanoa et.al. [13] is revealed that using soft colors increases the performance of the system. Stimulation type is another factor of the stimulus interfaces. Visual stimulation can be provided by changing one or more properties of an item on the matrix, such as position, angle, pattern rotation or size. There is not a stimulus type that can be defined as the most successful for all subjects, however it is also revealed that selection of user specific stimulus type increases information transfer rates as well as accuracy [14-15]. During the stimulus presentation, number of sequences is another important factor on BCI system performance. Because P300 potential amplitude is very low, higher character prediction accuracy cannot be accessed by using small number of sequences. Despite the fact that increasing the number of sequences improves the target character prediction accuracy, it also causes to lower the bit rate. Number of sequences varies according to the level of attention and concentration of the subjects and is a selectable parameter for synchronous BCI
applications [16]. On the other hand, there is not a consensus on effects of interstimulus interval on classification accuracy yet. Although high target character prediction accuracy is achieved by using longer interstimulus interval by Farwell and Donchin [4], high classification accuracy is obtained using short interstimulus interval by Meinicke et.al [17] and also Seller et.al [18]. A module that enables BCI operators to easily set up these parameters facilitate the stimulus interface design process. Furthermore, BCI operators easily customize stimulus paradigms for the use in numerous comparative analysis.

There are several BCI platforms that provide an easy way for designing a BCI system [21]. These platforms are generally specialized on a specific paradigm such as row/column paradigm for P300 based applications. However, according to the user preferences or the application to be controlled, privatization of the stimulus paradigm may be needed. Selection of visual stimulus paradigm and optimization of BCI system parameters for each user individually enables to achieve the best system performance [18].

In this study, a general-purpose visual stimulus module that enables the selection of visual stimulus paradigms and specific parameters is designed for P300-based BCIs. The designed stimulus module contains three different paradigms including row/column paradigm, single character paradigm and region based paradigm. The module also provides to set the parameters such as stimulus type, analyze type, stimulus timing, stimulus and background colors practically and offers an easy way for comparative studies that investigates the effects of various paradigms and parameters to P300 responses. Preliminary tests of the designed module carried out on three paradigms with the participation of three subjects.

The rest of the paper is organized as follows: Section II is a brief explanation of the visual stimulus paradigms which are included in the stimulus module. The visual stimulus module that is designed in this study is introduced in Section III. Then, experimental design is presented in Section IV. Experimental results are presented in Section V. Finally, Section VI concludes the paper.

II. VISUAL STIMULUS PARADIGMS

A. Row/Column Paradigm

Row / column (RC) paradigm was developed by Farwell and Donchin [4] and has been used in many studies. In this paradigm, letters, numbers or commands are placed so as to form the elements of a matrix. Stimuli are presented by intensification of rows or columns on matrix randomly. In case of using a matrix of 6x6, stimulus interface contains 12 stimuli, and consists of 6 rows and 6 columns. Row and column that contain target character are grouped as the target stimuli and remaining 10 rows and columns on the matrix are grouped as non-target stimuli. The matrix used in this paradigm contains 36 characters and because of giving stimulus as rows and columns, target probability is 1/6 [4].

B. Single Character Paradigm

Single character (SC) paradigm is designed by Guan et.al.[8]. The idea behind the design of this paradigm is that P300 amplitude is inversely proportional to target probability. In single character paradigm, stimuli are given by intensification of each character in the matrix individually [8]. In this way, in case of using a matrix of 6x6, probability of eliciting P300 potential is reduced to 1/36. However, assuming that number of sequences are equal, compared to the row/column paradigm, single character paradigm requires three times longer operating time for selecting a character. This paradigm is preferred especially for control applications that use icons, words or characters which are in different size at the same stimulus interface [22].

C. Region Based Paradigm

Region based (RB) paradigm is designed for reduction of perceptual error resources that are encountered in matrix based paradigms, such as row/column and single character paradigms [23]. In this paradigm, characters are grouped in several regions instead of rows or columns of a matrix. Stimulus presentation and the character selection processes are achieved in two levels. After selecting the target region at the first level, characters of the selected region are shown on the screen. At the second level, characters of the selected group flash individually. Subject concentrates on a particular character on the screen and the final target character is selected [24].

Region based paradigm may increase the number of characters that are used in stimulus interface by increasing the number of nested levels. It also ensures lower oddball probability as in row/column paradigm (In this study, because of using 7 regions, oddball probability is 1/7). Besides, the paradigm provides reduction of crowded effect and adjacency errors [25].

III. VISUAL STIMULUS MODULE

In this study, we designed a visual stimulus module for P300 based BCI studies. The module provides to customize stimulus interface by selecting paradigms and specific parameters. As well as the other BCI operations of the BCI system, such as data acquisition and signal processing and classification, stimulus interface is also designed by using Matlab. The designed visual stimulus module is given at Figure 1. The module includes three different stimulus paradigms for both online and offline applications. Details of the module is as given below.

Analysis Type: There are two types of data recording and analysis methods: offline and online.

Offline Analysis: Offline analysis is the method that signal processing, classification and character prediction procedures are performed after data recording procedure.

Online Analysis: In online analysis, signal processing, classification and character prediction procedures are performed simultaneously with data recording.

Paradigms: The module enables to create three visual stimulus paradigms: row/column paradigm, single character paradigm and region based paradigm.

Row/Column Paradigm: Stimulus are given by intensification of rows and columns in the matrix.

Single Character Paradigm: Stimulus are the random intensifications of each characters on the matrix individually.

Region Based Paradigm: Stimulus are grouped on several regions. Stimulus are given by intensification of the regions individually. Character selection procedure requires a two-level process.

Stimulus Type: Stimulus type is another parameter of the module. Changing size, color, thickness or both of size and color of the stimulus are stimulus types that can be applicable by the module.

Number of Sequences: Number of sequences defines the number of intensification of each items on the screen. Number of sequences affects the time required to select a character and also affects information transfer rate of the system. Although the number of sequences is a selectable parameter for synchronize online application, asynchronous online applications are independent from number of sequences.

Target Characters: The target character option is used for determination of character prediction accuracy by comparing the target and predicted characters after analysis are completed. On the other hand, target characters are used to give feedback for online sessions.

Stimulus Timing: Timing of a stimulus sequence is a widely investigated criterion on P300 based BCIs. The stimulus module enables to set all timing details of a stimulus sequences.

Stimulus Duration: This period defines the intensification duration of a stimulus.

Interstimulus Interval (ISI): Interstimulus interval is the time interval between two consecutive intensifications.

New Character and Feedback Interval: It is a time period to inform user that a new selection will start. At this period, all of the stimulus on the stimulus interface are intensified together in order to inform subjects that the cycle for the previous character has been completed and a new cycle for a new character is going to start. This interval is also important for resting of the subjects. Moreover, in online applications, the intended character is determined and also feedback is provided to the users during this period.

Colors: Both characters on the matrix and background color of the matrix can be changed according to user preferences and experimental setup.

Outputs of the Visual Stimulus Module: After the analysis type, paradigm and parameters are selected, stimulus interface is run by the BCI operator. The stimulus sequences are generated randomly. In order to reduce perceptual error sources, during the stimulus presentation, consecutive presentation of the same stimulus, i.e. cell, region or row/column is prevented.

Figure 2a and 2b represent the row/column paradigm and single character paradigm interfaces respectively. In this study, for row/column paradigm and single character paradigm, interfaces are designed for spelling applications. In Figure 2, character color and size are the stimulus types for both paradigms. Figure 2c and 2d represent the stimulus interfaces for region based paradigm. Region based paradigm is designed for environmental control applications and figures related to the commands are used as stimulus. Figure 2c is the first level of the stimulus interface and Figure 2d is the second level of the first region on the first level.

At the end of the stimulus presentation, program automatically creates three files to keep stimulus indexes, EEG signal, and selected parameters. Stimulus file contains
stimulus indexes that generated randomly by the program. Signal file contains raw EEG data recorded on several channels. All the parameters used during data recording are also saved in a file named parameters.

**Synchronization:** At BCI applications, simultaneous recording of EEG data and stimulus indexes is quite important in terms of accurate determination of the timing of P300 responses. Therefore, the prepared stimulus module interacts with the EEG device directly during data recording and transfers randomly generated stimulus codes to the EEG device. In this way, EEG data can be recorded with stimulus indexes simultaneously and P300 responses in EEG data can be divided exactly. In this study, 16 channel V-amp biosignal amplifier (Brain Products GmbH) is used for recording EEG signal. Synchronization is provided by sending trigger signals to the device through the LPT (Line Printer Terminal) port. Trigger signals consists of device connection code, run of stimulus interface code, new character code, stimulus codes of each character, completion code of a run.

**IV. Experiments**

In order to validate the visual stimulus module, we set up the stimulus paradigms by using the module. All the three interfaces were tested on healthy subjects. The study was approved by the ethics committee of Faculty of Medicine, Gazi University. Three subjects participated voluntarily in the experiments. None of the participants had P300 based BCI experience before. All of the participants were male and the mean age of the participants was 27. EEG signal was recorded on Cz position with an active electrode. The reference and ground electrodes were placed at right earlobe and AFz respectively. All the electrode impedances were kept below 10kΩ.

Three different experimental setups, including row/column, single character and region based paradigms, were established by using the designed stimulus module. The subjects were asked to select 4 items at each three sessions which are designed with different paradigms. The number of sequences was 15, stimulus duration was 150ms and interstimulus interval was 300ms for all paradigms. Therefore, total time for selection of a character was 15*12*300ms =54s for row/column paradigm, 15*36*300ms=162s for single character paradigm and 15*2*7*300ms=63s for region based paradigm.

The EEG signals were recorded with V-amp amplifier (Brain Products GmbH) at a sampling rate of 250 Hz. EEG signals were segmented 1s time windows after each stimulus onset. Segmented EEG signal was filtered at 5 Hz by a 5th order Butterworth lowpass filter. Grand average ERP waveform of target responses was yielded by averaging the EEG signal.

Statistical analyses were carried out using the SPSS 15.0. One-way statistical analysis of variance (ANOVA) was carried out for determining difference of amplitude and latency among the paradigms. A p-value <0.05 was considered as statistical significance level.

**V. Results and Discussion**

In this section, we present the preliminary results of the designed visual stimulus module. Subjects were asked to select four characters by using the three stimulus interfaces which were established by the visual stimulus module. P300 waveform of a character was obtained by averaging the EEG signal for all three stimulus paradigms individually.

As an illustration, averaged P300 potentials that were obtained from Subject 1 at electrode location Cz by using the three different visual stimulus paradigms are seen in Figure 4. As seen from the Figure 4, all of the paradigms created P300 responses with different properties on the same subject. Maximum amplitudes of P300 responses were 1.68 μV, 4.27 μV and 2.35 μV, and P300 latencies were 492 ms, 496 ms and 620 ms for row/ column, single character and region based paradigms respectively. The highest P300 amplitude was achieved in case of using single character paradigm. The preliminary results confirmed the theory that smaller oddball probability may elicit higher P300 amplitude.
In order to determine whether or not P300 amplitude and latency differ among the paradigms, one-way statistical analysis of variance (ANOVA) test was carried out on three subjects. The analysis of P300 peak amplitude revealed a significant difference among the paradigms \( F=47.66, p=0.00 \). Table 2 shows the \( p \) values for Bonferroni post hoc test that was used for pairwise comparison of the paradigms. According to the results, RC paradigm is significantly different from SC paradigm \( (p=0.000) \) and RB paradigm \( (p=0.025) \). On the other hand, SC paradigm is also significantly different from RB paradigm \( (p=0.000) \) in terms of maximum P300 amplitude. The results revealed that P300 amplitude was elicited in the different paradigms were significantly different from each other.

Average P300 peak latencies were 443 ms for RC paradigm, 514 ms for SC paradigm, 604 ms for RB paradigm. The test results revealed a significant difference \( F=28.62, p=0.000 \) among the paradigms in terms of latency. Bonferroni test results also revealed that there were significant differences between the paradigms RC-SC \( (p=0.026) \), RC-RB \( (p=0.000) \) and SC-RB \( (p=0.007) \). According to the preliminary results, although the signal was recorded under the same conditions, amplitude and latency of P300 potential that was elicited in the different paradigms may vary.

Table 2 shows the \( p \) values for Bonferroni post hoc test of averaged peak amplitudes/latencies for the three visual stimulus paradigms.

RC: Row/Column Paradigm, SC: Single Character Paradigm, RB: Region Based Paradigm

VI. CONCLUSION

There is not a common paradigm or parameters that can be accepted as the most successful to elicit P300 potentials for all BCI users. The most optimal paradigms or related parameters differ between both healthy and disabled subjects, even among healthy subjects. Besides, a stimulus paradigm that can be considered as the most suitable for all BCI application is not identified. In this study, we designed a visual stimulus module for P300-based BCI applications. The stimulus module offers to design three P-300 based stimulus paradigms and to set specific parameters. Selecting subject-specific paradigm and parameters would provide subjects to achieve a higher classification and target prediction success in real time applications. Since it provides a common platform for different stimulus paradigm presentation, the designed module is especially useful for comparative experimental studies.

Although this module is designed for spelling and control applications currently, it is possible to adapt the stimulus interfaces to a variety of applications by replacing characters and symbols on the stimulus screens easily. In the future, new stimulus paradigms will be reproduced and the module will be enriched in terms of stimulus paradigms. Besides, the module will be improved by addition of signal processing and classification tools. In this way, the module will also offer operators the opportunities to analyze the raw EEG signal, practically.

ACKNOWLEDGMENT

This study has been supported by the Scientific and Research Projects Department of Gazi University (BAP, Project no: 07/2012-15 and 07/2012-29).

Abstract—Pulse Oximeter devices are widely used as a non-invasive method for instant monitoring of blood oxygen saturation and heart rate. In this paper, a wireless microcontroller based pulse oximeter is proposed to measure the oxygen delivered to the patient via the oxygen flowmeter. In the first step, the signals received from reusable SpO₂ sensor (finger probe) are processed by a microcontroller to determine the blood oxygen saturation and heart rate. Depending on the current blood oxygen saturation value, wireless signals are sent to the non-invasive ventilation flow meter vacuum regulator to deliver the necessary oxygen into the patient. Oxygen supplied to the patient is automatically controlled according to the oxygen saturation change.

Keywords—Pulse Oximeter, Oxygen saturation, Ventilation, Oxygen flow meter, Oxygen regulator, Circuit design, Wireless control.

I. INTRODUCTION

Oxygen is the common drug to be used in the care of patients who present with medical emergencies. Currently, ambulance and emergency department teams are likely to give oxygen to all breathless a large number of patients [1].

The amount of oxygen saturated hemoglobin in arterial blood is expressed with oxygen saturation [2]. Formerly, the most common method of assessing oxygenation was the use of arterial blood gases [3]. This is painful for patients and has the serious complications of vascular injury or occlusion and infection. The methods of applying also pose the risk of needle stick injury to staff [4].

Today, pulse oximetry is a safe and simple method of assessing oxygenation [2]. At the same time, they are cheap and easy to carry devices. Pulse oximeter is a measuring device as peripheral arterial oxygen saturation in the blood non-invasively. Pulse oximeter shown in Figure 1, can be monitored from bedside monitors as used alone. Pulse oximeter is required intraoperatively monitors. During patient monitoring using pulse oximeters the early detection of untoward events is the most important, especially as it may contribute to the prevention of hypoxic insults [5].

Pulse oximetry is a routine device used in surgery, intensive care units and operating rooms, due to its cheapness. It is a non-invasive device and easy to be used. [6].

Oxygen flowmeter illustrated in Figure 2 is used to give the oxygen to the patient through the humidifier, nose nozzle and mask. Vacuum regulator allows patients to adjust the vacuum level. It has the manometer to see visually the pressure. Vacuum regulator is set manually as shown in figure 2.

The patient may need to be supported by mechanical ventilation when the respiratory system fails [7]. Mechanical ventilation is common form of life support in the intensive care unit (ICU) [8]. Although mechanical ventilation is one of the ultimate life-supporting technologies, in recent years, there has been renewed interest in the injury that it can cause. The concept that high airway pressures during positive pressure ventilation can cause gross injury manifest has been well known and investigated for a long time [9]. It was found that an average of 40% of the patients died in the process of finalizing mechanical ventilation. It was found that also a high overall mortality in the intensive care unit [10].

In the literature, there have been several studies on pulse oximetry. Although the small number of wireless applications, studies involving with oxygen flow meter have not been a part of literature. Some of the studies in the literature on pulse oximetry and wireless communications are as follows: Watthanawisuth and his team (2010) worked on the monitoring of pulse oximetry with wireless wearable system [11]. Qing Cai, Jiming Sun, Ling Xia ve Xingqu Zhao (2011), have created a wireless pulse oximeter sensor using a wrist strap [12]. Turban and Niwayama (2011) have worked on reducing the power consumption of wireless pulse oximeter [13]. Rekha Chandra, Safer and Srividya (2015) worked on the development and miniaturization of wireless pulse oximeter [14]. Render, frosty and Dalkılıç (2014) worked based on the Arduino Healthduino wireless Mobile Health Monitoring System, cloud-based database, doctors and patients mobile applications [15]. In the study by using RF technology. Adochie and colleagues wireless pulse oximeter is designed. Also it has been monitored with WiFi or GSM / GPRS technology [16].

The studies mentioned above do not both measure oxygen saturation and supply oxygen automatically to the patients. The aim of this study is to design a system that measure first the oxygen saturation and provide the required oxygen to the paints via a wireless and mechanical ventilation system. For this purpose, a microcontroller is used to measure the blood oxygen saturation. A wireless signal including the measured blood oxygen saturation data is sent to the non-invasive ventilation flow meter vacuum regulator to deliver the required oxygen into the patient. This process is repeated as the doctor's recommendation continues. Thus, according to symptomatic status of the patient, mechanical ventilation causing pre-intervention to acute respiratory failure is no mere required. By using proposed device in this study, O₂ saturation can be
precisely arranged and delivered to the patients. Microcontroller programming with proper protocols based on the different patient stories and different diseases can prevent the problems caused by human influences.

![Figure 1: Pulse oximeter.](image1)

Figure 1: Pulse oximeter.

Figure 2: Oxygen Flowmeter, Vacuum regulator.

II. PULSE OXIMETRY

Respiratory system is specialized to allow gas exchange between ambient air and blood. The 97% part of oxygen composes of chemical compounds with the hemoglobin in the red blood cell and rest of 3% composes of dissolved in the fluid plasma and cells. Oxygen saturation is defined as the ratio of hemoglobin to total hemoglobin bound to oxygen in the blood.

The O₂ saturation is close to 100% under normal conditions. The O₂ saturation between 97% and 100% represents good gas exchange within the person. Hypoxia is mentioned above when SpO₂ level falls below 90% and may require respiratory support. Identifying hypoxia conditions in an early stage is important. Thus an early intervention becomes possible and therapy starts immediately.

According to the blood gas analysis method, ‘arterial oxygen saturation’ is represented by the symbol SaO₂ in the literature. This parameter corresponds to the oximetry method ‘arterial oxyhemoglobin concentration’ (represented by the measured SpO₂ symbol). The main difference between SaO₂ and SpO₂ parameters is that SpO₂ presents the amount of oxygen bound to the hemoglobin molecule found while SaO₂ denotes the total amount of oxygen in the arteries [17].

Oximeters are devices that determine the oxygen concentration of various species of Hb [18].

A. PRINCIPLES OF PULSE OXIMETER

Light is transmitted, absorbed, or reflected when it passes through matter. The relative absorption or reflection of light at different wavelengths is used in several monitoring devices to estimate the concentrations of dissolved substances. This type of measurement is called spectrophotometry and is based on the Beer-Lambert Law. According to the Beer-Lambert Law, if a known intensity of light illuminates a chamber of known dimensions, then the concentration of a dissolved substance can be determined if the incident and transmitted light intensity is measured [18].

The pulse oximetry is based on two physical principles. The first one is the light absorbance of oxygenated hemoglobin and the second one is the absorbance at different wavelengths with pulsatile (AC) component [19]. Pulse oximeter is based on the principles to absorb light different level by oxygenated hemoglobin with reduced hemoglobin [14].

The form of Hb is important issue. In the adult blood usually contains four species of Hb: HbO₂, reduced Hb, methemoglobin (metHb), and carboxyhemoglobin (COHb). Each of Hb species has a different light absorption profile. The different absorption constants for each Hb species over a range of light from red to infrared are shown in Figure 3 [18].

Pulse oximetry uses the wavelengths of 660 nm and 940 nm because these wavelengths are available in semiconductors. The oximeters measure red and infrared light transmitted through and reflected by a tissue bed. There are several technical problems to accurate estimation of SaO₂ by this method. For example, many light absorbers other than arterial Hb are in the transmitted light path (e.g., skin, soft tissue, venous). A group of absorbers in a typical sample of living tissue is shown in Figure 4 [18].

![Figure 3: Hemoglobin extinction curves](image2)

Figure 3: Hemoglobin extinction curves

International Conference on Advanced Technology & Sciences (ICAT’16) September 01-03, 2016 Konya-Turkey
The AC component represents absorption of light by the pulsating arterial blood at the top of the figure. The DC (baseline) component represents absorption of light by the tissue layer. The pulse oximeters mostly use only two wavelengths of light, typically 660 nm (red light) and 940 nm (infrared light). The pulse oximeter first determines the fluctuating or AC component of absorbance at two wavelengths. Secondly it divides this value by the DC component to obtain the pulse-added absorbance which is independent of the incident light intensity. Thus, the oximeter then calculates the ratio (R) of the two pulse-added absorbance (one for each wavelength) [19]:

\[
R = \frac{AC_{660}/DC_{660}}{AC_{940}/DC_{940}}
\]  

(1)

Pulse oximetry is calibrated using the calculated value of R. An example of a pulse oximeter calibration curve is shown in Figure 5 [22].

The attenuation characteristics of light passing through the fingertip consist of three components: tissue loss, and (vein) the weakening of the artery (artery) attenuation. Tissue attenuation and veins attenuation have a constant characteristic. Arteries (arterial) blood flow in fingertip causes light attenuation variation. The reason is the change in the oxygen saturation of the blood pumped to the body blow to the heart of each pulse. Heart rate (pulse) signal is superimposed on the fixed component which is weakening. Thus, arterial oxygen saturation can be calculated by subtracting from the total attenuation of the attenuation constant and vein tissue attenuation components [17].

The SpO₂ value can be read incorrectly in some situations, environmental effects, and technical. These conditions are:

- Very bright light in the operating room (such as more lighting).
- Abnormalities in value of carboxyhemoglobin and methemoglobin.
- Electrocautery device can be prevented by transportation of signal to diode when it running.
- It may be affected by light emitted from the surgical light in the hall.

SpO₂ value cannot be measured or read incorrectly when the patient's fingernails very long, fingernails with diamonds, henna, dyed and so on.

III. PULSE OXIMETER MANUFACTURING AND WIRELESS TELEMETRY FOR VENTILATION OXYGEN SUPPORT

In this study, a telemetry control system is proposed to support oxygen to the patients based to the data measured by pulse oximeter. The schematic diagram of proposed wireless telemetry system for ventilation oxygen support with pulse oximeter is shown in Figure 7.
A. PULSE OXIMETER MANUFACTURING

The pulse oximeter block diagram in Figure 7 is illustrated in Figure 8 in detail. Pulse oximeter is proposed to design using microcontroller.

It consists of a photodiode and two LEDs including red and infrared LEDs. The $\text{SpO}_2$ sensor LEDs are connected as shown in Figure 9. The LEDs are controlled by the microcontroller PWM signal. However, the microcontroller PWM output cannot provide enough power to drive properly led. LEDs are forced to give enough energy by the led driver circuit. A finger probe measures the oxygen saturation via pulse oximeter probe as analog signal. Since the only one photodetector for the two LED signals, the signals cannot be received at the receiver at the same time, thus requiring switching of signals. Double the switching drive integrated, red and infrared LEDs with two signals from the microcontroller does turn on and off. The timing diagram to drive the LEDs is shown in Figure 10.

Photodiode generates an analog current depending on the light absorption. This current must turn into voltage. That transformation is performed in analog signal conditioning circuit. The analog signal conditioning circuit is illustrated as in Figure 11.

The $\%\text{SpO}_2$ is calculated when the signal is applied to Analog-Digital Converter (ADC) module in microcontrollers. Signal conditioning circuit consists of three stages. First stage is amplifier (transimpedance amplifier), which takes a few micro-amps current by photodiode and turning into a few millivolts. Transimpedance amplifier is an amplifier as well as current-voltage converter. The signal passes by High Pass Filter (HPF). Therefore background light interference is reduced. High Pass Filter output is upgraded with second stage gain amplifier.

There are two filter applications. The first one is a passive RC filter illustrated within a circle in Figure 11. The second one is in the microcontroller as software. The digital filter is called FIR. Microcontroller include Digital Signal Processing (DSP) unit. DSP performs digital Finite Impulse Response (FIR) that is the filtered data. FIR is a software filter. The filtered data is used to calculate the pulse amplitude. The pulse amplitude is used to calculate $\text{SpO}_2$ and heart rate.

Finally microcontroller sends the computed data about blood oxygen saturation to the second microcontroller via wireless unit.
B. WIRELESS OXYGEN FLOWMETER CONTROL

Flowmeter manually operate in general. In this study it is operated automatic control with a motor and motor driver circuit. It uses pulse oximeter wireless data for automatic control.

1) OXYGEN SUPPLY AND EQUIPMENT

Oxygen is supplied for patients from two sources, including central system and O₂ tubing. Flowmeter (oxygen flow measuring equipment) and humidifier (humidification oxygen canister) is located in the patients unit. It is shown in Figure 2.

The pressure in the oxygen tube is very high to provide oxygen to the patient. The pressure to be used medically appropriate level (40-70 psi-pounds) must be reduced. Therefore, regulator is used in order to regulate the pressure. Regulator is an arranger by display.

Flowmeter adjusts the flow rate per minute of oxygen delivered to the patient. Humidifier is a chamber used depending flowmeter. It allows the moisture of the oxygen from the oxygen source.

In patients with respiratory; nasal cannula, simple face mask, partial mask recycled, recyclable mask, nebulizer mask and oxygen header methods are used. In patients without respiratory mask balloon system (Bannings valve-mask) is used. [14].

2) MOTOR CONTROL CIRCUIT

In this application, a motor is mounted on the flowmeter. The data is taken from a pulse oximeter with wireless communication module.

The motor control system is shown in figure 12. This system provides motor control with wireless data from pulse oximeter. It is controlled motor speed and left-right rotation by implementation of the appropriate voltage values.

\[ \text{motor} = K_1 * A_1 + K_0 * A_0 \]

Equation 2 is used for to determine motor speed.

K₀ and K₁ expressions in the equation 2 are coefficients used to determine the applied voltage to the motor according to the received value.

If the pulse oximeter measurement SpO₂ value falls under %95, then the motor works. If it falls under %90 then the oxygen transferred to the patient is increased. If the measurement value rise above 95%, then rotation reversed valve is closed.

Motor situation and SpO₂ values can be changed easily in the microcontroller. Thus working system can be programmable according to doctor’s protocol.

IV. RESULTS

Developments in electronics and sensor technology yields several advantages for biomedical applications. For example, analog and digital devices for bio-signal treatment can easily be employed by microcontrollers.

Biosensors and pulse oximeter probes can be the candidate subject for different researches. The conventional analogue probes are required to be updated. Instead of these instruments, it is possible to develop better digital probes.

This study has not been finalized yet. The pulse oximeter telemetry system presented in this study is cheap, fast, easy to use & setup and medical risks low example. The mechanical ventilation risks for using hypoxia control were explained. Furthermore mechanical ventilation devices are very expensive. The manual flowmeter using simple oxygen support is not enough for hypoxia control. This application eliminates both drawbacks of applications.

This study leads to some other studies such a new design of pulse oximeter that decrease the heat and other pigments effect, a new device that adjusts blood pressure, bilirubin, cholesterol, glucose levels and hemoglobin counter.

Abstract— Carpal tunnel syndrome (CTS) is the most common entrapment neuropathy. In most patients, the diagnosis can be proposed based on patient history and clinical symptoms, with electrophysiological findings. The mild CTS may not produce any nerve conduction abnormalities and this can make standard conventional tests not enough in diagnosis the mild CTS. The aim of this study was to evaluate Compound Muscle Action Potential (CMAP) morphology as more sensitive and specific parameters without any additional testing for diagnosis the mild CTS. A total of 77 clinically diagnosed patients with CTS were prospectively enrolled. Data was evaluated from 70 normal hands and 46 hands with the diagnosis of the mild CTS with standard electrophysiological (EDX) tests and clinical findings. The specificity and sensitivity rate were calculated to evaluate the utility of CMAP negative peak (NP) morphology parameters evaluated duration (CMAP NPHalf-Duration) and area (CMAP NPHalf-Area and CMAP NPFull-Area) by comparing the standard EDX test (Median Distal Motor Latency (DML) and peak to peak amplitude of CMAP (CMAP NPAmplitude) recorded from the abductor pollicis brevis (APB) muscle. Although CMAP NPHalf-Duration and CMAP NPFull-Duration had no statistically significantly difference between the mild CTS and normal group (p>0.05), DML, CMAP NPAmplitude, CMAP NPHalf-Area and CMAP NPFull-Area in the mild CTS group were statistically significantly different (p<0.05). The present study shown that CMAP NPFull-Area had the highest sensitivity and moderate specificity rate (90.0% and 42.2%, respectively). Furthermore, it was confirmed again that DML was a valuable motor nerve conduction technique for the diagnosis of the mild CTS with high sensitivity and moderate specificity (84.8% and 84.8%, respectively), and it had more sensitive than CMAP NPHalf-Area high sensitivity and moderate specificity (80.0% and 38.7%, respectively). This study provided the evidence of CMAP NPFull-Area and CMAP NPHalf-Area that could be predictors of the mild CTS.

Keywords— carpal tunnel syndrome, motor nerve conduction study, clinical electromyography, signal processing

I. INTRODUCTION

Carpal tunnel syndrome (CTS) is the most common entrapment neuropathy caused by median nerve compression at the wrist causing pain, paresthesia, and functional problems [1]. Its prevalence ranges from 1-5% in the general population [2]. CTS is diagnosed on the basis of clinical signs and symptoms and is confirmed by an electro diagnostic (EDX) tests. Nerve conduction study (NCS) and electromyography (EMG) are a standard part of the evaluation for CTS. They are useful to support the diagnosis of CTS, to assess severity, to provide a baseline for postoperative assessment in patients with unsatisfactory surgical result, and to exclude other abnormalities such as polyneuropathy, myopathy and radiculopathy [3]. The EDX tests rest upon the demonstration of impaired median nerve conduction across the carpal tunnel in the context of normal conduction elsewhere. Nerve compression results in damage to the myelin sheath and manifests as delayed distal latencies and slowed conduction velocities with resulting in a reduction of the median nerve compound motor action potential amplitude (CMAP) or sensory action potential amplitude (SNAP). Several EDX techniques have been established as standard and conventional methods for diagnose of CTS [4-5]. Although NCS and EDX tests have been widely used in diagnosing CTS, there are still ongoing debates particularly on accurate because sensitivities of EDX tests have ranged between 49% and 84% with specificities of 95% or higher. Furthermore, EDX test may have a substantial rate of false-negative findings, and so rely instead on clinical findings, especially in mild CTS that may not produce any nerve conduction abnormalities [6-9]. The patients have signs and symptoms of CTS, but the conventional studies may show equivocal or false negative. On the other hand, there are patients with median slowing at the wrists but who do not have CTS. Consequently, the main point of contradiction is that EDX tests yield negative results on symptomatic persons or positive results on no symptomatic persons [10].
signs) were performed before the EDX tests. The patients who had electrical evidence of CTS and patients with suspected clinically CTS but no EDX was used in the diagnosis of mild CTS. And then we compared these parameter’s sensitivity in the mild CTS.

It is generally accepted that median sensory conduction is more sensitive than motor conduction in the EDX of CTS. However, the low sensitivity of standard median motor EDX techniques in detecting motor axon abnormality also needs to be considered [13]. CMAP results from the sum of all the synchronously activated muscle fiber action potentials generated through all the axon destined to the APB muscle. The CMAP is an indirect measurement of the number of axons that conduct between the stimulating and recording points. A change in the CMAP emerges in peripheral nerve disorders. It is most prominent in entrapment neuropathies and demyelinating neuropathy, in which conduction is either blocked or delayed because of segmental demyelination [14]. Although distal CMAP duration prolongation is useful diagnostic tool for chronic inflammatory demyelinating polyneuropathies (CIDPs), the parameters analysed of the morphology of the distal CMAP can be also potentially useful parameters in the diagnosis of the mild CTS. In this manner, it cannot be needed significantly more time-consuming conventional EDX techniques which the patient can refuse extensive testing because of poor tolerance to electrical stimulation.

The aim of this study was to evaluate diagnostic value of the half-duration and the full-duration of CMAP negative peak (NP) and the half-area and the full-area of CMAP NP as a complementary test in diagnosis of mild CTS. And then we compared these parameter’s sensitivity and specificity with both DML and CMAP amplitude obtained conventional EDX tests.

II. METHODOLOGY

A. Study Group

A total 77 subjects (25 female, 5 male) with suspected CTS was retrospectively enrolled in Gazi University Faculty of Medicine between January 2014 and December 2014. After EDX tests in EMG Laboratory, 70 normal hands belonging to patients with suspected clinically CTS but no electrophysiological evidence of CTS and 46 symptomatic hands belonging to patients with mild CTS were included in the present study.

Physical examination consisted of evaluating of muscular strength, sensory function and provocative clinical test (Tinel signs) were performed before the EDX tests. The patients who have numbness, tingling pain, or paresthesia in the median nerve distribution, and have precipitation of these symptoms by repetitive hand activities and relieved by resting, rubbing, and shaking the hand were included. The patients who have history or clinical signs suggesting systemic disease such as double-crush injury, diabetes, chronic renal failure, gout, rheumatoid arthritis, thyroid diseases and have clinical or electrophysiological signs suggesting pathological conditions such as myelopathy, polynuropathy, radioculopathy, myopathy were excluded. We selected only the mild CTS diagnosed according to the criteria of our laboratory and used for diagnosis and classifying of the CTS [15-16].

B. Electrophysiological Measurements

A Medelec Synergy EMG device (Medelec, Surrey, UK) was used in the study. Filters were set at 20 Hz and 2 kHz for motor studies. Stimulation was supramaximal and sensitivity was 1 ms. The sweep speed was set at 1 ms/division and sensitivity was selected as 20 µV/division. Cup electrodes (Ag-CI) were used for motor NCVs. In the NCVs, the distance between the recording electrodes is 3-5 cm. The active electrode was over the endplate region of the main bulk of the APB muscle innervated by the nerve being tested in order to obtain the maximal response with no initial positivity. The reference electrode was over the tendon of the muscle. The ground electrode was placed on the between the stimulating and recording electrodes providing a zero voltage reference point. Electrical stimuli were delivered by a constant current stimulator through bipolar surface electrodes. The distance between two felts is 3 cm and the diameter of the electrodes is 8 mm. It was applied supramaximal for a period of 0.1-0.5 ms and approximately and in a density of 10-30 mA. Skin temperatures were continuously monitored and maintained between 32–34°C during the procedures and the room temperature was maintained between at 22°C and 25°C.

1) Motor NCS: DML was recorded with a distance of 5 cm between the stimulation point of the nerves at the wrist and the APB muscles. DML was measured from the stimulus onset to the initial negative response, and the CMAP amplitude was measured from baseline to negative peak and measured in millivolts (mV), shown in Figure 1. Markers which indicated the onset, negative peak, positive peak and end of the CMAP waveforms were automatically determined by the Medelec Synergy software. In case of incorrectly placed, markers were manually repositioned.

2) CMAP Morphology: As shown in Fig.1, CMAP NP full-duration was measured from initial deflection from baseline (1) to the first baseline crossing (3). CMAP NP half-duration was measured from initial deflection from baseline (1) to the peak point on negative peak (2). The calculation of half-duration might be more accurate. Because full-duration of CMAP NP might return to baseline very slowly. In addition, CMAP NP half-area and CMAP NP full-area were calculated.

3) Signal Analyses: All CMAP duration and area measurements were manually marked and calculated by Signal5 Software (CED, micro1401, Camridge, UK). Using this software, CMAP signals were full-rectified and compared.
peak and baseline markers with not rectified original signal. Because a baseline shift or other electrical interference may lead to a problem for reliable measure of the area. The terminal positive deflection of the CMAP having multiple baseline crossings and phases was not calculated in the measurement because the end of the repolarization phase was frequently difficult and complex to determine [14,18].

Fig. 1 Components of the Compound muscle action potential (CMAP) [17].

C. Statistical Analyses

The mean and standard deviations were calculated for statistical analysis using SPSS 20.1 (The Statistical Package for Social Sciences, Chicago, IL, USA). The two-tailed Student’s t-test was used for comparative statistics. In order to assess the differences (age and gender) between the normal control group and the abnormal group, Chi-square test was performed. For the statistical significance, the probability level of 5% (p ≤ 0.005) was preferred.

Validity was assessed by the ability of CMAP amplitude, duration and area to discriminate between the mild CTS and the control groups using area under the receiver operator characteristic curve (ROC). The ROC curve was obtained by plotting the sensitivity of all possible cut-off points for a test on the y-axis against ‘1-specificity’ (false positivity) on the x-axis. As a measure of the overall performance of a diagnostic test, the area under the ROC curve (AUC) was estimated using a form of the trapezoid method, and 95% confidence interval of the AUC was estimated by the bootstrap method approach. Accuracy was measured by the area under the ROC curve. One criterion for evaluating the cut-off point of a test was to maximize the sum of sensitivity and specificity. It was thought of optimally better cut-off for differentiating patients. It is known that searching for a more sensitive test might present the drawback of decreased specificity, leading to false positives [19]. It was considered cut-off points for both high sensitivity and high specificity.

III. RESULTS

Totally 77 subjects with CTS suspicion were clinically examined with conventional EDX methods in EMG laboratory. While total 29 subjects (25 women (86.2%) and 4 men (13.8%), age = 55.14±7.5) were diagnosed as the mild, total 48 subjects (39 women (81.2%) and 9 men (18.8%), age= 41.62±13.8) were assessed with normal findings. Totally 116 hands (70 normal hands and 46 asymptomatic hands) belong to subjects were included in this study. The characteristic of study population is given in Table 1.

DML = distal motor latency, CMAP = compound muscle action potential; NP= negative peak; ms= milisecond; mV=mili volt; SD= standard deviation; p= statistical significance value; AUC= area under curve. 

DML significantly differed between groups. There was statistically significant difference in terms of CMAP NPPt.Area and CMAP NPt.Area between the mild CTS and control group (P<0.001). However, there was no significant difference between the control and mild CTS groups.
in terms of CMAP NP\textsubscript{Half\_Duration} and CMAP NP\textsubscript{Full\_Duration} between groups (P=0.331 and P=0.208, respectively).

In the diagnosis of mild CTS, CMAP NP\textsubscript{Half\_Area} parameter (cut-off ≤ 41.9, 90.0% sensitivity and 42.2% specificity) had the highest sensitivity and second high specificity rates. DML parameter (cut-off ≥ 6.82, 84.8% sensitivity and 47.6% specificity) had the highest specificity and second high sensitivity rates. Although CMAP\textsubscript{Amplitude} (cut-off ≤ 11.00, 80.0% sensitivity and 36.5% specificity) and CMAP NP\textsubscript{Half\_Area} (cut-off ≤ 20.5, 80.0% sensitivity and 38.7% specificity) parameters showed similarly high sensitivity and specificity rates, Both of CMAP NP\textsubscript{Half\_Duration} and CMAP NP\textsubscript{Full\_Duration} parameters had similarly the lowest sensitivity and specificity rates.

AUC values of DML (AUC = 0.800, 95% CI), CMAP\textsubscript{Amplitude} (AUC 0.766, 95% CI), CMAP NP\textsubscript{Half\_Area} (AUC = 0.727, 95% CI) and CMAP NP\textsubscript{Full\_Area} (AUC = 0.753, 95% CI) parameters having a “good” ratio were significantly different from 0.5 and that therefore it was considered that these parameters had an ability to distinguish between the mild CTS and healthy subjects. However, it was found that both of CMAP NP\textsubscript{Half\_Duration} (AUC = 0.560, 95% CI) and CMAP NP\textsubscript{Full\_Duration} (AUC = 0.572, 95% CI) parameters having a “fail” rate had no ability of the test to correctly classify those with and without the mild CTS. ROC curves belong to all parameters is shown in Figure 3.

**Fig. 2** ROC curves (a) MDL (b) CMAP\textsubscript{amplitude} (c) CMAP NP\textsubscript{half\_duration} (d) CMAP NP\textsubscript{full\_duration} (e) CMAP NP\textsubscript{half\_area}, and (f) CMAP NP\textsubscript{full\_area}

**IV. DISCUSSION**

The major finding of this study there were significant differences in the all the CMAP amplitudes, DML, CMAP\textsubscript{Amplitudes}, NP\textsubscript{Half\_Area} and CMAP NP\textsubscript{Full\_Area} between the mild CTS and normal control groups. This result on stimulating at the wrist may be an manifestation of axonal loss, conduction block or a combination. In the mild CTS, the primary abnormality observed with EDX measures was conduction slowing, which represents focal demyelination. Whereas distal latencies can reflect nerve conduction slowing of the fastest fibers. CMAP duration can depend on temporal dispersion among the distal motor fibers. On the other hand, some factors such as the distribution of conduction velocities of individual axons within the nerve, the distance between stimulating and recording electrodes, the morphology of each single-fiber action potential and phase cancellation between individual single-fiber action potentials also might have influenced CMAP morphology and in particular CMAP duration.

Ginanneschi et al. found similar results of the sensitivity of wrist-to-APB motor conduction studies using submaximal stimulus intensities. Padua et al. claimed that CMAP\textsubscript{Amplitude} was decreased only in patients with severe CTS as a result of the loss of motor units [15]. On contrary this, we found that CMAP\textsubscript{Amplitude} was not decreased only in patients with severe...
CTS as a result of the loss of motor units but also in mild CTS. Unlike our finding, Nashed et al. found that there was no difference in peak-to-peak MUAP amplitude between the mild CTS and the control groups [20]. It can be result in due to their very small study group (9 control group and 8 mild CTS)

In many previous studies, CMAP NP full-duration prolongation assessed by measuring NP is commonly used in CIDP as diagnostic parameter [21-24]. CMAP duration prolongation can be rare in conditions that lead to distal latency prolongation in CTS. But we found that CMAP NP full-duration prolongation has not been incorporated in the diagnostic criteria for mild CTS. Similarly, Cleland et al. found that, in contrast to CIDP, dispersion of the median CMAP was uncommon, even in advanced carpal tunnel syndrome, being seen in only 8 of 103 (7.8%) hands [18]. Isose et al., in comparison of CMAP duration between normal controls and CTS patients, found very low sensitivity (for cut-off =5.8 ms., 23% sensitivity and for cut-off = 6.6 ms, 12% sensitivity) like our results [25].

The significant difference shown in NP full and half area may be considered as a manifestation of a very mild affection of motor axonal loss in even the mild CTS cases which are accepted as normal in terms of motor fibers involvement regarding the classification. Similar findings were found in DML which is also in normal range in mild cases. The classification suggests to evaluate cases as moderate when the DML is abnormal (prolonged as compared with the normal limits).

V. LIMITATIONS

The main limitation of our study was the lack of sufficient and reliable cut-off values for CMAP duration, amplitude and area. Larger studies are needed to confirm the reference range of CMAP with diagnostic studies including larger sample sizes and well-defined study groups. Because cut-off values can be influenced by the choice of patients with axonal loss in the control group.

Other limitation of our study is the control group who were referred to the ENMG laboratory with the suspicion of CTS. Some of these patients might be very mild cases in whom the electrodiagnostic tests are normal. Therefore allocation of control subjects who are also clinically normal would be more valuable to detect milder differences.

VI. CONCLUSIONS

In mild CTS, motor fibres can be more often affected than was originally thought and CMAP area also can reflect the number of muscle fibers in the CMAP. In this regard, we suggest distal CMAP area would be added into one of the EDX criteria for mild CTS in addition to conventional motor NCS. For further studies, it can be evaluated with new studies comprising large study groups and patient groups in different stages of CTS and including SNAP parameters (e.g., duration, area and amplitude) as well as wrist-elbow motor NCS including CMAP parameters (e.g., duration, area and amplitude).

Abstract—Dementias are termed as neuropsychiatric disorders. Brain images of dementia patients can be obtained through magnetic resonance imaging systems. The relevant disease can be diagnosed by examining critical regions of those images. Certain brain characteristics such as the cortical volume, the thickness, and the surface area may vary among dementia types. These attributes can be expressed as numerical values using image processing techniques. In this study, the dataset involves T1 medical image sets of 63 samples. Each particular sample is labeled with one of the three dementia types: Alzheimer's disease, frontotemporal dementia, and vascular dementia. The image sets are processed to create different feature groups. These are cortical volumes, gray volumes, surface areas, and thickness averages. The main objective is seeking brain sections more effective in establishing the clinical diagnosis. In other words, searching an optimal feature subset process is carried out for each feature group. To that end, a wrapper feature selection technique namely genetic algorithm is used with Naive Bayes classifier and support vector machines. The test phase is performed by using 10-fold cross validation. Consequently, accuracy results up to 93.7% with different classifiers and feature selection parameters are shown.

Keywords— Genetic algorithm, Feature selection, Dementia, Classification, Magnetic resonance imaging.

I. INTRODUCTION

Dementia diseases are termed as neuropsychiatric disorders, and encounter rate of them increases severely with age [1]. Brains of patients with dementia denote several differences in some ways such as cortical volume, thickness, surface area, according to disease type. The most common three dementia types may be sorted as Alzheimer’s disease (AD), vascular dementia (VaD) and frontotemporal dementia (FTD) respectively. In neuroimaging science, an unknown diagnosis is tried to be determined via medical images. Magnetic resonance imaging (MRI) is a technique interprets the anatomy. The T1 pulse sequence is one of the basic sequences in MRI that achieving remarkable tissue contrast and provides a good correlation when larger amounts of iron are present [2]. 2-dimensional brain images in slices can be acquired with MRI. These sliced output files have digital imaging and communications in medicine (dicom) file extension frequently, and project brain to a particular axis. Besides, aforementioned files contain patient information. It is possible to reach measurements of brain regions using those medical imaging files with image processing techniques. In theory, unknown diseases can be labeled with the aid of classification algorithms taking numerical expressions of brain sections as input parameters. Meanwhile, some features may be qualified as more precious.

In the beginning of this research, some classification tests were performed with taking all extracted brain features as input set. The accuracy results were not satisfying at all. Therefore, finding the lowest size feature set having high precision classification result constitutes the motivation of the study. Briefly in this study, samples with three dementia types are tested to seek a valuable feature subset with genetic algorithm (GA) based wrapper feature selection method over different classification algorithms.

A. Literature Review

When it comes to the literature research of interdisciplinary brain imaging studies, there are numerous indicative papers. The number of the studies using free-access datasets such as Alzheimer’s Disease Neuroimaging Initiative (ADNI), AddNeuroMed, etc. is quite high. The number of the studies using their own dataset is also a great deal more. In addition, some software tools are utilized for operations such as the construction of the virtual brain, feature extraction, etc. in computer science studies.

In 2011, Freesurfer v4.5.0 brain analyzing software tool was used for analyzing the brains of 295 AD, 444 mild cognitive impairment (MCI), 335 control subjects from the ADNI database. 23 regional volume and 34 cortical thickness features for 1074 MRI scans were used for the orthogonal partial least squares (OPLS) classification [3]. In another research, the performance of different methods through several brain regions was compared upon the features obtained from T1 MRI scans after the Freesurfer process.

509 AD, MCI or elderly control individuals aged between 55 and 90 from ADNI database were processed. Features were extracted and grouped as voxel-based (grey matter, white matter and cerebrospinal fluid in given voxel), vertex-based (the features are defined on the cortical surface) or...
In neuroimaging science studies, software tools used often as exemplified in the literature section. In this work, FreeSurfer v5.3.0 was used for medical image processing and analysis. FreeSurfer is a functional, connectional and structural human brain analyzing tool that comprises a set of image processing, numeric, etc. algorithms [8]. In a few words, the tool associates sliced medical imaging files structurally with the help of header information. Later on, the virtual 3-dimensional brain is modeled by following image processing techniques iteratively. For each individual samples, the same procedure is repeated. Working principle of

### II. Dataset

The dataset used in this research belongs to the picture archiving communication systems (PACS) of Eskişehir Os mangazi University’s Radiology Department.

The set consists of 63 dementia patients namely AD, FTD and VaD. Each sample is labeled only with one of these three clinical diagnoses. Samples are either male or female and ages of them vary between 50 and 90. Image sets were obtained from *Discovery MR750w* (GE, Milwaukee) and *Magnetom Vision plus* (Siemens, Erlangen) MRI systems last 2 years. Counts of dementia types over genders and MRI systems are shown in Table I.

In this work, T1 weighted image sets are used. Each sliced T1 weighted scan has MR modality and 2-dimensional MR acquisition type. Slice thicknesses of all image sets are between 4.5-5 millimeters. Also, all images are grayscale at least $256 \times 256$ image resolution and have dicom file extension.

### III. Methodology

The basic idea of this study is achieving the optimal feature subset having the highest accuracy. The method incorporates several consecutive operations. T1 weighted image sets, obtained from brain imaging studies via MRI systems, are preprocessed with brain modeling software. Freesurfer brain analyzing tool is used for preprocessing the sliced medical images and feature extraction from the virtual brain. After then, feature matrices in different measurements are created. Feature selection algorithm is applied to each feature group separately to determine the subset having high classification accuracy result. For this purpose, GA based wrapper feature selection algorithm over different classifiers is performed.

Tools and algorithms mentioned in the following subsections are put into practice to obtain results.

#### A. Feature Extraction

In neuroimaging science studies, software tools used often as exemplified in the literature section. In this work, FreeSurfer v5.3.0 was used for medical image processing and analysis. FreeSurfer is a functional, connectional and structural human brain analyzing tool that comprises a set of image processing, numeric, etc. algorithms [8]. In a few words, the tool associates sliced medical imaging files structurally with the help of header information. Later on, the virtual 3-dimensional brain is modeled by following image processing techniques iteratively. For each individual samples, the same procedure is repeated. Working principle of

### B. Paper Organization

In Section 1, an introduction to the research and literature review are presented. In Section 2, the dataset is described. In Section 3, the methodology of this research is explained, additionally in subsections, feature extraction, classification, feature selection, and testing methods are noticed succinctly. In the following section, tests and results are reported. Finally in the last section, the conclusion is made and feature plans are mentioned.
Freesurfer can be summarized as three major steps basically. Firstly, correction and verification operations for input files are processed. Secondly, volumetric registrations, removing neck actions, white matter segmentations, and also some visual smoothing transactions occur at this step. At the end of the last step, containing spherical instructions followed by cortical parcellation, brain modeling is completed [9], [10]. During the procedure, data is transferred the way that the output of each sub-step will be the input of another step, analysis process continues gradually. When the procedure is completed with success, visual and statistical files become accessible. Depending on computer hardware, the entire Freesurfer process described may take quite some time. In 2011, Cuignet et al. reported that a single Freesurfer modeling could take roughly a day [4]. Likewise in 2012, Gronenschild et al. uttered that this whole process found to be completed in 30 hours and what is more, analysis may be affected by tool versions or operating system differences [11]. In this research, Freesurfer operations over T1 medical images were executed with a computer having Intel®Core™i7-4700 2.40 GHz CPU, 1600 MHz 16 GB RAM hardware, and Ubuntu 14.04 x64 operating system. Multiple Freesurfer processes run parallelly for groups of samples. In detail, 3-dimensional modeling of brain structure for each sample was accomplished at the end of approximately 15 hours time period. No manual editing was used after analysis.

In the Literature Review section, some of the significant features are listed. Accordingly, from the Freesurfer statistics files, cortical volume features for whole brain structure, moreover, gray volume, surface area and thickness average features for left and right parts of the brain are taken into consideration in this study. Values are exported via bash scripts. Lastly, each feature is normalized to a length of 1 while creating feature matrices.

B. Classifiers

1) Naive Bayes Classifier: Characteristics for each class are thought independently. Theoretically, features are supposed to be uncorrelated by implementing the Bayes’ rule with naive independence assumptions. Conditional probabilities are estimated for all classes. The sample, whose class label is unknown, is labeled with the name of the class having maximum probability [12]. NB (Naive Bayes) method is also known as a conditional classifier.

2) Support Vector Machines: SVM is based on the methodology of perceptron algorithm. The principle of SVM is searching for a line that separates the plane into two classes. With using kernel functions, the algorithm tries to maximize the distance between the optimal hyperplane and nearest support vectors [13]. Furthermore, one to all strategy may be preferred for multi-class problems in like manner. This algorithm is also known as a maximum margin classifier.

C. Feature Selection

In classification studies, when all features are used as inputs, the input set may contain insignificant features and consistent results may not be achieved. Classification results can be enhanced using the worthwhile feature subset. In this work, GA was used for eliminating insignificant features from whole feature set. The principle of the algorithm is based on the disappearance of weak genes by natural selection and survival of the best ones evolving from one generation to another during biological adaptation [14], [15]. In mathematical approach, GA searches an optimal solution for a problem from one set to another. In the methodology, the solution comes from a set of numerical values namely chromosomes. Populations are configured to any constant size and contain a set of various chromosomes. A fitness function is needed to compute the cost when a particular chromosome is selected for a possible solution to a problem. This function calculates the fitness cost of each chromosome in the population. Finding an optimal solution is performed in generation cycles. In each generation, the search is directed toward finding the best solution until then. The algorithm transfers better chromosomes to build new generation population iteratively. Sometimes, elites having the best fitness are preferred to be placed in new generation directly. Likewise, reproduction functions such as crossover, selection, mutation, are used for creating next generations. Crossover function produces two child chromosomes that are synthesized by parents. Selection function describes which individuals are chosen for the next level. Mutation function changes chromosome parts randomly [14], [16]. In this study, the main objective of using GA is seeking an optimal feature subset by wrapper feature selection approach via classification accuracy for selected chromosome. Chromosomes specify which features are paid attention to in bit strings. In other words, chromosomes act like selection masks. Related bit indices in the living chromosome, that are equal to 1, are entitled to be in the sub-feature set. After then, feature subset takes place as the input of fitness cost function. From this point of view, the fitness cost function is defined as the accuracy result of the selected features in the classification process.

D. Cross Validation

k-fold cross validation technique carries out to compute overall classification performance. k-fold cross validation term implies that (1/k)th of the whole dataset is chosen as a test set, and the rest is chosen as a train set automatically for all k rounds. It is ensured that each sample becomes a test sample just once. In this study, before GA was implemented, the dataset had been partitioned into 10-folds randomly. Each test run started with the same folds. Classification performances were based on 10-fold cross-validation for NB & SVM classifiers. Eventually, test performances are reported as the percentage of correctly classified cells in confusion matrices.
IV. Tests and Results

The testing phase proceeded in two different ways. According to the number of input classes, 3-Class and 2-Class GA based wrapper feature selection tests over NB and SVM classifiers were performed. In 3-Class tests, for each feature group, best feature subsets that classify all dementia types were found. To put it another way, the whole dataset was analyzed. Also in 2-Class tests, features that separate particular dementia type from other types with high classification accuracy results were examined. In other words, these tests were performed as one versus the others. For both tests, some GA parameters were set distinctly in order to arrange operation time considering the input class count.

GA parameters of 3-Class tests were chosen as: 10% for elite count, 90% for crossover fraction. Roulette selection function, single point crossover function and uniform mutation function with 13% rate created new generations. 3-Class (AD, FTD, VaD) classification tests performed over NB classifier with 800 for population size and initial population was created randomly in bit sting chromosome type. Algorithm worked with maximum 1000 generations. With given parameters, genetic algorithm results of 3-Class tests are shown in Table I.

Before the 2-Class tests began, samples, that did not belong to the examined class, were labeled as others (Oth). For each dementia type, this procedure was repeated. Afterwards, GA parameters of 2-Class tests were chosen as: 10% for elite count, 90% for crossover fraction. Roulette selection function, single point crossover function and uniform mutation function with 13% rate created new generations. 2-Class (AD v Others, FTD v Others, VaD v Others) classification tests performed over NB and SVM classifiers with 400 for population size and initial population was created randomly in bit sting chromosome type. Algorithm worked with maximum 500 generations. With given parameters, genetic algorithm results of 2-Class tests with NB and SVM are shown in Table III and Table IV respectively.

When all test results are analyzed, feature subsets having significant classification accuracies are found. Also, subset findings are in smaller sizes than the input matrices. In classifier comparison, NB performs slightly better than SVM for 2-Class tests.

Cortical volume features are striking to the eyes as the most significant feature group. In addition to the groups, behind the confusion matrices and best feature subset counts, valuable features are observed as left lateral ventricle, left putamen, brain-stem, left vessel, right cerebellum white matter, right putamen and 5th ventricle. Moreover, left thalamus proper, left pallidum, 3rd ventricle, 4th ventricle, left choroid plexus, right lateral ventricle, right caudate, right amygdala, right ventralis, white matter hypointensities and optic chiasma may also be included to the list as the secondary valuable.

V. CONCLUSION

In neuroimaging science, comparing classification results among different researches may not be straightforward due to attributes of each dataset like sample size, disease types, etc. Additionally, image preprocessing algorithms for feature extraction step, and also testing phase parameters may affect the classification performance. These issues have been reported in some researches previously [4], [5]. Therefore, the consistency of the work within itself may become much more considerable. In this work, a wrapper feature selection approach through certain classifiers with specific consistency of the work within itself may become reported in some researches previously [4], [5]. Therefore, the effects of freesurfer version, workstation type, and macintosh operating system version on anatomical volume and cortical thickness measurements,” PloS one, vol. 7, no. 6, pp. e38234, 2012.

SMART DEVICES BASED REMOTE PATIENT MONITORING SYSTEM

Abstract— Nowadays, smart devices have become an indispensable part of our lives with the advancement of technology. Developments of wireless and technology have led to the emergence of innovation providing facilities and solutions to the problems in health care. With developing technology, measured parameters can monitor on smart devices which required to follow in the diagnosis and treatment process of chronic illness and diseases. For example for this studies, remote monitoring of blood glucose level for diabetes patients or remote monitoring of blood pressure for patients. In this study, the smart device based remote patient monitoring system realized using microcontroller and Wi-Fi module. Vital parameters are measured over patients such as blood pressure, pulse, body temperature. Moreover, ambient moisture and temperature values are determined by device. The measured parameters are recorded on the device and the parameters are transmitted to the experts via web-based mobile interfaces. With this work, physiological parameters of the patients can be measured in their current location. Consequently, patients will be able to follow parameters without requesting help from health personnel’s on real time. Moreover, they can send their parameters to expert people.

Keywords—Remote patient monitoring, telemedicine, smart devices

I. INTRODUCTION

Rapidly advancing technological developments lead to radical changes in the health sector. In this context, new concepts and applications have been emerging such as telemedicine, e-health, e-prescribing, electronic health records, smart card in health sector. Telemedicine which is defined as the concept of using communication technologies among people from a distance for diagnosis, treatment and follow-up in order to forward the physiological data, storage and delivery of healthcare is closed to this study [1].

Some factors that cause the spread of telemedicine applications;
- increase in the cost of health care due to the increase in population,
- need to reduce patients in the hospital,
- effective utilization requests of doctors,
- it can be determined in a more effective treatment with the achievement of long-term statistics about the disease.

Also usage of telemedicine can be divided as remote patient monitoring, diagnosis and treatment of disease, medical education, and research [2]. Ministry of Health carried out many e-health projects using progressive technology and intelligent system [3].

Health sector has serious problems due to growing and aging world population and also significant increase in the number of chronic patient. So, technological developments and intelligent systems have been used extensively in the health sector in order to resolve these issues and find out solutions. Nowadays, smart devices have become an indispensable part of our lives and are used extensively. In this context, independent of time and distance in the field of health wireless technology and sensors have been used effectively for monitoring and storing patient's physiological data from anywhere with convenient storage solutions. In the field of health, remote patient monitoring concept have emerged. This concept is especially beneficial for bed-ridden patients or those having difficulty to reach a doctor. Another benefit of this concept is that it reduces the density of the number of patients coming to the hospital. Thus, the applications of smart devices in the field of health provide the possibility to send the necessary vital data to experts regardless of the location of patients [4].

In the literature, remote patient monitoring and telemedicine areas have been studied quite extensively. Chettri has to work based on smart phones with patient tracking and wireless data communication system in order to follow up patients data such as blood pressure, ECG, SpO2, temperature[5]. Another study, PIC microcontroller based on over the Internet. The study of remote patient monitoring system for measuring SpO2 and pulse rate data was conducted [6]. Diabetes is a chronic disease and the patients who have diabetes need to check their glucose level on a regular basis. For this purpose, a system containing smart phones has been developed and the measured level of glucose of the patients is easily monitored by the authorized person. For the ease of the monitoring process, this study is quite useful for patients who have diabetes [7].

Our study has differences and advantages by comparison with previous study. These differences are;
- vital parameters such as blood pressure, pulse, temperature, and body temperature are measured with the same apparatus,
- possibility of reaching the parameters at any moment thanks to generated interface,
- android mobile interface which observation of changes in vital signs,
• The database created for storing the measured values (can observe measurement frequency and values).
• The systems send to message doctor and close family when the critical values determined for the patient.

Wired measurement systems used to measure vital parameters of the people. Then, vital parameters sent to a database. If Wi-Fi connects, real-time and registered measurement results are recorded to patient record system. A convenient interface that permits the display of smart devices has been developed.

In this way,
• In the process of diagnosis and treatment of a disease, parameters can be monitored remotely on a regular basis with high quality and patient data can be accessed whenever required.
• Patients can be share their data at the same time with the authorized personnel or people can keep a record of their parameters and can compare it with the former recorded data.
• With remote monitoring of patients, it is expected that the hospital venues will be reduced, and also it may reduce the waste of time used for go to the hospital.
• Workload of the hospitals will be reduced.

II. MODELLING OF SYSTEM

Ensuring database of vital data is shown in Figure 1.

Arduino with the connection of sensors in the system is able to obtain blood pressure, pulse, body temperature, temperature and humidity of ambient data. Moreover, RTC and Wi-Fi modules are connected, so it is possible to use LCD

Blood pressure and pulse rate were obtained using MPX5050 pressure sensor which generates a voltage value that is produced by the pressure within the cuff. Body temperature data was taken with 18B20 temperature sensor using Arduino and environment temperature and humidity data were taken with DHT11 sensor. The measured data via the Arduino Mega have sent respectively through Wi-Fi module. Arduino application is used to transfer data to the web service written in order to evaluate the measured data. Arduino MEGA with algorithm for data processing of system is given in Figure 2.

![Figure 1: Ensuring database of vital data](image1.png)

![Figure 2: Arduino MEGA with algorithm for data processing of system](image2.png)

Patient data received by the Arduino module sent to the created web service for recording. The Arduino Mega and Wi-Fi connection is given in Figure 3.

![Figure 3: The Arduino Mega and Wi-Fi connection](image3.png)
Blood pressure and pulse rate measurements were carried out using PIC18F2550. In this study, the oscillometric method was preferred. Finally, the PIC18F2550 and Arduino communication was conducted and systolic and diastolic pulse values in PIC were sent to the Arduino. Arduino distinguished the values here and printed them on the LCD screen.

Changes in vital data of patients and humidity and temperature data of ambient were transferred to android operating system-based mobile devices via Wi-Fi. This system design of android was carried out with MIT app inventor 2 programming.

System consists of five main screens. These are a login screen, an information screen which gives information about person, a user record screen, a user interface which has user list, and a user data screen which has real and past time data of users.

The patient is required to fill up the information that is considered as important by the doctor such as full name, gender, age, health history etc. User data screen and information screen are shown in Figure 4.

All parts of the system is shown in Figure 6.

After Arduino code is compiled and loaded to controller, patient's data are sent to the database via Wi-Fi. Figure 7 shows the circuit is used 18F2550 microcontroller and external devices for adjusting the physical condition of the sleeve.

Table I. The parts used in the system setup.

After obtaining the personal information of the patient, Wi-Fi connection is made possible to gather the data via the sensors connected to the Arduino. Database screen generated for patients is shown in Figure 5. As shown in Figure 5, data is displayed by typing the patient's ID at any time.

Next step, design is made for modules and it is combined in a single electronic card. RTC module and sensor communication is shown in Figure 8. As shown in Figure 8, the circuit consists of RTC module, 18B20 body temperature sensor, Wi-Fi module and DHT11.
Finally, you can see General view of the system show in Figure 9.

### III. CONCLUSIONS

Nowadays more developments in biomedical field is valuable in terms of investing in people health. So, this study will facilitate the monitoring of human health, providing information about the health of person and information can be accessed on demand. Remote monitoring of the patient with smart devices is practical thanks to ease of movement. It can be utilized to diagnose and long-term monitoring of certain diseases as a portable data logger. Moreover, at next studies, system can be minimize and system weight’s can be reduced. Besides vital data, for medical purposes sensor data such as ECG, EKG, pulse oximetry, blood pressure, ventilation can be added to the system. The data obtained can be interpreted as artificial intelligence techniques and inferences can be made. If the spread of the system with an application that can be downloaded to smart devices, people can be informed more clearly.

Abstract— Three-dimensional (3d) bio-printing is one of the major research fields of future, as yet at the beginning stage but producing promising solutions in medicine. As technology evolves, novel systems emerge for positioning even a single cell to the desired place to create functional tissues. The precision of these systems determine the functionality of outputs. In general, bio-printers use Ink-jet, Micro-extrusion and Laser Assisted printing methods to construct a solid tissue or a part of an organ. Ink-jet method, also known as drop-on-demand bio-printing approach, is based on spraying cells by means of thermal or piezo electric pulses from numerous nozzles and is commonly used when forming tissues like skin and cartilage. Micro-extrusion method is used when complex biological structures like blood vessels or solid organs are bio-printed. Laser Assisted method is more preferred for biomaterial or implant production. Components of these systems have direct effects on the output since they determine where and how much biological material will be deposited in every layer. The aim of this study is to design and construct a novel micro-extrusion module for bio-printing applications. The designed module consists of three-dimensional (3d) printed body parts from Polylactic acid (PLA), Nema type stepper motors, ball screws (SFU1204), ball screw nuts (M12), flexible couplings (5 x 8 x 25 mm), steel rods (M8), SCE EE series bearings (SCE 8 UU), UFL series bearings (UFL 08), LMEF series bearings (LMEF 8 UU), SK series rod holders (SK 08) and has an ability to control three commercially available syringes with blunt ended needles. For precise micro-extrusion, galvanized steel rods support ball screw driven linear motions. Ergonomically, syringes can be easily mount and locked and this system also has laser holders that can be used for targeted photo polymerization.

Keywords— Bio-printing, Micro-extrusion module, Three syringes, Photo polymerization.

I. INTRODUCTION

Three-dimensional (3d) bio-printing is based on biomaterial localization in limited conditions to construct functional tissues or a part of an organ generally using ink-jet, micro-extrusion and laser assisted bio-printing methods [1]. The applicability of these systems is similar to two-dimensional (2d) printers, however this technology uses biological materials instead of an ink [2]. The system of a bio-printer consists of electrical, mechanical and software components to carry out controlled biological material deposition [3]. Mechanical components such as main frame, bearings, rods and other parts have direct effect on the movement ability and determine the physical limits of the machine. Electrical parts are used to control these mechanics and can be mentioned as a mainboard, typical driven stepper or servo motors, mechanical or optic limit switches, thermistor or thermocouples, heaters and other human computer interfaces like LCD (Liquid Crystal Display) or keypad. The software can be separated as Firmware that is also embedded in MCU (Micro Controller Unit) and host software can be controlled via PC (Personal Computer). Firmware is a library that determines the whole system by means of loops, variables and values that have direct effects on efficiency. Although there are several differences between a milling, drilling or grinding machine and a 3d bio-printer, the implementation of these systems and fundamental components have similarities. In fact, printing technology, print head and printed material are developed or chosen independently of one another when designing stage of these systems according to the purposes [4]. Printouts are dependent on the precision of the whole microfabrication system and biomechanical characteristics of the bio-inks [5].

It should be noticed that additive manufacturing technology is accepted as a different way of producing things from the traditional methods, nevertheless they both have similar components [6].

The design of the system of interest is shaped by means of purposes that determine the limits of imagination.

A. Basics of Bio-printing Technologies

As technology evolves, novel systems emerge for positioning even a single cell to create functional tissues [7]. The precision of these systems determine the functionality of outputs. In general, bio-printers use Ink-jet, Micro-extrusion and Laser Assisted printing methods to construct a solid tissue or a part of an organ [8]. Ink-jet method uses generated droplets down to 20 microns in diameter via the magnitude of applied thermal or piezo-electrical forces [9]. As a result of spraying living cells from numerous nozzles, non-complex
biological structures like skin and cartilage can easily be formed with ink-jet based printing. Figure 1 illustrates one of the numerous nozzles from a print head that uses ink-jet bio-printing approach.

Micro-extrusion method has an ability to form complex biological structures like blood vessels, heart valves and solid organs [10]. Extrusion of biomaterials can be performed by means of a piston, an extrusion screw or compressed air. All these print heads have similar continuous material deposition with different types of mechanisms. Syringes are used as hydrogel tanks and chosen according to the deposition technique. Blunt end needles are preferred as nozzles and diameters of needles depend on the cell sizes used in bio-printing process. Print heads and the biomaterials used should be chosen carefully in order to prevent shear stress of hydrogels that may occur during material deposition [11]. Shear stress can cause cell death that directly affects the functionality of output tissue constructs. Figure 2 illustrates the three deposition techniques used in micro-extrusion bio-printing approach.

Laser assisted method is more preferred for implant production [12]. The wavelength of laser beam is critical for cell viability when biological materials are exposed and this has a direct effect on the output. In order to prevent cell death and improve output tissue’s functionality, an energy absorbance layer is used. This method is based on selective biomaterial detachment from donor side to the substrate via laser pulses, and is the most expensive technique when compared with all techniques. Thus, laser assisted method is used for more precise applications. Figure 3 illustrates the laser assisted bio-printing approach.
II. MATERIAL AND METHOD

Prototype manufacturing has stages extending from blueprints to the end usage. Initially, target system is drawn as 2d (two-dimensional) sketches. The main frame or other parts are shaped according to the desired functionality. The model of design is taken to its final form by means of a 3d Computer Aided Design (CAD) software. This helps to see the whole assembly and bill of materials (BOM).

Figure 4 illustrates the assembled parts of prototype on CAD software [13].

Figure 5 illustrates the designed syringe holders.

Table 1 illustrates the BOM of the whole module.

The main frame and syringe holders were manufactured from Polylactic acid (PLA) polymer with 60% infill rate and 200 μm layer height by using a 3D printer. Figure 6 illustrates the 3D printed main frame.

Support parts are removed after the printing is completed. Figure 7 illustrates the assembly of the module.

III. CONCLUSIONS

The designed micro-extrusion module successively passed the bio-printing tests. Advantages of this system can be summarized as follows:

- Number of printing heads can be duplicated according to the needs and complexity of the target tissue constructs,
- Design can be scalable for different types of mechanical and electrical components,
- Steel rods support ball screw driven linear motions for precise micro-extrusion,
- Ergonomically, syringes can be easily mounted and locked,
- System has laser holders that can be used for targeted photo polymerization,
- Heaters and temperature sensors can be easily mounted,
- This module has compatibility for any type of bio-printer.

First bio-printing tests were carried out on a bio-printer after integration of the designed module. In order to test durability and accuracy of this system, hybrid hydrogels of wide concentration range were prepared as bio-inks from natural polymers. Figure 8 illustrates the bio-printing process by means of the assembled micro-extrusion module.

Abstract—A breast tissue type detection system is designed, and verified on a publicly available mammogram dataset constructed by the Mammographic Image Analysis Society (MIAS) in this paper. This database consists of three fundamental breast tissue types that are fatty, fatty-glandular, and dense-glandular. At the pre-processing stage of the designed detection system, median filtering and morphological operations are applied for noise reduction and artifact suppression, respectively; then a pectoral muscle removal operation follows by using a region growing algorithm. Then, 88-dimensional texture features are computed from the GLCMs (Gray-Level Co-Occurrence Matrices) of mammogram images. Besides, a formerly introduced 108-dimensional feature ensemble is also computed and cascaded with the 88-dimensional texture features. Finally, a classification process is realized using Fisher’s Linear Discriminant Analysis (FLDA) classifier in four different classification cases: one-stage classification, first fatty – then others, first fatty-glandular – then others, and first dense-glandular – then others. A maximum of 72.93% classification accuracy is achieved using only texture features whereas it is increased to 82.48% when cascade features are utilized. This consequence clearly exposes that the cascade features are more representative than texture features. The maximum classification accuracy is attained when “first fatty-glandular – then others” classification case is implemented, that is consistent with the fact that fatty-glandular tissue type is easily confused with fatty and dense-glandular tissue types.

Keywords-breast tissue; digital mammography; feature extraction; computer-aided detection

I. INTRODUCTION

Breast cancer is the second major cause of female deaths all over the world [1]. Although early diagnosis helps mortality to reduce, suspicious mass detection from mammograms becomes harder as breast tissue type becomes denser. Hence, it will be efficient to use a Computer-Aided Detection (CAD) system which can first define the breast tissue type of a mammogram, then detect and diagnose the type of breast cancer. Basically three major problems occur during breast tissue type classification: digitization noise, artifacts like labels of the mammograms, and pectoral muscle regions in the images. Since digitization noise appears as a high-frequency component in an image, smoothing filter implementation such as mean and median filtering is needed for noise reduction [2]. Besides, histogram processing operations [2], curvelet transform [3], wavelet transform [4], and top-hat transform [5] are commonly used noise reduction methods in the literature.

Another problem is the formation of unwanted artifacts like right/left breast or Craniocaudal (CC)/Mediolateral-Oblique (MLO) shooting labels in the background. This problem is generally handled by the separation of the breast parenchyma from the background applying morphological operations [2], thresholding [6], using gradients [7], and active contours [8].

Almost the most important intensity-based problem for breast tissue classification is the existence of pectoral muscles on the mammogram images. Pectoral muscles show up like triangle geometry at any of the top corners on the mammogram having brighter intensities than breast parenchyma. The studies on pectoral muscle removal in the literature generally focus on intensity-based and wavelet-based approaches. These approaches are examined under three main topics which are line detection techniques, statistical techniques, and other approaches.

Recent studies on breast tissue type classification mainly performed by Scale Invariant Feature Transforms (SIFT) descriptors [20-23] and texton histograms [20, 22, 24]. In addition to them, local features obtained from Local Binary Pattern (LBP) [20, 24], Haralick texture descriptors [25, 26], Soh features [26], visual word histograms [27], and histogram moments [28-29] are other well-known techniques used for breast tissue type classification.

In this paper, the design of a CAD system for breast tissue type classification of mammogram images is aimed. In accordance with this purpose, noise reduction and artifact suppression are initially realized on mammogram images in the database using median filter and morphological operations, respectively. Then, a pectoral muscle removal process is executed using region growing algorithm. These pre-processing operations are elaborately explained in Section 2. A feature extraction procedure explained in Section 3 is performed on the pre-processed mammogram images. The experimental study employed in this paper and all conclusions are given in Sections 4 and 5, respectively.
II. PRE-PROCESSING

Digitization noise, low/high-level artifacts in the background and presence of pectoral muscles, as shown on the sample mammogram image in Fig. 1, obstruct intensity-based breast tissue type classification of mammogram images. Hence, a pre-processing stage is essential in order to reduce noise, suppress artifacts, and remove pectoral muscles on original mammogram images.

A. Noise Reduction

Smoothing filters are used for noise reduction although they cause loss in gross details in an image. Hence, the use of filters that can remove noise as well as preserving edge details is essential. In this paper, noise reduction is carried out via median filtering. The median filter is a commonly preferred non-linear filter for noise reduction [30]. This filter is capable of preserving edge information while removing differences between pixels in the pre-defined neighborhood.

B. Artifact Suppression

Morphological operations are applied for both low and high-level artifact suppressions after noise reduction step. In this respect, the mammography images are converted into their corresponding binary level images. Then, the largest area is assumed to be breast parenchyma on each binary level image since its area should be greater than the area occupied by an artifact.

C. Pectoral Muscle Removal

Region growing algorithm is performed for pectoral muscle removal process in this study. Region growing algorithm, a region-based segmentation method, splits all pixels in an image directly into sub-regions by taking the pre-defined similarity conditions for the growing process into consideration [31]. This algorithm is based on an enlargement of regions by aggregating the pixels with similar properties. For this purpose, initially, a similarity condition and a seed point or a set of seed points are defined. Specified seed/seed set is considered as the initial sub-region and the pixels around 4 or 8-neighbors of each pixel are considered in terms of similarity condition.

III. FEATURE EXTRACTION

A. Gray-Level Co-Occurrence Matrix (GLCM)

GLCM is one of the commonly used methods for texture analysis and it compares the gray-level differences of any two neighbor pixels in a specified displacement and direction on an image [32]. In other words, GLCM of an image comprises of a function of the angular relationship and a distance between pixels in the neighborhood [33]. The GLCM of an image I, of size \( N \times N \), is formulated in (1):

\[
p(i, j) = \sum_{x=0}^{N} \sum_{y=0}^{N} [1, I(x, y) = i \text{ and } I(x + \Delta_x, y + \Delta_y) = j]
\]

where \( p(i, j) \) in (1) refers to the joint probability of co-occurrence of intensities \( i \) and \( j \) at a given offset \((\Delta_x, \Delta_y)\) where \( x \) and \( y \) are the spatial positions in the image. The offset \((\Delta_x, \Delta_y)\) specifies the distance \( d \) and the angle \( \Theta \) between the pixels \((x, y)\) and its neighborhood.

B. GLCM Texture Features

Texture features, introduced by Haralick et al. [34], Soh et al. [35], and Clausi [36], are extracted from the GLCMs of mammograms in this paper. These features and their mathematical representations are given in Table I.

Texture features, extracted in this paper, give information about the homogeneity, symmetry, complexity, and contrast in the GLCMs of the mammogram images.

IV. EXPERIMENTAL STUDY

In this paper, a CAD system that classifies mammogram images into the breast tissue types of fatty, fatty-glandular, and dense-glandular is proposed. Firstly, a pre-processing of mammogram images is performed where median filtering and morphological operations are applied for noise reduction and artifact suppression, respectively; then a pectoral muscle removal process follows by using region growing algorithm. Secondly, at the feature extraction stage, 88-dimensional texture features are computed from the GLCMs of mammogram images. Finally, classification is realized using Fisher’s Linear Discriminant Analysis (FLDA) in four different classification cases.

A. Database

A publicly available mammogram database constructed by the Mammographic Image Analysis Society (MIAS) is used in this paper [37]. This database consists of three health status classes (normal, benign, malignant) for each of three breast tissue type classes (fatty, fatty-glandular, and dense-glandular). It has 322 MLO mammogram images (106 fatty, 104 fatty-glandular, and 112 dense-glandular) with 330 diagnosis (207 normal, 69 benign, and 54 malignant). The images in the MIAS database are of size 1024x1024 at 200 μm/pixel resolution and they are in “.pgm” imaging format.

All mammogram images in the database are resized into a size of 256x256 for ease of operation. Sample images of each class in the MIAS database are shown in Fig.2. The rows and columns in the Fig.2 show three different samples of health status and breast tissue types.

![Sample mammogram images in the MIAS database.](image)

B. Feature Vector Construction

In this paper, the texture features, given in Table I, are computed from the GLCMs of the mammogram images.

The GLCMs of mammogram images are obtained in four different rotation directions which have an angle of $\theta = 0^\circ, 45^\circ, 90^\circ, 135^\circ$ using four different pixel distances $d = \{1, 2, 3, 4\}$. Hence, four co-occurrence matrices are evaluated for each rotation direction, and 22-dimensional textural feature vectors are computed from each of co-occurrence matrices. Then, the average of these four matrices is calculated so that a 22-dimensional feature vector is constructed for the corresponding direction. Ultimately, 88-dimensional feature vectors for each mammogram image are obtained by concatenating four different 22-dimensional feature vectors of each direction.
C. Classification

Breast tissue type classification is performed in one-stage and two-stage processes in this paper. In the one-stage classification process, mammogram images are directly categorized as having fatty, fatty-glandular, and dense-glandular tissue types. Besides, the two-stage classification process is carried out in three different ways: first fatty – then others, first fatty-glandular – then others, and first dense-glandular – then others.

In the first stage of the “first fatty – then others” classification process, the mammogram images are primarily classified as fatty and non-fatty mammograms. Then, in the second stage, the mammograms labeled as non-fatty are classified as fatty-glandular and dense-glandular. Similarly, in the “first fatty-glandular – then others” classification case, mammograms are firstly classified as fatty-glandular and non-fatty-glandular, and then non-fatty-glandular mammograms are classified as fatty and dense-glandular. Finally, in the “first dense-glandular – then others” classification case, mammograms are initially categorized as dense-glandular and non-dense-glandular, and then non-dense-glandular mammograms are classified as fatty and fatty-glandular.

D. Performance Evaluation

In this paper, a breast tissue type detection system is designed for four different classification cases using FLDA classifier. Average and fold-by-fold classification accuracies of FLDA classifier are given in Table II when only texture features are used.

The maximum average classification accuracy of 72.93% is achieved when “first fatty-glandular – then others” classification case is implemented.

In addition to the GLCM texture features, the 108-dimensional feature ensemble introduced in [38] is computed in order to increase the data representability of the existent GLCM features. This 108-dimensional feature ensemble is formed as the concatenation of some statistical and frequency-domain features to the LCP-based feature vectors [38]. Then, the 88-dimensional texture features and the 108-dimensional feature vectors are spliced. Consequently, 196-dimensional feature vectors are obtained for each mammogram image. Average and fold-by-fold classification accuracies are given in Table III when the spliced 196-dimensional features are used.

V. CONCLUSION

In this paper, a Computer Aided Detection (CAD) system for breast tissue type classification is designed, and it is verified on a popular mammogram database compiled by the Mammographic Image Analysis Society (MIAS). This database consists of the mammograms of three fundamental breast tissue types namely fatty, fatty-glandular, and dense-glandular. The 88-dimensional texture features computed from GLCMs of the mammogram images, are concatenated to the 108-dimensional feature ensemble. Ultimately, 196-dimensional feature vectors are obtained for each mammogram image and then they are classified using Fisher’s Linear Discriminant Analysis (FLDA) classifier in four different classification cases: one-stage classification, first fatty – then others, first fatty-glandular – then others, and first dense-glandular – then others.

A maximum of 72.93% classification accuracy is achieved using only texture features while it is increased to 82.48% when the final 196-dimensional feature vectors are employed. This consequence clearly implies that the final concatenated feature vectors are more descriptive than texture features. Besides this finding, the increase in the number of the dimension for the evaluated feature vectors reveals more representative vectors so that mammogram images are eventually characterized more effectively.
The maximum classification accuracy is reached when "first fatty-glandular – then others" classification case is performed. It is already known by radiologists that fatty-glandular tissues can easily be confused with fatty and dense-glandular tissue types. Hence, it would be wisely to detect glandular tissues can easily be confused with fatty and dense-glandular tissues. Therefore, it would be wisely to detect glandular tissues can easily be confused with fatty and dense-glandular tissues. This reality is quite coherent with the classification process that gives maximum classification accuracy.

REFERENCES

Abstract—In this study, a novel perfect absorber (PA) array based on four-headed arrow nanoparticles for biosensing applications in mid-infrared regime is presented. Proposed PA array has a dual-band spectral response, and the locations of resonances can be adjusted by varying the geometrical dimensions of the structure. Nearly unity absorbance is obtained from the PA array for both resonances. Different dielectric spacers (MgF\(_2\), SiO\(_2\), and Al\(_2\)O\(_3\)) are used to investigate the effects of dielectric spacer on the absorbance characteristics of proposed PA array. Absorbance characteristics of PA array are analyzed by using finite difference time domain (FDTD) method. High field enhancement is achieved by the interaction of the sharp corners of arrow nanoparticles. Linear correlation between the resonance frequencies and the refractive index of cladding mediums is determined. Due to the high refractive index sensitivity and near-field enhancement, the proposed dual-band PA array with adjustable spectral responses can be useful for biosensing applications in mid-infrared regime.

Keywords—Perfect absorber, Plasmonics, Nanoparticle, Mid-infrared regime, Biosensing applications

I. INTRODUCTION

A new research area of plasmonic structure is getting attention, known as plasmonic perfect absorbers (PAs) [1–6]. The concept of metamaterial PAs came from microwave regime, due to the advancement in the nanotechnology; it can be scaled down to the terahertz regime [7, 8]. The possibility of perfect absorption is revealed by appropriately engineering the electric and magnetic response of the incident field in gigahertz regime [7, 8]. The PAs are composed of periodically arranged resonant metallic nanoparticles and thin metal layer separated by a dielectric spacer [2, 5, 9]. There are many advantages of this kind of structures which include high absorptivity, small thickness, and low density [10]. With this type of device configuration, wide-angle, wide-band, and polarization-insensitive high absorption near unity can be achieved by matching the impedance of metamaterial absorbers to free space or with microcavity, hole arrays, and metallic surfaces [5, 9-11]. PAs operating in the infrared and visible regions have been used for biomedical sensing, surface-enhanced spectroscopy, and near-field scanning optical microscopy applications [1-15].

In this study, a four-headed arrow nanoparticle shaped PA array for biosensing applications in mid-infrared regime is presented. The optical properties of plasmonic PA array are investigated by using the finite difference time domain (FDTD) method [16]. In order to understand the physical origin of the resonant behavior and determine the field enhancement of the nanostructure, near field distributions at the resonant frequencies are obtained. Due to dual band spectral response and enhanced near field distribution, the proposed PA array can be useful for biosensing applications in mid-infrared regime.

II. NUMERICAL ANALYSIS

Schematic view of proposed PA is illustrated in the Fig. 1(a). It consists of a dielectric spacer layer between nanoparticle-based top layer and gold (Au) film on a dielectric substrate (Si). Dielectric substrate thickness is 500 nm, gold film thickness is 200 nm, dielectric spacer layer thickness is 125 nm and four-headed arrow shaped gold nanoparticle thickness is 50 nm. In Fig. 1(a), L and d indicate the length and weight of rectangular nanorods, respectively. \(h_1\) indicates the heights of left and right triangular nanoparticles and \(h_2\) indicates the heights of top and bottom triangular nanoparticles. \(w_1\) indicates the base-weights of left and right triangular nanoparticles and \(w_2\) indicates the base-weights of top and bottom triangular nanoparticles. Periodicities, \(P_x\) and \(P_y\), of the array are 2000 nm. During the simulations, the analyses are performed under y-polarization illumination source and geometrical dimensions are chosen as \(L = 1000\) nm, \(w_1 = 750\) nm, \(w_2 = 700\) nm, \(h_1 = 400\) nm, \(h_2 = 350\) nm, and \(d = 350\) nm. Periodic boundary conditions are chosen as x- and y-axes, and perfectly matched layers are used along the z-axis. The dielectric constants of the materials are taken from Ref. [17].

Different dielectric spacers (MgF\(_2\), SiO\(_2\), and Al\(_2\)O\(_3\)) are used to investigate the effects of dielectric spacer on the absorbance characteristics of proposed PA array. The absorbance (A) spectra of the structure for different dielectric spacer (MgF\(_2\), SiO\(_2\), and Al\(_2\)O\(_3\)) are given in Fig. 1(b). It can be seen from Fig. 1(b), all structures exhibit dual-resonant behaviors in mid-IR regime. Also for all dielectric spacers, the absorption rates are nearly unity.
Figure 2(a) shows the absorbance (A), reflectance (R) and transmittance (T) spectra of the PA with MgF₂ dielectric spacer. The absorbance spectra are calculated by A = 1 - R - T [13]. Proposed PA has dual resonances and both of them rate as %99.9 at the first (f₁ = 57 THz) and at the second (f₂ = 136 THz) resonances. Electric field distributions are given in Figs. 2(b) and 2(c) at first (f₁) and second (f₂) resonances, respectively. The near field enhancements are greater than 2000 times are concentrated on the sharp corners of the structure. Molecules in these corners may undergo a much stronger interaction with the electromagnetic field than those that lie well away from metallic particles. This means that the dielectric environment of the near surface region of the proposed PA array can strongly influence the resonant frequencies. This phenomenon is the basis of the mid-infrared biosensing capabilities of proposed PA array.

Figure 3(a) illustrates the A, R, and T spectra of the structure with SiO₂ dielectric spacer L = 1000 nm, w₁ = 750 nm, w₂ = 700 nm, h₁ = 400 nm, h₂ = 350 nm, and d = 350 nm. Proposed PA has dual resonances and both of them rate as %99.8 at the first resonance (f₁ = 58 THz) and %99.9 at the second resonance (f₂ = 132.5 THz). Electric field distributions are given in Figs. 3(b) and 3(c) at first (f₁) and second (f₂) resonances, respectively. The near field enhancements are greater than 1500 times are concentrated on the sharp corners of the structure.
Figure 5 demonstrates the changes in the spectral response for different d, L, h₁, h₂, w₁, w₂, and P parameter values. When the d (weight of rectangular nanorods) increases, both of the resonance frequencies increase (Fig. 5a). Absorption spectra for L (length of rectangular nanorods) variation is given in Fig. 5b, which shows that both resonance frequencies of the structure decrease with the increasing length of rectangular nanorods, both of the resonance frequencies decrease. As the h₁ (heights of left and right triangular nanoparticles) increases, only second resonance frequency decreases slightly (Fig. 5c). When the h₂ (heights of top and bottom triangular nanoparticles) increases, only first resonance frequency decreases (Fig. 5d). When the w₁ (base-weights of left triangular nanoparticles) increases, only second resonance frequency decreases (Fig. 5e) however only first resonance frequency decreases (Fig. 5f) with increasing w₂ (base-weights of the top and bottom triangular nanoparticles). The dependence of absorption spectra on the periodicity (P) is shown in Fig. 5g, which shows that only second resonance frequency is affected by the periodicity (P) variation. The optical characteristics of the proposed PA arrays are dependent on geometrical parameters (Fig. 5). The resonance frequencies of the proposed PA arrays can be tuned by changing the geometrical dimensions of PA arrays.

In order to control the refractive index sensitivity of proposed PA array, the top of the structure is covered with cladding layers with different refractive indices (Fig. 6a). The cladding layer thicknesses are 100 nm. Linear correlation between the resonance frequencies and the refractive index of cladding mediums are determined. As the refractive index of the cladding medium increases, both of the resonance frequencies decreases (Fig. 6b).

![Fig. 6 (a) Schematic view of the proposed PA with cladding medium (b) Linear dependence between resonance frequencies and refractive indices](image)
III. CONCLUSIONS

In conclusion, a novel plasmonic PA array based on four-headed arrow nanoparticles for biosensing applications in mid-infrared regime is presented. The spectral response and near field distributions of the proposed PA array are obtained by using the FDTD method. The effects of the dielectric spacer on the spectral responses of the proposed PA array are determined. The highest absorption rates and near field enhancements are obtained PA array for MgF$_2$ dielectric spacer. Due to the dual-band spectral response and enhanced near-field distributions, the proposed dual-band four-headed arrow based PA array with adjustable spectral responses can be used for mid-infrared biosensing applications.

Abstract — Orthopaedics is a highly technical field that employs a broad range of techniques, from microvascular surgery to bone fixation implants, to metallic and polymeric composite implants for joint replacement, to sophisticated methods of fixation involving all regions of the skeleton. The use of implants and devices requires sophisticated technical information on the part of the surgeon for the best chance of successful operations. The technical characteristics of applying internal and external fixation implants are critical to achieving bone union in the appropriate position and to avoid implant failure. The major problems encountered in plate fixation of fractures are early plate failures, screw breakage, and screw pull-out. The primary function of the plate is to maintain alignment as an internal splint, and to create compression between the fracture ends such that bone can transfer some of the applied load itself. There are two parameters that effect the performance of plates. Material properties which are the fundamental behaviours of a substance independent of its geometry and structural properties which are the ability of an object to resist bending under torsion, axial load, or bending is a function of its shape and distribution of material around the cross section. The goal of fracture fixation is understanding the basic parameters so that the device used for fracture fixation provides support for repair until adequate healing can occur. The purpose of this study was the investigation of the bending performance of the new designed plate by Finite Element Analysis (FEA) and biomechanical tests. Analysis of Ti6Al4V alloy was carried to estimate the bending limit. The results from the ANSYS FEA simulations were validated with experiments based on ASTM F382 standards.

Keywords — Finite Element Analysis (FEA), Biomechanics, Four-Point Bending, Plate Fixation.

I. INTRODUCTION

Osteosynthesis plates are often used in orthopaedic trauma surgery to provide fixation of fractured bone which act as structural support for the bone during bone healing and as a stress sharing or shielding device, depending on the fracture type and the construct of the fixation [1]. Using for healing of femur bone fracture, a bone beam assembly is shown in Fig 1. Metal plates for internal fixation of fractures have been used for more than 100 years. Although initial shortcomings such as corrosion and insufficient strength have been overcome, more recent designs have not solved all problems. Further research is needed to develop a plate that accelerates fracture healing while not interfering with bone physiology [2].

In the surgery applications, patients with fractures are generally treated using bone plates made of stainless-steel, Cr–Co and Ti alloys. Although exhibiting reasonable fatigue strength, the stiffness of these metals (in between 110 and 220 GPa) is much higher than that of human cortical bone (around 20 GPa) [3]. As a result, the majority of the load is carried by the plate rather than by the underlying bone [4].

Although the application of a plate may seem simple, it is necessary to understand how the plate functions in order that optimal strength and stability of the internal fixation can be achieved. So, plates used for internal fixation are strongest in tension or compression and weakest in bending [5]. Bending behavior of a bone plate is one of the most critical mechanical properties from an application viewpoint, and is generally evaluated by maximum bending moment and bending stiffness calculated from the initial linear moment against the total bending angle (angulation) of the plate [6]. Static strength is measured using destructive 4-point bending tests. From the static test data, Bending Stiffness (BS), Yield Bending Moment (YBM) and Maximum Bending Moment (MBM) are calculated [7].

FEA of the bone–bone plate assembly was carried out to calculate callus deformation, contact stresses, in order to simulate the surgery process and post-surgery loading conditions [8,9]. It’s important to find out the stress concentrations and deformation zones of implants, so FEA using ANSYS is the best method for analysis of stresses and deformations of Ti6Al4V [10]. Saidpour was studied that FEA was performed to examine the mechanical performance of different six-hole fracture plate designs under bending loading [11].

The main objective of this study is to evaluate mechanical testing and FEA of a new designed and manufactured Ti6Al4V material internal fixation plate using CNC machining, in order
to investigate the state of stress and strain in the assembly, as well as to examine and compare the performance of the assembly under different load conditions.

II. MATERIALS AND METHODS

A. Design of New Locking Compression Plate (LCP)

Nowadays, conventional plating is increasingly replaced by using internal fixators. Internal fixators are “plates” (splints) with completely locked screw heads. These implants are not pressed onto the bone and do not need any contact between implant and bone [12]. According to Perren, the foreign body effect that reduces resistance to infection is less caused by the foreign material than by necrosis (induced by the implant) and the dead space effect. In conventional plate osteosynthesis, necrosis of the cortical bone compressed under the plate is produced systematically. In contrast, locking plate fixation does not result in bone necrosis [13]. The move from a conventional plate to the locking plate is not truly an evolving implant, but rather a change in concept [14].

In this study, a new LCP was designed and technically detailed. It was 161 mm long and 13.5 mm wide with eight holes. The thickness of the plate was 4 mm. The plate has spherically counter bored 27 mm diameter round holes. The distance between the centers of the two inner holes was 14 mm. The remaining holes were equally spaced by 18.5 mm. Engineering design of the plate can be seen in Fig. 2.

B. Material Properties

Mechanical properties of biomaterials play a key role in deformability of bone plates. In this study, the metallic bone plate test sample (GR23 (Ti6Al4VELI)) which is newly designed and manufactured is used. This titanium alloy is approximately twice as flexible as stainless steel and at least one-third stronger. It’s also more resistant to corrosion than stainless steel, which has a tendency to experience crevice corrosion at the contact point between screw heads and plates. Plate failure can take place through these corrosion pits [15]. In addition, titanium material generally used in locking plates, does not form a foreign body membrane and therefore does not create a dead space effect with the implant [14]. The mechanical properties for Ti6Al4V can be seen in Table 1.

C. Four Point Bending Test Procedure and Testing

Because a bone structure is asymmetrical, the stresses may not be equally distributed. Bending may be produced by four forces (four-point bending) [17].

This test describes methods for static four-point bend testing of intrinsic, structural properties of metallic bone plates for surgical fixation of the skeletal system. The purpose is to measure bending strength and bending stiffness intrinsic to the design and materials of metallic bone plates.

Four-point bending test conducted using two rolling supports spaced A-B and C-D (38 mm), B-C (40 mm) and loading supports A-D (116 mm) shown in Fig. 3. The load and support rollers are manufactured using hardened steel. Loading point is the rolling type, and the diameter of both the loading and support rollers are 5 mm and 10 mm.

The Metallic Bone Plate test samples shown in Fig. 4 were tested in accordance with the “ASTM F 382-99 Standard Specification and Test Methods for Metallic Bone Plates” [18] test procedure using 2.5 kN capacity tensile test machine at room atmospheric conditions.

During test, applied equal loads at each of the loading points (a single load centered over the load points) at a constant rate of displacement as presented in Fig. 5. Measure the relative deflections between the support and loading points. C and D points are fixed points. These boundary conditions are similar to four point bending standards.

**III. RESULTS**

**A. Experimental Test Results**

Six test sample of new LCP was manufactured by CNC machining method was tested according to four point bending test standards. Force peak, force yield, deflection yield, deflection peak results were obtained for each test sample. Minimum, maximum and mean values of test results were demonstrated force at peak 1975.354N, 2252.391N, 2085.923N; force at yield 525.244N, 1530.818N, 1015.724N; deflection yield 0.212 mm, 5.588 mm, 2.904 mm; and deflection peak 15.759 mm, 18.713 mm, 17.236 mm, respectively.

It is clear from chart that at the mean force point (force at peak (N) = 2085.923) deflection can be seen as 17.236 mm as an average. Same is valid at yield point. Experimental Test Results are presented in Table II and in Fig. 8.

### IV. CONCLUSIONS

Selection of plate geometry and material for surgical implants plays a vital role in bone fracture healing process. In this paper, newly designed and manufactured bone plate was modelled and analysed. Through these bending test and FEA, we have found out the bending performance and safe bending limits of the new designed plate. As a result, this plate design can be used successfully in the treatment of bone fractures.

The Assessment of Time-Domain Features for Detecting Symptoms of Diabetic Retinopathy

Gülin Elibol, Semih Ergin
Department of Electrical and Electronics Engineering, Eskisehir Osmangazi University, Eskisehir, Turkey [gelibol, sergin]@ogu.edu.tr

Abstract—Diabetes affects the capillary vessels in retina and causes vision loss. This disorder of retina due to diabetes is named as Diabetic Retinopathy (DR). Diagnosing the stages of DR is performed on a publicly available database (DiaraetDB1) via detecting the symptoms of this disease. Time-domain features are extracted and selected to classify a fundus image. Fisher’s Linear Discriminant Analysis (FLDA), Linear Bayes Normal Classifier (LDC), Decision Tree (DT) and k-Nearest Neighbor (k-NN) are used as the classification methods in the experimental benchmarking. The recognition accuracies are obtained using all features (68 features) and selected features separately. k-NN is observed as the best classification method for without feature selection case and it gives averagely 92.22% accuracy. For feature selection case, LDC gives the best average accuracy as 92.45% with maximum 7 carefully chosen features.

Keywords—sequential feature selection, diabetic retinopathy, microaneurysms, hemorrhages, exudates.

I. INTRODUCTION

Insufficient generation or low level of insulin causes the diabetes. This disease affects many parts of body, more particularly affects blood vessels of a retina. Diabetic Retinopathy (DR) is resulted from the damage of tiny blood vessels inside diabetic patient’s retina [1]. DR is a major cause of vision loss and blindness [2]. It has four stages that are mild non-proliferative, moderate non-proliferative, severe non-proliferative and proliferative. Besides, an early diagnosis can prevent a permanent visual disability.

Diagnosing DR is realized via detecting the symptoms of retinopathy from fundus (retinal) images that show the posterior part of eye. The symptoms of this disease are called as microaneurysms (MA), hemorrhages (HR), soft exudates (SE) and hard exudates (HE). Microaneurysm is the quite first symptom of DR. Due to a loss of pericyte, capillary vessels protrude and red small dots occur on the top layer of retina [3]. Microaneurysm also refers as red small dots. The second symptom is hemorrhages. The vessels are bleed due to lack of feeding. Their appearances are similar to microaneurysm, but they are shown at the inner layer and outer plexiform [4]. Another symptom is soft exudates. It occurs when the layer of nerve fiber is clogged because of small arteries choked. Soft exudates are also known as cotton-wool spots [5]. Soft exudates are mostly confined with micro-aneurysm and vessels that are hyper-permeable. The last symptom is hard exudates. They are accumulation of yellow fat and protein that are seeping from capillary vessels and microaneurysms [6]. These symptoms of DR are shown in Fig. 1 [7].

The early stage of this disease is mild non-proliferative DR. In this stage, microaneurysms occur at the retinal vessels. The next stage is moderate non-proliferative and micro-aneurysms are increased, hemorrhages and hard exudates are started during this stage. The third stage is severe non-proliferative DR. The lack of oxygen became apparent in retina and then hemorrhages and hard exudates are increased. In this stage, the scar tissue that is leading the visual loss is occurred. The last stage is proliferative DR and the new unhealthy vessels are started to generate due to the increase in lack of oxygen and lack of feeding. These new vessels are very delicate and started to bleed and then they may cause to a visual loss at any moment.

In literature, diagnosing the stages of DR is starting with detecting MA. In [8], a three-stage system is proposed to detect MA via using filters. First of all, the candidate regions of MA are determined from fundus images and then 15 features are extracted from these regions to classify MA. Those features are area, eccentricity, perimeter, compactness, mean, standard deviation, homogeneity, etc. A feature selection is not performed and hybrid classifier that combines Gaussian Mixture Model (GMM) and Support Vector Machine (SVM) is used. Another method for classifying DR is the detection of HR. In this methodology, HR is detected and then it is classified into three classes which are normal, moderate, severe non-proliferative DR [9]. Random Forests Tree is used for classification and eventually the proposed system has 90% accuracy while moderate and severe non-proliferative cases were 87.5% accurate. In [10], MA and HR are both detected for non-proliferative stages of DR. A geometric-based criteria, which are size, shape, roughness, edge sharpness, color, depth, etc., are used to classify HR and MA. In this study, the stage of DR is determined according to the number and location of them. Ultimately, the suggested system achieves sensitivity and specificity values of 89.47% and 95.65% for the classification of DR versus normal. Neural Network (NN) is used to classify moderate, severe non-proliferative, proliferative DR and normal stages using features such that red, green, blue layer perimeter, and area [11]. The proposed system gives more than 80% accuracy.
addition to these, detecting exudates also gives information about non-proliferative DR. In [12], hard exudates are detected and then mean, standard deviation, compactness, size, edge strength, etc. features are extracted from RGB fundus images. Multi-layer perceptron is applied and the given approach yields a 100% mean sensitivity, 84.0% mean specificity and 92.0% mean accuracy. Hard and soft exudates are identified and features are extracted using Gray Level Co-occurrence Matrix [13]. Entropy, contrast, energy and homogeneity are used as features and SVM is applied to classify fundus images into moderate and severe non-proliferative DR.

In this paper, the aim is to detect the symptoms of diabetic retinopathy. These symptoms are MA, HR, HE and SE. DIARETDB1 database, which is publicly available, includes 89 different retina images (fundus) including all symptoms. A new database is generated with five different classes for each symptom and normal (healthy) retinas. 17 time-domain features are extracted through four different window sizes constituted from each retina image. The features which have more discrimination power are selected via Sequential Forward Feature Selection (SFS) method. Fisher’s Linear Discriminant Analysis (FLDA) [14], Linear Bayes Normal Classifier (LDC) [15], Decision Tree (DT), and k-Nearest Neighbor (k-NN) are utilized as the classification algorithms to benchmark [16, 17].

The rest of the paper is organized as follows: Section II presents the extraction of features from fundus images. Section III explains the used classification algorithms briefly. Section IV presents the experimental work. Finally, conclusions and future work are given in Section V.

II. FEATURE EXTRACTION

Time-domain features are extracted using gray values of pixels [18]. 17 features are extracted from each fundus image for one window size. 3x3, 5x5, 7x7 and 9x9 windows are formed, therefore 68 features ($f_1, f_2, ..., f_{68}$) are obtained for each fundus image. An example of utilized non-proliferative gray level images is shown in Fig. 2. For normal (healthy) retinas, the values of all pixels in the utilized image are zero. The whitish pixels are indicated the parts for symptoms of MA, HR, SE and HE.

![Fig. 2 Non-Proliferative Gray Level Fundus Image](image)

The extracted features are calculated from the pixel values in the corresponding window. For each window size ($2r+1 \times 2r+1$), the center pixel of the window is located at $(p_{r+1}, p_{r+1})$ and the other indices of the pixels are shown in Fig. 4 and the extracted features for each window size are given in Table 1 [18].

III. CLASSIFIERS

Fisher’s Linear Discriminant Analysis is a well-known algorithm in pattern recognition field and it is used to find linear combination of features that categorizes classes of events. This algorithm is mostly used for two purposes that are linear classifier and dimensionality reduction. It projects data to find linear combinations with large ratios of between-class to within-class scatter. This ratio is referred as covariance matrix. According to Fisher’s criteria, a covariance matrix is calculated by multiplying the inverse of the within-class covariance and between-class covariance. The inter-class difference is maximized by means of this new covariance matrix.

Linear Bayes Normal Classifier is another algorithm applied in this study. In this method, a linear classifier is computed between classes that have normal densities with equal covariance matrices. The joint covariance matrix is weighted using class covariance matrices. A regularization is applied to eliminate small variance directions and then a new covariance matrix is computed via the leading principal components and smallest eigenvalues [19].

Decision Tree has decision nodes, branches, and leaf nodes that are referred as features, conditions, and classes, respectively. Information gain or purity are used to create nodes. Conditions (branches) are utilized to determine the following node. Algorithm proceeds with the related branch considering the correctness of the condition, however if the condition is false, it jumps into the other branch. Finally, a leaf node is reached and then the class information is obtained.

K-Nearest Neighbor has a lazy learning and it is a distance based classifier. Classification procedure is carried out according to the similarities of events. An event is assigned to a class that is the most common amongst its k-neighbor classes.

IV. EXPERIMENTAL STUDY

In this paper, the detection of the symptoms for DR disease from fundus images is proposed. First of all, 68 features are extracted from generated database that has 185 images with 5 classes. Secondly, classification is performed with all features. FLDA, LDC, DT and k-NN are used and the recognition accuracies are obtained. Thirdly, a feature selection method (SFS) is performed on all features and ultimately, the fundus images are again classified via same classifiers.

A. Database

A publicly available fundus image database that is DIARETDB1 is used [7]. This database includes 5 classes which are normal, mild, moderate, severe non-proliferative and proliferative DR. It has 89 fundus images (5 normal, 84 have non-proliferative and proliferative DR). These images have a size of 1500x1152. Each image is masked and preprocessed by some image processing operations and then they are saved in “.png” format. Besides, the ground-truths of them are provided. A new database is generated from ground-truths of those images. This new database has 185 images with 5 classes which are the same as abovementioned classes. The classes and the number of images are given in Table 2.

<tr>
<td>Soft Exudates</td>
<td>31</td>
</tr>
</tbody>
</table>
B. Feature Vector Construction

All fundus images in the database are separated into patches for the ease of extracting features. One image has divided into four patches and each of them has equal size of 375x288. The time-domain features, given in Table I, are computed from each patch. The average (mean) values of features are calculated from four patches for each fundus image and they are treated as feature vector for corresponding fundus image.

C. Classification

The generated database is divided into a training and a test sets which have 80% and 20% of the number of images in the database, respectively. The five-fold cross-validation is conducted while classification is performed by four different classifiers using MATLAB PRtools toolbox [19]. Then, the Sequential Feature Selection algorithm is applied to the training dataset. During this stage, the “sequentialfs.m” function in MATLAB is carried out and the criteria for feature selection is accuracy results from classification. Classification with four different classifier is repeated with only selected features for comparison.

D. Performance Evaluation

The classification results for all folds without feature selection (68 features) are shown in Table 3. All calculated accuracy values are higher than 90%. k-NN gives the best results while using all features. The mean accuracy is 90.59% (FLDA) and 91.03% (LDC).

After SFS is applied, the indices of the selected features are shown in Tables 4 and 5.

The accuracies for all folds after selection are shown in Table 6. FLDA has used maximum 15 features (only 22% of all features) and accuracies for all folds are increased. The mean accuracy after feature selection is 92.12% for FLDA. The mean accuracy is also amplified for LDC. It uses maximum 7 features, which is less than that of FLDA, and its mean accuracy increased by 1%. In addition to these results, mean accuracy for DT is almost the same, however it gives these approximately same results with maximum 6 features. On the contrary of these classifiers, mean accuracy of k-NN is decreased by 5% and it exposes the worst recognition. The classification results and total number of selected features for each classifier and fold are explicitly shown in Table 6.

V. CONCLUSION

In this study, four different classifiers are compared in terms of accuracy and number of selected features on the DIARETDB1 database. The aim is to find the most appropriate classifier and feature set for detecting symptoms of DR. As a conclusion, it is deduced that k-NN is superior to all other methods for detecting MA, HR, SE, HE symptoms by using 68 features. Besides, DT provides nearly same performance with all features. After the usage of selected features, DT gives nearly same results, but the accuracies of FLDA and LDC are prominently increased with considerably less features.

Trabzon, Turkey
{saras, ali.gangal}@ktu.edu.tr

Abstract—Records are usually taken as multichannel in most of the studies about lung sounds. However, these studies which conducted as a multi-channel are not appropriate to auscultation procedure and as not suitable for the single-channel electronic stethoscope that is improved today. In this study, common lung sounds were recorded with using a single channel electronic stethoscope in accordance with auscultation procedure. Common lung sounds (healthy, rhonchus, fine and coarse crackles) were separated previously healthy and pathological data sets, then into two different data sets with four classes. Various attributes are derived using Mel-frequency cepstral coefficients which are widely used in speaker recognition. Support Vector Machine is used during the classification stage after applying the Principle Component Analysis to these features. Results that obtained from analysis have shown us that the mean of Mel-frequency cepstral coefficients which have successful results in two data sets and curve fitted to them can be used in the separation of common lung sounds.

Keywords—Electronic auscultation, Mel-frequency cepstrum coefficients, Principle Component Analysis

I. INTRODUCTION
Auscultation is the processes of listening internal sounds in a human body by using a stethoscope. Lung sound auscultation contains relevant information about the structure and function of the respiratory system [1]. Auscultation process that is used electronic stethoscope is called electronic auscultation. Lung sounds can easily be recorded through electronic stethoscopes which are developed in recent years. These records are used in the training of physicians and computerized lung sound analysis. If a physician who is not professionally well-trained cannot correctly recognize abnormalities of lung sounds and disorders. Hence, computerized lung sound analysis is important for them [2]. Computerized analysis studies can be summarized in four categories [3]:

I. Modeling: Defining a physical model for human lungs,
II. Detection-Estimation: Detection of abnormal sound components or estimation of flow cycle from pulmonary sounds data,
III. Classification: Classification of healthy and adventitious lung sound components
IV. Mapping: Building visual representations of the lung sounds based on the acoustic information.

There are many literature review studies for classification categories in last few years [4-7]. Highlights from these publications; quite different recording methods, use of improper procedures to multi-channel auscultation records, datasets are not sufficiently clear, as that of reasons understood limited the comparability of the results. Gurung et al. [4] reported that commercialization of computerized lung sound analysis devices was not suitable because of the failure of standardization between methods of studies that recording lung sounds, computer algorithms for signal analysis and statistical methods for data analysis. We believe that using a single channel electronic stethoscope during the recording step, which is in accordance with auscultation procedure will be more efficient, unlike the previous multi-channel studies. Each microphone must be carefully placed in the record, as though records that taken as multi-channel contain much more information. In addition, some of the physical characteristics of a person from who has received the record (hairy skin structure, obesity, etc.) make it difficult in multi-channel recording and directly affects the quality of the record.

In this study, the common heard lung sounds were recorded by a single-channel electronic stethoscope which is appropriate to auscultation procedure. Two different datasets were created from the records. The first dataset contains healthy and pathological data. The second dataset contains commonly heard lung sounds. Mel-frequency cepstral coefficients (MFCCs) coefficient is used to obtain features which are commonly used in speech processing. The average and standard deviation of the MFCCs and the curve fit to these two parameters are also used as features. The performance of these features is increased by applying Principle Component Analysis (PCA). Support Vector Machine (SVM) method is used in the classification step. When the results were analyzed; using the mean of MFCCs and curve fit parameters to these averages would be appropriate suggested for classification of lung sounds.

II. MATERIALS AND METHODS
A. Datasets description
Healthy and adventitious (pathological) lung sounds were described by American Thoracic Society. Commonly heard adventive lung sounds were separated into four classes as fine crackles, coarse crackles, rhonchus, and wheeze. Wheezing
can be noticed easily without the need of a stethoscope [8]. So, it was not recorded in our study. Recording set shown in Fig.1.

Fig. 1 Recording set for electronic auscultation

In the recording procedure, we used an electronic stethoscope (Thinklabs ds32a+) which has analog output and can adaptable to the digital recorder as one channel. All records are taken in stethoscope’s diaphragm mode (20-2000Hz) with 32000 Hz sample frequency. In this study, 60 healthy, 60 rhonchi, 37 fine and 18 coarse crackles (totally 175) lung sound records were taken from persons who applied to the Department of Chest Diseases, School of Medicine at KTU. All records were taken and labeled by a specialist doctor in accordance with the auscultation procedure. Two different datasets were created with utilizing from the records;

Dataset1: The first dataset consists of two different classes, including 60 healthy and 115 pathological lung sounds. These records are then divided into two approximately, 87 data is used for the test data set for 88 education.

Dataset2: Training and test data are the same as DataSet1. Unlike the Dataset1 pathological sounds are divided into three different classes in itself. Thus, the second data set is healthy, rhonchus, fine and coarse crackle was created from four different classes including crackle.

B. Mel Frequency Cepstrum Coefficients

MFCC model the frequency of human ear’s perception and one of the most preferred method for recognizing the sound. Performed studies showed that human perceived the sounds linear to the 1 kHz and logarithmic up the 1 kHz. [9,10]. Mel Frequency Cepstrum is a domain developed according to the human hearing characteristics. Physicians make an assessment of lung diseases by listening to the sounds during auscultation. Thus, MFCCs are used as feature in this study. Physiological studies have shown that human auditory system follows a linear frequency spacing below 1kHz and a logarithmic spacing above 1 kHz. The main advantage of using Mel-frequency scaling is that Mel frequency scaling is very approximate to the frequency response of human auditory systems. Fig 1. shows the block diagram of MFCC calculation process.

Fig. 2 Block diagram of MFCC calculation process.

The aim of the pre-emphasizing that is the first stage, to compensate the spectrum of the voiced regions which have a sudden drop. Pre-Emphasis Filter is carried out by correlation as in Eq.(1).

\[ y[n] = x[n] - 0.95x[n - 1] \]  

MFCC method is applied to over the short segments that are accepted have stable acoustic properties of the sound [9,10]. Therefore, the signal is divided into frames. In this study, we used 20 miliseconds frames with 50% overlapped. Each frame includes a part of the previous frame with the overlap. Hamming window which is showed in Eq. (2) is used to reduce the discontinuity at the beginning and the end of the frame. Thus, with suppressing the parts do not include information at the beginning and the end of the signal, corruption is prevented.

\[ w(n) = 0.54 - 0.46\cos \left( \frac{2\pi n}{N-1} \right), 0 \leq n \leq N - 1 \]  

After windowing the lung sound signal, Fast Fourier Transform is used to transfer these time-domain samples into frequency-domain ones. The Mel Frequency scale is defined in Eq.(3) where \( f \) is the frequency in Hz.

\[ Mel(f) = 2595. \log \left( 1 + \frac{f}{700} \right) \]

Power spectrum obtained from each windowed frame passed through a filter array of a triangular filter according to the Mel scale. In this study, Mel filter bank that includes 20 triangular filters is used and shown in Fig. 3. The sensitivity of feature vectors’ is provided to reduce with applying logarithm. Log energies of the frames are transformed to the time domain with the discrete cosine transform in the last stage. Thus, MFCCs are obtained for each frame. 12 of MFCC coefficient was calculated in this study.
A number of frames may vary depend on the length of the signal. 12 MFCCs were calculated for each frame in this study. A matrix is obtained consisting of MFCCs as a result of this process. The row number of this matrix is equal to the frame number, the number of columns is 12. The mean and standard deviation of columns of matrix and parameters of a curve fit to these coefficients have been used as feature.

C. Curve Fitting

Means and standard deviations of MFCCs in the training set analysis showed that their dispersion was exponential.

For exponential curve fitting, we used a model given by (4). These nonlinear model parameters were estimated by the Least Squares method. Using parameters of an exponential curve fitted to means and standard deviations, the number of features dropped from 12 to 2. Means of MFCCs for a sample for four different lung sounds which are in the training set of Dataset2 and curves fitted to these averages shown in Fig. 4.

\[
y = p(1).e^{p(2)x}
\]  

(4)

Standard deviations of the MFCCs and curves fitted to these standard deviations also in quite similar structure to the Fig-2. When the curves fitted to the parameters of the standard deviations of MFCCs obtained from Dataset2 training set plotted to their each other distribution of classes are illustrated in Fig 3.

![Fig. 3 Mel-Scale Filter Bank](image1)

![Fig. 4 Fitted exponential curves to means of MFCCs for a sample of training set in dataset2](image2)

![Fig. 5. Fitted exponential curves’ parameters estimated from standard deviations of MFCCs for training dataset2.](image3)

D. Principle Component Analysis

PCA is a conversion technique that ensures to reduce the less size of data set which includes many of variables related to with their each other by protecting the data as much as possible [11]. PCA provides to transport the variables which are belong to data set to a coordinate plane that is represented in lower size by discovering eigenvalues and eigenvectors of the data matrix. The reason of being useful is to create new features by finding most dominant features in the desired number from covariance matrix which is formed from data of classes. Thus, it ensures the redundancy of the data set to be minimized and at the same time maximizing the differences.

We assume that X has occurred from observation vector M of row and N \(\times\) 1 of a column as a training set data matrix. Variables would be zero means when the average vector of calculated from the mean vector education vectors are subtracted from each observation vector, and its mean is shown by X. Then the covariance matrix of zero-mean training vector (5) is calculated as in Eq. (5).

\[
C = \tilde{X}X^T = \frac{1}{M-1}\sum_{i=1}^{M}(x^i - m)(x^i - m)^T
\]  

(5)

Eigenvalues and eigenvectors of the covariance matrix are calculated using Eq. (6). C is including N \(\times\) N-dimensional matrix, \(\lambda\) is including any scalar and \(\nu\) are including a column different from zero,

\[
C\nu = \lambda\nu
\]  

(6)
The number λ that providing Eq. (6) is eigenvalues of C and v is also eigenvectors that associated with λ. Eigenvalues are ranked from small to large. G projection matrix is created with using first P number of in-line vectors that corresponding to these in-line eigenvalues. Selected eigenvectors are ranked from being the largest eigenvalues as forming rows of the matrix.

\[ G^T = \begin{bmatrix} g_1 \\ g_2 \\ \vdots \\ g_p \end{bmatrix} \]  

(7)

Projection of vectors that would be specified by feature vector is taken up on the G matrix as in Eq.(8).

\[ y^i = G^T x^i \quad i = 1,2, ..., M \]  

(8)

Thus, the training stage was completed. The next step is to perform a classification aimed that to make class assignments using features in training phase when an unused test data come in education.

III. CLASSIFICATION

K-fold cross-validation is used for being too much more reliable and decisive before the test results classification, in the training phase. In this method, all data is divided into subclasses for the k number approximately equal size number. This classification algorithm is trained and tested for k time. While one of the pieces was taken as test data in each time, remaining pieces creating were taken for training data. As a result, k number of different test result would have been found. The average of these results gives testing accuracy of the algorithm, according to the Kohavi’s study [12]. In our study, we chose k=5 for determining the folds.

Support vector machines (SVM) is a method developed by Vapnik and based on statistical learning theory [13,14]. The difference of SVM from the other classifiers is it’s trying to find solutions that reduce to the minimum the possibility of classification [15]. When training examples of dimensions of n are given by x and the class label is given by y written \( y_i \in \{-1,1\}, i = 1,2, ..., n \), the algorithm tries to find the best separating surface which is given as \( x + b = 0 \). In this case, the optimization problem that was written as

\[ y_i(w \cdot x + b) - 1 \geq 0, \quad \forall_i \]  

(9)

is restricted as the distance \( 2/||w|| \) is being the biggest between the nearest training surface with differential surface. Training examples that are nearest to the separator surface are represent a small subset of all of the training examples and are called as support vectors [16]. The biggest separation classifier is simple and is suggested for classification that can be separating linear. However, K is used when the data cannot be categorized as a linear space which is a core function that ensures to transition with A transformation, from X space to H-space that is data could classify as linear a larger sized.

\[ K(x,z) = \phi(x), \phi(z), \quad \forall \ x, z \in X \]  

(10)

In this study, Gaussian Radial Basis Function was used as seed function, which can be expressed as;

\[ K(x,z, \sigma) = exp \left( -\frac{||x-z||^2}{2\sigma^2} \right) \]  

(11)

Where \( x, z \in \mathbb{R}^n \) are two samples that are n-dimensional column vectors in the original space.

Multi-classed classification is made by combining the binary classifiers [13]. One-vs-one method is used for multi-class SVM in our study. k(k-1)/2 binary classifiers are created for a classification problem have k classes with considering all combinations of pairs of classes.

IV. RESULTS

MFCCs were obtained for two different datasets generated from common lung sounds. k-fold cross-validation was used for the reliability of test results in the training phase of classification. k is determined as 5, depending on the number of additional data. Following features was obtained from the MFCCs and used in both two datasets;

f1: Means of MFCCs
f2: Fitted curve to means of MFCCs
f3: Standard deviations of MFCCs
f4: Fitted curve to Standard deviations of MFCCs

The effect of the PCA analysis to classification performance also was investigated. SVM classifier was used for the classification phase. The results obtained from the analysis of Dataset1 which was consisting of healthy and pathological classes are presented in Table 1.

</table>

All test data is classified as completely true for DataSet1. The confusion matrix of features of \( f_1 + f_2 \) that gives success 85.06% is given in Table-3 for Dataset2, similar to \( f_1 \) feature result. Healthy data can be classified without error and can also be seen clearly distinguished from other classes when the table examined. However, the number of records for coarse crackles and fine crackles are not enough, so more data is needed because of adequate learning not being.

V. CONCLUSION

Common lung sounds were recorded with using single-channel electronic stethoscopes which are appropriate for auscultation procedure in this study, different from multi-channel studies in the literature. The MFCCs used as a feature that has often been used in speech processing. A great performances improvement is obtained by mean of MFCCs and curve fit them. This study shows that the MFCC-PCA combination is well adapted to classify common lung sounds. Better and more accurate results can be obtained if the numbers of data, especially coarse crackles increase in future studies.

Abstract—Microstrip folded dipole antenna to use in RFID tag is presented in this study. This RFID tag antenna is designed for identifying orthopedic implant which can be placed knee or also intracorporeal. The proposed antenna consists of one pair of symmetrical folded arms for miniaturizing. The proposed antenna is designed for two different ISM (Industrial, Science and Medical) frequency bands. Firstly, for ISM band of microwave (2.4–2.48GHz), the antenna structure is printed on an FR4 substrate with dimensions of 34×12×1.515mm³ and the surface area 34×12mm² is suitable for human knee implant. Dielectric constant of used FR4 is εr=4.3 and loss tangent is 0.035. The obtained results show that the resonant frequency of the antenna is 2.45GHz with return loss -49dB and bandwidth 260MHz. The peak gain is 0.103dB at 2.45GHz which is higher than traditional intracorporeal antenna design applications. For the second ISM band of UHF (Ultra high frequency) (860–960 MHz), the tag antenna design is conducted on FR4 substrate with 1.48 mm thickness with surface dimensions of 37.2×12mm² and the same dielectric constant is εr=4.3 and tangent loss is 0.035. In UHF band, the simulated resonant frequency is 888MHz. In this frequency, antenna’s return loss is -25.93dB and bandwidth is simulated for 74MHz. The peak gain of the antenna is -10.7dB. All folded dipole antennas are designed and simulated by CST Microwave Studio.

Keywords—Implant Identification, RFID Tag, Folded Dipole Antenna, Orthopedic Implant.

The most significant part is tag antenna in a RFID system, because the material and the size of the antenna can be varied according to the application field. For example, a RFID system can be used in human body, on a metal object or inside a materiel which have different dielectric losses. Therefore antenna design parameters as its geometry can vary according to its application medium. Commonly, most applications require the tag antenna be compact in size, low cost and easy to fabricate.

Orthopedic implant is a kind of joint implant to replace severely injured or diseased joints for people who suffer from joint problems and aim to bring those people back to a normal life [5]. Each knee implant system is made up of three components as seen on Fig. 1: femoral component, polyethylene component, tibial component. Nowadays these implants are very common in orthopedic surgeries for patients who have severely injured joints. The total number of knee and hip replacement surgeries per year in US keeps increasing in the recent years and will hit 3.48 million in 20 years [6].

This study, as general manner, suggests RF identification of implants while in the human body by designing the most important part so as antenna of RFID tag. Tag antenna has been designed for knee implant which is orthopedic implant (Fig. 1). As in different works, tag antennas usually are placed on polyethylene part.

I. INTRODUCTION

Nowadays, Radio Frequency Identification (RFID) technology has been widely use in various and different areas such as logistic, security, library, airline, military, animal forms, sports, healthcare and other areas [1].

A typical RFID system is made up of a tag and a reader: a digital data processing integrated circuit (IC) device called RFID tag is combined with an antenna, a reader that communicates with the tag antenna by means of electromagnetic waves and a host data storing system embodies the information of the identified item and communicates with other remote data processing systems [2].

The RFID systems use frequency bands of low-band range 125–134kHz, high frequency (HF) 13.56MHz ultra high frequency (UHF) 860–960MHz, microwave 2.45GHz, super high frequency 5.8 GHz and ultra-wide band (UWB) 3.1-10.6GHz [3, 4].

Fig. 1 Parts of orthopedic knee implant [7].
When the implant replacement surgery has finished, doctors and surgeons have difficulty to observe and obtain the detailed information of the implant. So that, especially orthopedic implant placement and modification stage, information within the implant to move with the patient while making this process, reduce cost and time, improve data reliability, is planned to be used RFID system [5]. Existing method for implant identification have some problems. For example information about patient or implant is not stored with implant; mostly it is stored in archives, which can raise the risk of data loss. Another case, many hospitals still use paper based archives to keep the patient history whose management is a huge cost and hardship. The other, it takes much time to search for the implant and patient information, which does not only increase the risk of mistakes but also increases the cost [8].

As known, active RFID tags have both large antenna size and constantly radiated electromagnetic waves harmfully. The proposed solution should be a battery free implantable RFID tag attached on the orthopedic implant. Thus, tag antenna will work only within reader antenna’s electromagnetic wave energy. This design has been achieved with a microstrip folded dipole antenna which can be placed on the knee implant size. Microstrip folded dipole antenna is widely used in the applications of Wireless Local Area Network (WLAN) and 2G wireless communication system as the structure of G-shape. In this study, this structure is introduced as a new method of reducing the size of tag antenna because of limits of knee implant size. In this way RFID tag antenna can be implemented easily on the orthopedic implant to identify patient, implant and surgery information [9].

In this study two tag antennas have been designed in the same geometry but in two different operation frequencies in two different ISM bands as 2.45GHz microwave and 860–960MHz UHF band to select suitable solution. It has been decided how the antenna size changes and optimum antenna design is implemented in intracorporeal using simulation results. Primary aim is reducing the size of the dipole antenna here. Therefore, design of microstrip folded dipole antenna is experimented to use in intracorporeal applications. Finally, these two designed antennas have been compared for antenna size, frequency, gain, return loss to get clearly understood tag antenna can be placed on knee implant.

II. TAG ANTENNA DESIGN

The tag antenna design is the most critical part of RFID system. Here, the design of tag antennas may be varies depending of application region. For implant identification, in human body, the dimension of tag antenna must be limited with the implant size.

Operating frequency (f), speed of light (c) and, effective dielectric constant (ε_{eff}) are requisite to calculate length of a microstrip dipole antenna. Fig. 2 shows the geometry of traditional microstrip dipole antenna. Half of the wavelength is equal the length (L) of the microstrip dipole antenna. The following equations 1 and 2 are used for calculate length of a traditional microstrip dipole antenna like Fig. 2.[10]

\[ \varepsilon_{eff} = \frac{\varepsilon_r + 1}{2} \left[ \frac{1 + \frac{2}{\varepsilon_r}}{1 + \frac{2}{\varepsilon_r}} \right]^{\frac{1}{2}} \]  

\[ \lambda = \frac{c}{f \sqrt{\varepsilon_{eff}}} \]  

- ε_{eff} = Effective dielectric constant,
- ε = Relative dielectric constant,
- T = Thickness of microstrip material,
- Y = Width of microstrip dipole arm ,
- f = Operating frequency,
- c = Speed of light,
- λ = Wavelength.

Equation 1 shows how can calculate effective dielectric constant (ε_{eff}). This parameter is needed to calculate wavelength in equation 2. So the length of microstrip dipole antenna can find simply.

Fig. 2 The geometry of traditional microstrip dipole antenna

Fig. 3 shows the geometry of RFID tag antennas which is suggested for knee implant identification in this work. In this geometry, A and B terminals are connected with two radiation arm and shorting strip. The width (Y1) of the radiating arm is adjusted at 2.7 mm for centre frequency of both 2.45GHz and 888MHz. The microstrip folded dipole antenna consists of two radiating arms separated by a 2.4mm width slot (s). This slot is used for compact tag chip which involve the information about knee implant.

Fig. 3 The geometry of microstrip folded dipole antenna.

The width (d) and length (w) values of the shorting strip are fixed at an optimum ratio to provide a good impedance matching. Table 1 tabulates the optimum dimensions of the
tag antenna which can be placed on knee implant in two different frequencies. The antenna is fed by 50Ω coaxial cable from points A and B by using discrete port type in CST Microwave Studio. Microstrip folded dipole antenna has symmetrical geometry, so that feeding points can be selected from A to B or opposite way.

Dimension of tag antenna have to be compact to place on knee implant which is in intracorporeal. For this reason conventional dipole antenna is folded and takes the smaller size geometry as in Fig. 3. The length of the conventional dipole antenna is 168mm working at 888MHz. The proposed folded dipole antenna is reduced in length size with ratio of 77% according to conventional dipole antenna. For 2.45GHz this ratio is calculated as 48%. As a result, this structure of dipole antenna reduces the size of antenna and provides optimum antenna geometry to place on knee implants.

### III. SIMULATION PLATFORM

Signal attenuation occurs when the RF signal penetrates in biological tissue as known [11]. Simulations have to be made according to measurement platform to take actual outcomes. So simulation platform is designed for actual measurements. All antenna designs are simulated with CST Microwave Studio according to this model as shown in Fig. 4.

III. SIMULATION PLATFORM

Signal attenuation occurs when the RF signal penetrates in biological tissue as known [11]. Simulations have to be made according to measurement platform to take actual outcomes. So simulation platform is designed for actual measurements. All antenna designs are simulated with CST Microwave Studio according to this model as shown in Fig. 4.

Fig. 4 Simulation model of RFID tag antenna in CST

Biological tissue and polyethylene material reduce RF signal efficiency and downscale dimensions of tag antenna [11]. Layer of skin can be chosen form CST library. But polyethylene material has to be added in CST to make simulation realistically. For this simulation dielectric constant of polyethylene is selected 2.6 and loss tangent is added 0.00031 [12].

IV. RESULTS

Fig. 5 shows that the resonant frequency of Antenna 1 is 888MHz in UHF band. At this frequency, the return loss $|S_{11}|$ is -25.93dB and bandwidth is taken nearly 74MHz.

![Fig. 5 The characteristic of $|S_{11}|$ (return loss) for 888 MHz](image)

Fig. 6 shows simulated return loss of proposed Antenna 2 which works at 2.45GHz resonant frequency. This simulation result shows that the resonance frequency of the tag antenna is at 2.45GHz with return loss -48.50dB and bandwidth 277MHz.

![Fig. 6 The characteristic of $|S_{11}|$ (return loss) for 2.45 GHz](image)
Fig. 7 and Fig. 8 show that simulated radiation patterns at 888MHz and 2.45GHz. The peak gain of the microstrip folded dipole antenna is seemed -10.7dB for Antenna 1.

![Simulated radiation patterns](image)

Fig. 7 Simulated radiation pattern at 888MHz (Antenna 1)

Fig. 8 shows that the peak gain of Antenna 2 at 2.45GHz is 0.99dB. This gain is satisfactory and higher than traditional dipole antenna in intracorporeal applications.

![Simulated radiation patterns](image)

Fig. 8 Simulated radiation pattern at 2.45GHz (Antenna 2)

As a summary in results section, Table II shows comparison of frequency, gain, bandwidth, and return loss of Antenna 1 and Antenna 2. Antenna 2 has good advantages than Antenna 1 taken from simulation results to be realized in the future.

V. CONCLUSION

This paper proposes microstrip folded dipole antenna to identify an implantable RFID tag to embed on orthopedic knee implants. For this purpose, two tag antennas have been designed in the same geometry but in two different operation frequencies in two different ISM bands as 2.45GHz microwave and 860–960MHz UHF band. The simulation results are presented that the antenna designed at 2.45GHz is suitable and realistic intracorporeal designs. Especially, return loss, bandwidth, gain values and patterns sustain this antenna can be realized.

For the future work, selected antenna will be printed and measured in the phantom medium.

Classification of Structural MRI for Detecting Alzheimer’s Disease

Ayşe Demirhan

Electronics and Computer Education, Technical Education Faculty
Gazi University, Ankara, Turkey
ayseoguz@gazi.edu.tr

Abstract—Alzheimer’s Disease (AD) is a pathological form of dementia that degenerates brain structures. AD affects millions of elderly people over the world and the number of people with AD doubles every year. Detecting AD years before the effects of disease using structural magnetic resonance imaging (MRI) of the brain is possible. Neuroimaging features that are extracted from the structural brain MRI can be used to predict AD by revealing disease related patterns. Machine learning techniques can detect AD and predict conversions from mild cognitive impairment (MCI) to AD automatically and successfully by using these neuroimaging features. In this study common structural brain measures such as volumes and thickness of anatomical structures that are obtained from The Open Access Series of Imaging Studies (OASIS) and made publicly available by https://www.nmr.mgh.harvard.edu/lab/mripredict are analysed. State-of-the-art machine learning techniques, namely support vector machines (SVM), k-nearest neighbour (kNN) algorithm and backpropagation neural network (BP-NN) are employed to discriminate AD and mild AD from healthy controls. Training hyperparameters of the classifiers are tuned using classification accuracy which is obtained with 5-fold cross validation. Prediction performance of the techniques are compared using accuracy, sensitivity and specificity. Results of the system revealed that AD can be distinguished from the healthy controls successfully using multivariate morphological features and machine learning tools. According to the performed experiments SVM is the most successful classifier for detecting AD with classification accuracies up to 82%.

Keywords—Alzheimer’s Disease, neuroimaging, structural MRI, multivariate analysis, image classification, machine learning techniques

1. INTRODUCTION

Alzheimer’s disease (AD) is the most common form of dementia and affects millions of people around the world. AD is not a curable disease but the progress of the disease can be slowed down if it is detected in an early stage. AD causes pathological changes on the brain. These changes can be detected before clinical symptoms begin. Mild cognitive impairment (MCI) is a stage before AD and healthy aging. MCI is likely to turn into AD. 12% of people with MCI convert to AD in a year and 80% of people with MCI convert to AD after 6 years. [1-4].

Structural magnetic resonance imaging (MRI) is a non-invasive imaging technology that is used successfully for detecting AD. MRI is sensitive to the degenerations that AD caused on the brain such as tissue damage or loss. Hippocampus, entorhinal cortex and posterior cingulate cortex are the brain regions that are most effected from AD. These brain regions are also predictive of transition of MCI to AD. Tissue loss related to AD correlates well with the scores of the clinical cognitive tests that reveal a cognitive decline. High resolution T1-weighted MRI is the best tool to detect hippocampal atrophy. Structural brain measures such as volumes and thickness of anatomical structures are obtained from the T1-weighted MRI and these measures are used to detect any degenerations on the brain regions. MRI-based estimates help to early diagnose of the AD that can be used to slow down the progress of the disease [5-6].

Computational methods are required to predict subjects with AD and subjects who is under risk to show cognitive decline that can turn into AD in years. Machine learning methods are used for this purpose over years to detect AD and predict conversions from MCI to AD. SVM is one of the most popular method for classification of AD vs normal control (NC) and AD vs MCI. Magnin et al. proposed a method to classify AD patients and NC by using a whole-brain MRI analysis. They have extracted features by using a histogram analysis. They have utilized characteristics of the distribution of the brain tissues such as gray matter (GM), white matter (WM) and cerebrospinal tissue (CSF) that gives information about neurodegenerative disease like AD [7]. Cocoso et al. have used pruning strategy to customize a training set that will not affected by anatomical variability and pathology. They have used prior tissue probability maps in a standard stereotaxic space to generate a set of samples, then they reduced fraction of incorrectly labelled samples in this set and used a supervised kNN classifier for classifying the MRI scans using the corrected set of samples [8]. Amoroso et al. utilized BP-NN for classification of 288 subject to discriminate AD vs NC and AD vs MCI. Their method includes three steps. First, they applied rigid registration and histogram based equalization to the MR images. Then they have calculated important features like hippocampal volume or its thickness from a volume of interest that contains both the left and right hippocampi regions. Finally, they utilized a BP-NN for classification and obtained 0.81 overall accuracy [9].

In this study, structural MRI is classified for detecting AD using machine learning methods and structural brain measures such as volumes and thickness of anatomical structures. We utilized SVM, kNN and BP-NN for classification task with 5-fold cross validation.
II. MATERIALS AND METHODS

A. Data

T1-weighted cross-sectional structural brain MRI scans of the OASIS database [10] are used to extract structural brain measures of anatomical structures and made publicly available at https://www.nmr.mgh.harvard.edu/lab/mripredict by Sabuncu and Konukoglu [6]. These morphometric brain features including volumes and thickness of the anatomical structures of the brain are analysed in this study to classify AD and mild AD. 190 subjects from the OASIS database is used to obtain brain measures for binary classification. These subjects were the ones that the automatic image processing steps of FreeSurfer (https://freesurfer.nmr.mgh.harvard.edu) is successful. FreeSurfer is a brain MRI analysis software that is used widely and freely available. Table I summarizes the demographic features of the data.

</tr>
</tbody>
</table>

Table I. Features of the Dataset

Fig 1. T1-weighted cross-sectional brain MRI scans of subjects with (a) AD, (b) AD mild and (c) NC.

Subjects who has clinical dementia rating (CDR) >=1 was defined as AD and CDR>0 as AD mild. AD mild include subjects suffering from MCI and not clinically demented. Fig 1 shows sample MRI scans from the OASIS database belonging to the subjects with AD, AD mild and NC whose subject numbers in the database are OAS1_0003_MR1, OAS1_0035_MR1 and OAS1_0062_MR1, respectively.

B. Feature Sets

Four sets of morphological brain features are used for prediction of AD that are obtained using FreeSurfer. Details of feature extraction process can be found at [6]. The brief explanation of the feature sets is given below.

1) Feature Set 1 (aseg): This feature set includes volumes of the 45 anatomical structures. Because of head size variations, these volumes are normalized with each subject’s intracranial volume.

2) Feature Set 2 (aparc): This feature set includes 34 average thickness measurements within the cortical parcellations per hemisphere.

3) Feature Set 3 (aseg + aparc): The union of the aseg and aparc feature sets is a 113 dimensional vector.

4) Feature Set 4 (thick): 10,242 vertices per hemisphere is calculated. The cortical thickness values are sampled onto the fsaverage5 template. These values are smoothed on the surface by using an approximate 5 mm Gaussian kernel.

C. Support Vector Machines

SVM is the most popular binary classification algorithm used for the prediction of diseases from the structural MRI [4, 11]. SVM learns class differences in a supervised manner by using labelled training samples. SVM classifies a binary labelled data by mapping the data to a very high-dimensional feature space. A separating hyperplane is constructed in the feature space that is used as a decision surface to separate the training data. This hyperplane is defined as \( w^T x + b = 0 \), where \( b \) is the bias for the input vector \( x \) and \( w \) is the weight vector. Informative subsets of the training data are used as support vectors to determine the decision surface. The margin between support vectors are minimized by maximizing \( \| w \| \). Classes are determined by two subspaces that are obtained after training. Fig. 2 illustrates support vectors and decision surfaces of a SVM [4, 12].

Fig 2. Support vectors and decision surface.

There are three different kernels namely polynomial, radial basis function (RBF) and sigmoid, that are used for nonlinear feature mapping of the SVM. In this study, sequential minimal
with 5 grid search is employed for selection of the best parameter set for all folds. Error function is computed relative to the hidden units by backpropagation. BP algorithm adjusts the weights that will map input to the output by updating their weights using connection from the previous layer. The final layer calculates the output.

### D. K-nearest Neighbour Algorithm

kNN is a supervised classifier that computes closest \( k \) training samples of the data point that will be classified in the feature space. The data is classified with the label of the most representative neighbour among the closest ones that are detected by kNN. kNN which is a non-parametric classifier learns from the training data. Large size of the training data increases the prediction performance of the kNN by estimating the true class distributions in feature space [8]. The value of \( k \) that is the number of nearest neighbours to the classified data is the key parameter for the algorithm.

### E. Neural Network

Neural networks are used widely in medical image classification task since there is no need any information related to the probability distribution of the data and a priori probabilities of different classes [14, 15]. Backpropagation (BP) uses a feed-forward and supervised learning algorithm. Feed-forward NN has three main layers. First layer is the input layer. Then there are hidden layers. Each hidden layer has a connection from the previous layer. The final layer calculates the output of the NN. Each layer consists a number of neurons that will map input to the output by updating their weights using gradient descent learning rule. BP algorithm adjusts the weights of the neurons in the steepest descent direction that the performance function decreases most rapidly. Gradient of the error function is computed relative to the hidden units by back propagation of the error.

### III. RESULTS AND DISCUSSION

Subjects that has AD (N=25) and mild AD (N=70) are discriminated from NC subjects (N=95) by using four different sets of structural brain measures [6] that reveals the degeneration of the AD on the brain which leads to classify normal and abnormal brain scans. SVM, kNN and BP-NN are used for the classification. 5-fold cross validation is applied for all classification tasks to assess the generalizability of the performance. The number of cases and controls were the same for all folds. Results of the classification are evaluated in terms of their accuracy, sensitivity and specificity.

SMO learning function and RBF kernel is employed for SVM. \( C \) and \( \sigma \), the two parameters of the RBF kernel should be determined carefully for a successful classification of SVM. A grid search is employed for selection of the best parameter set with 5-fold cross validation to reduce the selection-related bias. A coarse grid is generated by growing values of \( C = [2^0, 2^3, ..., 2^{15}] \) and \( \sigma = [2^{-5}, 2^{-4}, ..., 2^{15}] \). A finer grid search is performed after identifying a better region on the coarse grid [16].

\[
K(x, x') = \exp \left( -\frac{\|x-x'\|^2}{2\sigma^2} \right)
\]

\[ (1) \]

### TABLE II CLASSIFICATION ACCURACIES OF THE SVM

Gradient descent learning algorithm is used for training of the BP-NN. One hidden layer with 5 neurons are trained with 5-fold cross validation with 1000 epochs at each fold. These parameters are determined empirically according to their classification performance. Results that are obtained using BP-NN are given in Table IV. OoM means out of memory that BP-NN could not converge up to 1000000 epochs. Different number of hidden layer neurons and learning algorithms did not help BP-NN to converge using thick feature set. The most successful feature set was aseg for the BP-NN for both AD and mild AD cases.

<td>OoM</td>
<td>OoM</td>
</tr>
</tbody>
</table>
Performance comparison of the classifiers and the feature sets is given in Fig. 3. SVM was the most successful classifier independent from the feature set and the aseg was the most successful feature set independent from the classifier type. The highest classification accuracy is achieved with the combination of the SVM and the aseg feature set. Classifying AD mild was more difficult then classifying AD since the disease related changes on the brain is more evident in the AD case.

Abstract— Nowadays robotic systems are used in many fields. One of them is the health sector. Surgical robots which are used in the health sector are physically similar to each other but their purposes are quite different. Also surgical robots have major mechanically differences.

Using of robotic systems in surgical procedures is revolutionary. Robots are taking the role of the surgeon at simple surgical procedures.

In addition to this, in recent years rehabilitation robots have gained importance at the health sector. These robots used in physical therapy significantly facilitates the task of both patients and medical personals. In addition, robotic solutions found an important place also at prosthetic technology.

In this study, used from past to present robotic systems at the health sector are examined, made classification depends on the purpose, advantages and disadvantages of this robots have been investigated. Some advices given by us for situations considered to be negative.

Keywords— Surgical robots, rehabilitation robots, prosthetic technology, health sector

I. INTRODUCTION

Today robots are used in the health sector as an important adjunct. Especially tele-operation robots considerably facilitating remote intervention. In this study, some of surgical robots are examined and classified.

II. CLASSIFICATION OF SURGICAL ROBOTS

Medical robots are classified under three main headings as a Assistive Technologies, Surgical Robotics and Other Surgical Robots.

A. Assistive Technologies

Robots and machines which improve the quality of life of disabled and elderly people, mainly through increased personal independence.

1) Prosthetic Devices:
   - Advanced under actuated multi-degree of freedom hand for below elbow amputees
   - Fingertip pressure built-in sensors
   - Neuro prosthetic electrodes implanted in or around the nerve stump to detect the user’s volitional commands and to feedback sensations from the pressure sensors (and others)
   - Implant custom stimulator/amplifier

Figure 1: Evolution of the active hand prostheses (from EURON Roadmap, 2004)

Figure 2: Cyberhand Advanced Prosthetic Hand Advanced (EU Project coordinated by SSSA, Pisa)

Figure 3: C-Leg (Otto Bock Health Care, Inc., USA)
2) Orthotic / wearable devices

(a)  
(b)  
(c)  

Figure 4a, 7b, 7c. Wearable devices

3) Robotic Aids

Figure 5 Robot MANUS (Exact Dynamics BV, The Netherlands)

Figure 6 VAID EU project (Coordinated MOVAID by SSSA, Italy)

4) Personal Assistants

Figure 7 Companion in Touch Health, Goleta, CA, USA)

5) Rehabilitation robotics

Rehabilitation Robotics has been defined a special branch of robotics which focuses on machines that can be used to help people recover from severe physical trauma or assist them in activities of daily living. This field has evolved from a more common field known as Rehabilitation Engineering. Rehabilitation Engineering is closely related to physical therapy and it utilizes its three main focus areas. The three main areas of physical therapy are the cardiopulmonary, neurological, and musculoskeletal.

B. Surgical Robotics

1) Neurosurgery Robots

Figure 10 Neuromate (IMMI/ISS), 1996

Figure 11 Neurobot (Imperial College)
2) Minimaly Invasive Surgery (MIS) Robots

Figure 12 ZEUS (Computer Motion), 1998

C. Other Surgical Robots

1) Radiological Robots

Figure 18 CyberKnife

2) Ultrasonic Robots

Figure 19 Ultrasonic robots

3) Remote Center of Motion Mechanisms

Mechanisms that the part of surgical robot which make the main work in surgical operation. Especially uses for the purpose of laparoscopy at MIS.
III. CONCLUSIONS

After examination it was seen that especially the MIS robots fill too much space in the operating room. In addition, contain too many mechanical and electronic components of this robot, increases the possibility of failure.

Long and complex control algorithms of this robots are disadvantages in manufacturing of this robots.

For remotely controlled robots, communication delays are negatively affects the operation.

In particular, the high sensitivity of the brain and eye surgery is a problem that must be overcome to large-bodied robots. To overcome the problems such as cost, precision, communication, minimizing the robot body is one of the solutions. Use of RCM mechanism in operation will reduce both costs and time of operation.

Abstract— Chronic kidney disease is a prolonged disease that damages the kidneys and prevents the normal duties of the kidneys. This disease is diagnosed with an increase of urinary albumin excretion lasting more than three months or with significant reduction in a kidney function. Chronic kidney disease can lead to complications such as high blood pressure, anemia, bone disease and cardiovascular disease. In this study we have investigated to determine the factors that decisive for early detection of chronic kidney disease, launching early patients treatment processes, prevent complications resulting from the disease and predict of disease. The study aimed diagnosis and prediction of disease using the data set that composed of data of 250 patients with chronic kidney disease and 150 healthy people. First, the chronic kidney disease data was classified with machine learning algorithms and then training and test results were analysed. The estimation results of chronic kidney disease were compared with similar data and studies.

Keywords— Chronic Kidney Disease, Machine Learning, Classification.

I. INTRODUCTION

Today, technology is progressing day by day and the entry into almost every aspect of life and the data is obtained and stored in various areas. There are examples in every area of life which data is available and stored such as to keep track of income and expenses of the companies, to storage of information of students in school, to keep information that obtain as a result of personal work. Although often created large data sets used to store data, it is possible to convert data into information through a variety of operations on data and predict the future by the available data. Generally, techniques used for the conversion of the data according to the purpose information processing is known as data mining. By the application in daily life of information obtained data mining large gains can be achieved [1].

One of the areas where the application of data mining is the health field. In this area, determining in advance of possible illness, identifying the different cases where the disease associated with the forward-looking assumptions and patient conditions is possible by the studies on the generated data.

The job of the kidneys is to filter the blood. All the blood in your body passes through the kidneys several times a day. Kidneys have a responsibility to throw waste from the body, to control fluid balance and to regulate the electrolyte balance. The system is not working properly kidney stones and kidney failure may occur here.

Factors which increase the risk of kidney disease are diabetes, hypertension, smoking, obesity, heart disease, kidney disease in the family, alcohol, drug abuse, drug overdose, age, race, sex, symptoms of kidney disease, urinary function changes, difficulty during urination, blood in the urine, back or back pain at the edges, fatigue, dizziness, lack of attention, always feeling cold, rash-itch, ammonia breath, metallic taste, nausea, vomiting and shortness of breath [2].

Chronic renal disease is a long-term disease that is being damaged kidneys and preventing them from doing actions which the normal duties of the kidneys such as cleaning the blood from harmful substances, the body maintain fluid balance, blood pressure regulation and hormone production. The disease is diagnosed with a significant reduction in urinary albumin excretion, increased or renal function for more than three months. This disease can lead to complications such as high blood pressure, anemia, bone disease and cardiovascular diseases [3].

Currently, there are many programs which host data mining algorithms. Some of these programs and software are Weka, R, Orange, Kniece etc. These programs generally contain the same algorithms. But algorithms vary functioning forms of information because the algorithm authors are different and algorithms are developed. In our study, the support vector machine and decision tree algorithms of Weka program are used. Support vector machine is one of the simplest and effective methods used for classification. The decision tree algorithm is one of the machine learning methods and classification, is represented by tree branches and leaves forming a simple tree structure [4].

The study is to investigate the predictability of the disease. Using a variety data of chronic kidney patients and normal patients. In this study, we used a data set of 400 persons obtained from the “UCIMachine Learning Repository” data warehouse which is including the information of patients and people without [5].

II. LITERATURE REVIEW

Vijayaranis forecast kidney disease by using Navie Bayes and support vector machine algorithms. Mainly in the research, focused on finding the best classification algorithm according to the classification accuracy and execution time performance factors. It was found that the performance of the support vector machine algorithm to be better than Naive Bayes classifier from the experimental results [6].
Srinivasa has developed a dialysis support system with a kidney failure data and decision tree algorithm [7].

Kaladharhas achieved 97% success with J48 algorithm and 98% success with RandomForest algorithm in recognition of kidney stones with Weka[8].

Zadehhas achieved 80.85% success with WJ48 algorithm and 85.11% success with W Simple Cart algorithm for early detection of dialysis with Weka[9].

Hyaribus the decision tree algorithm in the practice of chronic renal disease with Weka[10].

Song, has achieved 80% success with decision tree algorithm for renal failure disease using Weka[11].

Kumarhas achieved 96% success in identifying kidney stones using multi-layered network structure neural network algorithm with [12].

III. METHODOLOGY

A. Dataset

A dataset that usedis composed of data of 24 different variables that obtained from 250 patients with chronic kidney and obtained from 150 patients with non within 2 months from a hospital. The presence of 24 various tests measure to each patient is important in this data set in terms of demonstrating the applicability of conclusions derived from the results of studied to daily life.

These data and properties are shown in Table 1.

</tbody>
</table>

As shown in Table 1, patient data is also included age, blood pressure and appetite information in addition to various information of assays. The values and units of this data varies according to the type of data. 1, 2, 10, 11, 12, 13, 14, 15, 16, 17 and 18 of the variables in data are get units specified numerical values; 3, 4 and 5 of the variables in data are get specific numerical values; and others consist of the specified non-numeric values and the initial values are written in parenthesis next to the data. There is also a 25th variable in the data of the person that to hold the information “ckd” if a person patient and “notckd” if a person not the patient.

B. Support Vector Machine

There are many algorithms can be used for classification in Weka software. Support vector machine is one of the very effective and simple methods that used for classification. Simply, support vector machine is an algorithm that working the method of to draw a line in the plane between the two groups and the separation of these two groups. In Figure 1, separating the groups from each other by the algorithm is shown.

In Figure 1 the first verify are drawn two groups identified the closest element to each other, representing these elements, for to separate the two groups placed in a two-dimensional plane by support vector machine. The process of separating two different groups from each other is maintained for determining the correct point on the equidistant two lines drawn between the two towards. In the Weka, SMO (Sequential Minimal Optimization) algorithm is using like the support vector machine algorithm[14].

C. Decision Tree

In the decision tree algorithm method, the class labels are level of the tree leaves, leading to the leaves and the process on start arms are expressed forming a tree structure[15]. The tree structure as a result of the decision tree algorithm is shown in Figure 2.
Analysing the test results in Table 2; for both algorithms, it was found that the error values of from Test-1 results are lower than the error values of from Test-2. Because of the data size used to train the algorithm in Test-1 is larger than the data size of the Test-2 process; algorithms are better educated, forecast accuracy higher than Test-2 and forecast transactions are also lower as a result of the error values in the Test-1 processing. Therefore it the magnitude of the training data affects estimation process. Kappa statistic values are also outside the error values in the table. To be close to 1 of this value indicates the accuracy of the estimation process. The reliability and validity of the estimate decreases when the kappa statistic closer to zero. The decision tree formed in the Test-1 results of J48 algorithm is shown in Figure 3.

</tbody>
</table>

When examined the decision tree in Figure 3; it is observed that begins with the capability of serum creatinine (sc). Because the leaves of decision trees are ranked according to earnings criteria, it can say that the first decisive feature in the estimation process is this feature. Other features that make up the branches of the decision tree are also of importance for the estimation process, respectively. Each leaf is divided into branches by >, < = and <= operations. The last leaf of the branches, it is reaching the (ckd) value or (unckd) value if the people are patients or not patients. The first number listed in parentheses next to this value illustrates the total weight of examples in the leaves, the second number indicates the weight of the incorrect classification. In addition, in the estimates, the total number of leaves of the created tree (Number of Leaves), and the size of the tree (Size of the Tree) are also indicated. Also a decision tree created in the Test-2 results and a decision tree is formed in the Test-1 result are the same. This is also shows that the size of the training data don’t
changing characteristics that impact on estimates but the size of the data affects education level of learning algorithm. The results of estimation procedures of SMO algorithm, the weight vector which will be made of the best estimate process is determined by creating a weighting coefficient for each feature. In Figure 4, SMO algorithm weights as a result of the features that generate Test-1 operations are shown.

FIGURE IV. The SMO Algorithm Weight Vector Form of Test-1 Results

In Figure 4, when the weight of the vector by the result of SMO algorithm examined, it has been observed that some features of the weight is calculated as zero. As it is understood from this result, zero weight values properties do not have an effect on the process of the estimating. The characteristics which its coefficient equal zero has no effect on the estimation process. Because all the features form the weight vector with coefficient values, the features having nonzero coefficients are not possible to sort by the coefficient values.

Weight vectors generated as a Test 1 and Test-2 results of SMO algorithm are the same. This is also showed that effective to change properties on the estimated size of the data affect the level of training algorithm. It has been show that the data size cannot change the properties that effective on the estimates but it showed that the algorithm affect the level of education.

Confusion Matrix of J48 and SMO algorithms formed in Test-1 and Test-2 results are shown in Figure 5.

FIGURE V. The Confusion Matrix of J48 and SMO algorithms

As it is seen from the confusion matrix of algorithms; J48 classification algorithm was not making a mistake in Test-1 and the error is 0%. However, 21 patients were classified as non-patients and 9 non-patients were also classified as patient and the error is 8.33% in Test-2. SMO algorithm were classified 4 patients as non-patients in the Test-1 results and error is 2.94%. And 9 patients were classified as non-patients and 5 non-patients were also classified as patient and the error is 3.88% in Test-2.

V. CONCLUSIONS

Chronic Kidney Disease a longer disease that prevents the normal duties of the kidneys and causing any damage the kidneys. The early detection of this disease is very important in terms of health and treatment costs. In this study, using the data of consisting the 250 chronic kidney disease patients and 150 non-patient people data set, classification of patients was estimated by the help of support vector machine and decision tree algorithm. Training and testing process of algorithms were measured by creating two different sets of data. As a result of different data size and prediction operations performed with different algorithms, it has been shown that the size of the training data algorithms to be largely effective for the estimating.

In the classification stage, decision tree has been more successful than the support vector machine recognition of 97% to 100% recognition. Forecasting and phase accuracy, it has...
been observed that made an accurate estimate of 100% rate with the decision tree in the Test-1 data set and an accurate estimate of 91.67% rate in the Test-2 data set. Also it has been observed that made an accurate estimate of 97.06% rate with the SVM in the Test-1 data set and an accurate estimate of 96.12% rate in the Test-2 data set.

With the data used in this study showed that the decision tree gives better results than the support vector machine for the early diagnosis of chronic kidney disease. High rate results was obtained in terms of performance as compared with results in the literature

REFERENCES

Abstract—In this study, it is aimed to reduce the variability of parameters in the liquid level system controlled by PID controller for a laboratory scale device. An integrated methodology consisting of experimental design and feedback PID (proportional-integral-derivative) controller was proposed to optimize and control the deviation from the average value in the offset value, variability in the offset value and the time to reach the set value in this liquid level system. The optimal valve opening levels that minimizes the average of the offset value (µ), variance (s2) and the first time to reach the set value (t) were determined as 40%, 5%, 50% and 80%, respectively, using TOPSIS (Technique for Order Preference by Similarity to an Ideal Solution)-based Taguchi method by Minitab®. A quite successful control was established in the verification test which performed with specified levels of optimal valve opening. Recovery rates in the control performance before and after optimizing the parameter were calculated as 9.53% in the deviation from the average value in the offset values, 29.37% in the variability in the offset value and 11.27% in the time to reach the set value. MATLAB/Simulink was used to simulate the liquid level system.

Keywords—Laboratory Scale Liquid Level System, TOPSIS based Taguchi Parameter Design, PID Controller and Performance Improvement

I. INTRODUCTION

Liquid level loops are frequently encountered in many process industries such as waste water management systems and petrochemical processes [1] – [4]. Especially in the petroleum industry, liquid level is a crucial parameter for production at oil wells [5]. In recent years, many researchers studied on controlling of liquid level systems [6]. Sbarbaro and Ortega (2007) proposed a new approach to control the multi-tanks systems [7]; Almutairi et al. (2007) proposed several sliding mode control diagrams for the coupled tanks [8]; Lee and Shin (2009) applied constrained control to liquid level system using conventional PI (proportional-integral) controller [1]. Zhang et al. (2011) modelled and controlled the liquid level in a coke fractionation tower using non-linear based predictive control [9]. Noel and Pandian (2014) proposed an integrated methodology including artificial neural network based reinforcement learning approach for controlling of a nonlinear liquid level system [10]. Sadeghi et al. (2014) designed a method based on parallel distributed compensation via fuzzy Takagi-Sugeno model for a liquid level system [11]. Singh et al. (2014) reduced flow rate fluctuation for tank in series with PI controller [12]. Zhang et al. (2014) offered PI controller based on predictive functional control for liquid level in a coke fractionation tower [9], [13]. In the literature, many studies contain process optimization and control applications have proposed for various industrial areas. Some of these studies are as follows; Tao et al. (2014) applied predictive control based PID design with genetic algorithm for chamber pressure in coke furnace [13]; Zhang et al performed model predictive control optimization based PID control for temperature in an industrial surfactant reactor [14]; Zhang and Yang (2014) developed an incremental- PID-controlled particle swarm optimization algorithm for EGG-data-based estimation of operator functional state [15]; Sahu et al. (2015) proposed teaching-learning based optimization algorithm based fuzzy-PID controller for automatic generation control of multi-area power system [16]; Gizi et al. (2015) formulated an integrated approach programmable logic controller-fuzzy PID methodology to determine optimal PID parameter in automatic voltage regulator [17].

Many difficulties are experienced in liquid level control systems owing to the variability in the parameters and flow resistance [3]. Parameter variations that should be controlled can be originated from pumps, agitators or the natural causes [3]. In this study, it is aimed to reduce the variability of parameters in the laboratory scale liquid level system controlled by PID controller. Purpose of reduction of parameters’ variability and noise effect with the methodology including multi-criteria decision making (MCDM) based Design of Experiment (DoE) for finding optimal valve opening levels and process control performance improvement. Moreover, the improvement rate was also specified by finding valves’ opening levels to optimize the process control performance. Giving a positive and negative effect on the system, system performance was evaluated after the parameter optimization. Matlab/Simulink® was used to simulate the laboratory scale liquid level system (LSLLS).
II. Proposed Materials & Methodology

A. Materials

Liquid level control techniques can be applied experimentally by LSLLS building up standard industrial material (Figure 1). It is possible to observe the control techniques used in the industry. P, PI and PID control methods can be examined experimentally with LSLLS.

The reaction of the control data can be measured with changing operation conditions. Pressure tracking can be done in four different points via manometer. Liquid level in the plexi tank can be measured by HK Instruments DPT-R8 differential pressure sensor. Accuracy of DPT is ±1.5% or ±6 Pa under 250 Pa. Control data can be recorded by the Pangu KT104 digital data recorder. It can record and show process data graphically and visually. Width of the cylindrical liquid tank of LSLLS is 75 cm and height of the tank is 200 cm. Experimental set has a pneumatic proportional valve consist of Young Tech Instruments YT100 electrical junction box, positioner, PVD T-PA40 pneumatic actuator and an 1.0 inch inner diameter ball valve.

Valve no. 1 breaks the water come from the water pump, Valve no. 2 is the by-pass valve connected to pneumatic proportional valve, Valve no. 3 is located at the plexi tank water inlet and Valve no. 4, drain valve, is located at the plexi tank water outlet. The block diagram of the LSLLS was given in Figure 2.

B. Proposed Methodology

Proposed methodology contains two stages including parameter optimization and control. In first stage, optimal valve opening levels was determined to minimize the deviation from the average value in the offset value, variability in the offset value and the time to reach the set value in this liquid level system using TOPSIS based Taguchi methodology. In second stage, process control performance of the system was monitored via optimum valve opening; dynamic behavior of LSLLS with positive and negative step change was examined, closed-loop block diagram was established by Matlab/Simulink® and process control performance improvement rate was calculated between former and optimal valve opening levels. Flow diagram (including 10 flow steps used in the study in process control performance optimization of LSLLS) is given in Figure 3.

C. Determining Performance Criteria for the Success of Process Control

Three performance criteria for the success process control were defined as deviation from the average value in the offset value, variability in the offset value and the time to reach the set value [18]. Target values and weights of performance criteria were given in Table 1.

Offset values is steady-state difference between the set point which is 60 cm with the actual point obtained in liquid level control system. The average of these values were defined as mean of the offset values, the variance of these values were defined as variance of the offset values, respectively. Time to reach the set point was described as the first time to reach 60 cm. 8th, 7th and 4th values were designated to mean of the offset values, the variance of these values and time to reach the set point, respectively. All criteria representing process control performance are required to be minimized.

D. Determining Levels of Performance Criteria

Each globe valve which has ½ inch inner diameter effect on performance criteria has three levels and their description was shown in Table 2. Tank no. 1 filled with city water was used as fluid in the system. Process parameters, valve opening levels, were set before each experiment’s implementation. The system was run for
Several model approaches can be used for process control applications. Theoretical models which are obtained by process physics and chemistry can be used in industry. Development of theoretical models may not be a practical way when model requires process variables and unknown parameters (i.e. physical and chemical properties) including many equations. Development of an empirical model from experimental data directly can be an alternative approach [20].

### III. RESULTS AND DISCUSSION

#### G. Results

In Table 3, columns 2–5 represent the four control factors and their levels. In this study, a Taguchi’s $(3^4)$ orthogonal array was used to implement the experiments and results are given in Table 3 [21]. Findings relevant to the deviation from the average value in the offset value, variability in the offset value and the time to reach the set value in this liquid level system were given in columns 6–8. Table 3 also contains PID tuning parameters such as proportional gain, integral gain, derivative gain which is shown in columns 9-11.

#### H. TOPSIS Based Taguchi Design

In this study a Taguchi orthogonal array $(L_{9\times3})$ was selected to implement the experiments. Signal to noise ratio (S/N) were calculated for the smaller the better type responses and given in columns 2-4. Let $n_i$ be the S/N for the response $j$ of experiment $i$ and let $y_{ijk}$ be the experiment result for the response $j$ of experiment $i$, in the $k^{th}$ replication; $n$ is the total number of replications [19], [22]. The calculation of the S/N ratio can then be determined as [23];

$$n_j = -\log K_C \left( \frac{1}{n} \sum_{k=1}^{n} y_{ijk}^2 \right)$$  (2)
In Table 4, columns 5-7 are shown as decision matrix which is essential step of the TOPSIS method [27]. The positive ideal solution \((S_i^+)_i\) and negative ideal solutions \((S_i^-)_i\) and \(C_i^*\) \((i=1\ldots9)\), are the surrogate responses for the multi-response minimization problem [19].

The average responses by factor levels can be designated using the additive property [19], [24]. Their associated factor effect plots are given in Figure 4 [19]. Since the effect values are smaller-the-better, normalization methods caused the final parameter design of \(A_2B_2C_3D_2\) which is given in Table 5.

### I. Validation of experiment and PID tuning parameters’ calculation

In order to confirm the optimum valve opening levels achieved using the TOPSIS based Taguchi method, an experimental study was implemented to check whether the deviation from the average value in the offset value, variability in the offset value and the time to reach the set value could really be minimized by the proposed optimum valve opening levels. The confirmation study improvement for mean of the offset values, variance of the offset values, valve opening levels. The confirmation study improvement value could really be minimized by the proposed optimum variability in the offset value and the deviation from the average value in the offset value, experimental study was implemented to check whether the achieved using the TOPSIS based Taguchi method, an

In Table 6 demonstrated that proposed results satisfies the expected set point. PID tuning parameters of validation experiments were calculated as 0.57 for proportional gain, 4.54 for integral gain, and 13.64 for derivative gain using well-known statistical model definition techniques.

### J. Development of a Closed-Loop Feedback Block Diagram Using Matlab/Simulink®

Transfer function of a laboratory scale liquid level system can be modelled utilizing orifice and mass balance equation to describe the dynamics of chemical process given in Seborg et. al. [20]. A block diagram representing the laboratory scale liquid level system was obtained by Matlab/Simulink® tool can be seen in Figure 5. PID controller tuning parameters was received as 0.57 for proportional gain, 4.54 for integral gain, and 13.64 for derivative gain. System response against step change can be seen in Figure 6.

Underlined values are the predicted levels before the parameter optimization*
which is MCDM based experimental design and process control methodology to improve process control performance in a laboratory scale liquid level system. Following the TOPSIS based Taguchi procedure, process control performance of the system was monitored using optimal valve opening levels. The validation experiment illustrated that the difference in process control performance between the optimal valve opening levels and estimated valve opening levels is significant.

Improvement of parameters between valve opening levels and estimated valve opening levels were calculated as follows; mean of the offset values average, 9.53%, variance of the offset values, 29.37% and time to reach the set point, 11.27%. In addition, improvement of parameters between valve opening levels with a positive step change and estimated valve opening levels were calculated as follows; mean of the offset values average, 34.79%, variance of the offset values, 53.57% and time to reach the set point, 68.08%. Furthermore, improvement of parameters between valve opening levels with a positive step change and estimated valve opening levels were calculated as follows; mean of the offset values average, 58.97%, variance of the offset values, 11.22% and time to reach the set point, 21.50%. It can be seen from the results of system behaviour, that they satisfied the expected success process control performance of LSLLS (Figure 7).

**Kırklareli, Turkey
srkn_911@hotmail.com

Abstract—This study has been composed for the aim of making a comparison of the requirements for heating energy within TS 825, between the houses built with reinforced concrete frame technique which most commonly used in today’s Turkey and the houses built with the traditional building techniques. For this purpose, energy requirements of two storey detached reinforced concrete frame building calculated according to TS 825, separately for with thermal insulation and without thermal insulation. Obtained values, compared with energy requirements according to TS 825 of traditional buildings with mixed structural system used combination masonry and wood frame structure. According to the results of the calculations for the reinforced concrete structure according to the TS 825, the maximum permitted annual heating energy requirement 29.99 kWh/m3. Building with thermal insulation appropriate to the TS 825, annual heating energy needs calculated as Qyear =29.47 kWh/m3. Building without thermal insulation appropriate to the TS 825, the annual heating energy requirement is calculated as Qyear = 91.84 kWh/m3. A building without thermal insulation consumes three times more energy than a house with thermal insulation. The third building with the traditional construction system, annual heating energy needs calculated as Qyear =27.76 kWh/m3. But the annual heating energy requirement is calculated as Qyear =60.77 kWh/m3/ţür. The value obtained by calculation, more than twice the permitted value. When the calculation results of both the traditional building and the reinforced concrete building is compared, the thermal insulation made form of a house has the minimum energy consumption. And it has been determined that the energy consumption value of a traditional building is less than a reinforced concrete building. As a result, modern reinforced concrete structures, if they are not insulated very high level of energy consumed. For this reason, the value of thermal conductivity with new buildings must be appropriate to the region. Appropriate thermal insulation requirements, can be achieved using thermal insulation materials, or as with examples of traditional building, can be achieved using high thermal values building components.

I. INTRODUCTION

The natural resources of the earth are continuously depleted due to the rapidly increasing World population, developing industries and technology, including the unplanned urbanization, and based on this depletion, many global and local environmental problems occur. For example, the Carbone dioxide level of the atmosphere surrounding the earth (CO2) reached to a 400 ppm (400 in a million) since 1958 in accordance with the measurements carried out on 9th May, 2013. This increase in the CO2 is the most important reason for the global warming and climate variation [1]. It is an obligation for Turkey to decrease the greenhouse gas emissions used in the buildings is an important part of the inventory. The emission increased 3.92% annually in average since 1990. There is an increase of 5.1% as per the data of the year 2010. The most part (16.2 millions) of 20 million tonnes (approximately) increase of Carbone dioxide equivalent is energy based. 2.2 million of the rest is industrial based, while 1.7 million is agricultural. While 9.4 million tons of energy based increase is due to the natural gas and coal used in electric power production, 3.2 million tons of the rest is for transportation, and the 3.4 million tonnes is based on the electric power used for iron & steel, cement industry [2]. One of the main reasons of carbon emission is the usage of fossil based energy resources. The buildings globally have one of the biggest shares in energy usage. The power consumption ratio of housing industry in Turkey is 35% as per the data for the year 2010 [3]. The power consumption in the buildings increased 44% since 2002 to 2010 in Turkey [4]. Fossil fuel based Greenhouse gas emissions used in the buildings is an important part of the inventory. The emission levels are calculated via the energy provided by the fuel. The power consumption level increased to 280 Millions of TJ in 2002, while this amount was 240 million of TJ (Tera joule) in 1990. In terms of greenhouse gas, the carbon dioxide emission level reached to a level of 52.6 million tons in...
2011, while this amount was 23 million tons in 1990 [2]. One of the main reasons for the increase in the power consumption of buildings is based on the socio-economic increase of the users, yet this cannot be prevented through various measures to be taken. The buildings consume the biggest part of the power energy during the utilization stage within the lifecycle [5]. The biggest part of the utilization is based on the heating and cooling matters. The first stage of decreasing the power energy consumption in the utilization process is to design an effective planning in the structure. After this comes the generalization of renewable energy resources in the buildings, producing building elements with low heat conductivity, as well as usage of low-energy household appliances. Producing of low-heat-conductivity building elements can be carried out using structural materials with low heat conductivity, as well as increasing the thickness of structural materials, generating fixed air gap between the building elements or using heat-insulation materials.

The applications & practices for decreasing the power consumption in the buildings are still not being utilized in required levels, even if some of them cause no extra expenditure. In accordance with the housing power consumption survey carried out by Turkish Statistical Institute in 1998, 84% of the existing buildings are single-glazed, and only 16% of them do have the roof insulation. In line with the “Comprehension Survey” data carried out by the Heat, Water, Noise and Fire Insulation Association, only 9% of the consumer utilized the insulation, when the consumers applying insulation on the buildings they’re residing are in question [6]. However, the traditional buildings in our country are designed taking the climate data into consideration, thus integrating the traditional building materials in a manner keeping the heat transmission coefficient low. Therefore, this study was carried out to analyse the traditional buildings within the framework of today’s standards, as well as making a comparison in terms of today’s buildings and power consumption. In this manner, a housing Project designed taking the climate data into consideration was analysed in line with TS 825 both as insulated and uninsulated in terms of power consumption. A traditional building in the central area of Kırklareli was analysed, as well. The obtained results were evaluated and concluded.

When the previous studies are analysed concerning this subject matter, a study which has the most similar perspectives with this article was carried out by Korumaz et al. The power consumption performances of four traditional Gaziantep buildings and three modern Gaziantep buildings were compared in accordance with the TS 825 version 2000 in a study carried out in 2006. The traditional buildings in this study are stone-walled as typical in the regional architecture. Two of the modern buildings are in form of apartment building, while one of them is a detached house (villa), their carrier systems are reinforced concrete framing, with no heat insulation. According to the results obtained in the comparisons carried out, the power consumption performance of traditional buildings is better than the modern buildings in terms of both average heating energy needs, and of annual heat loss ratio [7]. A comparison on thermal conditions was carried out based on the measurement made obtained in a traditional building and a modern building under the same climate conditions in a study carried out by Priya et al. With this study, it can be clearly understood that the traditional buildings are much more comfortable than the modern houses, in India, Tamil Nadu, Nagappatina coastal areas with moist and hot climate [8]. The traditional buildings and modern buildings in Kerala located in the South India in coastal areas were compared through the measurement of such factors as thermal comfort conditions, temperature, humidity, air flow, thus obtaining results through these measurements with a survey, in a study carried out by Dilia et al. With this study, it can be clearly understood that the traditional buildings in Kerala are quite effective in providing a comfortable environment, regardless of the climate conditions [9]. The thermal performances of an experimental solar house, traditional house and a modern house were subjected to a comparison in a study carried out in Cyprus. This comparison was carried out with a software – Energy 10 - applying PC simulation. With this study, it was confirmed that the comfort conditions can be enhanced on a ratio between 10% - 45% with passive solar energy techniques based on the analysis results. When the annual power consumption performances of these three separate buildings were compared, it was confirmed that the power consumption in the experimental solar house (121KWh/m²) was quite lower than the modern house (368 kWh/m²) and the traditional house (243 kWh/m²) [10].

II. TS 825 THERMAL INSULATION REQUIREMENTS FOR BUILDINGS

A study for saving fuel via decreasing the heating loss in the buildings, TS 825 (Thermal insulation requirements in the Buildings) standard was first published by Turkish Standards Institute (TSI) in February 1970. It was given the name being used today during the first revision applied in June 1979, and it was revised for the second time in April 1985. In line with the demands received from the relevant sector, it was re-regulated with a large-scale revision for providing power saving in April 1998. In this revision, the calculation methodology was completely renewed with local and foreign standards [11]. The last revision for this standards was carried out in 22.05.2008, and additionally a modification was applied to this revision on 17.07.2009. The objective of TS 825 standard is to determine the standard calculation methodology and values to be used for limiting the power consumption amounts, increasing the power saving ratio, as well as calculating the power requirements [12]. For a building to be in conformance with the TS 825 standard, the annual heating energy needs of the building as calculated (Q) must be lower than the annual heating energy edge value in the standard. The accuracy of the total heat transfer coefficient (U) as calculated for exterior walls, ceiling, surface or floor (as
the surfaces of building causing the heat loss) must be controlled in accordance with the values as set forth by the standard, taking the specific provisions into consideration. Certain calculations must be carried out for possible condensation in the surfaces of building causing the heat loss, and strict attention should be paid for not causing any condensation, or keeping the condensation level under the evaporation level, in a harmless level.

It must be ensured that the internal surface temperatures are designed in a manner of which value is 3°C (max.) less than the internal environmental temperature value, for not causing mould growth and disrupting the comfort conditions, including not causing any condensation on the exterior surfaces of the building with heat loss [12].

III. CALCULATION OF ANNUAL HEATING ENERGY REQUIREMENTS OF TRADITIONAL BUILDINGS AND MODERN BUILDINGS AS PER TS 825

Two separate buildings were selected to compare the power consumption amounts of traditional and modern buildings in the residential building example. One of these two buildings is a detached house in Kırklareli with a reinforced concrete framing, and the other one is a traditional building structured in the beginning of 20th century in Kırklareli’s central area. In this study, TS 825 Temperature Insulation Calculation Program was used, as designed by Association of Gas & Concrete Manufacturers in Turkey. With this program, various structures and many sections, doors, Windows et al. can be generated with the software which is in full conformance with the acceptance requirements and methods as set forth in TS 825. Using this software; specific heat loss, annual heating energy requirements, condensation schedules and diagrams can be easily prepared, thus generating reports on this matter [13]. In these calculation the internal temperatures of the buildings were deemed to be 19°C, the fuel to be coal, and the ventilation method to be natural. On the following, you can see the analyses made for these buildings within the scope of TS 825 Standard.

A. Analysis of a Modern Reinforced Concrete Building within the Scope of TS 825

The building is located on a 350m² land, as two-storey and detached house. On the ground floor; the living room and hall are located on the facade, while the kitchen, entry, bathroom and stairs are on the rear front. On the upstairs; the bathrooms are located on the facade, while the bathroom and walk-in closet are on the rear entry. The terrace is located on the South front of the structure (Figure 1). The infill walls of the structure with reinforced concrete framing carrier system are made of bricks. The joineries were planned to be heat insulated double-glazed plastic. Various measurements for the structure are listed on the following table (Table 1).

TABLE 1. THE DIMENSIONS OF THE BUILDINGS ELEMENT OF REINFORCED CONCRETE FRAME BUILDING

1) Calculation of the Annual Heating Energy Requirements of the Heat-insulated Building with Reinforced Concrete Framing: The annual heating energy requirement for the building approved by TS 825 is $Q' = 29.99 \text{kWh/m}^3$ (max.). The annual heating energy requirement for the building is $Q_{\text{year}} = 29.47 \text{kWh/m}^3$, as calculated. Total heat loss of the
building is 336.22 W/K. 220.90 W/K of this loss is through transmission, while 115.32 W/K of it is through ventilation. The table indicating the building elements causing the loss through transmission is on the following (Table 2). When the data on the table is analysed, the biggest heat-loss occurs due to the windows. No condensation was observed on the building elements as per TS 825. Additionally, the temperature difference between the internal surface and interior environment is lower than 3°C, which is in conformance with the standard requirements. On certain building elements, condensation, which is lower than evaporation, was detected.

2) Calculation of Annual Heating Energy Requirements of an Uninsulated Building, with Reinforced Concrete Framing: The measurement was performed on the reinforced concrete framing building with 20 cm horizontal perforated brick infilling walls, and with no heat-insulation material on the building elements. Only on the joineries, heat-insulated double-glazed plastic joinery was applied. The annual heating energy requirement for the building approved by TS 825 is Q’ = 29.99 kWh/m³ (max.). However, the annual heating energy requirement for the building is Qyear = 91.84 kWh/m³, as calculated. The value obtained through the calculation is approximately three times higher than the allowed value. The total heating-loss of the building is 832.98 W/K. 717.66 W/K of this loss is through transmission, while 115.32 W/K of it is through ventilation. The table indicating the building elements causing the loss through transmission is on the following (Table 3). When the data on the table is analysed, the biggest heat-loss occurs due to the reinforced concrete elements (flooring, column, and beam). No condensation was observed on the building elements as per TS 825. However, the temperature difference between the internal surface and interior environment is higher than 3°C, which is not in conformance with the standard requirements. On certain building elements, condensation, which is lower than evaporation, was detected.

B. Analysis of a Traditional Building as per TS 825
A building, built Kırklareli on 1908, is selected as the Traditional Building example. The carrier system of the building is masonry stone-wall with 65 cms of thickness until the sub-basement level. Above the sub-basement, there is a timber-framed Wall with mudbrick-filling with the thickness of 15-17 cms on average on the facade. This Wall is covered with natural Stones with approximately 10 cm thickness (Figure 2). Other fronts were covered with bricks having thickness of 35 cms approximately however there is still a wooden structure within the brick wall. The mezzanine floor laying’s are structured with wooden beams, and these beams do have wooden laying elements on them. The ceiling is made by nailing plaster board under the wooden beams. Fibered lime plaster was applied between the partition joints.

![Image 1: Wood frame Wall with stone coated](image1)

![Image 2: Stone walls and masonry wall combination](image2)

Figure 2b. Stone walls and masonry wall combination

![Image 3: Sections of the wood frame walls and masonry walls in traditional buildings](image3)

Figure 2. sections of the wood frame walls and masonry walls in traditional buildings
The building is designed as per internal-hall planning type. The entrance of the building is directly connected to the Street, thus having a niche with 5-6 steps of a stair. The ground floor has 4 bedrooms and a cellar, while the upper floor has 3 bedrooms and a living room. The corners of each of the bedrooms located near the column has a window (Figure 3).

The annual heating energy requirement for the building approved by TS 825 is $Q' = 27.78 \text{ kWh/m}^3$ (max.). However, the annual heating energy requirement for the building is $Q_{\text{year}} = 60.77 \text{ kWh/m}^3$, as calculated. The value obtained through the calculation is approximately two times higher than the allowed value. The total heating-loss of the building is $974.02 \text{ W/K}$ of this loss is through transmission, while $135.91 \text{ W/K}$ of it is through ventilation. The table indicating the building elements causing the loss through transmission is on the following (Table 7). When the data on the table is analysed, the biggest heat-loss occurs due to the reinforced concrete elements (flooring, column, and beam).

No condensation was observed on the building elements as per TS 825. However, the temperature difference between the internal surface and interior environment is higher than 3°C, which is not in conformance with the standard requirements. On certain building elements, condensation, which is lower than evaporation, was detected.

IV. EVALUATION

As per the results obtained from the calculations made, the annual heating energy requirement for the building approved by TS 825 is $Q' =29.99$ kWh/m³ (max.). The annual heating energy requirement for the building after the TS 825 standard requirements are applied, is $Q' =29.47$ kWh/m³. The annual heating energy requirement for the building is calculated as $Q_{\text{year}} =91.84$ kWh/m³ without the heat-insulation. The building without heat-insulation needs three-time higher heating energy than the heat-insulated building. The annual heating energy requirement for the traditional building plan as approved by TS 825 is $Q' =27.78$ kWh/m³ (max.). The annual heating energy requirement for the traditional building, is $Q_{\text{year}} =60.77$ kWh/m³. The calculated value is two times higher than the allowed-value. When the calculation results of traditional building and reinforced concrete building are compared, the energy consumption of the reinforced concrete building – with heat-insulation – is on the lowest level (Table 6). It is also confirmed that the energy consumption value of the traditional building is lower than the reinforced concrete building without heat-insulation. Therefore, it can be clearly concluded that the building elements used in the traditional buildings are quite effective for thermal characteristics.

TABLE 6. THE ANNUAL ENERGY CONSUMPTION VALUES OF REINFORCED CONCRETE BUILDING AND TRADITIONAL BUILDING

</tr>
</tbody>
</table>

When a comparison is made as building elements based, the highest amount of heat loss is caused by the Windows in a reinforced concrete building with heat insulation. For reaching to the peak level concerning the energy consumption performance of this building, high-performance joineries and windows should be used. Additionally, for the reinforced concrete building without heat insulation, the highest heat-loss is caused by the laying’s and reinforced concrete building elements. On the traditional buildings, the joinery area on the exterior front is enlarged, since the windows are designed as French Windows. Thermal conductivity of the joineries designed with wooden materials and as single-glazed is relatively higher. Therefore, a significant part of the energy - loss in the buildings is caused by the joineries. The traditional buildings were built in accordance with the day’s technology, building elements, climate conditions and user requirements. Additionally, the usage conditions of traditional buildings are quite different that today’s conditions. For example, there are separate bedrooms in traditional buildings for both summer and winter, these are two separate rooms used in both summer and winter, thus changing the function of the room, as well. In traditional Turkish buildings, this room is used as a living room, for sleeping, eating, like a kitchen or bedroom. Today, these activities are performed in separate rooms in the modern buildings like bedroom, living room, kitchen, et al. In other words, it can be clearly said that an “economy” is applied on the traditional building rooms. All the calculations made are for achieving the complete heating of traditional building. Therefore, the principle of “heating only the room in use” (in traditional buildings) is ignored in this study. In traditional buildings, the windows are generally located on the South fronts. In this way, passive solar energy is can be obtained, besides the heat-storage features of such building elements as brick, stone and mudbrick are comparatively better than the horizontal perforated bricks, gas-concrete building elements used in today’s modern buildings. Since the building elements with heat-storage characteristics get heated and cold slowly, the comfort conditions for the building can be sustained for a longer period of time, without the need of additional energy consumption.
V. CONCLUSION

Reinforced concrete is the most preferred building element in today’s carrier systems used in Turkey. Buildings with reinforced concrete system do not indicate any difference as per the region it is located, thus not being reflected any climate characteristics in its structure. The reinforced concrete building elements, by itself, cannot meet the comfort requirements, neither. In this study, it is confirmed that the reinforced concrete buildings without heat-insulation cause higher heating energy losses. After using heat-insulation materials, heating energy consumption is dramatically decreased. The energy consumption of traditional buildings structured with such building elements as stone, mudbrick and wood, is comparatively higher than the reinforced concrete building with heat insulation. The weakest link in the traditional buildings in terms of protection of energy is detected to be the windows. The ratio of energy loss caused by the windows and door joineries is 1/3 within the whole energy loss. This ratio can be dramatically decreased by reducing the size of joinery area, as well as using heat-insulated windows. Heat transmission values of the Wall elements (U value) is higher than the value as required by TS 825 for 3rd level areas, yet it is within the acceptable range. Heat transmission values of such horizontal building elements as plasterboard ceiling and wooden floor are comparatively higher than the walls.

As stated on certain traditional building examples, this heat transmission value can be decreased by using such materials as mudbrick mortar fodder. The total performance of the building can get closer to the heat-insulated building, by this way. The traditional buildings have been designed with traditional building elements taking the climate conditions into consideration. On the other hand, the modern buildings can be designed with modern building elements and advanced building Technologies by means of PC technology, in a more efficient and very cost effective manner. In addition to these features, modern designers should not ignore benefitting from the traditional building having the experiences of the past.

A MATLAB SIMULATION OF POSITIONING OF POLITICAL PARTIES IN THE OPINION SPACE

Abstract—Catch-all parties appealing to wider groups of citizens position themselves near the center of the opinion space representing the median voter’s opinion, but small parties tend to represent border-line, extreme opinions. In this paper, we verify these observations with a simple simulation searching for optimal positions of political parties in a multi-dimensional circularly-uniform opinion space that will maximize the average level of representation throughout the space. The results indicate that optimal positions are seemingly unique in cases two or more parties compete in a perfectly proportional voting system. We argue that more involved forms of such simulations may be used to foresee the consequences of policy shifts of parties, changes in the perceptions, or any other deviations from the highly idealized situation analyzed here.

Keywords—Simulation, Matlab, Political parties, Spatial theory, Electoral competition

I. INTRODUCTION

A. A Literature Review on the Spatial Theory

In a brief historical review of the use of mathematical models in political science, Johnson [1] describes the beginnings of the spatial model, which implied that the position of the median voter in a one-dimensional opinion space was the equilibrium point for the competing political parties. However, as noted in that same review, this view could not be extended to higher dimensions. Ortin [2] notes such a convergence is the expected result when two political parties compete in a one-dimensional opinion space, with full knowledge of voters’ preferences, but when the information about those preferences is uncertain, the parties distinguish themselves with their ideologies, meaning the results are also uncertain. However, that argument is probably only valid for majoritarian electoral competitions where the winner takes all. As noted by Dow [3], taking neutral positions near the center is the typical behavior of parties competing in majoritarian systems, whereas proportional representation may also reward small parties shifting to off-center positions.

Actual election results indicating deviations from the median voter theorem are also discussed by Schofield [4]. In an effort to account for those deviations, he attempts to construct a model extending a previous one by allowing for valence, i.e. the biased opinions of voters about the parties or the candidates. He presents highly rigorous mathematical theorems, but his conclusions are limited to some qualitative remarks about the positions taken by parties according to their voter-attributed valence values.

Degan and Merlo [5] also note the spatial theory implies that voters vote ideologically; in other words, they decide according to how close the parties or candidates stand in the multiple dimensions of the opinion space with respect to the voters. Busch [6] is another author who dwells on the implication that voters decide after comparing their political stances with those of the parties, with the added note that the accuracy of the comparisons is limited by how well the voters observe the changes in party policies, for example, along the left-right ideology dimension. Budge and McDonald [7] also point to the left-right ideological scale as a primary factor in voters’ decisions in different democratic countries, but analyze how the voting affects the election outcomes and the subsequent policy changes of the parties.

The perceived positions on a left-right scale, however, cannot be seen as the only determinants of voters’ decisions. Grittersova et al. [8] argue that major, or “mainstream parties,” tend to be evaluated according to their left-right stances, but smaller, radical parties (i.e. “niche parties”) rely on the support they build on issues along other dimensions, such as the economic stances they take, especially when “incumbents are forced to adopt austerity policies.” The party size, as measured by the average number of seats that it usually obtains in the legislative body, appears as another – albeit moderately influential- factor in Dahlberg’s study [9]. The author notes that it will be harder for voters to accurately determine the ideological stances of major parties appealing to larger opinion ranges, leading to the conclusion that catch-all parties take mostly neutral stances along basic opinion dimensions, without alienating many voters with more specific ideological stances.

B. The Reasoning Behind the Presented Model

From this brief literature review, we can draw a conclusion that voters cast their votes according to the perceived distances between their own and political parties’ positions in a multidimensional opinion space. As mentioned in the introduction of the paper by Thurner [10], we can attribute a “utility function” to a voter, specifically, “a decreasing function of the Euclidean distance from the voter’s ideal point.” The distance in the opinion space between the voter and a political party will determine the value of that utility function, namely, how well that specific party represents that particular voter.

With such a model in hand, one can search for equilibrium points at which parties will settle for maximizing their vote shares or probabilities of winning, as analysed by Patty [11], but studies on such models usually seek for Nash equilibria, which do not seem to exist outside fairly limited conditions, such as when three or more candidates compete [12]. It is natural to presume that candidates seeking maximum possible voters will try to take shortcuts by shifting towards the most neutral points in the opinion space, but so can the others, meaning that far-sighted candidates may be better off by preserving their political stances [13], rather than losing their appeal to voters for whom they had higher utilities.
restrictive spatial models have been proposed, as reviewed by Williams [14], to build upon the Downsian model of vote-maximizing electoral competition. Rather than trying to limit the complicated interplay between the policy shifts of parties, we feel the need to build a simpler, more basic model which places the emphasis on the voters rather than the parties, and search for the optimum positions which would maximize not the vote shares of parties, but the combined utility of the parties, i.e. the average level of representation as perceived by the voters.

II. PRESENTATION OF THE MODEL

C. Underlying Assumptions

With seemingly no similar work in the political literature, a new model like the one presented here must be constructed on a fairly basic foundation based on rather simplifying assumptions:

1) It is clear that only in a proportional voting system do political parties value their level of appeal to voters, rather than the actual number of votes they hope to gain in an election. Only then can every party hope to partake in a ruling coalition, if no single party is the winner. Consequently, we start with the assumption that a perfectly proportional representation system with no thresholds is in effect.

2) The opinion space on which parties compete must have a certain geometrical shape and voters must be distributed over that space according to a certain density function. As a starting point, we assume a circularly shaped opinion space in a two-dimensional space over which voters distributed according to a uniform density function whose equation is given below.

\[ C(x, y) = \begin{cases} 1, & x^2 + y^2 \leq 1 \\ 0, & x^2 + y^2 > 1 \end{cases} \]

This assumption will lead to a fairly simple sandbox (well, “sand-dish”) model, but that will be sufficient to draw basic conclusions about the equilibrium points.

3) We assume that voters and political parties perfectly know where they each stand in the opinion space. This is probably the most unrealistic assumption, but once we present the most basic form of this model, more realistic forms can be constructed by working perceptual imperfections and biases into the model in later studies with other collaborators.

4) For the utility function for a political party over the circularly uniform opinion space, we employ a type of Gaussian function which peaks at unit value at the exact position of the party on the opinion space, but does not extend outside the uniformly circular opinion space:

\[ F_i(x, y) = \exp \left( -\frac{4 \ln(2) \left[ (x - x_i)^2 + (y - y_i)^2 \right]}{w^2} \right) \times C(x, y) \]

We assume this function gives the utility of party with the index \(i\) located at the \((x_i, y_i)\) position as perceived by the voter located at the position \((x, y)\). As a measure of the

II. PRESENTATION OF THE MODEL

C. Underlying Assumptions

With seemingly no similar work in the political literature, a new model like the one presented here must be constructed on a fairly basic foundation based on rather simplifying assumptions:

1) It is clear that only in a proportional voting system do political parties value their level of appeal to voters, rather than the actual number of votes they hope to gain in an election. Only then can every party hope to partake in a ruling coalition, if no single party is the winner. Consequently, we start with the assumption that a perfectly proportional representation system with no thresholds is in effect.

2) The opinion space on which parties compete must have a certain geometrical shape and voters must be distributed over that space according to a certain density function. As a starting point, we assume a circularly shaped opinion space in a two-dimensional space over which voters distributed according to a uniform density function whose equation is given below.

\[ C(x, y) = \begin{cases} 1, & x^2 + y^2 \leq 1 \\ 0, & x^2 + y^2 > 1 \end{cases} \]

This assumption will lead to a fairly simple sandbox (well, “sand-dish”) model, but that will be sufficient to draw basic conclusions about the equilibrium points.

3) We assume that voters and political parties perfectly know where they each stand in the opinion space. This is probably the most unrealistic assumption, but once we present the most basic form of this model, more realistic forms can be constructed by working perceptual imperfections and biases into the model in later studies with other collaborators.

4) For the utility function for a political party over the circularly uniform opinion space, we employ a type of Gaussian function which peaks at unit value at the exact position of the party on the opinion space, but does not extend outside the uniformly circular opinion space:

\[ F_i(x, y) = \exp \left( -\frac{4 \ln(2) \left[ (x - x_i)^2 + (y - y_i)^2 \right]}{w^2} \right) \times C(x, y) \]

We assume this function gives the utility of party with the index \(i\) located at the \((x_i, y_i)\) position as perceived by the voter located at the position \((x, y)\). As a measure of the perceived range of opinions the party appeals to, we propose the parameter \(w\), which, in fact, determines the full-with-at-half-maximum of this Gaussian function.

5) To model a competition between two or more parties over the uniformly circular opinion space, we assume that a voter’s choice will be for the party whose utility function is the greatest at the voter’s position. For example, if \(n\) parties are competing, the combined utility function of the parties over the uniformly circular opinion space can be expressed as follows:

\[ P_i(x, y) = \max\{F_1(x, y), F_2(x, y), \ldots, F_n(x, y)\} \times C(x, y) \]

D. Simulations

The uniformly circular opinion space and the utility functions were evaluated numerically, on a 201x201 mesh grid.
of the Cartesian coordinate system extending from -1 to +1 along both dimensions.\(^1\)

In order to simulate the policy changes of the parties towards the equilibrium positions where the best average level of representation is achieved, random initial locations were selected for the party utility function centers and the optimal locations were obtained by implementing the built-in optimization function available in Matlab. These simulations were repeated 50 times for each combination of FWHM values of party utility functions in two or three party competitions. FWHM values, which represented the extents of voter bases of the parties ranged from -1.0 to 1.0 in dimensionless units also employed to determine the extent of the opinion space.

### III. Results

The most noticeable was that, in all trials for every combination of FWHM values, the final locations provided the same average level of representation, i.e. the same average level for the combined utility function over the circularly uniform opinion space. Of course, this average value actually appears to be the same within the uncertainties of the mesh representation of the opinion space; we derive our confidence from the fact that the percentage error of the mean for the average level of representation was never greater than 0.6%.

The optimal party locations obtained from all the repetitions of the simulations were almost always different in Cartesian coordinates, but they looked the same when normalized according to the position of the major party (the one whose utility function had the largest FWHM value). Therefore, transformation were applied from Cartesian coordinates to polar coordinates where the major party’s angular position was accepted to be 0 in radians.

#### E. Two-Party Results

Optimal party locations averaged over all 50 trials of specific FWHM combinations are presented in the following table.\(^2\)

</table>

Uncertainties of the locations are noticeable in cases the FWHM ratio of the minor to major party is too small, implying that niche parties with extremely small voter bases play little roles in optimizing the average level of representation throughout the opinion space. In such cases, the niche party is also found to be located at the very edge (even beyond) of the opinion space, leaving the major party comfortably fixed at the neutral center.

This behavior is apparent in other FWHM combinations; the major party is closer to the center when the minor party has a smaller base, but shift away from the center to balance the voter base of the minor party. Judging from the angular differences of the locations, parties are expectedly located at the opposite

---

\(^1\) The above figures were obtained by plotting the sample functions on a smaller mesh grid of 41x41 for a simpler visualization.

\(^2\) Percentage errors of the mean are given in parentheses if they are equal to greater than 0.1%.
ends of a line passing through the neutral center of the opinion space. This result implies that the two parties must have taken opposite stances in both dimensions of the opinion space in order to maximize the average level of representation as perceived by the voters.

Fig. 3 The relative placements of the political parties with respect to ratios of their voter bases.

Fig. 2 shows the relationship between the ratios the optimal radial locations of the major party to minor party and the FWHM ratio, i.e. the ratio of the extents of parties’ voter bases. It is noted that the locations of the parties with identical voter bases mirror each other, and the larger the voter base of the major party, the close it is to the neutral center.

F. Three-Party Results

Table II shows only a fraction of the results, namely, the optimal locations for parties with identical voter bases. Again, judging from the percentage errors of the means, all simulations for the same FWHM combinations seem to arrive at the same average level of representation. Optimal locations providing this average representation value may possibly be unique, because for these combinations of identical FWHM values, radial and angular locations are similar, but we can make no assertions without implementing a more reliable optimization routine over an opinion space represented by a larger mesh size.

IV. DISCUSSION

This study aimed at determining the optimal positions for the parties in a circularly uniform opinion space that would maximize the average level of the voters, if a perfectly proportional representation system is in effect. The results for the simulations performed for the two-party competitions show that there are such positions and they appear to be unique, when normalized to the location of the major party. The results for the three-party competitions also suggest that unique optimal positions exist, but more elaborate studies are needed to ascertain that.

The results verify the common-sense observations about the political stances taken by catch-call parties with large voter bases and niche parties with small voter bases. Comparisons of the normalized locations show that catch-all parties can afford to take neutral stances without losing appeal to a wide spectrum of opinions, but niche parties or ones with smaller bases realize their vote potentials only by taking more extreme positions on one or both dimensions of the opinion space, so that they can appeal to extremist voters who would not subscribe to neutral views.

However, the results for the three-party competitions tell a different story. Judging from the results presented in Table II, one may conclude that when the competing parties have similarly wide voter bases, they will differentiate themselves in one or both opinion dimensions; the larger the voter base, the more distance they will shift from the neutral center.

It must be remembered that all these conclusions are based on the overly-simplifying assumption that parties and voters all know each other’s exact positions over an idealized representation of the opinion space. This naïve assertion probably makes the conclusions dismissible, but a substantial potential exists for further studies based on more elaborate simulations involving more realistic assumptions.

The literature about the mathematical models of the voting systems and electoral competitions abound with studies which focus on finding Nash equilibria for the positions taken by political competitors; there seems to be no prior study discussing the existence of the equilibrium that would be optimum in terms of voters’ overall satisfaction with the level of representation they perceive. This is the primary reason why the literature review presented in this paper is rather brief.

Prior studies also focus more on electoral competitions of two parties in majoritarian voting systems, probably because they are in effect in certain countries dominating the world politics. The classical median-voter theorem still has validity over such competitions; the competitor will focus on amassing votes at the expense of each other, resulting in undifferentiated political stances near or at the neutral center. This study has taken a different path derived from the hypothesis that parties competing in a perfectly proportional voting system can afford to focus on maximizing the overall satisfaction over their traditional voter bases, instead of greedily seeking for more votes by trying to appeal to voters outside that base. The simulations were performed to determine whether all competing parties starting from randomly selected positions would always arrive at the same final positions, and the results strongly suggest that this is the case. When normalized according to the location of one party, the set of final positions appear to be unique for each distinct combinations of voter base sizes. They are also optimal in the sense that they maximize the average value of the combined utility function of the parties.

These optimal locations may seem to be of little use, because of the highly idealized nature of the model, but the real aim of this presentation is to establish ground for more detailed studies with more collaborators from different disciplines, preferably with political scientists taking the lead. The models constructed in those studies will not only serve as educational demonstrations tools, but they will also help analyze the
probable effects of the policy shifts of the parties in more accurate models of actual electoral competitions.

About One Approach to Intelligent Managing of Health Specialists Labor Market

Masuma H. Mammadova, Zarifa G. Jabrayilova
Institute of Information Technology of National Academy Science of Azerbaijan
AZ1141,Azerbaijan Republic, Baku c., B.Vahabzadeh str.,9
depart15@iit.ab.az

Abstract— Paper illustrates specific features of the health specialists (HS) labor market, which dictate the variance of fuzzy conditions of demand and supply of HS and the multiple-choice pattern of their reconciliation. Levels of modelling of the supply and demand interaction in the HS labor market are singled out. Task formulation and the purpose of managing the demand and supply of HS are discussed. A microlevel model of supply and demand management in the HS labor market based on fuzzy situation analysis and fuzzy pattern recognition is proposed.

Keywords— health specialists labor market, supply and demand, demand model, supply model, situational management, fuzzy reference and actual situations, fuzzy situation recognition.

I. INTRODUCTION

The results of health system activity and quality of medical service rendered to the population completely depend on quality and quantity of health specialists (HS). Therefore, the improvement of medical staff stock and raise of health specialists professional level are important challenges the special attention of each country and generally of World Health Organization (WHO) is given to [1–3]. Currently great significance is attached to highly qualified staff training, additional training for perfection of professional qualities, knowledge and skills of health specialists, staffing and improvement of health quality indicators.

Despite all abovementioned, the tendency of staff shortage, personnel decrease is now observed [4–7]. It is announced that number of staff shortage in USA for 2020 is prognosticated to be 85000 people, and for 2025 the demand and supply will gain the upper hand from 46000 to 90000 [8]. The number of doctors per 10000 people for 2011–2014 has decreased in Ukraine from 49 to 48, in Belorussia – from 54 to 39, in Azerbaijan – from 37 to 35 [9]. In Turkey the number of people per a doctor is 595, whereas this indicator equals 262 in Germany, 203 in Ukraine, 290 in Azerbaijan.

Under the total number of doctors it is provided to take into account all highly-educated doctors who work in treatment, sanitary, social security institutions, scientific and research institutes, postgraduate education training and other health bodies.

Health specialists also include nursing staff (paramedic, obstetrician, nurse). Most of world countries state about the shortage of nursing staff [5]. Despite the doctor/nurse ratio number in Finland equals 1:4.3, in Norway –1:4.7, and in Denmark –1:5.6, these countries still announce the fact of nursing staff shortage [6], as in Britain nurse shortage number was presented up to 35000, and in Finland up to 100000. One of the factors generating this problem is application of information and communication technologies, as well as modern innovative medical technologies in medical sphere, formation of e-health, and it reasons the partial decrease of demand for doctors and increase of demand for nursing staff [10, 11].

Thus, present picture in the sphere of doctor and nursing staff displays the excess of demand over the supply in health specialist labor market, and it makes the issues of regulation and management of demand and supply for health specialists essential at governmental and WHO level [1–4]. Successful solution of this problem requires complex approach to the problem, and development of comprehensive strategy encompassing staff compensation, working conditions, their recruitment and retention issues. Still, there is not any standard model in this direction as well as any country to borrow its “best practice” in order to find appropriate problem solution to the stated issue. According to the results abovementioned issues in health specialist policy have been partially embraced in such countries leading in the medical sphere as England, Belgium, Germany, Ireland, Spain, Lithuania, Slovenia, Finland, Australia and Canada. In these countries necessary source for monitoring of health specialist labor market is availability of an information base maintaining reliable, precise and new data.

II. SPECIFIC FEATURES OF THE HEALTH SPECIALISTS LABOR MARKET

Thus, here are the following challenges to define demand and supply for health specialists:

- What will be future short-, medium- and long-term perspectives for demographic, epidemiological, social and cultural characteristic features of the population;
- Increase of which chronic illnesses, psychological states is prognosticated, and emerging probability of new future diseases in the result of migration flow and climate changes;
- What are the requirements for appropriate future medical service;
- What will citizens’ and users’ requirements be, who will be financing appropriate medical services;
- What kind of specialists and their amount (general practitioner, specialist physicians, paramedics, nurses and others) will be required; what responsibilities and
education of the health specialists together with their compensation rates will be in demand.

In order to find the answers to all abovementioned questions and in the development of correct staffing policy the priority is given to sociological survey method, initiating by WHO from 1990. Topicality of this approach reasoned by the lack of scientific methodology in this field, and shortage of scientific works devoted to this issue.

The new demands on health specialists (HS) emphasize a strong ability to adapt to change and innovations, flexibility, multifaceted skills, mobility, and ability to switch between different areas of activity, which correspondingly require continuous updating of professional knowledge and skills by means of both formal and informal education [12, 13].

However, academic publications have failed to properly focus on the system analysis of the HS labor market and the development of adequate technology and support techniques for managerial decision making in reconciling the supply and demand to reflect the specific features of this sector of the economy and the preferences of its main factors.

The specific features of the HS labor market, the uncertainty of information flows about its state, the much-varied profile of data on HS and the difficulties of measuring it, and the ambiguity of indicators characterizing it predetermine the variety of possible fuzzy states of supply and demand for HS and the multioption pattern of reconciling them. Comparisons and evaluations of these conditions and the choice of the reconciliation policy can be efficiently accomplished with the use of intellectual methods and technologies. The latter help to integrate the versatile information on the supply and demand conditions and facilitate the development of a set of alternatives for managerial decisions and the selection of the most efficient one among them. Management in such systems is considered as a process of identification of the demand and supply condition at a given point in time and decision making suitable in the current situation.

III. MODELING THE INTERACTION BETWEEN SUPPLY AND DEMAND IN THE HS LABOR MARKET

The rise of an information economy emphasizing knowledge as its major value produces a significant influence on labor market deformations. The emphasis shifts toward human resources and the creative aspect of activities, which modifies the basic foundations of a “transaction” in the supply and demand relationship [14, 15].

Nowadays, it is impossible to gain the maximum results from an employee with minimal expenses on his/her development. No expectation is warranted of a creative approach to job tasks or quality level of performance without considerations for the HS preferences (aspirations, interests, and motivations) facilitating his or her professional and often personal development [16, 17].

The task of modeling and managing the interaction between demand and supply in the market for HS can be considered at micro and macro levels. The micro level identification of the supply and demand conditions is viewed from the point of individual subjects in the HS labor market and their behaviors and strategies. At the macro demand level, the basic unit is an enterprise because it is at the enterprise level that the demand for HS is shaped in terms of structure and volume, as well as requirements regarding professional and personal competencies. In this case, the task of defining the level of conformity between supply and demand consists in the development of efficient selection and recruitment of HS.

At the macro level, the task of modeling and managing the interaction between demand and supply in the HS labor market, depending on the objectives, comes to balancing the supply and demand for HS within different territorial and geographic areas (at the industrial, regional, and nationwide levels, etc.).

This paper analyzes the supply and demand relationship in the HS labor market at the micro level. Success in performing job functions depends on the HS intellectual potential, level of certain professional and personal competencies, willingness to properly employ them in the workplace, and desire and ability to expand and update professional knowledge and experience in line with functional requirements. Against this context, it seems worthwhile to address the labor market as an intellectual environment [18], where the commodity is knowledge, abilities, and skills.

By intellectual smart management of the HS labor market, the authors mean managerial decision making to bring down the imbalance between the demand for HS and their supply, which comes to a choice between possible alternatives of the supply and demand reconciliation policy toward solutions that will satisfy as fully as possible the aims and conditions of the objectives set and the needs, preferences, interests, aspirations, and capabilities of the key market subjects, i.e., employers and HS, while bringing down the gap between the demand and supply as much as possible.

IV. FORMULATION OF THE PROBLEM

Suppose \( M = Y \), \( K \), \( G \), \( Q \), \( U \) sets the model of demand for HS defining the competence requirements for those applying to a particular position. It represents the system of employers’ preferences for candidates to a particular position expressed as a set of sought competencies of the right candidate and shapes the reference search profile of an HS. Here, \( Y \) is the set of vacancies expressed by candidate requirements for HS positions by employers; \( K = (L, C) \) is the set of basic competencies characterizing HS, comprising the set \( L \) of personal competencies required for working in HS and the set \( C \) of professional competencies reflecting the required functional abilities for filling a particular vacancy; \( G \) is the system of the employer preferences with respect to levels of particular measures;
\[ Q : V : K \cdot U^p \rightarrow G \] is the decision rule (evaluation model) for mapping the set of preferences to the set of competencies;

\[ U^p \] is the set of conditions offered to candidates applying for IT vacancies.

The supply model \( M_S = \{ S, K, W, Q^*, U^* \} \) reflects actual value of competencies and preferences of each individual HS, thus defining the search profile (professional profile) of HS. Here,

\[ S \] is the set of HS looking for work and aspiring to a particular position;

\[ K = (L, C) \] is the set of personal and professional competencies of an individual HS, a potential candidate to a particular vacancy;

\[ W \] is the set of preferences of an HS;

\[ Q^*: S \cdot K \cdot U^* \rightarrow W \] is the mapping of the set of preferences of an HS to the set of competencies;

\[ U^* \] is the workplace requirements of the HS.

The interaction between the set of reference demand conditions for HS and the set of actual conditions shaping their supply create the set of unique semistructured (fuzzy) situations.

The purpose of managing supply and demand in the HS labor market is to identify (recognize) among the sets of actual search profiles of HS and reference search profiles the particular combination (pair) that shows the highest degree of agreement (convergence) of elements both from the point of preferences (reference requirements) of the employer and from the point of aspirations of the candidate.

With a mechanism available to evaluate supply and demand conditions and the degree of their conformity through the prism of the subjects’ interest in the HS labor market, managerial decisions can be made as to the selection of the best candidate to a position (consequently, the selection of the best job).

In formal terms, the problem of identification of supply and demand conditions can be defined by three components \( D = \{ V, S, R \} \), where:

\[ V \] is the set of vacancies;

\[ S \] is the set of HSs;

\[ R \] is the set of rules defining the relationship between the elements of sets \( V \) and \( S \), i.e., rules helping to compare the descriptions of actual conditions of HS with all reference conditions of the demand side.

The recognition and evaluation of supply and demand conditions take the form of the mapping \( F : D \rightarrow Z \), where \( Z \) is the solution of the problem \( D \) set with the intellectual system as a particular target condition meeting the purpose of recognition and evaluation in a particular situation.

V. PROBLEM SOLUTION

Assume the demand in the HS labor market is defined by the set:

\[ V = \{ V_1, V_2, ..., V_k \} \] or \( V = \{ V_j \}, j = 1, k \) expressed in terms of the number of vacancies;

\[ L = \{ l_1, l_2, ..., l_n \} \] or \( L = \{ l_j \}, j = 1, n \) is the set of personal features required in a candidate to a particular position (job, workplace);

\[ C = \{ c_1, c_2, ..., c_m \} \] or \( C = \{ c_f \}, f = 1, m \) is an open set of competencies sought to fill an HS vacancy;

\[ U^p = \{ u_1, u_2, ..., u_p \} \] or \( U^p = \{ u_f \}, f = 1, p \) is a set of conditions offered to applicants to vacant HS jobs.

The demand model \( V = (L, C) \) can be described by three matrices \( V_L = [l_i]_{kn} \), \( V_C = [c_f]_{km} \) and \( V_U = [u_1]_{ap} \), where every row \( (v_i) \) characterizes individual vacancies in the HS market; columns \( (l_i, c_i) \) represent the constantly expanding base of personality traits and competencies; elements \( l_{kn}, c_{km} \) of \( V_U \) express the level of individual characteristics required to fill the vacancy at the given time \( t \); and \( u_{ap} \) are the values of measures characterizing the conditions proposed to applicants for particular vacancies. Competency weights can also be taken into account; i.e. \( \omega = \{ \omega_1, ..., \omega_m \} \) is the set of weights of personal competencies, and \( L = \{ l_j \}, j = 1, n \); \( \omega = \{ \omega_1, ..., \omega_m \} \) is the set of weights of professional competencies \( C = \{ c_f \}, f = 1, m \).

The degree of conformity between vacancy \( V_i \) and \( l_{ij} \) and \( c_{jfr} \) is defined as fuzzy sets with membership functions

\[ \mu_{h_i}(V_i) : V \times L \rightarrow [0,1], \quad \mu_{c_{jfr}}(V_i) : V \times C \rightarrow [0,1] \] expressing the levels of individual competencies required to fill the vacancy as set by the employers.

Simultaneously, the conditions proposed to applicants are described by matrix \( V_U = [u_1]_{ap} \), where membership functions \( \mu_{h_i}(V_i) : V \times U \rightarrow [0,1] \) represent fuzzy degrees of factors representing the conditions of employment.

Assume the supply in the HS labor market is given as set \( S = \{ S_1, S_2, ..., S_q \} \) of HS looking for work and aspiring to a particular vacancy;

\[ L = \{ l_j \}, j = 1, n \] is the set of actual competencies characterizing HS;

\[ C = \{ c_f \}, f = 1, m \] is the set of actual competencies in each individual applicant to a vacancy;

\[ U = \{ u_f \}, j = 1, p \] is the set of preferences of an HS expressed as his/her requirements for an HS vacancy.

The supply model \( S = (l, C) \) is also given as three matrices \( S_L = [l_{kn}], S_C = [c_f]_{km} \) and \( S_U = [u_1]_{ap} \), where each row \( (S_q) \) characterizes individual candidates to proposed
vакансий в HS job market; columns \( l_{i,n}, c_{m} \) reflect the constantly expanding base of personal traits and competencies; elements \( l_{i,n}, c_{m} \) are the levels of individual attributes required to fill a vacancy; and \( u_{i,n} \) are the values of measures describing the HS requirements for a vacancy.

The degree of competency by an HS \( S_i \) is defined as follows:

\[
\mu_{ls}(S_i) : S \times L \rightarrow [0,1], \quad \mu_{cs}(S_i) : S \times C \rightarrow [0,1] \tag{2}
\]

The HS requirements for a vacancy are expressed by the matrix \( S_{i,v} = [l_{i,n}, c_{m}] \), and \( \mu_{ls}(S_i) : S \times U \rightarrow [0,1] \) reflects fuzzy measures of the IT specialist’s requirements.

In fact, there are two sets of fuzzy situations describing the conditions of demand \( \widetilde{V}_k \) and supply \( \widetilde{S}_q \) in the HS labor market:

\[
\widetilde{S}_q = \left< \mu_{ls}(S_q) \right>, \quad \widetilde{V}_k = \left< \mu_{cs}(V_k) \right> \tag{3}
\]

Here, set \( \widetilde{S}_q = \left< \mu_{ls}(y) \right> \) accounts for fuzzy reference situations, and set \( \widetilde{V}_k = \left< \mu_{cs}(y) \right> \) accounts for fuzzy real situations.

For the purpose of managing supply and demand in the HS labor market, the problem of identification of the supply and demand conformity and subsequent hiring decision can reasonably be posed as a task of fuzzy profile recognition and evaluating the degree of fuzzy conformity of situations by measures and their levels. The search and decision making in these situations comes to comparisons of each fuzzy search profile of HS (applicants to one or several particular vacancies) with each reference search profile of employers and to identifying pairs with the highest degrees of convergence. In this setup, making a decision (logical conclusion) on the convergence (alignment) between supply and demand is based on situational management employing steps of evaluating the degree of convergence between two fuzzy situations. Approaches to convergence evaluation between any actual situation and each reference situation can involve single-stage or multistage procedures of identifying the degree of fuzzy inclusion of situation \( \widetilde{S}_q \) in fuzzy situation \( \widetilde{V}_k \), degrees of fuzzy equality of \( \widetilde{V}_k \) and \( \widetilde{S}_q \) and fuzzy community of \( \widetilde{V}_k \) and \( \widetilde{S}_q \), and other measures of convergence [19, 20].

VI. POSSIBLE SCENARIOS OF SUPPLY AND DEMAND IN THE HS LABOR MARKET

After the identification of the most acceptable employer (decision maker) – HS “pair” is completed on the basis of the degree of convergence among the sets of actual and reference search profiles, several possible scenarios are possible:

**Scenario 1.** One vacancy (employer request) – one applicant (HS). In this case, if the degree of fuzzy convergence between two situations (reference search profile and candidate’s search profile) is not lower than the employer’s set threshold, then the decision is made to hire.

**Scenario 2.** The employer’s preferences are met by several applicants (HS) at an acceptable degree of convergence of two fuzzy situations. They form a subset of fuzzy situations (alternatives), and the most suitable one should be selected.

In this case, the employer acting as an expert (decision maker) can be offered the following methods of decision making [21, 22]:

(a) compare the degrees of convergence of reference and actual situations by the significance levels of the criteria characterizing the applicants to the vacancy and make a decision based on the convergence in the more significant criteria;

(b) expand the list of evaluation criteria, further define input situations, and repeat the procedure of recognition;

(c) reduce the problem to multicriterion choice of the best solution (alternative) taking into account the relative significance of criteria characterizing HS.

**Scenario 3.** Several employers who are interested in hiring of one HS are identified. A reverse problem occurs in this case: a subset of fuzzy reference situations (alternatives) is given in the form of proposed vacancies of different employers with fitting conditions, from which the HS has to choose in accordance with his preferences. In this scenario, the decision maker role lies with the IT HS who can:

(a) compare the degrees of convergence between his aspirations and the criteria defining hiring conditions and make a decision based on the convergence of the most significant criteria;

(b) expand the list of criteria for workplace evaluation, further define input situations, and repeat the recognition procedure;

(c) reduce the problem to a multicriterion choice of the best solution (alternative) taking into account the relative significance of criteria characterizing workplaces.

VII. CONCLUSION

The proposed method is one of the possible options to help employers make reasonable hiring decisions to fill vacancies. The need for such assistance is dictated by a number of factors including the dynamic patterns of the business environment, the narrowing life cycles of implementing new ideas and technologies, and the need for systematic implementation of innovations to maintain competitive strength of the organization. In such circumstances, modern employers must constantly adapt their solutions to constantly changing managerial situations. Moreover, nowadays, the share of decisions to be made in uncertain and unconventional situations is rising significantly at all levels of management. While human resources are the main factor of competitive strength for organizations, the issues of support of decision
making in managing staff and its intellectual potential have gained strategic importance.

Abstract— In this study, coupled interaction of a simply supported Euler-Bernoulli bridge beam with a quarter car travelling with a constant speed on the bridge is presented. Motion equation of the coupled system is derived from Lagrange equations using the kinetic and potential energies of the both system at the contact point. The obtained set of ordinary differential equations is solved in time domain with a special software prepared by computer using the fourth order Runge-Kutta integration method. For special dimensions of the non-random irregularities on the bridge beam, the effect of the irregularity including with the effect of flexibility of the beam on the passenger comfort are analysed in terms of ISO-2631 standard.

Keywords— Non-random road profile, Vehicle-bridge-interaction, Passenger comfort, Euler-Bernoulli bridge beam, quarter car model.

I. INTRODUCTION

The dynamic behaviour of structure under the influence of moving loads as an important issue in engineering has taken place in the literature. For analytical solution of various problems of moving loads, the studies [1], [2] are essential in this field. Considering dynamic behaviour of structures under moving loads with variable velocity, [3]–[5] have studied the dynamic behaviour under the influence of accelerating mass on beams of different types. On a flexible structure without neglecting the effects of damping and inertia of the mass is a moving mass problem and some accurate solutions of these kind of problems using Finite element method (FEM) can be found in [6]–[9]. Moving mass problems in defence systems, for the interaction projectile and barrels are applicable and studies [10]–[13] are significant for the forced vibrations of the barrels due to the projectile and barrel interaction. One of the main applications of the vehicle bridge interaction problems that are the studies in this field are generally divided into nine categories. The effect of the suspension systems, road surface roughness effects, bridge length, the vehicle braking, the vehicle mass, vehicle speed, bridge damping, bridge unit length of the mass, the effect of the acceleration of the vehicle [14]. Despite The early simple cases of a moving concentrated force on a simply supported beam with constant speed [1], the vehicle bridge interaction particularly in bridge engineering applications, are quite important. The first studies in the literature in this area is focused the dynamics of bridges but vehicle dynamics is neglected [15], [16]. Later moving mass with constant or variable velocity over a railway bridge is an important research topic today and some useful solutions of so simple cases of it can be found in [17]. For evaluating the vehicle, bridge interaction in terms of passenger comfort of a vehicle on a flexible structure for constant velocity has been given in [18]. One of the major applications of train / rail interaction, for example, [19] proposed a two-axle vehicle on an Euler-Bernoulli beam the bridge interaction using finite element model. The other Wheel/rail interaction applications using FEM can be found in [20]–[22]. Another research interest in this field is on the effect of road roughness.

In general, depending of the accuracy of the modelling of both vehicle and bridge models, the vehicle-bridge interaction problems are very complicated in order to analysing the interaction considering the passenger comfort. In this study, the effects of basic parameters that affect the system are studied using a quarter car model.

II. MATHEMATICAL MODELLING

The quarter-car model with two degrees of freedom contains vehicle body and axle with masses \( m_1, m_2 \), and connecting elements that consist of springs and dampers with the same features and linear characteristics. In the model shown in Figure 1, \( k_1, k_2 \), represent, respectively, the stiffness of the tire and suspension.
Symbols $c_1$, $c_2$, on the other hand, represent, respectively, the damping coefficients of the tire, suspension. In addition, the mass of the suspension system is included in the mass of the vehicle body. The parameters $y_1$ and $y_2$ represent vertical movement of the tires at their point of contact with the bridge. These movements are affected by the deflection of the tires at their point of contact, and the roughness of the road at the same points. The vertical movement of the bridge $w_b(x, t)$ represents the deflection of any point $x$ on the beam of the bridge at time $t$, relative to a reference point on the left-hand support of the beam. The symbol $v$ represents the constant velocity of the vehicle as it moves from the left end of the beam to the right end. The function $r(x)$ represents the roughness of the bridge surface, and will be explained in detail in the following sections.

In the formulation for the VBI analysis following assumptions will be adopted:

- The bridge is modelled as a simple supported beam based on Euler-Bernoulli theory.
- The vehicle was modelled four and six DOF as lumped parameter.
- Only one car was accepted moving on the bridge with constant velocity $v$.
- The car’s wheels are always in contact with the bridge. There are not any jumping involved.

With these assumptions, the kinetic and potential energy of the vehicle-bridge-passenger interaction, as shown in Fig. 1a, is expressed as follows respectively:

$$E_k = \frac{1}{2} \int_0^L \mu \left[ \dddot{w}_i (x,t) + \left( m_i \ddot{y}_i + m_i \dot{y}_i^2 \right) \right] dx, \quad (1)$$

$$E_p = \frac{1}{2} \int_0^L \left[ \rho_i v_i(x,t) + \left\{ \left( y_i - w_i(x,t) \right) \dddot{y}_i + k_i \left( y_i - y_i \right) \dot{y}_i \right\} \right] dx, \quad \text{for} \quad i = 1, 2, 3, 4, \quad (2)$$

Approaches, such as the principle of virtual work, Hamilton’s principle, and D’Alembert’s principle can be used for the equation of motion of the system, as shown in Fig. 1a. This study uses Lagrange’s equations, formed using the kinetic energy and potential energy equations of the vehicle-bridge integrated system, and the mode expansion method. The Galerkin equation for the deflection $w_b(x, t)$ of any point $x$ on the beam at time $t$ is expressed as follows:

$$w_i(x, t) = \sum_{i=1}^n \varphi_i(x) \eta_i(t), \quad (3a)$$

$$\ddot{w}_i(x, t) = \sum_{i=1}^n \ddot{\varphi}_i(x) \eta_i(t), \quad (3b)$$

$$w^*_i(x, t) = \sum_{i=1}^n \varphi_i^*(x) \eta_i(t), \quad (3c)$$

$$\varphi_i(x) = \frac{1}{\sqrt{2L}} \sin \left( \frac{i \pi x}{L} \right), \quad i = 1, 2, …, n. \quad (4)$$

Rayleigh dissipation function for the vehicle-bridge integrated system is expressed as follows:

$$D = \frac{1}{2} \left[ c \dot{y}_i^2 + c_i \left( \ddot{y}_i - w_i(x, t) \right) + c_i \left( \ddot{y}_i - \ddot{y}_i \right) \right], \quad (5)$$

In Eq. (5), $c$ is the equivalent damping function for bridge beam. In addition, the Lagrange equation ($L = E_k - E_p$) of the system is equal to the difference between the kinetic energy and the potential energy. If the Lagrange equation is rearranged for six independent coordinates, the following is obtained:

$$\frac{d}{dt} \left( \begin{array}{c} \frac{\partial L}{\partial p_i(t)} \\ \frac{\partial L}{\partial p_i(t)} + \frac{\partial R}{\partial p_i(t)} \end{array} \right) + \frac{\partial R}{\partial p_i(t)} = 0, \quad k = 1, 2. \quad (6a)$$

$$\frac{d}{dt} \left( \begin{array}{c} \frac{\partial L}{\partial \eta_i(t)} \\ \frac{\partial L}{\partial \eta_i(t)} + \frac{\partial D}{\partial \eta_i(t)} \end{array} \right) + \frac{\partial D}{\partial \eta_i(t)} = Q, \quad i = 1, 2, 3, 4. \quad (6b)$$
The motion equation of the vehicle-bridge-passerger model with six degrees of freedom shown in Fig. 1 is obtained by using the orthogonality condition and the Galerkin approach expressed for beam deflection (Eq. (3)). Motion equations for the vehicle axle, the vehicle body are expressed, respectively, as follows:

\[ m_1 \ddot{y}_1 - k_1 (y_1 - y_t) + k_1 (y_t - y_i (x,t)) - c_1 (\dot{y}_1 - \dot{y}_t) + c_1 (\dot{y}_t - \dot{w}_1 (x,t)) = 0 \]  

(7a)

\[ m_2 \ddot{y}_2 + k_2 (y_2 - y_1) + c_2 (\dot{y}_2 - \dot{y}_1) = 0 \]  

(7b)

The effects of road profiles with roughness of varying location, width, depth, and number on vehicle dynamics were examined. Non-random roughness as shown in Fig.12 is divided into two categories: periodical and discrete. In mathematical terms, non-random irregularities are expressed as in Eq. (8) [19]:

\[ r_j (x) = \frac{1}{2} \zeta (1 - \cos 2\pi x / \gamma) \]  

(8)

Here \( \zeta \) represents the depth or height of the road defect, and \( \gamma \) represents its width. Eq. (8) is expressed as a series as in Eq. (9).

\[ r_j (x) = \begin{cases} 
\frac{1}{2} \zeta \left(1 - \cos \frac{2\pi (x - C)}{\gamma}\right), & \text{for } C \leq x \leq C + \gamma \\
0 & \text{elsewhere},
\end{cases} \]  

(9)

\[ C = B + k(A + \gamma), \quad k = 0, 1, \ldots, N_i 
\]

(10)

\[ N_i = (L_d - B) / (A + \gamma), \]  

(11)

Here \( B \) is the distance between the defect on the bridge and the left end of the bridge, which is taken as the reference point, \( L_d \) represents the distance between two consecutive road defects, and \( N \) refers to the number of defects.

III. NUMERICAL EXAMPLES

In this study, in order to analyse interaction of vehicle-bridge-road in Figure 1, the parameters of the vehicle and bridge listed in Table 1 are chosen. Considering various conditions the interaction between the vehicle-bridge is represented by a system of ordinary differential equations; and then it is solved using the fourth order Runge-Kutta method and a special code written in MATLAB. On a flexible structure like a bridge, the effect of the non-random irregularity has been investigated using different cases that are given in Table 2. Case 1 and Case 2 are shown in Figure 2.

For the two cases, the vertical responses of the axle and body are presented in Figure 3, for a constant speed of the vehicle \( v=25 \) m/s. In the Case 1, the vehicle has just past over the bump after 0.5 second from the start. In the second case, that represents three successive bumps, the vehicle is over the bumps at the time of 0.5, 0.56, and 0.62 seconds respectively. In addition to the effect of the flexible bridge, the effects of the bumps can be easily noticed from Figure 3.

The effect of the height of the bump \( \zeta \) on the responses of the vehicle components is given in Figure 4. For three value of \( \zeta \) that are 1, 4, and 7 cm the responses of the axle are 1, 3.5, and 6 mm respectively, the responses of the body are smaller when compared to the responses of the axle, as can be seen from Figure 4 at the right.

IV. CONCLUSIONS
In this study, a vehicle-bridge and road interaction is presented using a two DOF quarter car. The conditions of the road have been considered using definite non-random irregularities. Beside the effect of the flexible structure, the effects of the bumps are also important for the responses of the vehicle components and passenger comfort where it may be important in vehicle design, transportation safety, and bridge health and usage life.

REFERENCES

Abstract—This study aims to present the statistical process control (SPC) on ash content data of -10+0,5 mm product of heavy medium cyclone device at Dereköy coal washing plant in Soma, Turkey. The ash content data were determined both non-normally distributed and autocorrelated. This research explains the ways how SPC can be applied for this kind of data in terms of ensuring data normality by Johnson transformation and removing autocorrelation by ARIMA(2,0,0) or AR(2) time series model in order to proper application of SPC on ash content data.

Keywords—Coal preparation, ash content, statistical process control, Johnson transformation, ARIMA

I. INTRODUCTION

About 90% of Turkey’s coal resource are low quality lignite which have lower calorific value and higher ash and sulphur contents and it corresponds to approximately 11.56 billion tons [1]. In order to increase their qualities, the lignites are subjected to washing process at coal preparation plants which are mainly based on heavy dense separation methods.

During an industrial production stage, a suitable quality control of a product produced is essential in almost whole industrial field. Statistical process control (SPC) is one of the most known and preferred method used for this aim since its many advantages [2]. The SPC is practical and simple to apply. The SPC have two basic assumptions on data investigated. During the application of SPC, the data are assumed to have normal distribution and independent, i.e. not autocorrelated. Many authors have reported that if these assumptions are verified, the SPC charts generated by data assumptions give different results than those considering them [2-5]. In literature, many researchers have shown that both data normality [6-12] and autocorrelation between consequent data [13-18] had a reverse effect on the performance of SPC charts and should be taken into account.

The SPC is also applied on the mining field and mineral processing products in order to monitor and control the quality of product. Some of these applications were related to coal preparation [19-21]. Previous studies have shown that both data normality and autocorrelation have also affected the SPC results when applied on mining and mineral processing field [22-29].

Ash content is one of the most known and preferred parameter for the coal quality. The moisture, calorific value, organic and inorganic sulphur content etc. are also used to quantify a coal product quality.

In this study, the SPC was applied on the ash content of -10+0,5 mm product of heavy dense cyclone. Since the ash content data were determined as both nonnormally distributed and also autocorrelated, Johnson transformation method was applied successfully to the ash data and then the autocorrelation was successfully removed by ARIMA(2,0,0) or AR(2) time series model prior to SPC.

II. MATERIAL AND METHOD

The data used in this research were obtained from Dereköy coal washing plant in Soma, Turkey. The flowsheet of the plant which was modified from Şengül [30] is presented in Fig. 1. Ash content data of -10+0,5 mm product produced by the first heavy dense cyclone which is shown with a star symbol in Fig. 1 were used as data set to apply SPC. Detailed information about the coal washing process shown on the flowsheet has been already given in elsewhere [31] and therefore will not be repeated again in this work. Totally 356 data obtained in 2010 were used and for the evaluation of data both trial versions of Minitab 16.0 and Statgraphics XV softwares were used.

Fig. 1 Simplified flowsheet of Dereköy coal preparation plant (Modified from Şengül [30]).
III. RESULTS

A. Properties of ash content data

Normality check results showed that the original ash content data was not obeying normal distribution. According to the normal probability plot and normality test results presented in Fig. 2, p value of the test was <0.005 with Anderson Darling (AD) value of 3.593 indicating that ash content data distribution deviated from normal distribution. In order to fit the data to the normal distribution, Johnson transformation was found the best method. Fig. 2 also shows probability plot of Johnson transformed ash data the transformation summary and equation with normality check results. The unbounded system (SU) Johnson transformation gave the best transformation equation for the ash data evaluated since this transformation has a p value of 0.836 (>0.05) with AD value of 0.219. The transformation equation obtained was:

\[ z = -0.799 + 1.712 \sinh^{-1}(x - 7.961) / 2.083 \]  \hspace{1cm} (1)

Where; \( z \): Johnson transformed ash value, \( x \): raw ash value.

For raw ash content, the following Eq. 2 can be used to back transform the ash value \( (x) \) corresponding Johnson transformed ash value of \( z \) by solving Eq.1:

\[ x = 7.961 + 2.083 \left( e^{(2z+0.799)/1.712} - e^{(2z+0.799)/2} \right) \]  \hspace{1cm} (2)

![Probability plots of original and Johnson transformed ash data](image)

Fig. 2. Probability plots of original and Johnson transformed ash data the best transformation equation and summary

Fig. 3 presents the time series plots of original and Johnson transformed ash content comparatively. As seen in Fig. 3, both the original and transformed ash data were stationary and there was no need to take difference process to make the data stationary.

![Time series plots of original and Johnson transformed ash data](image)

Fig. 3 Time series plots of original and Johnson transformed ash data

B. Autocorrelation and ARIMA model

The transformed ash data were checked if there were any autocorrelation between consequent ash content data values. Table 1 summaries the autocorrelation values for 24 lags. As seen from Table 1, the transformed ash data had two important autocorrelation at lags 1 and 2. Graphical representation of autocorrelation of Table 1 is given in Fig. 4. As seen clearly, there are two important spikes at lag 1 and 2 and then between the 95% confidence intervals.

In order to remove the autocorrelation, the best time series model was determined. It was found that ARIMA(2,0,0) or AR(2) model was the best model for the Johnson transformed ash data of -10±0.5 mm product. The details of determination of ARIMA type time series model have been already well documented from the literature [32-33] and therefore more information can be found there and from literature listed therein.

The AR(2) model summaries are given in Table 2. From these parameters, the next ash content can be estimated by the previous ones and the estimation equation is as the following:

\[ X_t = \delta + \phi_1 X_{t-1} + \phi_2 X_{t-2} + \alpha_t \]  \hspace{1cm} (3)

Where, \( X_t \) is the observation at time \( t = 1, 2, 3, \ldots \), \( \delta \) is constant calculated from \( \mu(1-\phi_1 - \phi_2) \), \( \mu \) is the mean of the process, \( \phi_1 \) and \( \phi_2 \) are autoregressive parameters, \( \alpha_t \) is the random noise at time \( t = 1, 2, 3, \ldots \), assumed to be independent and identically distributed (i.i.d) normal \( (0, \sigma_\alpha^2) \). \( \sigma_\alpha^2 \) is the variance of random noise (white noise variation). From Eq. 3 and Table 2, the following Eq. 4 of AR(2) time series model can be used to predict future ash content from the previous data:

\[ X_t = 0.0102 + 0.3339 X_{t-1} + 0.0935 X_{t-2} \]  \hspace{1cm} (4)

For a reasonable time series model, the residuals (the difference between the actual and predicted values) should be independent and identically distributed (iid). The residuals of AR(2) model was subjected to diagnostic tests for the iid. Fig. 5 shows the residual plots and Fig. 6 gives the autocorrelation plot of AR(2) model which was resulted from diagnostic tests. Both the results of Fig. 5 and Fig. 6 indicated that the model residuals had a mean of zero (0) with 0.9064 white noise variance and distributed normal and independent i.e., not autocorrelated.

Fig. 9 I-chart of Johnson transformed ash content under independence assumption

D. ARIMA control charts of Johnson transformed ash data

ARIMA (Auto Regressive Integrated Moving Range) Charts take into account data independence i.e. autocorrelation between subsequent observations measured [34]. From this point of view, ARIMA charts are contrary to X-Charts. In ARIMA Charts, autocorrelation is determined by a time series model and unusual points are detected by process deviations.

Since AR(2) was found the best time series model to remove autocorrelation, the AR(2) chart is constructed with data vary around the mean \( \mu \) with control limits like I-charts. Process mean, \( \mu \) can be found by AR(2) parameters as;

\[
CL = \mu = \frac{\delta}{1 - \phi_1 - \phi_2} \quad (5)
\]

Since the process is autocorrelated, its standard deviation, \( \sigma_x \), depends on the parameters of time series model and as stated by Bisgaard and Külahçı [5], it is equal to for AR(2) model;

\[
\sigma_x = \sqrt{\frac{(1-\phi_2)}{(1+\phi_2)[(1-\phi_2)^2-\phi_1^2]}} \quad (6)
\]

The standard deviation of random shocks, \( \sigma_z^2 \), i.e. white noise variance in Eq. 6 have been estimated by both the mean squared error (MSE) of fitted AR(2) model and the mean range (MR) of residuals.

In this chart, data are drawn around a centreline located at \( \mu \) with control limits of;

\[
\mu \pm 3\sigma_x \quad (7)
\]

As given in Table 2, Johnson transformed ash data have been simulated well by AR(2) model with, \( \delta = 0.0102, \mu = 0.0178, \phi_1 = 0.3339, \phi_2 = 0.0935 \), where \( \alpha_i \) has mean of 0 and standard deviation of \( \sigma_{\alpha_i} = 0.952 \).

By solving Eq. 6, the variances of Johnson transformed ash content is \( \sigma_z^2 = 1.1671\sigma_x^2 \) which means that it is about 1.17 times larger than the residual white noise variance.

The AR(2) chart parameters where the random noise variance (\( \sigma_z^2 \)) is estimated by average moving range of AR(2) residuals (\( \overline{MR} \)) and then process sigma (\( \sigma_x \)) was calculated by Eq. 6 was 0.96. The generated control charts in these conditions for Johnson transformed ash data is given in Fig. 10. When the Fig. 10 examined carefully, it was seen that there were no out of control points actually compared to Figs. 8 and 9. To give correct decision about a process quality parameter like ash content in our example, one should consider both data normality and autocorrelation. If we only assume instead of verifying them, we would use the Fig. 8 and would conclude that there were 17 points that out of control during the washing of coal by the first heavy dense cyclone in terms of ash content.
When the control limits are determined for long term, mean squared error (MSE) of ARIMA model is used as process sigma, \( \sigma_x [34] \). The ARIMA chart after constructing control chart for long term limits is shown in Fig. 11. In this chart, process sigma, \( \sigma_x \) was estimated by Eq. 6 and white noise variance, \( \sigma_e^2 \) is calculated by MSE of AR(2) model which is given in Table 2. As seen, the chart in Fig. 11 are considerably wider bounds than the charts in Fig. 9 and Fig. 10 since the estimated process \( \sigma_x \) is a function of both white noise or random shock and fitted AR(2) model parameters (Table 2).

The chart type in Fig. 11 was constructed to monitor the long-term behavior of -10+0,5 mm product of first heavy dense cyclone. It is used to determine the process deviations from long-term mean more than expected given the dynamics of the process [34].

Since \( a_t \) is assumed to be independent and identically distributed (iid) normal \((0, \sigma_a)\), control limits of residuals chart in case of process is control are calculated by the following Eq. 9 [3]:

\[
CL = \pm K \sigma_a
\]

Where \( K \) is a constant chosen as 3 usually [3].

The resulted ARIMA residual charts obtained for ash content are shown in Fig. 12a where sigma \( (\sigma_a) \) is estimated from residual mean of moving range \((\bar{MR})\) and in Fig. 12b where \( \sigma_a \) is estimated residual MSE of AR(2) model.

As seen in Figs. 12a number of points beyond \( \pm 3\sigma_a \) limits are 2 when the \( \sigma_a \) is estimated from both \( \bar{MR} \) and On the other hand, there was no out of control points when the \( \sigma_a \) is estimated from MSE of AR(2) model for the AR(2) residuals of Johnson transformed ash data (Fig. 12b).

Since the aim was to reduce the ash content as soon as possible during the coal washing process. Therefore, the out of points beyond LCL cannot be considered uncontrolled process actually. From this point of view, the process can be under control in terms of ash content in 2010.

E. ARIMA residual chart of Johnson transformed ash data

In order to detect unusual points of ash data, ARIMA residuals charts were constructed for several conditions. In ARIMA residuals charts, a time series model is determined to fit data then the autocorrelation is subtracted and finally residuals obtained are monitored [3]. In this research, the residuals are the difference between actual ash values and their forecasts by AR(2) model. The residuals, \( a_t \), can be calculated by rewriting the Eq. 4 [5] as:

\[
a_t = X_t - \phi_1 X_{t-1} - \phi_2 X_{t-2} - \mu (1 - \phi_1 - \phi_2)
\]

IV. CONCLUSIONS

In this research, statistical process control chart was applied to monitor the ash content of -10+0,5 mm product of the first heavy dense cyclone at Dereköy coal washing plant in Soma, Turkey. It was shown that the SPC charts would be incorrect when they are constructed by only assuming the data.
normality and autocorrelation. Both data normality and 
autocorrelation are important properties that should be 
verified prior to generating the SPC charts. Johnson 
transformation achieved normality of nonnormally distributed 
ash content data. AR(2) time series model described the 
autocorrelation best for the transformed ash content data. The 
ARIMA control chart where the process sigma was estimated 
from the mean squared error (MSE) of AR(2) model can be 
used for the long term monitoring in determination of control 
limits of ash content of -10±0.5 mm coal product. In addition, 
the unusual points can be detected by AR(2) residuals 
chart during the production stage of coal produced by the first 
heavy dense cyclone. According to the ARIMA residual 
charts, -10±0.5 mm product can be considered under control 
in terms of ash content in 2010.

Investigation of Winglet Shape Effect on the Drag and Lift Force of Aircraft Wing

Mehmet Hanifi DOĞRU*

*Asst. Prof. Dr.
Gaziantep University, Aeronautics and Aerospace Faculty, Pilotage Department,
Gaziantep / TURKEY,
mhdogru@gantep.edu.tr

Abstract—In this study, different winglet shape is investigated to compare lift and drag forces. The computational fluid dynamic (CFD) analysis of three dimensional (3D) flow over wing is used for this examination. Winglets are angled extensions or vertical projections at the tip of a wing. Winglets are used to increase aerodynamic performance of wings. They are widely used on commercial airplanes for the purpose of reducing induced drag, vortices, and increasing lift. Winglets reduce wingtip vortices. Twin tornados (vortices) formed by the difference between the pressure on the upper surface of an airplane's wing and on the lower surface. High pressure on the lower surface creates a natural airflow, which makes its way to the wingtip and curls upward around it. The drag force is generated by pressure distributions over the body surface. Winglet reduce the amount of drag. Efficiency of aircrafts are increased by decreasing drag force and fuel consumption is decreased using winglets. When an aircraft is designed, lift and drag forces must be analyzed and the structural design should be based on these forces. Hence, lift and drag forces on the three dimensional wing, which has different winglet types, are analyzed by using a commercial CFD program ANSYS in this study.

Keywords—Winglet, Aircraft Wing, Computational Fluid Dynamic, Lift Force, Drag Force.

I. INTRODUCTION

Aerodynamic forces, which are lift and drag forces, are occurred on a body, which is immersed in the air due to the relative motion between the body and the air. Aircraft wing generates aerodynamic forces, when it is moving within the air. Drag force can be defined as the force component parallel to the direction of the relative motion. Lift force also can be defined as the force component perpendicular to the direction of the relative motion. In addition, thrust is also aerodynamic force. It can be obtained by propeller or jet engine of aircraft. The other force acting on a wing is weight. The weight is not an aerodynamic force. It is body force. Aircrafts should be design according to these forces.

The effect of a pair of thin stationary winglets on the aerodynamics of a bluff body was studied by the Savage and Larose [1]. The aerodynamic and aeroelastic characteristics of winglet were studied experimentally in terms of the moment coefficients and aerodynamic forces. Rate of change of moment coefficients and aerodynamic forces with angle of wind incidence and the motional aerodynamic derivatives. It was observed that the winglets provided important aerodynamic damping and reduced the sensitivity of the rectangular prism to torsional aerodynamic instability.

Usage of CFD tools by the aerospace field to increase understanding of fluid dynamic and aerodynamic phenomena has been rapidly increasing during the past decade [2]. Also numerical simulation has become a significant and growing aspect of the aircraft design process. Thanks to CFD, dependency on wind tunnel investigations are reduced so consequently design cost is also reduced. As a result of these developments, wing performances are increased using the CFD tools.

A wing is a surface used to produce an aerodynamic force (shown in Fig. 1) normal to the direction of motion by travelling in air or another gaseous medium. A wing is an extremely efficient device for generating lift. Its aerodynamic quality, expressed as a lift-to-drag ratio, can be up to 60 on some gliders and even more. This means that a significantly smaller thrust force can be applied to propel the wing through the air in order to obtain a specified lift [3].

The drag and lift forces using CFD which can also be determined through experiments using wind tunnel testing. The analysis of the two dimensional subsonic flow over a NACA 0012 airfoil at various angles of attack and operating at a Reynolds number of $3 \times 10^6$ was presented. The CFD simulation results showed close agreement with those of the experiments, thus suggesting a reliable alternative to experimental method in determining drag and lift. [4].
A simple method was given for the evaluation of the induced lift by the Eppler [5]. The rollup of the wake is not considered. It probably had less effect than the induced lift, at least for the high aspect ratios of gliders. The results from several parameter variations were presented. They concerned dihedral and winglets as well as sweep back.

A winglet optimization procedure for a Medium-Altitude-Long-Endurance (MALE) Un-manned-Aerial-Vehicle (UAV) was presented by the Panagiotou and friends [6]. Aerodynamic and performance parameters were defined during the conceptual and preliminary design phases. The winglet optimization procedure was a part of the detail design phase. The flow around several winglet configurations was investigated, using CFD. Lift, drag and pitching moment coefficient charts, along with vorticity contours and tip vortex images, were presented.

Design of wing tip devices at high and low speeds was described by Büscher and friends [7]. A comprehensive parameter study was carried out using a rapid aerodynamic prediction tool named Lift and Drag Component Analysis (LIDCA). Adding to an available lifting-line method a databased module for airfoil data was employed that uses results of two-dimensional flow simulations by multidimensional interpolation. The results of the most effective wing tip designs were analyzed at both flight conditions. Also, options for improving the performance at take-off were suggested.

A series of multi-objective winglet shape optimizations were performed to find the Pareto front between the wing aerodynamic drag and the wing structural weight for a wing equipped with a winglet by the Elham and Tooren [8]. The paper discussed the addition of winglets to existing aircraft designs. In order to estimate the aerodynamic and structural characteristics of a non-planar wing, a quasi-three-dimensional aerodynamic solver was integrated with a quasi-analytical weight estimation method inside an optimization framework. The optimization results showed that about 3.8% reduction in fuel weight and about 29M$ reduction in 15 years DOC of a Boeing747 type aircraft can be achieved by using winglets.

II. NUMERICAL STUDY

1) Description of the geometry model

Aircraft wing model is created in SolidWorks. Naca 2415 airfoil (shown Fig. 2) which is asymmetric is used to design wing. The wing has variable chord length and 20 m span length. Boeing 737 wing (shown Fig. 3 and Fig. 4) is modelled with Naca 2415 airfoil.

2) Mesh generation

When fluid flow is analyzed, flow domains are split into smaller sub domains. The governing equations are then discretized and solved inside each of these sub domains. Unstructured mesh which has 711050 cells and 158198 nodes was constructed by the Ansys Mesh generator for the winglet. The meshed area around the wing is as shown in Fig. 5 and meshed winglet is as shown in Fig. 6.
Unstructured mesh which has 709875 cells and 138837 nodes was constructed by the Ansys Mesh generator for the backside winglet. The meshed area around the wing is as shown in Fig. 7 and meshed backside winglet is as shown in Fig. 8 and Fig. 9.

Unstructured mesh which has 599408 cells and 140625 nodes was constructed by the Ansys Mesh generator for the normal flat wing. The meshed area around the wing is as shown in Fig. 10 and meshed normal flat wing is as shown in Fig. 11.

III. NUMERICAL METHOD AND BOUNDARY CONDITIONS

ANSYS FLUENT software which is based on the finite volume method is used to perform numerical calculations. Gravity is to be neglected. Pressure based and steady-state solution methods are selected to perform calculations. Sparat Allmaras is chosen as turbulence model. Momentum is modeled using second order functions. Boundary conditions are set for the different areas of each mesh, such as wall face with zero velocity, symmetry faces, velocity inlet and pressure outlet for the fluid. Density of the air is 1.225kg/m³, and the kinematics viscosity of the air is 1.7894e-5. Free stream velocity of 50 m/s is assumed. All parameters of the above are applied to set for simulations.

IV. ANALYSIS RESULTS

In this section, lift and drag forces of Boeing 737 wing are calculated using CFD analysis at different wing tip types. Static pressure and velocity results are as shown in Fig. 12 and Fig. 13 for the winglet. Static pressure and velocity results are as shown in Fig. 14 and Fig. 15 for the backside winglet. Static pressure and velocity are as shown in Fig. 16 and Fig. 17 for normal flat wing.
Fig. 12. Pressure (Pa) value of winglet

Fig. 13. Velocity (m/s) value of winglet

### V. CONCLUSIONS

In this study, Boeing 737 wing tip types are investigated in terms of the lift and drag force due to aerodynamic forces are the most critical parameters in the design step. Lift and drag forces on the three dimensional NACA 2415 Airfoil Wing is analyzed at different wing tip types.

It is seen that winglet is more effective on the lift force when the figure 18 is investigated. Winglet is better than normal flat wing nearly % 2 and is better than backside wing nearly % 1.5 in terms of the lift force.

Drag force is critical parameter for the fuel consumption. When the figure 19 is investigated, it is clearly seen that new design backside winglet is better than winglet nearly % 54 is better than normal flat wing % 57.

Biogeography-Based Optimization Algorithm for Designing of Planar Steel Frames

Osman Tunca*, Serdar Çarbaş*
*Department of Civil Engineering, Karamanoğlu Mehmetbey University, Karaman, Turkey
{osmantunca,scarbas}@kmu.edu.tr

Abstract—The optimization can be defined as a solution of problem under specific conditions to achieve a specific purpose. Optimization strategies commonly used for solving various problems have gained great importance in recent years especially in engineering. Evolving optimization methods over the years has many varieties such as shape optimization, topology optimization, size optimization etc. The latest trend of optimization methods is metaheuristics which are more useful with easy applicable to complex problems regarding to traditional optimization methods. So that metaheuristics have supplanted the traditional methods particularly in engineering by the time. In this study, a planar steel frame which is designed according to the requirements comprised by AISC-LRFD (American Institute of Steel Construction-Load and Resistance Factor Design) has been optimized by aid of biogeography-based optimization (BBO) algorithm.

Keywords—Planar Steel Frames, Optimum Design, Stochastic Search Techniques, Biogeography-Based Optimization, Metaheuristics.

I. INTRODUCTION

Many of design problem in engineering are too complex and multifaceted due to nonlinear characteristics. Stochastic optimization methods are compatible for dealing with nonlinear and complex design problems especially in civil engineering. Since stochastic optimization methods do not need any gradient information, these methods can be much more applicable especially in civil engineering problems.

In the literature, there are immense efficient studies on various metaheuristic optimization methods inspired by natural phenomena in structural engineering field. For instance, charged system search algorithm has been used in design optimization of skeletal structures [1], simulated annealing, evolution strategies, particle swarm optimizer, tabu search method, ant colony optimization, harmony search and simple genetic algorithm have been used in design of real size pin jointed structures [2], swarm intelligence based algorithms, harmony search method and charged system search have been practiced shape and topology optimization design of skeletal structures [3], firefly algorithm has been used to obtain the optimum design of retaining walls [4], harmony search algorithm has utilised optimum design of concrete cantilever retaining walls [5], genetic algorithm has applied multi-storey composite steel frames [6]. Among these, biogeography-based optimization (BBO) algorithm has outstanding popularity due to its capacity of rapidly converging to near-global optimum [7]. Biogeography is the study of the geographical distribution of biological organisms [8]. It is related to immigration, emigration and population of species etc. Robert MacArthur and Edward Wilson [9] have investigated on mathematical models of biogeography interest. They have focused on the distribution of species among at neighboring islands. Then, inspired by the science of biogeography Dan Simon presented a new computational intelligence algorithm, so-called biogeography-based optimization (BBO) algorithm [10]. There are some studies in different areas include the application of BBO; such as constrained optimization problems [11], best compromise solution of economic emission dispatch [12], optimal job scheduling in cloud computing [13], soft-sensor models [14], AC transmission system devices [15]. In structural engineering, BBO is also promisingly utilized in obtaining the optimum design of cost optimization of reinforced concrete cantilever retaining walls under seismic loading [16], optimization of spatial steel frames [17], optimal carbon dioxide emissions of the RC retaining wall design [18].

In this paper, optimum design of planar steel frames according to AISC-LRFD (American Institute of Steel Construction-Load and Resistance Factor Design) [19] is investigated by using BBO algorithm. Main purpose of this study is to find minimum design weight of a planar steel frame by selecting suitable steel sections taking into account of code requirements according to AISC-LRFD. Code specifications necessitate the consideration of a combined strength constraint with lateral torsional buckling for beam-column members. Furthermore displacement constraints as well as inter-storey drift restrictions of multi-storey frames are also included in the design formulation. Further constraints related with the constructability of a steel frame are also considered.

II. OPTIMUM DESIGN FORMULATION TO AISC-LRFD

The discrete optimum design problem of steel frames where the minimum weight is considered as the objective can be explained as follows:

Find a vector of integer values \( \mathbf{I} \) (Equation 1) representing the sequence numbers of steel sections assigned to \( N_o \) member groups

\[
\mathbf{I} = [I_1, I_2, \ldots, I_{N_o}] \tag{1}
\]

to minimize the weight \( \mathbf{W} \) of the frame.
\[ W = \sum_{i=1}^{N_i} \rho_i A_i \sum_{j=1}^{N_j} L_j \]

where \( A_i \) and \( \rho_i \) are the length and unit weight of the steel section adopted for member group \( i \), respectively, \( N_i \) is the total number of members in group \( i \), and \( L_i \) is the length of the member \( j \) which belongs to group \( i \).

The members subjected to

\[
\frac{(\delta_j - \delta_{j-1})}{h_j} \leq \delta_{\phi}, \quad j = 1, \ldots, ns
\]

\[
\delta_j \leq \delta_u, \quad i = 1, \ldots, nd
\]

\[
V_u \leq \phi V_n
\]

\[
\left( \frac{P_n}{\phi P_n} \right) + \left( \frac{8 M_{ax}}{9 \phi M_{ax}} \right) \leq 1.0 \quad \text{for } \frac{P_n}{\phi P_n} \geq 0.2
\]

\[
\left( \frac{P_n}{2 \phi P_n} \right) + \left( \frac{M_{ax}}{\phi M_{ax}} \right) \leq 1.0 \quad \text{for } \frac{P_n}{\phi P_n} \leq 0.2
\]

\[
B_{j_{pb}} \leq B_{j_{bc}} \quad j = 1, \ldots, nj
\]

\[
D_s \leq D_{s_{-1}} \quad s = 1, \ldots, nu
\]

\[
m_s \leq m_{s_{-1}}
\]

Equation (3) represents the inter-storey drift of the multi-storey frame. \( \delta_j \) and \( \delta_{j-1} \) are lateral deflections of two adjacent storey levels and \( h_j \) is the storey height. \( ns \) is the total number of storeys in the frame.

Equation (4) defines the displacement restrictions that may be required to include other than drift constraints such as mid-span deflections of beams. \( nd \) is the total number of restricted displacements in the frame. \( \delta_u \) is the allowable lateral displacement. The horizontal deflection of columns is limited due to unfactored imposed load and wind loads to height of column/300 in each storey of a building with more than one storey. \( \delta_u \) is the upper bound on the deflection of beams which is given as (span/300) if they carry plaster or other brittle finish.

Equation (5) represents the shear capacity check for beam-columns. \( \varphi \) is resistance factor in shear, \( V_n \) required shear strength, \( V_n \) is nominal shear strength.

Equation (6) defines the local capacity check for beam-columns. \( M_{ax} \) is nominal flexural strength, \( M_{ax} \) is applied moment, \( P_n \) is nominal axial strength, \( \vartheta \) is applied axial load, \( \varrho \) is resistance factor for columns if the axial force is in compression, \( \vartheta \) is resistance factor in bending. It is apparent that computation of compressive strength \( \vartheta P_n \) of a compression member requires its effective length.

Equation (7) is included in the design problem to ensure that the flange width of the beam (B) section at each beam-column connection at joint \( j \) should be less than or equal to the flange width of column section. \( nj \) represents the total number of joints in the frame.

Equations (8) and (9) are required to be included to make sure that the depth (D) and the mass per meter (m) of column section at storey \( s \) at each beam-column connection are less than or equal to width and mass of the column section at the lower storey \( s-1 \). \( nu \) is the total number of these constraints.

### III. BIOGEOGRAPHY-BASED OPTIMIZATION (BBO) ALGORITHM

The BBO algorithm is one of the recent additions to the metaheuristic algorithms, introduced by Dan Simon in 2008 [8]. The BBO algorithm was developed by simulating the theory of island biogeography, which describes the extinction and migration of a species between islands. In the BBO algorithm, the island term is defined as an isolated area for species. The two main indices, called the habitat suitability index (HSI) and suitability index variables (SIVs), control the extinction and migrations. The HSI describes the suitability of the habitats for life. Habitats with a high HSI provide good living conditions for the species, which are related to value of the objective function. These habitats have a low immigration rate and high emigration rate since they are already nearly saturated. Fig. 1 shows the relationship between species count, immigration rate and emigration rate [8]. In the figure, \( I \) and \( E \) represent the maximum immigration and emigration rates, respectively, \( \lambda \) and \( \mu \) are the immigration and the emigration rates, respectively, \( S_0 \) is the equilibrium number of species and \( S_{max} \) is the maximum species count.

![Fig. 1 Species model of a single habitat where \( \lambda \) is immigration rate and \( \mu \) is emigration rate](image)

The BBO algorithm consists of two main parts: migration and mutation. In the migration part, the new solution is generated by modifying the independent design variable of the old solution. The probability of the modification is related to the immigration rate of the solution. If an independent variable is to be modified, then the value of the independent design variable is determined using the roulette wheel selection method, which is related to the emigration probability. The emigration probability is calculated as follows [16]:

\[
P(x_j) = \frac{\mu_j}{\sum_{i=1}^{ps} \mu_i} \quad j = 1, \ldots, ps
\]

where \( ps \) is the population size.

Mutation is used to increase the number of species in the islands. If mutation occurs, the new solution is generated.
using a random search, as described in Equation (11). The mutation probability of each design is described in Equation (12).

\[ x_i = x^a_i + \text{rand}(0,1)(x^u_i - x^a_i) \quad i = 1, \ldots, ps \]  

\[ m(s) = m_{\text{max}} \left( 1 - \frac{P_i}{P_{\text{max}}} \right) \]  

where \( x^a_i \) and \( x^u_i \) are upper and lower bounds of the \( i \)th design variable \( x_i \), \( \text{rand}(0,1) \) is a random number between 0 and 1, \( m_{\text{max}} \) is the maximum mutation probability defined by the user, \( P_i \) is the number of species in the habitat, and \( P_{\text{max}} \) is the maximum number of species.

Each design is analyzed under the external loading and the design constraints given in Equations (3)–(9) are checked. If a candidate design does not satisfy the design constraints, its objective function value is penalized in accordance with constraint violations using Equation (13):

\[ f_{\text{cost},i} = f_{\text{cost}}(1 + C)^i \]  

where \( f_{\text{cost}} \) is the objective function value given by Equation (2), \( f_{\text{cost},i} \) is the penalized objective function value, \( C \) is the summation of constraint violations calculated using the constraint functions stated by Equations (3)–(9), and \( \epsilon \) is the penalty coefficient, which is taken as 2.0 in this study. In general form, constraint violations are calculated as:

\[ C_i = \begin{cases} 0 & g_i(x) \leq 0 \\ g_i(x) & g_i(x) > 0 \end{cases} \quad i = 1, \ldots, NC \]  

where \( g_i(x) \) is the \( i \)th constraint function, \( x \) is the vector of design variables, and \( NC \) is the number of constraint functions in the optimum design problem.

IV. DESIGN EXAMPLE

In present study, optimization of a six-storey, two-bay planar steel frame shown in Fig. 2 is considered as design example. The frame consists of 30 members that are collected in 8 groups as shown in the figure. The allowable inter-storey drift is 1.17cm while the lateral displacement of the top storey is limited to 7.17cm.

Furthermore, the wide-flange (W) profile list of ready sections is used to size the structural members. The material properties of steel are taken as follows: modulus of elasticity \( E = 208 \) GPa \((30,167.84 \text{ ksi})\) and yield stress \( F_y = 250 \) MPa \((36.26 \text{ ksi})\), and unit weight of the steel \( \rho = 7.85 \) ton/m³.

The investigated example includes minimum weight design of a planar steel frame structure. The optimum design to this frame with the BBO is sought by implementing the algorithm over a predefined number of iterations such as 20,000. In order to evaluate the accuracy of the final solution obtained with the BBO, the optimum solution is compared to those previously reported in the literature by some other robust metaheuristic algorithms, and the results are evaluated. The frame is formerly designed by three different optimum design algorithms that are based on three different metaheuristic algorithms such that cuckoo search algorithm, particle swarm optimizer and big bang-big crunch algorithm as reported in Ref. [20].

Due to the stochastic nature of the BBO, design problem is independently solved several times and the best result collected is used for comparison. The population size is set to 75, and the number of elites that specify how many of the best solutions to keep from one generation to the next is set to 2.0 for the design example. The mutation probability per solution per independent variable is selected as 0.01, as well. These parameter values are assigned as constant that are arbitrarily chosen within their recommended ranges by Simon [7, 8] based on the observed efficiency of the technique in different problem fields. It is obvious that best values of these parameters depend on the size of search space.

The section designations attained for each member group by BBO algorithm and by the others posted in the literature are tabulated in Table I. Besides, minimum frame weight located by the BBO algorithm is compared with the available results reported in the literature based on a cuckoo search optimization (CSO), a particle swarm optimizer (PSO), and a big bang-big crunch (BB-BC) algorithm [20]. Also, maximum constraint values for each algorithm are illustrated in this table. According to these results, the BBO algorithm locates an optimum design weight of 62.090kN, \((6331.44\text{ kg})\) which is lighter than the design weights obtained by the other techniques. The optimum design produced by BBO is 9.17, 15.94, and 16.51% lighter than those attained by CSO, PSO, and BB-BC, respectively.

Fig. 2 Six storey- two bay planar steel frame
It is noticed that in optimal design attained by BBO algorithm inter-storey as well as to ultimate strength constraints values are very close to their upper bounds while the top storey drift constraint is 5.321cm which is relatively less than its upper bound 7.17cm. This clearly indicates that strength ratio and inter-storey drift constraints dominate in the design. It is apparent from Table I that while biogeography-based optimization algorithm required more structural analysis than particle swarm and big bang-big crunch algorithms, it required less structural analysis than cuckoo search algorithm to reach the optimum design. It should be worthwhile to mention that the biogeography-based optimization algorithm used in this study is the standard one not the improved version.

The design history of BBO algorithm is illustrated in Fig. 3. It is apparent from the figure that BBO algorithm shows rapid convergence rate. Therefore, it can be concluded that BBO algorithm has relatively demonstrated best performance in yielding the optimum design of six-storey, two-bay planar steel frame, so far.

### V. CONCLUSIONS

The optimum design algorithm developed in this study is based on biogeography-based optimization (BBO) technique which selects the optimum W-section designations from W-sections table for the beams and columns of a planar steel frame such that design constraints described in AISC-LRFD are satisfied and the frame has the minimum weight. In view of the results obtained it is concluded that the BBO method is an efficient and robust technique that can successfully be used in optimum design of planar steel frames and determines lighter optimum solutions compare to cuckoo search, particle swarm and big bang-big crunch methods. In the optimum design of six-storey, two-bay planar steel frame, the optimum design weight obtained by the BBO approach is 9.17, 15.94, and 16.51% lighter than the one attained by the other three metaheuristic techniques. Furthermore, the BBO technique basically has only three parameter to be specified by a user which are the population size, the number of elites, and the mutation probability. This provides robustness to the algorithm compared to many other metaheuristic techniques that require pre-determination of more parameters.

Blade Number Effect on the Thrust, Torque and Power of Propeller

İbrahim GÖV*

*Asst. Prof. Dr.
Gaziantep University, Aeronautics and Aerospace Faculty,
Aircraft and Aerospace Engineering Department,
Gaziantep / TURKEY
igov@gantep.edu.tr

Abstract—In this study, thrust, torque and power concepts are investigated according to different blade number. The computational fluid dynamic (CFD) analysis of three dimensional (3D) flow over propeller is used for this investigation. Power and torque concepts are the important parameter for the design of aircraft and airfoil. Thrust is also another critical parameter for the aircraft performance. A propeller is a type of fan that transmits power by converting rotational motion into thrust. A pressure difference is produced between the forward and rear surfaces of the airfoil-shaped blade. Each propeller blade is a rotating airfoil, which produces thrust and drag. Thrust parameter is directly proportionate with blade number. If the blade number of propeller increase, thrust will increase. If the blade number of propeller increase, the produced torque by propeller and the needed power to drive propeller will also increase. In this study, blade number (2, 3 and 4 blades) effect on the thrust, torque and power is investigated.

Keywords—Propeller, Finite Element Analysis, Power, Thrust, Torque

I. INTRODUCTION

A propeller is a type of fan that transmits power by converting rotational motion into thrust. A pressure difference is produced between the forward and rear surfaces of the airfoil-shaped blade, and a fluid (such as air or water) is accelerated behind the blade. Propeller dynamics, like those of aircraft wings, can be modelled by either or both Bernoulli's principle and Newton's third law [1]. Propellers are the most critical parts for the propulsion systems. In the literature, nearly all studies are focused on marine propellers. There are few studies exist about aero propellers.

Noh et al. [2] investigated different angle of attack values (25°, 35° and 45°) effect on aerofoil and flat shape louvers. The symmetrical 4 digit NACA aerofoil shape was used as louvers and it had 10 mm thickness. Solid Works Flow Simulation tool was used for CFD analysis. The results show that pressure drop is more widespread in flat louvers as compared to aerofoil louvers.

Hong and Dong [3] was presented a process for numerical analysis of radial circulation distribution of propeller blade. This process is based on the results of numerical simulation of the velocity field around propeller blades and in the wake. They observe a hump in the radial circulation from the traditional method because of computation errors. But, the direct method with CFD simulation can prevent from these errors.

A method to estimate full-scale propeller torque and thrust consisting of low-frequency and high-frequency components in waves by free-running model ship test was proposed by Ueno and Tsukada [4]. The method estimates full-scale fluctuating propeller torque and thrust in waves when analyzing wave component in the effective inflow velocity to propeller. This method also makes it possible to incorporate into free-running model ship tests any engine model simulating interaction between propeller torque and engine torque.

Driss et al. [5] applied an experimental validation and numerical simulation to study the turbulent flow around a small incurved Savonius wind rotor. For the analysis Solid Works flow simulation tool was used. Navier-Stokes equations and standard k-ε turbulence model were used. These equations were solved by a finite volume discretization method. To validate the numerical method, an experiment is performed with an open wind tunnel equipped by a small incurved Savonius wind rotor.

The effect of the ducted fan, which is located inside the ground effect region, is investigated experimentally according to the helicopter hovering concept by Doğru et al. [6]. For this investigation, the thrust of the ducted fan is measured using two different experimental methods, which are static pressure measurement system and spring method to calculate the thrust. The main objective of the study is to investigate the ducted fan effect on the elevation of a concept helicopter when the ducted fan is located in the ground effect region. As a result of this study, it appears that the lift force decreases, as expected.

There are three theories used in the design of propellers. They are: blade element, momentum and vortex theory. Most of today’s propellers are designed using blade element theory. In this study, a standard propeller and numerical calculation method is used for cases. The computational fluid dynamic (CFD) analysis is used for numerical calculations.
II. NUMERICAL STUDY

In the numerical study external flow type is used. In addition, “exclude cavities without flow conditions” and “exclude internal space” are selected since the present study is not interested in cavities or spaces.

Air is defined as fluid domain for the environment of the system as shown in Fig. 1. Also, Rotational domain is created as shown in Fig. 2. Naca 4412 aerofoil is used to obtain the propeller as shown in Fig. 3.

Fig. 1 Simulation domain

Fig. 2 Rotational domain

Initial conditions are defined as shown in Fig. 1. There is no velocity in the any direction because there is no crosswind. Temperature is assumed to be room temperature (20 °C) on the atmospheric pressure. This numerical study was performed at the 2500 RPM (261.71 rad/s). Rotational region is covered with the environmental pressure to simulate the real conditions after the boundary conditions are defined.

Fig. 3 Propeller aerofoil [7]

Pressure and velocity distribution is obtained from numerical study as shown in Fig. 4 and Fig. 5 respectively.
Velocity and pressure distribution is obtained from numerical study as shown in Fig. 6 and Fig. 7 respectively.

Fig. 10 Torque results according to blade numbers

Fig. 11 Thrust results according to blade numbers
Torque values are shown in Fig. 10 according to blade number. Also, thrust values are shown in Fig. 11 according to blade number.

IV. CONCLUSIONS

Thrust, torque and power values of propeller, which have different blade numbers (2, 3 and 4 blades) are examined. In this study, three dimensional flow over propeller is used for CFD analysis. Velocity and pressure distribution are obtained according to boundary and flow conditions. Maximum tip velocity is obtained nearly 112.67 m/s for all propellers.

This numerical study shows that; torque value is increasing linearly with respect to blade number. But, thrust value does not increase linearly as torque value. This means that, power requirement is increasing non-linearly due to blade number.

Generation of Digital Terrain Model From Unmanned Aerial Vehicle Image Data

Mustafa Zeybek*, Ismail Sanlioglu+

* + Geomatics Department, Engineering Faculty, Selcuk University
Konya/Turkey
{mzeybek, sanlioglu}@selcuk.edu.tr

Abstract—Nowadays, Un-manned Aerial Vehicle (UAV) platforms are having a practical and beneficial data source for analysing of terrain, surveying, three dimensional (3D) surface modelling of structures and extraction of constructions faades. Low-cost platforms with rotary or fixed wing UAVs are capable of performing the multi view geometry and structure from motion with amateur cameras in autonomous mode by autopilot systems. For the purpose of UAV flights are gathering images from sky which becomes powerful technique for many applications such as change detection, deformation monitoring and forestry applications in medium scale study areas. Mostly procedure of gathering raw image data is easier than a traditional photogrammetric pipeline with an image blocks calculations. Generation of very dense point clouds are possible after image alignment and estimating of camera pose by structure from motion (SfM) algorithms. Processing of raw point clouds can result as high accurate Digital Surface Model (DSM), further to that analysis of digital terrain model, in the other words bare earth extraction can be done. This paper presents the latest developments of UAV image processing methods with computer vision for distinctive applications, surveying and 3D modeling issues for landslide area. Automated processing steps are mentioned for image processing, camera orientation, DTM generation and orthomosaic production stage.

Keywords—UAV, DSM, DTM, Point Cloud, Landslide

I. INTRODUCTION

In order to investigate the procedure for the generation of digital elevation models (DEM’s) or another calling digital terrain models (DTMs) with a high accurate using unmanned aerial vehicles, a survey via a multi-rotor aircraft was performed over a Taskent province of Konya in Turkey. In practise, there is a comprehensive surveying techniques used to create digital terrain models at different scales and with different standards. Geodetic surveying methods, for instance total stations, global navigation satellite systems (GNSS), terrestrial laser scanning (TLS), airborne laser scanning (ALS), mobile laser scanning (MLS) are very impressive for the production of DTMs with very low measurement uncertainties on limited areas [1]. Airborne and satellite-based imaging systems have the most effective advantage of providing measurements from sky or space that are not obstacle by terrain blocks and hills for acquiring high resolution topographical data. Lately, unmanned aerial vehicles (UAVs) (also called unmanned aircraft systems UAS) have showed clearly their ability for the rapid generation of DTMs over large areas (approx. 400 ha at single flight), where the use of traditional techniques is not possible way to comparison on economy and manpower [2]. It has also make an impression on the main DEM techniques due to its advantages of high data processing speed, low flying height, and convenient flying preparation in the field [3]. There are studies have shown that UAV production DTMs are possible to generate high accuracy with several centimetres on DTM [3], [4]. Measuring at high precision DTM of the ground surface is the main matter with most studies [5]. In this paper, we have presented the efficient and high accurate DTM generation work flow from UAV images pipeline. This investigation provides better understanding and clarifying the production of DTM for rapid process, low-cost and middle size area mapping functionality investigation of UAV data.

II. STUDY SITE

The study area nearby the town of Taskent, Konya, Turkey was chosen as the investigation (Fig. 1).

The main purpose of this site selection is deformation monitoring due to the occurrence of landslide on steep slope and forestry area for extraction of displacement studies. Taskent landslide occurs annually on heavy precipitation seasons [6]. However, some of the landslide region is heavy forestry. Taskent landslide valley is situated in the south part of Taskent town. Taskent province approximately located on middle of Taurus mountain chain. The catchment area approximately covers 40 ha. Some part of the study area contains dense vegetation and tree canopy.

For the purpose of monitoring surface displacements, spatial coordinate information of bare ground surface are crucial data under vegetation canopy. Thus, DTMs generations are being important from DSMs produced from UAV images.

III. DATA ACQUISITION FROM UAV

Camera sensor is performed for gathering images from UAV platform. UAV platform was choosed as multirotor and stabilized gimbal system acquisition the image without blurred [7]. The platform has an efficient flight time of 45 minutes with 1000mah Lipo battery and it has potential to increase functionality against low wind speed. Flight speed is 5 m/s. Flying height can be set from 50 m to 500 m, depending on desired resolution of images.

It has autonomous flight capabilities with OEM-GPS and IMU (Inertial Measurement Unit) for global positioning of itself and finding heads of the platform for planned
block corridor. Furthermore, an active stabilizing camera mount equipped with a daily use compact camera (Canon SX260HS) is mounted. UAV vibrations are eliminating with rubber ball damper kit. Rubber ball dampers designed using a very flexible material in order to ensure a significant reduction of vibrations for isolating camera mounts from the motor vibrations of the drone[8].

IV. Field Campaign

On the field study, site has three different morphological specification. Bare surface, forestry and rough surface properties are mainly attract the attention on landslide. The main idea on this study monitoring landslide free of morphological features, detecting the real displacements on bare surface ie. without vegetation and with 3 Dimensional (3D) movements on rough concave featured surfaces. Due to the lack of UAV images can generate only top view of features, it is not possible to generate under tree or high vegetated areas on bare ground. However, different interpolation techniques and filtering vegetation techniques are estimates the ground surface from raw point cloud, as it mentioned in this paper. The proposed methodology for generation DTM from raw images is showed as flowchart in Fig. 2.

A. UAV Flights

Three different part of sections data had been investigated for this project with UAV image data and point clouds (Fig. 3, 4). Flight plans are evaluated on Mission planner open source software [9].

Flight overlaps on side and forward side are calculated, optimised for best acquiring data for cover whole interested area without leave any gaps between image blocks. Ground sampling is depend on the flight height and slope feature of the surface. In our study average size was 0.05 m/pix and flying height for 3 flights 160 m averagely. In order to increase the level of detail of generated surface, flying altitude need to decrease, but the research area is located in valley, its risky for low altitude flight, so the low flight heights avoided for our project due to the crash risk, thus we need to optimise the flying height on this level. The UAV platform control had been chosen automatically for take off...
and landing. Pixhawk autopilot system used for this platform [10]. Copter platform requires flat surface on the ground for perpendicular take off and landing operations on the ground.

UAV platform camera system is non-calibrated and simple amateur system. Hence, unstable camera geometry necessitates either a temporary transportable calibration field or self-calibration during data processing [5]. Pix4D software has a library for calibration of cameras automatically matches the images for calibration parameters. After initial matching procedures (aligning images/blocks) and importing Ground control points (GCPs), it is able to optimize parameters with field calibration procedures. Initial and optimized parameters can be seen on (Table I).

B. Ground Measurements GNSS Surveys

DTM productions from different periods are able to compare, and create a Global datum in space, we use ground control points (GCPs) which is measured by real time kinematic GPS/GNSS. RTK-GNSS technique refers to a DGPS process where carrier-phase corrections are sent in real-time from a reference receiver at a known coordinate and height location to other rover receivers. To get the best in precision using GPS systems, RTK systems had been used in the field for acquiring real time high accurate coordinate. The measurement procedure completed with two GNSS receivers, for setting up on know base station and a rover. Both GNSS units locked onto satellites over 4, and also communicated between themselves via a radio link. The semi-permanent base station had been imported its position as a know coordinate on the Earth’s ground surface to around a 10 cm accuracy, and it needs to close survey area approximately under 5 km but the rover gets its position relative to the base to millimetre accuracy. By just setting up the rover unit on the GCP artificial points, these RTK systems can operate at the same time produce millimetre accuracy coordinate data that can be used for create very accurate basic surveying measurements (Coordinates components: North, East, Up). These control points which the geodetic data acquired by GNSS - RTK are used to address absolute orientation on processing step. These points are also checked the accuracy of the point cloud particularly that generated from UAV image collections [11], [12]. Root Mean Square Error (RMSE) is used to measure uncertainty values between point cloud surface coordinates and GNSS (true value) coordinates. The RMSE result shows the quality control check values of the dataset. This control procedure is fundamental for quality of the orientation of images and bundle block adjustment results.

\[
RMSE = \sqrt{\frac{1}{n-1} \sum_{i=1}^{n} (e_i - \bar{e})^2} \tag{1}
\]

where \(e_i\) is observed values, \(\bar{e}\) is reference values and \(n\) is number of points.

V. Processing steps

Generated orthophoto covers about 31 ha of the study area. UAV image and GNSS-RTK measured GCPs are processed in state art of the commercial software Pix4D. The dataset (images, optional but recommended: images geolocation and GCPs) have to be obtained on the field before using Pix4Dmapper. Geolocation steps are done by open source software Mission planner. Exif values of the image are overwriting from the OEM-GNSS and tagging Ellipsoidal (Geographic) coordinates to the image properties. Image coordinates are estimated by time interval and interpolated from log file of autopilot system of UAV platform. A good dataset is required in order to automatically produce results with high quality and accuracy [13]. In order to take a good dataset, following steps have been finished:

- Designing the image acquisition plan (Mission Planner)
- Configuring the camera settings
- Geolocating images
- GCPs measurement before or after flight

In terms of to achieve high accuracy results, overlapping between images have to be acquired high triggering camera interval or very close corridors for side-laps. Therefore, the route of UAV platform plan has to be carefully designed to have sufficient image overlap. Notably, high detailed required GSD projects are depends on the flight altitudes. GSD value had calculated using by following equation [14],

\[
GSD = \frac{p}{c} \tag{2}
\]
where \( p \): CCD pixel size of camera, \( H \): flying height, \( c \): camera focal length

VI. NON-GROUND OBJECT FILTERING WITH FUSION

GroundFilter module from FUSION is designed to filter a cloud of LIDAR returns to identify those returns that lie on the probable ground surface (bare-earth points) [15]. It has capable of filtering any kind of point cloud file in .las file format or converted file format from ASCII standards. Most of the filtering algorithms have their own advantages and disadvantages, in this module does not produce a perfect set of ground returns in that it does not completely remove returns from large, flat or elevated surface such as building roofs. Mostly it is suitable for vegetated returns with the appropriate coefficients for the weight function and sufficient iterations. GroundFilter has shown that the default coefficients for the weight function produce good results in high-density point clouds (> 4 returns/sq m). The program could give a result with low-density point clouds but some training for parameter are needed to find best suited parameter values. Also, GroundFilter produces point sets for calculating vegetation heights. This module is also containing ground surface point sets stored LDA format. LDA formatted file is an indexed binary format that allows rapid random access to large datasets. Further models have been generated with other existed FUSION modules such as GridSurfaceCreate or TINSurfaceCreate utilities to produce a ground surface model.

![Fig. 5. Above ground height, red colors high and blue colors low height above ground](image)

**Fig. 5.** Above ground height, red colors high and blue colors low height above ground

FUSION software is running by command line. Filtering algorithm has been implemented linear prediction with an individual accuracy for each measurement of point sets and it works iteratively. Firstly, the surface is computed with equal weights for all points, or to be more precise, for all point height measurements. This surface runs in an averaging way between terrain points and vegetation points. The terrain points are more likely to have negative residuals, whereas the vegetation points are more likely to have small negative or positive residuals. These residuals are used to compute weights for each measurement [16].

![Fig. 6. Dense Point cloud, a) raw point cloud, b) filtered point cloud](image)

**Fig. 6.** Dense Point cloud, a) raw point cloud, b) filtered point cloud
VII. RESULTS

A. DTM Generation

DTM has modelled after ground points extracted from raw point clouds. Gridsurfacedcreate module of FUSION software was used for the surface generation with basic parameters. Over 8 million raw point set filtered and approximately 4 thousand bare ground points extracted. The cell elevation for the surface model is the average elevation of all points in a cell (1x1 m). The model cell size is the same as the intermediate surface cell size (specified by cellsize and smoothing is done depending on the /smooth:3x3 m and /median: 1x1 m switches. In general, the surface model produced by GroundFilter is coarse to be useful. It provides a quick check on the results of the bare-earth filtering as the resulting PLANS DTM file can be displayed for evaluation in the PDQ viewer. Thus further analysis had been done and the surface model created with DTM2ASC module. DTM2ASC converts data stored in the PLANS DTM format into ASCII raster files. Such files can be imported into SAGAGIS and Surfer software. Analytical hill-shade analysis for the presenting surface detail and smoothed surface features can be viewed and inspecting (Figure 9). Ground surface extracted models can be show by new map feature as above ground height. By this way, the canopy model analysis can be done (Figure 5). DTM resolution the average density of points of an irregular DTM, or the grid spacing of a regular DTM is one of the most issue for DTMs. These parameters should maintain a reasonable accuracy to describe the topographic surface using the minimum number of points [17] (Figure 3). Topographic or contour maps can present the quality of dense surface maps which include vegetation or non ground objects. In terms of the inspection of non filtered point cloud for terrain, contour maps are shows the deviations on the surface due to the non ground objects (Fig. 7).

Fig. 7 shows that profile view from part of DSM and DTM raster surface. Green lines of profile (Fig. 7), are DSM points and brown lines presents that generated surface from ground point of raster surface. It shows the quality of point cloud segmentation from raw point cloud data (Fig. 6). Most part of the DSM models are include vegetation from raw point cloud, thus need to extract from point cloud as proposed methodology mentioned in section VI. High dense and above ground filtration process showed that on Fig 9 approximately 40 m high trees detected on study site. For further analysis ie. landslide movement detection, raw point clouds can not be used without filtration of vegetation. Topographic mapping productions ie. contour, gradient and slope maps of study area can be generate after noise and non-ground objects points filtered from raw points. Fig. 10 shows the topographic contour map generated from filtered point cloud.

B. Orthophoto generation

Visualization of terrain with DSM and overlay orthophotos are improve the visualization of terrain in 3D models. Orthophotos are usually created using a bare earth elevation model and do not take into account occlusions. But elevation differences in elevation, eventually relief displacements are increasing on the steep edges for higher buildings or trees can be so large that they will obstruct the terrain and objects next to them. Thus, true orthophoto generation is substantial to cover terrain that matching image to the DSM. A true orthophoto is generating process to restore any occluded terrain while at the same time including as many terrain as possible in the surface model. True orthophotos are basically include all details on surface models. Generation of true orthophotos are commonly necessary for images of high detail or low altitude, and rough terrain. In this study mostly production of DTM are under investigation, however orthophoto generation had been done processing pipeline from Pix4D software (Fig. 10 b). Generated orthophoto quality is important for understanding level of terrain detail. The production of orthophoto ground sample distance (GSD) had 5 cm interval. It includes high detail of ground. Vegetation, rock surface, road lines etc. can bee seen from generated orthophoto. Further investigations are going to under estimate for landslide monitoring from DTM comparison and keypoint matched orthophoto by digital image processing algorithms. In this way, automatically change detections can be measured by 3D and 2D from UAV data.

VIII. CONCLUSIONS

UAV processing steps are highly automated and low cost features both makes this technique unique and stable on surveying applications. Image processing software and procedures are mostly rapid and user friendly. UAV is the newest technology for fast and accurate technique to generate DTM for low cost data collect and production system. The analysis of check points are showed that uncertainty (RMSE) of DTMs are enough for determine under decimetre level deformations on high density forestry landslide areas.
This accuracy levels are not only enough for mapping applications with UAV but also sufficient for medium scale deformation analysis and change detection applications by UAV platforms. For further detail few cm scale DTMs and orthophotos can be generate with high accuracy and very dense detail of levels with decrease flying height and improve georeferencing process with directional or in directional with increase GCPs number.

Abstract— Frequency selective surfaces (FSS) can allow and block electromagnetic (EM) waves depending on their shape and structure. In this study we demonstrate numerical analysis solutions of flexible micro strip band pass filter as FSS. Proposed design is produced from 50 micrometer thickness polycaprolactone (PCL) substrate which is electro spun nanofiber. The nanofiber flexible substrate is coated by nested two copper rings to constitute FSS. Designed unit cell showed band pass filter characteristic between 6.8 and 7.7 GHz. An array design of 3x3, consisting of same unit cells also displayed similar band pass filter characteristics at same frequencies.

Keywords— Frequency selective surfaces, nanofibers, microwave, Polycaprolactone, Dielectric substrate

I. INTRODUCTION

Frequency selective surfaces (FSS) can allow and block electromagnetic (EM) wave transfers depending on their shape and structure [1]. Generally, FSSs consist of unit cells in various geometries [2]. Based on shapes and sequences of conductors and holes the FSS are used as band pass filters, band stop filters and reflector antennas etc. at microwave (MW) frequencies [3-4].

EM wave passing or blocking criteria of an FSS is inferred from transmission and reflection coefficients. A transmission band of an FSS is determined as frequencies that show reflection coefficients show value of -3 dB and higher. That means more than half of the energy is being transferred through the FSS. Besides, desired reflection coefficients lower than -10 dB show the frequencies that the average reflected power drop is below 10% [4].

Nanofibers have diameters less than 1 µm [5]. Nanofibers are produced from metals, ceramics, natural and synthetic polymers [6]. Polymer materials can be spun to form a specific surface of nanofiber mats during their producing process [7].

In this study; we explore nanofiber mats as FSS and conduct their numerical analysis [8]. We proposed a design indicating band pass filter characteristic at microwave (MW) frequencies because of its micro-strip thickness.

For calculations, we used properties of polycaprolactone (C₆H₁₀O₆)n (PCL) nanofibers with 50 µm thickness. We have measured dielectric property (permittivity) of nanofiber mat experimentally with (Anritsu MS4624A- 9 GHz) network analyser and we found that εr=3.1 along the working frequencies. Conductive copper rings, whose conductivity is σ=5.8x10⁷ and 35 µm thickness, were used for constitution of FSS. For the purpose of design and modelling FSS simulation 3D simulation programs were used.

II. DESIGN

In this work, the proposed design of unit cells had 30 mm weight (W) and 30 mm length (L). Each unit cell had two copper ring foils. The radius of small ring (R1) is 6 mm and the big one (R2) is 10 mm. Each ring foil had 1 mm wideness (wl). The thickness of copper (t) was 0.035 mm and the thickness of PCL as substrate (d) was 0.050 mm. A top view of proposed unit cell for FSS and its sectional side view are shown in Fig. 1.

![Fig. 1 Proposed unit cell for FSS and its sectional side view](image-url)
In order to build FSS, the unit cells were repeated repeating in two directions (vertical and horizontal). An array of FSS consisted of 9 (3x3) unit cells. Therefore, the array structure had 90 mm of total size in each direction $W_A=L_A=90$ mm. The front view of (3x3) FSS array shown in Fig. 2.

![Fig. 2 The front view of (3x3) FSS array](image)

III. RESULTS

For numerical solution; designed structure excited electromagnetically from front and back side of the FSS since specify the response of EM waves. This study prepared at simulation medium with two port excitation. Each port excitation gives S parameter of the design ($S_{11}$, $S_{12}$, $S_{21}$, $S_{22}$). Reflection and transmission coefficients computed from these S parameters.

The calculated reflection and transmission coefficients of FSS are given in Fig. 3. The designed unit cell displayed band pass filter characteristics at frequencies between 6.8 and 7.7 GHz. These design and its characteristics showed that design can be used as FSS. As it can be seen in figure 3, transmission band exceeds the -3 dB (blue dashed line) and reflection band falls beneath -10 dB (black solid line).

Similar to the unit cell, the reflection and transmission coefficients of the (3x3) array works at the same frequencies as it can be seen in figure 4.

![Fig. 4 Calculated reflection and transmission coefficients of (3x3) array](image)

In this study a novel FSS design was proposed and simulated using PCL nanofibers as dielectric substrate material for FSSs. A single unit cell and an array of FSSs were tested using computational methods. The FSS structures designed and simulated as band pass surface and their numerical solutions were presented in this work. The increase in the number of unit cells in array will produce larger FSS surfaces. However the filtering property does not effected change and keeps allowing and disabling EM waves at same frequencies.

With this study, it is shown that nanofiber mats can be used as dielectric substrates at microwave frequencies. Therefore, it would produce novel devices and solutions for applications for today’s technology [6-9].

e-mail: mor.takunya@gmail.com

\textbf{Abstract—} In early papers \cite{4}, \cite{16}, and \cite{19}, there are several ways to generalize the usual \(T_0\)-axiom of topology to topological categories. In this paper, we characterize each of these various forms of \(T_0\) extended pseudo-semi metric spaces and investigate the relationships among them as well as compare each of \(T_0\) extended pseudo-semi metric spaces with the usual ones.

\textbf{Keywords—} Topological category, pseudo-semi metric spaces, products, \(T_0\) spaces.

\section{Introduction}

In 1906, Fréchet \cite{11} introduced the notion of metric spaces which play an important role in mathematics. There are numerous generalizations and procedures generalizing the notions of metric spaces by weakening or omitting some of its axioms. In 1931, Wilson \cite{3} introduced quasi-metric spaces (where the condition of symmetry is omitted) and further developed in \cite{3} and \cite{13} have a particular character and significance in the area of Quantum mechanics \cite{14} experimental psychology \cite{10}, biological studies \cite{18}, from those sciences in which measurement plays an essential role. In 1990, Adámek and Reiterman \cite{2} defined extended pseudo-metric spaces (where an pseudo-metric is allowed to attain the value infinity).

There are several ways to generalize the usual \(T_0\)-axiom of topology to topological categories \cite{4}, \cite{16}, and \cite{19} and the relationships among various forms of generalized \(T_0\)-axiom in topological categories have been investigated in \cite{5} and \cite{19}. One of the uses of \(T_0\) objects is to define various forms of Hausdorff objects and regular objects \cite{6}, \cite{7}, \cite{8}, and \cite{9} in arbitrary topological categories.

In this paper, we characterize each of various forms of \(T_0\) extended pseudo-semi metric spaces and compare each of \(T_0\) extended pseudo-semi metric spaces with the usual ones.

\section{Preliminaries}

Let \(\text{Set}\) denote the category of all sets and functions and \(\mathbf{E}\) be any category. Recall, in \cite{1}, \cite{12} or \cite{17}, that a functor \(U: \mathbf{E} \to \text{Set}\) is said to be topological, or that \(\mathbf{E}\) is a topological category over \(\text{Set}\), the category of sets, if \(U\) is concrete (i.e., faithful and amnestic (i.e., if \(U(f) \cong id\) and \(f\) is an isomorphism, then \(f = id\)), has small (i.e., set) fibers, and is such that every \(U\)-source has an initial lift or, equivalently, is such that each \(U\)-sink has a final lift.

Note that a topological functor \(U: \mathbf{E} \to \text{Set}\) has a left adjoint \(D\), the discrete functor, and \(U\) has a right adjoint, called the indiscrete functor. Recall, in \cite{1} or \cite{17}, that an object \(X \in \mathbf{E}\) is indiscrete if and only if every map \(U(Y) \to U(X)\) lifts to a map \(Y \to X\) for each object \(Y \in \mathbf{E}\) and an object \(X \in \mathbf{E}\) is discrete if and only if every map \(U(X) \to U(Y)\) lifts to map \(X \to Y\) for each object \(Y \in \mathbf{E}\).

Let \(B\) be a set and let \(B^2 \sqcup \Delta B^2\) be the wedge product of \(B^2\) \cite{4}, i.e., two disjoint copies of \(B^2\) identified along the diagonal, \(\Delta\). A point \((x, y)\) in \(B^2 \sqcup \Delta B^2\) will be denoted by \((x, y)_{1} (x, y)_{2}\) if it is in the first (resp. second) component of \(B^2 \sqcup \Delta B^2\).

Recall that the principal axis map \(A: B^2 \sqcup \Delta B^2 \to B^2\) is given by \(A ((x, y)_{1}) = (x, y, x)\) and \(A ((x, y)_{2}) = (x, x, y)\), and the fold map, \(\nabla : B^2 \sqcup \Delta B^2 \to B^2\) is given by \(\nabla ((x, y)) = (x, y)\) for \(i = 1, 2\) \cite{4}.

Let \((B^2 \sqcup \Delta B^2)^{j}\) be the final lift of the \(U\)-sink \(i_{1}, i_{2}: U(X^{2}) \to B^{2} \to B^2 \sqcup \Delta B^2\), where \(i_{1}\) and \(i_{2}\) are the canonical injection maps.

\textbf{Definition 2.1.} (cf. \cite{4}, \cite{5}, \cite{16}, \cite{19}). Let \(U: \mathbf{E} \to \text{Set}\) be topological, \(X\) an object in \(\mathbf{E}\) with \(U(X) = B\).

\begin{enumerate}
\item \(X\) is \(\overline{T_0}\) if the initial lift of the \(U\)-source \(\{ A : B^2 \sqcup \Delta B^2 \to U(X^{2}) = B^2 \}\) and \(\nabla : B^2 \sqcup \Delta B^2 \to UD(B^2) = B^2\) is discrete.
\item \(X\) is \(\overline{T_0^*}\) if the initial lift of the \(U\)-source \(\{id : B^2 \sqcup \Delta B^2 \to U(B^2) = B^2\}\) is discrete.
\item \(X\) is \(\overline{T_0}\) if \(X\) does not contain an indiscrete subspace with (at least) two points.
\end{enumerate}

\textbf{Remarks 2.2.} In general, for an arbitrary topological category, it is shown in \cite{5} that if \(X\) is \(\overline{T_0}\), then \(X\) is \(\overline{T_0^*}\) and there are no further implications between \(T_0\) and each of \(\overline{T_0}\) and \(\overline{T_0^*}\). In \(\text{Top}\), the category of topological spaces and continuous functions, by results proven in \cite{4}, \cite{5}, \cite{16}, \cite{19}
all of the $T_0$. $\overline{T_0}$ and $T_0^*$ are equivalent and reduce to the usual $T_0$.

Recall, in [15], that an extended pseudo-semi metric space is a pair $(X,d)$, where $X$ is a set and $d: X \times X \rightarrow [0,\infty]$ is a
function fulfills $d(x,x)=0$ for all $x$ in $X$ and $d(x,y)=d(y,x)$ for all $x,y$ in $X$.

A map $f:(X,d) \rightarrow (Y,e)$ between extended pseudo-semi metric spaces is said to be a non-expansive if it fulfills the property $e(f(x),f(y)) \leq d(x,y)$ for all $x,y$ in $X$.

The category of extended pseudo-semi metric spaces and non-expansive maps is denoted by $\text{psMet}$ [15].

Theorem 2.3. $\text{psMet}$ is a topological category over $\text{Set}$.
Proof. Define the forgetful functor $U: \text{psMet} \rightarrow \text{Set}$ by $U((X,d))=X$ and for a non-expansive map $f:(X,d) \rightarrow (Y,e)$ between extended pseudo-semi -metric spaces $U(f)=f: X \rightarrow Y$. It is clear that $U$ is concrete. Note that for any set $X$, the fiber of $X$, $U^{-1}(X)$ is isomorphic to the set of all extended pseudo-semi metrics on $X$ which means $U$ has small fibers. It remains to show that every $U$ - source has an initial lift. Let $(X,d)$, $i \in I$ be a class of extended pseudo-semi metric spaces and $f_i: \text{U}(X,d)_i \rightarrow X$, $i \in I$ be a class of functions. Define a extended pseudo-semi -metric $d$ on $X$ by:

$$d(a,b) = \sup_{i\in I} (d_i(f(a),f(b)))$$

for all $a,b \in X$. Note that $(X,d)$ is an extended pseudo-semi metric space and $\{f_i: (X,d)_i \rightarrow (X,d), \ i \in I\}$ is a set of non-expansive maps. Let $(Y,e_i)$ be any extended pseudo-semi metric space and for any function $h : Y \rightarrow X$, $h \circ f_i: (Y,e_i) \rightarrow (X,d)$, $i \in I$, be non-expansive maps. We need to show that $h: (Y,e) \rightarrow (X,d)$ is a non-expansive map. Note that for all $a,b \in Y$ and for all $i \in I$, $d_i(h(a),h(b)) \leq e(a,b)$ since $h \circ f_i: (Y,e_i) \rightarrow (X,d)$, $i \in I$, be non-expansive maps and consequently, $d(h(a),h(b)) = \sup_{i\in I} (d_i(h(a),h(b))) \leq e(a,b)$. This means that $h: (Y,e) \rightarrow (X,d)$ is a non-expansive map. Hence, $\text{psMet}$ is a topological category over $\text{Set}$.

2.4. Let $(X,d)$, $i \in I$ be a class of extended pseudo-semi metric spaces and $X$ be a nonempty set. A source $\{f_i: (X,d) \rightarrow (X,d), i \in I\}$ is initial in $\text{psMet}$ if and only if for all $a,b \in X$, $d(a,b) = \sup_{i\in I} (d_i(f(a),f(b)))$ [15].

2.5. Let $(X,d)$, $i \in I$ be a class of extended pseudo-semi metric spaces and $X$ be a nonempty set. A sink $\{f_i: (X,d) \rightarrow (X,d), i \in I\}$ is final in $\text{psMet}$ if and only if for all $a,b \in X$, $d(a,b) = \inf_{i\in I} (d_i(a_i,b_i))$ where $a_i, b_i$ in $X$ such that $f_i(a_i) = a$ and $f_i(b_i) = b$. This is a special case of [15].

2.6. The discrete extended pseudo-semi metric structure $d$ on $X$ is given by for all $a,b \in X$

$$d(a,b) = 0 \text{ if } a = b \text{ and } d(a,b) = \infty \text{ if } a \neq b [15].$$

2.7. The indiscrete extended pseudo-semi metric structure $d$ on $X$ is given by $d(a,b) = 0$ for all $a,b \in X [15].$

III. $\mathcal{T}_0$ EXTENDED PSEUDO-SEMI METRIC SPACES

Theorem 3.1. An extended pseudo-semi metric space $(X,d)$ is $\overline{T_0}$ if and only if $(X,d)$ is discrete.

Proof. Suppose, $(X,d)$ is $\overline{T_0}$ and $x,y \in B$. If $x = y$, then $d(x,y) = d(x,x) = 0$ since $d$ is an extended pseudo-semi metric on $X$. Suppose that $x \neq y$. Let $u=(x,y)$ and $v=(x,y)_2$. Let $\pi_i : X \rightarrow B$ be the projection maps, $i = 1,2,3$ and $d_{\text{dis}}$ be the discrete extended pseudo-semi metric structure on $X$. Note that $u$ and $v$ are distinct points of the wedge $X^2 \vee X^2$ and $d_{\text{dis}}(\pi_i(u),\pi_i(v)) = 0$, $d(\pi_i(u),\pi_i(v)) = d(x,y) = d(x,y) = d(\pi_{12}(u),\pi_{12}(v))$ since $d$ is an extended pseudo-semi metric on $X$. Since $(X,d)$ is $\overline{T_0}$ and $u \neq v$, it follows from Definition 2.1, 2.4, and 2.6 that $\infty = \sup\{d_{\text{dis}}(\pi_i(u),\pi_i(v)), d(\pi_{11}(u),\pi_{11}(v)), d(\pi_{21}(u),\pi_{21}(v)), d(\pi_{12}(u),\pi_{12}(v))\} = \sup\{0, d(x,y) = d(x,y)\} = d(x,y)$, and consequently, $d(x,y) = \infty$ if $x \neq y$. Hence, by 2.6, $d$ is a discrete extended pseudo-semi metric on $X$.

Conversely, suppose that $d$ is a discrete extended pseudo-semi metric on $X$. We will show that $(X,d)$ is $\overline{T_0}$. Let $d''$ be the product extended pseudo-semi metric structure on $X^2$, $d_{\text{dis}}$ be the discrete extended pseudo-semi metric structure on $X^2$ and $\overline{d}$ be the initial structure on the wedge $X^2 \vee \Delta X^2$ induced by the $U$-source $\{A : X^2 \vee \Delta X^2 \rightarrow U(X^0), d'(x) = x^3 \}$ and $\overline{d} : X^2 \vee \Delta X^2 \rightarrow U(X^2, d_{\text{dis}}) = X^2$. By Definition 2.1, we need to show that $\overline{d}$ is a discrete extended pseudo-semi metric on the wedge $X^2 \vee \Delta X^2$.

Let $u$ and $v$ be any points of the wedge $X^2 \vee \Delta X^2$. If $u = v$, then $\overline{d}(u,v) = 0$.

Suppose that $u \neq v$. If $\overline{d}(u) \neq \overline{d}(v)$, then $d_{\text{dis}}(\overline{d}(u),\overline{d}(v)) = \infty$ which implies that $\overline{d}(u,v) = \sup\{d_{\text{dis}}(\overline{d}(u),\overline{d}(v)), d(\pi_{11}(u),\pi_{11}(v)), d(\pi_{21}(u),\pi_{21}(v)), d(\pi_{12}(u),\pi_{12}(v))\} = \sup\{\infty, d(\pi_{11}(u),\pi_{11}(v)), d(\pi_{21}(u),\pi_{21}(v)), d(\pi_{12}(u),\pi_{12}(v))\} = \infty$. If $\overline{d}(u) = (x,y) = \overline{d}(v)$
for some \((x, y)\) in \(X^2\) with \(x \neq y\), then \(u\) and \(v\) have the form \((x, y)\) and \((y, x)\) for some \(x\) and \(y\) in \(X\).

If \(u = (x, y)\) and \(v = (x, y)\), then \(d(u, v) = \sup\{d_{dis}(\nabla(u), \nabla(v)), d(\pi_{11}(u), \pi_{11}(v)), d(\pi_{21}(u), \pi_{21}(v)) \} = \sup\{d_{dis}(x, y), 0\} = d(x, y)\) since \(x = y\).

Hence, by 2.6, \(\overline{d}\) is a discrete extended pseudo-semi metric on the wedge \(X^2 \setminus X^2\). Thus, \(\overline{d}\) is a discrete extended pseudo-semi metric on \(X\).

**Theorem 3.2.** All extended pseudo-semi metric spaces are \(T_0^+\).

**Proof.** Let \((X, d)\) be an extended pseudo-semi metric space. Let \(d^e\) be the product extended pseudo-semi metric structure on \(X^2\), \(d_{dis}\) be the discrete extended pseudo-semi metric structure on \(X^2\), and \(d_1\) be the final structure on the wedge \(X^2 \setminus X^2\) induced by \(U\)-sink \(i_1, i_2: U(X^2, d^e) \rightarrow \mathbb{X} \rightarrow X^2 \setminus X^2\), where \(i_1\) and \(i_2\) are the canonical injection maps, and \(\overline{d}\) be the initial structure on the wedge \(X^2 \setminus X^2\) induced by the \(U\)-source \(\{ id: X^2 \setminus X^2 \rightarrow U(X^2, d^e) \} = X^2 \setminus X^2\) and \(\overline{d} : X^2 \setminus X^2 \rightarrow U(X^2, d_{dis}) = X^2\), where \(id\) is the identity map. By Definition 2.1, we need to show that \(\overline{d}\) is a discrete extended pseudo-semi metric on the wedge \(X^2 \setminus X^2\).

Let \(u\) and \(v\) be any points of the wedge \(X^2 \setminus X^2\).

If \(u = v\), then \(\overline{d}(u, v) = 0\).

Suppose \(u \neq v\). If \(\nabla(u) \neq \nabla(v)\), then \(d_{dis}(\nabla(u), \nabla(v)) = \infty\) which implies that \(\overline{d}(u, v) = \sup\{d_{dis}(\nabla(u), \nabla(v)), d_{1}(u, v)\} = \sup\{\infty, d_{1}(u, v)\} = \infty\). If \(\nabla(u) = \nabla(v)\) for some \((x, y)\) in \(X^2\), then \(u\) and \(v\) have the form \((x, y)\) and \((y, x)\) for some \(x\) and \(y\) in \(X\).

If \(u = (x, y)\) and \(v = (x, y)\), then, by 2.4 and 2.5, \(\overline{d}(u, v) = \sup\{d_{dis}(\nabla(u), \nabla(v)), d_{1}(u, v)\} = \sup\{d_{dis}(x, y), 0\} = d_{1}(x, y) = d(x, y)\) since \(x = y\).

If \(u = (x, y)\) and \(v = (x, y)\), then, by 2.4 and 2.5, \(\overline{d}(u, v) = \sup\{d_{dis}(\nabla(u), \nabla(v)), d_{1}(u, v)\} = \sup\{d_{dis}(x, y), 0\} = d_{1}(x, y) = d(x, y)\) since \(x = y\).

Theorem 3.3. An extended pseudo-semi metric space \((X, d)\) is \(T_0^+\) if and only if \((X, d)\) is an extended semi-metric space.

**Proof.** Suppose that an extended pseudo-semi metric space \((X, d)\) is \(T_0^+\). We show that \((X, d)\) is an extended semi-metric space, i.e., for any \(x, y \in B\), if \(d(x, y) = 0\), then \(x = y\). Suppose that \(x \neq y\). Let \(A = \{x, y\}\) and \(d_A\) be the initial extended pseudo-semi metric structure on \(A\) induced by the inclusion map \(i: A \subset X\). Note that \(d_A(x, x) = d_A(y, y) = 0 = d_A(x, y)\) and \(d_A(x, x) = d(x, x) = 0 = d(y, y)\). Thus, \(d_A(x, y) = d_A(y, x)\). Thus, \((X, d)\) is an extended semi-metric space, it follows that \(x = y\), a contradiction. Hence, an extended semi-metric space \((X, d)\) cannot contain an indiscrete subspace with \(at least\) two points. Thus, by Definition 2.1, \((X, d)\) is \(T_0^+\).

**Remark 3.4.** In psMet, the category of extended pseudo-semi metric spaces and non-expansive maps, by Theorems 3.1-3.4, \(\overline{d}\) implies \(T_0^+\) implies \(T_0\) but the converse of each implication does not hold, in general. In Top, the category of topological spaces and cotinuous maps, by Remark 2.2, all of the \(T_0\), \(\overline{T_0}\) and \(T_0^+\) are equivalent and reduce to the usual \(T_0\). In general, for an arbitrary topological category, it is shown in [7] that if \(X = \overline{T_0}\), then \(X = T_0^+\) and there are no further implications between \(T_0^+\) and each of \(\overline{T_0}\) and \(T_0^+\).

**IV. Conclusions**

In this work, we have given the characterization of
each of the $T_0$, $\overline{T_0}$ and $T_0^*$ extended pseudo-semi metric spaces and showed that $\overline{T_0}$ implies $T_0^*$ but the converse of each implication does not hold, in general (Theorems 3.1-3.3 and Remark 3.5). On the other hand, in $\text{Top}$, the category of topological spaces and continuous functions, by results proven in [3], [13] and [18], all of the $T_0$, $\overline{T_0}$ and $T_0^*$ are equivalent and reduce to the usual $T_0$.

T₀ Reflexive Spaces

Mehmet Baran
Department of Mathematics, Faculty of Sciences
Erciyes University, Kayseri - Turkey
baran@erciyes.edu.tr

Abstract— In this paper, we characterize each of various forms of T₀ reflexive spaces and compare each of T₀ reflexive spaces with the usual ones.

Keywords— Topological category, reflexive spaces, ordered sets, T₀ spaces.

I. INTRODUCTION

Order theory is a branch of mathematics that studies various kinds of binary relations that capture the intuitive notion of a mathematical ordering. Orders appear everywhere – at least as far as mathematics and related areas, such as computer science, are concerned (see [10], [11], [16]–[18]).

There are several ways to generalize the usual T₀-axiom of topology to topological categories [2], [3], [12], [18], and the relationships among various forms of generalized T₀-axiom in topological categories have been investigated in [3], [18]. One of the uses of T₀ objects is to define various forms of Hausdorff objects [2], [4], [7]–[9] and the closed subobjects of a given object [2], [7], [8] of an arbitrary topological category which is used to generalize the usual regular and normal topological spaces to topological categories [5], [6].

In this paper, we characterize each of various forms of T₀ reflexive spaces and compare each of T₀ reflexive spaces with the usual ones.

II. PRELIMINARIES

Recall, in [1], [12] or [14], that a functor U : E → Set is said to be topological, or that E is a topological category over Set, the category of sets, if U is concrete (i.e., faithful and amnestic (i.e., if U(f) = id and f is an isomorphism, then f = id)), has small (i.e., set fibers, and is such that every U-source has an initial lift or, equivalently, is such that each U-sink has a final lift.

Note that a topological functor U : E → Set has a left adjoint D, the discrete functor, and U has a right adjoint, called the indiscrete functor. Recall, in [1] or [14], that an object X ∈ E is indiscrete iff every map U(Y) → U(X) lifts to a map Y → X for each object Y ∈ E and an object X ∈ E is discrete iff every map U(X) → U(Y) lifts to map X → Y for each object Y ∈ E.

Let B be a set and let B² ∨₃ B² be the wedge product of B² [2], i.e., two disjoint copies of B² identified along the diagonal, ∆. A point (x, y) ∈ B² ∨₃ B² will be denoted by (x, y)₁, (x, y)₂ if it is in the first (resp. the second) component of B² ∨₃ B².

Recall that the skewed axis map S : B² ∨₃ B² → B³ is given by S((x, y₁)) = (x, y, y) and S((x, y)₂) = (x, x, y), the principal axis map A : B² ∨₃ B² → B³ is given by A((x, y₁)) = (x, y, x) and A((x, y)₂) = (x, x, y), and the fold map, ∇ : B² ∨₃ B² → B² is given by ∇((x, y)) = (y, y) for i = 1, 2 [2].

Let (B² ∨₃ B²)ᵢ be the final lift of the U-sink i₁, i₂ : U(X²) = B² → B² ∨₃ B², where i₁ and i₂ are the canonical injection maps.

Definition 2.1. (cf. [2], [3], [13], [18]). Let U : E → Set be topological, X an object in E with U(X) = B.

1. X is T₀ if the initial lift of the U-source { A : B² ∨₃ B² → U(X²) = B²} and, ∇ : B² ∨₃ B² → UD(B²) = B² is discrete.

2. X is T₀" if the initial lift of the U-source { id : B² ∨₃ B² → U((B² ∨₃ B²)ᵢ) = B² ∨₃ B² and ∇ : B² ∨₃ B² → UD(B²) = B²} is discrete.

3. X is T₀ if X does not contain an indiscrete subspace with (at least) two points.

Remarks 2.2. In general, for an arbitrary topological category, it is shown in [3] that if X is T₀, then X is T₀" and there are no further implications between T₀ and each of T₀ and T₀". In Top, the category of topological spaces and continuous functions, by results proven in [3], [13], [18] all of the T₀, T₀ and T₀" are equivalent and reduce to the usual T₀.
The category $\text{RRel}$ of reflexive spaces (spatial graphs) has as objects the pairs $(B,R)$, where $B$ is a set and $R$ is reflexive relation on $B$, and as morphisms $(B,R)\to (B',R')$ those functions $f:B\to B'$ such that if $aRb$, then $f(a)Rf(b)$ for all $a,b\in B$. Note that $\text{RRel}$ is a topology categor over $\text{Set}$ [1], [10], [14].

2.3. A source $\{f:(B,R)\to (B',R), i\in I\}$ is initial in $\text{RRel}$ if for all $a,b\in B$, $aRb$ if and only if $f(a)Rf(b)$ for all $i\in I$ [1], [10], [14].

2.4. An epimorphism $f:(B,R)\to (B',R)$ is final in $\text{RRel}$ if for all $a,b\in B$, $aRb$ holds in $B'$ precisely when there exists $c,d\in B$, such that $cRd$ and $f(c)=a$ and $f(d)=b$ [1], [10], [14].

2.5. The discrete structure $R$ on $B$ is given by $aRb$ if and only if $a=b$ for all $a,b\in B$, i.e., $R=\Delta$ [1], [14].

2.6. The indiscrete structure $R$ on $B$ is given by $R=B^2$ [1], [14].

III. $T_0$ REFLEXIVE SPACES

**Theorem 3.1.** A reflexive space $(B,R)$ is $T_0$ if and only if $R$ is anti-symmetric.

**Proof.** Suppose $(B,R)$ is $T_0$ and for any $x,y\in B$, $xRy$ and $yRx$. We must show that $x=y$. Suppose that $x\neq y$. Let $u=(x,y)$ and $v=(y,x)$. Note that $\pi_1(A(u)R\pi_1(A(v)=xR\pi_2(A)\pi_2(A)\pi_1(A)\pi_1(A)\triangleleft \Delta 2\pi_1(A)$ and $\pi_2(A)\pi_2(A)\pi_1(A)\pi_1(A)\triangleleft \Delta 2\pi_2(A)\pi_2(A)$, which means $u=v=(x,y)$, a contradiction since $x\neq y$. Thus, $x=y$, i.e., $R$ is anti-symmetric.

Conversely, suppose that $R$ is anti-symmetric. We show that $(B,R)$ is $T_0$. Let $R'$ be the product relation structure on $B^4$ and $R_1$ be the initial structure on the wedge $B^2\vee\Delta B^2$ induced by the $U$-source $\{A:B^2\vee\Delta B^2\to U((B',R'))=B^2\vee\Delta B^2\}$ and $(\forall B':\vee\Delta B^2\to UD(B^2))=B^2$. By Definition 2.1, we need to show that $R$ is discrete, i.e., by 2.5, for any points $u$ and $v$ of the wedge $B^2\vee\Delta B^2$ if $uRv$, then $u=v$. If $uRv$, then $\pi_1(A(u)R\pi_1(A(v)=\pi_2(A)\pi_2(A)\pi_1(A)\pi_1(A)$ and $\pi_2(A)\pi_2(A)\pi_1(A)\pi_1(A)$, and $\forall (u)=\forall (v)$, and $u$ and $v$ have the form $((x,y),v)$ and $(x,y),v)$ for some $x$ and $y$ in $B$. If $u=(x,y),v$ and $v=(x,y),v$ , then $\pi_1((x,y))=(x,y),u$, $\pi_2((x,y))=(x,y),v$ for some $k=1$ or $2$ and consequently, $x=y$, i.e., $u=v$. If $u=(x,y),v$ and $v=(x,y),v$ , then $\pi_1((x,y))=(x,y),u$, $\pi_2((x,y))=(x,y),v$ for some $k=1$ or $2$ which implies $u$ and $v$ must lie in the component of the wedge $B^2\vee\Delta B^2$ which means $u=v$ for all $u$ and $v$. Thus, $R$ is discrete, i.e., by 2.1, $(B,R)$ is $T_0$.

**Theorem 3.2.** All reflexive spaces are $T_0$.

**Proof.** Let $(B,R)$ be a reflexive space, $(B^2\vee\Delta B^2)$ be the final lift of the $U$-sink $i_1,i_2:U(B^2,R'))=B^2\to B^2\vee\Delta B^2$, where $i_1$ and $i_2$ are the canonical injection maps and $R'$ is the product relation structure on $B^2$, and $R$ be the initial structure on the wedge $B^2\vee\Delta B^2$ induced by the $U$-source $\{i:R'=U((B^2\vee\Delta B^2))=B^2\vee\Delta B^2\}$ and $(\forall B^2\vee\Delta B^2\to UD(B^2))=B^2$ is discrete. By Definition 2.1, we have to show that $R$ is discrete, i.e., by 2.5, for any points $u$ and $v$ of the wedge $B^2\vee\Delta B^2$ if $uRv$, then $u=v$. Note that if $uRv$, then, in particular, $\forall (u)=(x,y)=\forall (v)$ for some $x,y\in B$, and consequently, $u$ and $v$ have the form $((x,y),v)$ and $((x,y),v)$. Then, by 2.4, if $u=(x,y),v$ and $v=(x,y),v$ , then $\pi_1((x,y),v)=(x,y),u$, $\pi_2((x,y),v)=(x,y),v$ for some $k=1$ or $2$ which implies $u$ and $v$ must lie in the component of the wedge $B^2\vee\Delta B^2$ which means $u=v$ for all $u$ and $v$. Thus, $R$ is discrete, i.e., by 2.1, $(B,R)$ is $T_0$.

**Theorem 3.3.** A reflexive space $(B,R)$ is $T_0$ if and only if $R$ is anti-symmetric.

**Proof.** Suppose that $(B,R)$ is $T_0$ and for any $x,y\in B$, $xRy$ and $yRx$. We must show that $x=y$. Suppose that $x\neq y$. Let $A=[x,y]$ and $R_A$ be the initial relation on $A$ induced by the inclusion map $i:A\subset B$. Since $R$ is reflexive and $x,y\in A$ , by 2.3, $xR_0y=yRx$ and $yR_0x=xRy$ , it follows from 2.6 that $R_A$ is indiscrete relation on $A$, a contradiction to $(B,R)$ is being a $T_0$ reflexive space. Hence, $x=y$ which shows that $R$ is anti-symmetric.

Conversely, suppose that $R$ is anti-symmetric and $A$ is any subset of $B$ with (at least) two points. Let $x,y\in A$ with $x\neq y$. If $R_A=A'$, the indiscrete reflexive relation on $A'$, then, in particular, $xR_Ay=yRx$ and $yR_Ax=xRy$. Since $R$ is anti-symmetric, it follows that $x=y$, a contradiction. Hence, a reflexive space $(B,R)$ can not contain an indiscrete subspace with (at least) two points. Thus, by Definition 2.1, $(B,R)$ is $T_0$.

**Theorem 3.4.** Let $(B,R)$ be a reflexive space. Then, the following are equivalent:

(i) $(B,R)$ is $T_0$.

(ii) $(B,R)$ is $T_0$.

(iii) $R$ is anti-symmetric.

**Proof.** It follows from Theorem 3.1 and Theorem 3.3.
Remark 3.5.

(1) In RRel, the category of reflexive spaces, by Theorem 3.4, \( \overline{T}_0 \) and \( T_0 \) are equivalent and implies \( T_0 \), but the converse implication does not hold, in general. In Top, the category of topological spaces, by Remark 2.2, all of the \( T_0 \), \( \overline{T}_0 \) and \( T_0^* \) are equivalent and reduce to the usual \( T_0 \). In general, for an arbitrary topological category, it is shown in [7] that if \( X \) is \( \overline{T}_0 \), then \( X \) is \( T_0^* \) and there are no further implications between \( T_0 \) and each of \( \overline{T}_0 \) and \( T_0^* \).

(2) Let for all \( i \in I \), \( (A_i, R_i) \) be reflexive spaces. Then, by Theorems 3.1-3.3, \( \prod_{i} A_i, R_i \) is a \( T_0 \), \( \overline{T}_0 \), and \( T_0^* \) reflexive space if and only if each \( (A_i, R_i) \) is a \( T_0 \), \( \overline{T}_0 \), and \( T_0^* \) reflexive space, respectively.

IV. CONCLUSIONS

In this work, we gave the characterization of each of the \( T_0 \), \( \overline{T}_0 \) and \( T_0^* \) reflexive spaces and showed that \( \overline{T}_0 \) and \( T_0 \) are equivalent and implies \( T_0 \), but the converse implication does not hold, in general. (Theorems 3.1-3.3 and Remark 3.5). On the other hand, in Top, the category of topological spaces and continuous functions, by results proven in [3], [13] and [18], all of the \( T_0 \), \( \overline{T}_0 \) and \( T_0^* \) are equivalent and reduce to the usual \( T_0 \).

Removal of Congo red (anionic dye) from aqueous solutions by adsorption onto olive pomace

Khalid Ali, Hani Zeidan, Mustafa E. Martı

hani-z82@hotmail.com

Abstract— The removal of textile dyes from industrial effluents is one of the most serious environmental challenges in recent years. The aim of this study is to remove a toxic dyestuff, Congo Red (CR) from aqueous solutions by adsorption using olive pomace (OP) as a low-cost and eco-friendly adsorbent. The characterization of the adsorbent was carried out using conventional techniques like Scanning Electron Microscopy, Infrared Spectroscopy and Energy-dispersive X-ray Spectrometry.

Aqueous CR solutions with different initial concentrations (100-5000 mg L-1) were prepared using ultra high pure water obtained from Millipore UHP Water System. Each solution was shaken with known amounts of OP (0.05-0.25 g) in a 50 mL conical flask at 150 rpm speed. Batch experiments were carried out to observe the effect of various experimental parameters such as contact time, temperature, aqueous phase pH, initial CR concentration and also adsorbent dose. It was seen that the adsorption equilibrium was reached in 210 min. The percentage of adsorbed CR increased with the increase in OP amount in the system (Highest removal~88.2%). The process was slightly affected from the initial pH of the aqueous solution. Hence, pH was not adjusted in the experiments. The studies on the adsorption kinetic and isotherms were carried out and best fitting models were suggested. From the kinetic studies, it was seen that the adsorption obeyed to the pseudo-second order kinetic model ($R^2$=0.97). It was seen that the adsorption process best described by Freundlich isotherm model ($R^2$≥0.91). Thermodynamic studies showed that the process was exothermic in nature.

The results generated in this work can be used for determination of the optimum conditions for the removal of synthetic toxic dyes from aqueous solutions via adsorption using OP.

Keywords— Adsorption, synthetic dye, olive pomace, kinetics, characterization, isotherms.

I. INTRODUCTION

Today, more than 100,000 types of commercial dyes are used in the market. Nearly one million tons of synthetic dyes are produced per year and 10% of them are released into the environment and natural resources as waste [1]. The production is increasing every day to be able to meet the needs of growing population and this also results in the release of dye effluents. The disposal of these coloured substances poses one of industry’s major problems in waste water treatment. This is because the discharge of coloured wastes is not only damaging to the aesthetic nature of the receiving streams but also toxic to aquatic life and even carcinogenic or mutagenic in nature [2].

Congo red, the dye used in this study, is an anionic azo dye and is known as carcinogen causes blood clotting, respiratory problems and on ingestion, it produces gastrointestinal irritation with nausea, vomiting and diarrhea [3,4]. So, there is a critical need to treat the wastewaters containing this toxic synthetic dye before its discharge.

Today, removal of synthetic dyes is an important research topic, as government legislation concerning the release of contaminated effluent has become more stringent. Physical and chemical methods such as biological oxidation, adsorption, foam flotation, electrolysis, coagulation-flocculation, ozonation, oxidation, filtration, membrane separation, photo catalysis and electrochemical methods have been used for wastewater decolourisation [5,6].

Adsorption is one of the most efficient methods for the removal of synthetic dyes from wastewater. It provides an attractive treatment due to its simplicity, efficiency and low-cost. Especially using low-cost adsorbent further decreases the cost of the process. Several types of adsorbents from nature or among the waste materials have been tested for the purpose. Olive pomace (OP) has a great potential for the removal of toxic chemicals such as heavy metals and synthetic dyes. It is free of charge and readily available in the industry. In this study it was tested to be used for the removal of Congo red, an anionic dye [7].

II. MATERIALS AND METHODS

A. Materials

The olive pomace (OP) used in this study was supplied by one of the olive oil production plants in Turkey. Congo red (CR) with chemical formula, $C_{23}H_{28}N_6O_6S_2Na_2$ and molecular weight as 696.68 g mol$^{-1}$, was purchased from Merck. The molecular structure of the dye is illustrated in Fig. 1.

![Molecular structure of Congo red](image)

Fig.1. Molecular structure of Congo red.
B. Experimental Procedure

A constant temperature shaker bath (Jeio tech) was used during the experimental studies. A solution of CR with a concentration of 10g·L⁻¹ was prepared and all solutions were prepared using this stock solution. Initial concentration of dye solutions were adjusted between 100- and 5000 ppm. All solutions were prepared by using ultra high pure water obtained from Millipore UHP Water System. The effect of adsorbent dose was studied in the range of 0.05 - 0.25g. The two phases (10 mL aqueous phase vs. solid phase) were contacted in 50 mL erlenmeyer flasks by shaking at 150 rpm. After reaching the equilibrium, the mixture was centrifuged and the phases were clearly separated. Aqueous phase was analysed for CR amount before and after the experiment using an UV–Vis spectrophotometer (Shimadzu MINI-1240) and adsorption capacity of OP for CR was calculated using these values.

Kinetic studies were carried out using 0.1 g OP and 250 ppm CR solution. The samples were withdrawn at predetermined time intervals within five hours. The results presented that equilibrium was achieved in 3.5 hours. In addition effects of several adsorption parameters were investigated and availability of adsorption isotherms was studied.

III. RESULTS AND DISCUSSION

A. Characterization of adsorbent

The characterization of the adsorbent, OP was carried out by FT-IR and several types of functional groups were observed. The FT-IR spectra of the dye-free and dye-loaded OPs presented similarities showing that the adsorption process is physical. The intense of the peaks were observed to decrease with the dye loading. The SEM images clearly confirmed the presence of dye molecules on the OP.

C. Equilibrium studies and adsorption isotherms

The effect of initial CR concentration is shown in Fig. 5. According to the results, removal efficiency decreased with the increase in initial concentration of CR from 100 to 5000 mg·L⁻¹. This could be interpreted by the increase in number of competitive molecules with the increase in the initial dye concentration. The percentage of adsorbed CR increased with the increase in OP amount in the system (Highest removal ~ 88.2%). The process was slightly affected from the initial pH of the aqueous solution. Hence, pH was not adjusted in the experiments.

Well known adsorption isotherms such as Langmuir and Freundlich were used to interpret the equilibrium data. It was seen that the adsorption process best described by Freundlich isotherm model ($R^2\geq 0.91$).

D. Thermodynamic studies and effect of temperature

The effect of temperature on the adsorption of CR on OP is shown in Fig. 9. The data indicates that increasing the temperature decreased the removal efficiency of the CR from aqueous solution. Thermodynamic studies showed that the process was exothermic in nature. The parameters calculated by thermodynamic data were shown in Table 1.

IV. CONCLUSIONS

In this study, olive pomace, a waste material of olive oil industry, has shown to be used for the removal of anionic dyes from aqueous solutions. The adsorption is highly dependent on various adsorption parameters such as adsorbent amount, contact time, pH and initial CR concentration. The adsorption capacity of OP for CR increased with the increase of the adsorbent mass. On the contrary, efficiency decreased with increasing the initial CR concentration. The change in pH was observed to have a slight influence on the adsorption of CR. The system reached equilibrium after 210 min. The kinetic data was indicating the applicability of the pseudo-second-order kinetic model. The equilibrium data was found to follow Freundlich isotherm model. Thermodynamic studies demonstrated that the process is exothermic in nature.

The results generated in this work can be used for determination of the optimum conditions for the removal of synthetic toxic dyes like CR from aqueous solutions via adsorption using OP.

\textbf{Abstract-} Data mining is the process of knowledge discovery in databases. One of the methods in data mining is association analysis. In this study we developed an application as association analysis by using SPSS Clementine data mining software. In the study, SPSS Clementine data mining Software Association analysis algorithms have been applied and compared. With the help of different association algorithms, new findings have been discovered for different market-basket analysis scenarios. We produce different association rules in each algorithm and this provides diversity for new customer strategies. This application of the study has been performed in a big shopping mall. The comparative results are reported and discussed.

\textbf{Keywords-} Data Mining, Market Basket Analysis, SPSS Clementine, Association Rules

\section{I. INTRODUCTION}

Data Mining is extraction process of important, new and useful information from large databases. Data mining is used to obtain meaningful patterns or rules and it is a widespread area of research.

In data mining “qualitative” and “quantitative” methods are used. In this context, in this research qualitative data are used for understanding and interpretation of the market basket data.

Data Mining is one of the most commonly used methods in the literature with the rules. Rules database and their relationship with each other is reviewed and with the help of the different algorithms, different results are obtained.

One of the application areas where the association rules are used is supermarket. Market basket analysis, called the relationship between the products purchased with the purpose of these studies is finding the association rules. In market basket analysis, customer’s buying habits are analyzed and products purchased together are determined.

Market basket analysis in supermarkets is carried out by using exchange of data chips for products that are purchased together. In this study, the different association algorithms are used and new findings were gained for different market basket analysis scenarios. Each algorithm includes different association rules and this provides variety. Relationship of different products with large scale of customers’ buying habits is determined. In this way, customers’ buying behaviors are analyzed and evaluated.

\section{II. LITERATURE SUMMARY}

When we look at the studies in the literature regarding the market basket analysis, Chen et al. (2005) uses the database for shopping records for a basket analysis application to determine the behavior. The information obtained from the analysis result of marketing, sales and operational strategies have been developed in this study [1]. Yang and Lai (2006), compared the performance of products based on knowledge decision on the promotion of online shopping behavior [2]. Umarani ve Punithavalli (2011) used different association rules algorithms on real-life data, such as retail sales and the market baskets [3]. Kamakura (2012), compared the traditional grocery cart with analysis and contrast sequential extension. Then, taking advantage of grocery shopping trips for the analysis of sequence data has suggested buying a picture frame [4]. Durdu (2012), used data mining tools and applications in the retail sector companies. He developed a customer relationship structure that is the basis for management activities [5].

Ceylan (2014), applied approach of association rules of data mining to reveal the relationship between the drugs [6]. Bayram (2014), made basket analysis for a company engaged in market research worldwide. He researched the relationship between traditional and modern channels [7]. Doğrul et al. (2015), researched accidents with association algorithms to extract beneficial information for human life. He used Apriori and GRI algorithms [8].

\section{III. MATERIALS AND METHOD}

In this study, the supermarket association rules with the application of internal market basket analysis, data mining is done.

\textbf{A. Market Basket Analysis and Association Rules}

Association Rules is a data mining approach. In this approach we discover interesting patterns of association marketing of large amounts of data. This provides benefits for decision-making and business management.
Association rules play an important role at information discovery from this database baskets [9]. One of the most common areas are the supermarket applications that use association rules. This application is known as the market basket analysis in the literature. Market basket analysis, which by revealing that the trend of the products sold with customer behavior, stock control, providing benefits to making the analysis, such as sales strategies [10]. Market basket analysis shows the distribution of customers from different perspectives. This information distribution planning, advertising design, sale - promotion, store layout and contributes decisions such as the granting of investment products [2].

Market Basket Analysis to clarify the relationship between the products sold in the analysis "support" and "confidence" as used two criteria. 'Rules of support measures' determines the rate at which it is repeated in all shopping for a relationship. The purchaser of the A product groups also revealed the possibility of buying the customers' B product groups [11].

B. The Algorithms Used for Association Analysis

A multi-algorithm that provides information from the data stack can be classified as sequential or parallel. Sequential algorithms are created and product set which contains logical expressions. Parallel algorithms allows the creation of large batches of product to parallelism [11].

1) GRI Algorithm: The Generalized Rule Induction (GRI) node discovers association rules in the data. For example, customers who purchase razors and aftershave lotion are also likely to purchase shaving cream. GRI extracts rules with the highest information content based on an index that takes both the generality (support) and accuracy (confidence) of rules into account. (Clementine Users Guide, 2007) [12].

2) Apriori Algorithm: The Apriori node extracts a set of rules from the data, pulling out the rules with the highest information content. Apriori offers five different methods of selecting rules and uses a sophisticated indexing scheme to process large datasets efficiently. For large problems, Apriori is generally faster to train than GRI; it has no arbitrary limit on the number of rules that can be retained, and it can handle rules with up to 32 preconditions. (Clementine Users Guide, 2007) [12].

3) CARMA Method: The CARMA model extracts a set of rules from the data without requiring you to specify In (predictor) or Out (target) fields. In contrast to Apriori and GRI, the CARMA node offers build settings for rule support (support for both antecedent and consequent) rather than just antecedent support [12].

IV. APPLICATION

In this study, we used SPSS Clementine for data mining application. The following procedure was applied:

i. Data collecting: Application is carried out in a supermarket we gathered data from the store. ii. Merge and cleaning: Differences found in the data collected in this step are fixed. Incorrect or analysis that may cause incorrect orientation of the data has been cleared. iii. Data conversion: This step was performed according to the model is transformed into data. Representations or identification of the data used by Apriori algorithm and the analysis model is changed.

After the necessary procedures carried out on the algorithm, we used GRI, Apriori and CARMA algorithm in the application of SPSS Clementine data mining. In SPSS Clementine program, model is solved with 3 types of algorithms. Association rules created in Figure 1, SPSS Clementine model is shown below. For modeling; 10 products are used. Figure 2 shows the 10 items assignment. We use 3 separate algorithms to reach the most accurate rules.
GRI, Apriori and CARMA algorithm the results are given in Figure 1, 2 and 3 below. We also show association rules for each algorithms in Table I, II and III respectively.

GRI algorithm results are presented in the following screen.

![GRI Model](image1)

**Fig.3. GRI Model**

GRI Algorithm based results are in Table I; a customer who buys product e, has 60% probability for buying product d. The possibility of coexistence of these products in shopping vouchers is 14.29%.

Abstract—In this study, a NARMA-L2 Controller based on online support vector regression is utilized to control a nonlinear continuously stirred tank reactor (CSTR) system. The main aim in study is to derive a SVR based NARMA-L2 controller via SVR NARX model of the system. For this purpose, firstly, SVR NARX model of the system is decomposed to its internal dynamics which can be represented via SVR-NARMA-L2 model, and then SVR-NARMA-L2 controller is designed via SVR-NARMA-L2 model of the system. The performance evaluation of the controller has been executed on a continuously stirred tank reactor (CSTR) and the results show that the NARMA controller together with NARMA model attain successful tracking performance with small modeling, transient-state and steady state errors.

Keywords—NARMA-L2 Model - NARMA-L2 Controller - Support Vector Regression - SVR-NARMA-L2 Controller - System Identification

I. INTRODUCTION

Nonlinearity is a significant feature of physical systems which complicates control design and degrades performance. The system model structures which enable to extricate the control signal from nonlinear inner dynamics of system model are very useful to derive model based controllers. NARMA-L2 controller, introduced by Narendra and Mukhopadhyay [2], is one of the most effective neural network controller architectures for nonlinear systems [1]. Basically, in NARMA-L2 model, the nonlinear system model can be represented via two subnetworks where the control signal is extricated from nonlinear dynamics of the system model via Taylor Expansion of the system model [1], [3], [4]. Thus, the NARMA-L2 model of the system can be easily converted to obtain the control signal utilized to compel system output to reference signal and NARMA-L2 controller is directly derived via NARMA-L2 model of the system. The lack of need for an extra network topology to design or train controller as in model reference adaptive control is an important advantage of the NARMA-L2 controller. In technical literature, there are various studies where artificial neural network (ANN) based NARMA-L2 controllers have been successfully used to control nonlinear systems [2], [3], [4], [5], [6], [7]. ANN based NARMA-L2 controllers suffer from modeling inaccuracies since the network topologies which are trained with back propagation algorithm (as in ANN and ANFIS) may get stuck at local minima resulting from their non-convex objective functions and system model is only obtained locally [1]. Therefore, SVM-based controller structures have been frequently deployed to derive model based adjustment mechanisms instead of ANN and ANFIS in recent studies [8], [9], [10], [11], [12], [13], [14], [15], [16], [17], [18], [19], [20], [21], [22]. The NARMA controller includes two submodels which are independent from current control signal applied to the system. The parameters of these submodels in NARMA based on ANN can be easily adjusted without explicit information of the exact outputs of these submodels since backpropagation algorithm and chain rule enable to drive update rules for each parameter of the submodels. To obtain the optimum mapping function in SVR, the input-output training pairs must be available, however outputs of NARMA submodels are not known a priori, so estimating NARMA model with SVR is a hard task [1]. This problem was overcome by deriving the NARX model of the system first, and then obtaining NARMA submodels via NARX model of the system in [1]. In this study, an adaptive NARMA-L2 controller based on SVR previously proposed in [1] is deployed to control the CSTR system. The paper is organized as follows: Section II briefly describes online ε-Support Vector Regression. The basic principles of SVR based-NARMA-L2 model and controller are explained in Section III. In section IV, tracking performance evaluation of the controller has been examined on nonlinear CSTR system. The paper ends with a brief conclusion in Section V.

II. ONLINE ε-SUPPORT VECTOR REGRESSION

Consider a training data set:

$$T = \{x_i, y_i\}_{i=1}^{N} \quad x_i \in \mathbb{X} \subseteq \mathbb{R}^n, \ y_i \in \mathbb{R}$$

(1)

where \(x_i\) is the \(i^{th}\) input data and \(y_i\) is the corresponding output value, \(N\) is the size of the training data and \(n\) is the dimension of the input space. The relationship among training data set in (1) can be represented via SVR model in (2):

$$\hat{y}(x) = \sum_{i=1}^{N} \lambda_i K(x, x) + b$$ \quad \(\lambda_i = \beta_i - \beta_i^*\)  \quad (2)

where \(\lambda_i\) is the ith Lagrange multiplier; \(K(x, x)\) is the corresponding kernel value of the ith input sample and \(b\) is the bias term [19]. The parameters of the regression function
in (2) are obtained via the following optimization problem:

\[
D = \frac{1}{2} \sum_{i=1}^{N} \sum_{j=1}^{N} (\beta_i - \beta_j^*) (\beta_j - \beta_j^*) K_{ij} + \varepsilon \sum_{i=1}^{N} (\beta_i + \beta_j^*) - y_i \sum_{i=1}^{N} (\beta_i - \beta_j^*)
\]

subject to

\[
0 \leq \beta_i \leq C, \quad 0 \leq \beta_j^* \leq C, \quad \sum_{i=1}^{N} (\beta_i - \beta_j^*) = 0, \quad i = 1, 2, \ldots, N
\]

where \(K_{ij} = \Phi(x_i)^T \Phi(x_j)\) is the kernel value which represents the similarity among the \(x_i\) and \(x_j\) training samples. The training samples are separated into three main subsets depending on their Lagrange and margin values as:

- Error support vectors (E), support vectors (S) and remaining samples (R) [23].

\[
\begin{align*}
E & = \{i \mid |\lambda_i| = C, |h(x_i)| \geq \varepsilon \} \\
S & = \{i \mid 0 \leq |\lambda_i| < C, |h(x_i)| = \varepsilon \} \\
R & = \{i \mid |\lambda_i| = 0, |h(x_i)| \leq \varepsilon \}
\end{align*}
\]

In the incremental online SVR algorithm, when a new training data \(x_c\) is received, its corresponding \(\lambda_c\) value is initially set to zero, which is later updated to \(\Delta \lambda_c\) [19]. Then, the largest possible change \(\Delta \lambda_c\) is calculated while at the same time keeping the system at the equilibrium state with respect to the new KKT conditions [19]. Depending on \(\Delta \lambda_c\), the bias and the Lagrange multipliers of the samples in support set (S) are adjusted. Detailed information related to recursive algorithm can be achieved via [23], [24], [25].

III. NARMA Controller based on Online SVR

A. Controller Design

NARMA-L2 model depicted in Fig. 1(b) can be deployed to identify the nonlinear dynamics of a system in a neighborhood of the equilibrium state [2]. The output of the NARMA-L2 model is given as follows:

\[
\hat{y}_{NARMA} = \hat{f}_n + \hat{g}_n u_n
\]

where \(\hat{f}_n = F_n(x_n)\) and \(\hat{g}_n = G_n(x_n)\) denote the submodels computed by some numerical or intelligent estimator and \(x_n = [u_{n-1} \cdots u_{n-\alpha} \cdots y_{n-n_y+1}]^T\) stands for the current input feature vector of the model where \(n_\alpha\) and \(n_y\) emblematise the number of the past control inputs and system outputs included in the feature vector, \(d\) indicates the relative degree [1]. The main supremacy of NARMA-L2 model is that the control signal \(u_n\) can be easily computed via \(\hat{f}_n = F_n(x_n)\) and \(\hat{g}_n = G_n(x_n)\) submodels by substituting \(r_{n+1}\) in place of \(y_{n+1}\) as follows:

\[
u_n \triangleq \frac{r_{n+1} - \hat{f}_n}{\hat{g}_n}
\]

since it is aimed to compel system to reference signal in closed-loop control [1], [5], [23], [24]. In NN based NARMA-L2 models, the adjustment rules for the weights of the \(F_n(.)\) and \(G_n(.)\) submodels can be easily derived via backpropagation algorithm and chain rule without requiring to know exactly the output of \(F_n(.)\) and \(G_n(.)\) submodels. Since the greatest difficulty of SVR based modelling is the necessity of input-output data pairs and the outputs of \(F_n(.)\) and \(G_n(.)\) are not known exactly, it is difficult to design SVR submodels for \(F_n(.)\) and \(G_n(.)\) separately [1]. Therefore, it has been aimed to derive the parameters of SVR\textsubscript{NARMA}\textsubscript{L2} model via the parameters of the previously obtained SVR\textsubscript{NARX} model of a system as in Fig. 1. Therefore, SVR\textsubscript{NARMA}\textsubscript{L2} which we called as “main model” should be divided to submodels as in Fig. 1(b). Let us assume that the regression function for SVR\textsubscript{NARX} model of the system depicted in Fig. 1(a) at time step \((n-1)\) is given as

\[
\hat{y}_{NARX_n} = \sum_{i=1}^{N} \beta_i K(x_i, x_c) + b_{\beta}
\]

and the corresponding regression functions for \(F_{n-1}(x_{n-1})\) and \(G_{n-1}(x_{n-1})\) are as follows:

\[
\begin{align*}
F_{n-1}(x_{n-1}) &= \sum_{i=1}^{N} \alpha_i K(x_i, x_{n-1}) + b_f \\
G_{n-1}(x_{n-1}) &= \sum_{i=1}^{N} \theta_i K(x_i, x_{n-1}) + b_g
\end{align*}
\]

Thus, output of the SVR\textsubscript{NARMA}\textsubscript{L2} model can be acquired as:

\[
\hat{y}_{NARMA_n} = F_{n-1}(x_{n-1}) + G_{n-1}(x_{n-1}) u_{n-1} = \sum_{i=1}^{N} \left[ \alpha_i + \theta_i u_{n-1} \right] K(x_i, x_{n-1}) + b_f + b_g u_{n-1}
\]
In order to attain a relation between SVR$_{NARMA-L2}$ and SVR$_{NARX}$, (8) and (10) can be equalized as follows:

$$\hat{y}_{NARX_n} \equiv \hat{y}_{NARX_n}$$

$$\sum_{i=1}^{N} \beta_i K(x_i, x_{n-1}) + b_\beta = \sum_{i=1}^{N} \left[ \alpha_i + \theta_i u_{n-1} \right] K(x_i, x_{n-1}) + b_f + b_g u_{n-1}$$

$$\beta_i = \alpha_i + \theta_i u_{n-1}, \ b_\beta = b_f + b_g u_{n-1}$$

The following assumption has been proposed to utilize this relation effectively and to approximate the parameters of the submodels by this approach[1].

**Assumption:** Let us consider that the following relations exist between the parameters of the submodels:

$$\alpha_i = \mu_1(.) \theta_i, \ b_f = \mu_2(.) b_g$$

Utilizing (17) and (13), the bias and the lagrange multipliers of the SVR$_{NARMA-L2}$ submodels $F_{n-1}(x_{n-1})$ and $G_{n-1}(x_{n-1})$ are obtained with respect to parameters of SVR$_{NARX}$ model as follows for the given values of $\mu_1(.)$ and $\mu_2(.)$:

$$\theta_i = \frac{\beta_i}{\mu_1(.) + u_{n-1}}, \ \alpha_i = \mu_1(.) \theta_i$$

$$b_g = \frac{b_\beta}{\mu_2(.) + u_{n-1}}, \ b_f = \mu_2(.) b_g$$

As mentioned before, the outputs of the submodels can be computed depending on the model parameters adjusted at the previous step (n-1) since the model parameters of $F_n(.)$ and $G_n(.)$ are not known at time step n. Therefore, the output of the submodels at prediction phase can be expressed as follows:

$$\hat{f}_n \equiv F_{n-1}(x_{n-1}), \ \hat{g}_n \equiv G_{n-1}(x_n)$$

where subscript “—” in (15) indicates that the models obtained in the previous time step n-1 are updated with the current state vector $x_n$ to obtain $\hat{f}_n$ and $\hat{g}_n$ [1]. Similarly, “+” in $\hat{f}_n^+$ and $\hat{g}_n^+$ indicate that the model trained in current step (n) has been deployed together with the current state vector $x_n$ as follows [1]:

$$\hat{f}_n^+ \equiv F_n(x_n), \ \hat{g}_n^+ \equiv G_n(x_n)$$

Thus, the control signal ($u_n$) produced by SVR$_{NARMA-L2}$ controller can be given as:

$$u_n \equiv r_{n+1} - \hat{f}_n^-$$

where $\hat{f}_n^- = F_n(x_n)$ and $\hat{g}_n^- = G_n(x_n)$ and $x_n = [u_{n-1} \cdots u_{n-n} \cdots y_{n} \cdots y_{n-n+1}]^T$. In a nutshell, SVR$_{NARMA-L2}$ controller can be derived without knowing the output of the submodels $F_n(.)$ and $G_n(.)$ separately. The structure of the proposed controller is depicted in Fig. 2 where $y_{n+1}$ is the output of the system, $\hat{y}_{n+1}$ is the estimated system output, $r_{n+1}$ indicates the reference signal and $u_n$ is the control signal produced by the controller.

**B. Adaptive Predictive SVR$_{NARMA-L2}$ Controller with Adaptive Filter**

NARMA controller generally produces a control signal with more oscillation and chattering compared to other controllers such as MRAC, MPC etc. [5]. Therefore, the unmodeled high frequency dynamics of the system can be excited in the case that the high frequency components of the signal are not filtered. For this purpose, the control signal can be filtered in order to reduce chattering and oscillation in control signal [5]. Therefore, the following first order adaptive low pass filter with an adjustable parameter is utilized

$$H(z) = \frac{u_{f_n}}{u_{c_n}} = \frac{q_{0_n}}{1 + (1 - q_{0_n})z^{-1}}$$

where $1 - q_0$, $q_0$ are “feed-backward” and “feed-forward” coefficients of the filter respectively [1]. The closed-loop tracking performance of the controller directly hinges on the decomposition parameters ($\mu_{j}(.)$, $j \in \{1, 2\}$) utilized to obtain SVR$_{NARMA-L2}$ submodels as well as the filter parameter ($q_0$). A predictive structure which conceives the K-step ahead future behaviour of controlled system has been deployed to adjust both $\mu_{j}(.)$, $j \in \{1, 2\}$ and $q_0$ parameters effectively as in Fig. 3. The objective function in (19) is used to adjust $\mu_{j}(.)$, $j \in \{1, 2\}$ and $q_0$ parameters via Levenberg-Marquard algorithm [25]

$$E(\theta) = \frac{1}{2} \sum_{k=1}^{K} \epsilon_{n+k}^2 + \frac{1}{2} \lambda [u_n - u_{n-1}]^2$$

where $\epsilon_{n+k} = r_{n+k} - \hat{y}_{n+k}$. The adjustable parameters can be optimized as follows:

$$\begin{bmatrix} \mu_{1_{new}} \\
\mu_{2_{new}} \\
q_{0_{new}} \end{bmatrix} = \begin{bmatrix} \mu_{1_{old}} \\
\mu_{2_{old}} \\
q_{0_{old}} \end{bmatrix} + \begin{bmatrix} J^T \end{bmatrix} \begin{bmatrix} J \end{bmatrix}^{-1} J^T \epsilon$$

where

$$J = \begin{bmatrix} \frac{\partial y_{n+k+1}}{\partial u_{f_n}} \\
\vdots \\
\frac{\partial y_{n+k}}{\partial u_{f_n}} \end{bmatrix} q_{0_n - \frac{b}{g_n}} - q_{0_n - \frac{b_n}{g_n}} (u_n - u_{f_n - 1})$$

The components of the system Jacobian matrix $J_m$ are given as:

$$\frac{\partial y_{n+k}}{\partial u_n} \approx \frac{\partial f_n(c_{n+k})}{\partial d_{n+k,j}} \frac{\partial d_{n+k,j}}{\partial u_n} + \frac{\partial g_n(c_{n+k})}{\partial d_{n+k,j}} \frac{\partial d_{n+k,j}}{\partial u_n}$$

$$\frac{\partial f_n(c_{n+k})}{\partial d_{n+k,j}} = -\frac{1}{2 \sigma^2} \sum_{j \in SV} \alpha_j \exp\left(\frac{-d_{n+k,j}}{2 \sigma^2}\right)$$

$$\frac{\partial g_n(c_{n+k})}{\partial d_{n+k,j}} = -\frac{1}{2 \sigma^2} \sum_{j \in SV} \theta_j \exp\left(\frac{-d_{n+k,j}}{2 \sigma^2}\right)$$

and $\frac{\partial d_{n+k,j}}{\partial u_n}$ is detailed in [1].
IV. SIMULATION RESULTS

The performance evaluation of the controller has been realized on a continuously stirred tank reactor system (CSTR). CSTR is a type of chemical reactor where isothermal, liquid-phase, successive multicomponent chemical reactions can be uniformly realised [29], [30], [31]. Kravaris and Palanki [29] expressed the dynamics of the system as follows:

\[
\begin{align*}
\dot{x}_1(t) &= 1 - x_1(t) - Da_1 x_1(t) + Da_2 x_2^2(t) \\
\dot{x}_2(t) &= -x_2(t) + Da_1 x_1(t) - Da_2 x_2^2(t) - Da_3 d_2 x_2^2(t) + u(t) \\
\dot{x}_3(t) &= -x_3(t) + Da_3 d_2(t) x_2^2(t)
\end{align*}
\]

(24)

where \( x_1(t), x_2(t) \) and \( x_3(t) \) are states obtained from the concentrations of reactant A, middle reactant B and product.
Fig. 4. System Output (a), Control Signal (b), number of support vectors (c), adaptive controller (d,e) and filter parameters (f).

Fig. 5. System Output (a), Control Signal (b), number of support vectors (c), adaptive controller (d,e) and filter parameters (f).
The robustness of the controller is examined under varying reaction conditions, so $d_2(t)$ is selected as the time varying parameter. In simulations, it has been observed that the controller performance is adequate to successfully manage to control system under parametric uncertainty. If the control signals in Fig. 4(b) and Fig. 6(b) are compared, it is observed that the controller produces a control signal which varies to compensate the parametric uncertainty. It can also be deduced that the number of the support vectors increase in order to identify the uncertainty.

**V. CONCLUSION**

In this paper, a novel NARMA-L2 controller is proposed where online support vector regression is used to form submodels of NARMA-L2 controller. $\text{SVR}_{\text{NARMA-L2}}$ is employed to approximate the system model, then the parameters of the $\text{SVR}_{\text{NARMA-L2}}$ model and $\text{SVR}_{\text{NARMA-L2}}$ controller are derived via $\text{SVR}_{\text{NARX}}$ model of the system. The main contribution of the paper is that it justifies the use of an online $\text{SVR}_{\text{NARX}}$ model of the system directly to derive online $\text{SVR}_{\text{NARMA-L2}}$ controller as opposed to existing works in technical literature where $\text{SVR}_{\text{NARX}}$ models are generally utilized for adjusting the parameters of the traditional controllers by approximating system Jacobians. The performance of the controller is examined on CSTR system. The robustness of the controller against system parameter uncertainty and measurement noise have been examined. The results indicate that the proposed controller is quite successful in attaining low tracking error, suppressing measurement noise and parametric uncertainties. In future works, it is planned to extend the derivation of $\text{SVR}_{\text{NARMA-L2}}$ model via $\text{SVR}_{\text{NARX}}$ to develop new SVR type adaptive controller design methods.

DEFINING THE PLANTATION ROLE TO MITIGATE THE URBAN HEAT ISLAND EFFECTS ON GLOBAL WARMING USING THERMAL SATELLITE SENSOR

Onur ŞATIR
Yazuncu Yil University Agriculture Faculty Department of Landscape Architecture Van, Turkey. osatir@yyu.edu.tr

Abstract— Urban heat island (UHI) is one of the major effects on climate change based on human activities. Each land use/land cover (LULC) has an own temperature on the ground according to the structural characteristics (built up material), areal diversity (cover degree) and land physical dynamics (topography). Nowadays, many optical satellite sensors can record the thermal wavelength that is coming from the land surface and land surface temperature (LST) may be defined as degree using some allocation equations. Purpose of this research is to detect the plantation effects to mitigate UHI effect. In this extent, Landsat, thermal satellite sensor used to obtain planted and non-planted area thermal characteristics in same physical conditions. Plant effects were evaluated considering plant species on mitigation of global warming. Adana city that is located in Southern Turkey was used to be sample plot because of high potential on plant species and hot and dry climatic characteristics. As a result of the study, particularly, deciduous trees were reduced UHI effect more than conifers and Citrus sp, and Eucalyptus sp mitigation effects were found as 6.4 °C and 6.6 °C respectively. On the other hand, conifers were less effective than deciduous trees and Pinus brutia mitigation effect was calculated to be 5.6 °C. Additionally, irrigated grasslands were mitigated the UHI worse than other plant covers and temperature difference between bare ground and grasslands were 4.3 °C. In this frame, true plantation strategies were suggested to mitigate UHI effects.

Keywords— Urban heat island effect, Land use/cover, Climate regulation, Plantation, Landscape design

I. INTRODUCTION

Green vegetation cover has an important role in urban areas. Some of the many benefits of urban green spaces are: air and water purification, mitigation of the impact of environmental pollution, carbon sequestration, regulation of microclimate, habitat for urban wildlife, recreational, spiritual and therapeutic value as well as social integration [1-2-3].

Urban heat island is one of the most known issue on anthropogenic effect of global warming. Urban areas have an artificial characteristics because of built up materials such as concrete, asphalt and metallic structures [4]. Built up material can be warm more than water and vegetative surfaces. In addition to this, high “C” and CH₄ based gases keep warm air around the city atmosphere. So air temperature and LST of built up areas are generally more than around.

LULC types of the surface is of significant effect on UHI and lots of the study investigated that plant cover reduced UHI effects according to the cover degree and types [5-6]. Satellite remote sensing plays a vital role about defining land use/cover and monitoring dynamics between nature and human. Additionally, remote sensing provides time, energy and cost saving [7]. Thermal remote sensing is used widely to derive daytime and night time LST in many purposes. However, UHI detection is always one of the top issues in remote sensing studies. Particularly, ASTER, Landsat and TERRA-MODIS sensors were the most popular thermal sensors in the literature on UHI detection [8-9].

The purpose of this study is to obtain the plantation effects on UHI in plant type scale. Plant types were detected using high resolution aerial photos (HRAP) (0.45m), and UHI mitigation effect of the plants were compared each other at the same physical conditions (topography, air temperature and close location).

II. STUDY AREA AND DATA

A. Study Area

Adana city that is located in Southern Turkey was selected to be study area because of high temperature (53 °C max. and -6 °C min.) and population (1.71 million in the city) [10-11]. Adana is the 6th populous city of Turkey and region has a very good soil and climate characteristic for the sub-tropic plants and agriculture and there are almost 25m² total green areas (private and open) per person [12] (Fig. 1).
B. Dataset

Two main dataset were used to be Landsat Thematic Mapper (TM) thermal data and high resolution aerial photos (HRAP) of the study area. Landsat TM satellite has 30m spatial, 8 bit radiometric and almost 16 days temporal resolution. Landsat TM thermal sensor has 120m spatial resolution. However, it combined with other wavebands in false 30m spatial resolution [13]. August 2010 thermal TM data was used to obtain LST of each LULC

HRAP data was recorded in August 2009 by the Turkish Air Force Mapping Unit. One photo from the Adana City Centre was used in 45cm spatial resolution in visible range to define LULC and plant species. Red pine (Pinus brutia), Sour orange (Citrus sp.), Eucalyptus (Eucalyptus camaldulensis), and irrigated grasslands were studied to see the mitigation effect on UHI (Fig. 2).

III. METHODOLOGY

Method is contained three main stages; A) thermal image processing to obtain LST from Landsat TM data, B) digitalize the various land use and covers from HRAP, C) compering the mitigation effect of green and non-green cover areas.

A. Thermal Image Processing

Landsat TM thermal waveband shows LST in 8 bit data format as digital number (DN) value. Thermal DN values must be converted to blackbody temperature. The conversion process used is based on a look-up table published in Bartoliucci and Chang, (1988) [14]. Blackbody temperature is not a real LST, so it should be multiplied by emissivity constant of the surface material. According to Lillesand and Keifer, (1994) [15], vegetative surfaces and concrete and asphalt surfaces constants were between 0.9 and 0.96 respectively. However, this value is variable based on tree types and cover types, so application of the emissivity constant to blackbody temperature can be increase the error of the study. Therefore, blackbody temperatures were used alone to define the plantation effect to UHI.

B. Manuel Digitalize the LULCs

Four main plantation areas (red pine, eucalyptus, sour orange and grassland) and bareground (bare soil), asphalt, old built up and new built up areas were defined in geographical information system (GIS) environment from HRAP. Location of the each LULC was visited to find the pure areas.

Red pine is a typical Mediterranean forest tree and it has been used as afforestation inside and around the city. Eucalyptus was used to dry swamp areas, but today there is no flood risk anymore, and these areas has a shadow effect, particularly around recreational areas. It is not a very good tree for landscape design because of limitation on week body structure, and woods may fall in a windy weather easily. Sour orange tree is a landmark of the Adana city, and this region is provided 10% of the citrus production of Turkey. Additionally, sour orange trees are used in plant design frequently, especially near by the pavement roads. Grasslands are mostly irrigated human made areas in recreational places and house gardens. Baregrounds are open spaces or empty agricultural areas in the city. Asphalt refers roads and some big open land like school gardens or bazaar areas. Built up areas classified two part to be old and new. Old built up areas constructed in 1950s and 1960s. These lands haven’t too much space and streets are too narrow. New built up areas built in 2000s and there are big spaces between apartments.

C. Defining the Mitigation Effect

Mitigation effect of the plants were defined compering difference between bare grounds, urban built up and planted areas in plant type scale. So that not only plantation effect was detected, but also other LULC LST values were defined in same conditions such as asphalt, old and new urban built up and bare ground.
IV. RESULTS

Results were introduced in three part for better understanding the UHI mitigation effect of plantation; A) hard surfaces thermal characteristics, B) Thermal characteristics of planted areas and C) UHI mitigation analyses of the plantation.

A. Hard Surface Thermal Characteristics

Asphalt, baregrounds, old and new urban built up areas were defined as hard surfaces. These lands are typical urban areas, and one of the major reason of UHI effect is hard surfaces in the city. To detect the mitigation effect of plantation, we have to know thermal characteristics of the hard surfaces primarily.

Four sample plot has been selected to perform hard surfaces temperatures. Asphalt area was selected from a school garden because of enough bigness to match with TM thermal sensor. Bareground is an empty agricultural area just inside the city. Old and new built up areas located in old city and new city centres. Selected plot thermal values and descriptive statistics were shown in Fig. 3 and Table 1. The highest LST was observed in bareground as 40.8 °C mean value and the lowest LST was 37.2 °C in new urban built up areas. Standard deviation of the old built up areas around 1.04 °C and it was mean that variability of the old city areas were higher than other hard surfaces because of irregular urbanization.

B. Thermal Characteristics of Planted Areas

A Red pine woodland, an eucalyptus woodland, sour orange garden and grassland area in the central park location were selected as sample plots. Descriptive statistics the thermal characteristics of these lands and LST values were presented in Fig. 4 and Table 2. The lowest LST value was observed in eucalyptus woodland to be 34.2 °C and the highest value was 36.6 °C in grassland areas. Standard deviation of the eucalyptus woodlands were higher than other plantation areas. Because, eucalyptus trees are located in riverside and some pixels were effected from cooling effect of the river due to mixed pixel effect. Some of the eucalyptus pixels were ignored in difference analyse and pure pixels were used.

C. UHI Mitigation Analyses of the Plantation

Mean LST values of the each LULC was defined and mitigation effects on UHI were obtained. The mitigation effects of the plants were defined for eucalyptus (Eucalyptus camaldulensis), sour orange (Citrus sp.), red pine (Pinus brutia) and grassland area to be 6.6 °C, 6.4 °C, 5.6 °C and 4.3 °C respectively. Eucalyptus woodlands were the best to mitigate the UHI effect in Adana City, and sour orange also has a significant effects on UHI mitigation. Both trees are deciduous evergreen trees and effects of them are higher than other because of leaf areas and leaf water and chlorophyll a content. On the other hand, red pine is a conifer tree and leaf cover, water and chlorophyll content are less than deciduous trees. Irrigated grasslands are located in the recreational areas such as urban parks and roadsides and private house gardens generally. However, mitigation UHI mitigation effect was not as significant as trees (Table 3).

V. CONCLUSIONS

This paper focussed on the plantation effect to mitigate the UHI using remote sensing and GIS technologies. There were several research on UHI and surface material thermal characteristics using remote sensing or meteorological measurements in the literature [16-17-4]. This research is outshined from others in plant type scale. In this extent, site specific thermal data from planted areas were evaluated about UHI mitigation. Eucalyptus, red pine, sour orange and grassland areas were selected sample plots and compared with hard surfaces based on thermal characteristics.

In conclusion, evergreen deciduous trees (eucalyptus and sour orange) were found the best plants to mitigate UHI effect. Sour orange is a symbol plant of the Adana City and it may be used around the main roads frequently to reduce UHI effect. Eucalyptus is not a popular tree for the urban landscape because of weak body structure and it may be broken easily in windy weather. However, it used in plantation to dry swamp areas in the past, and now these trees are a part of the urban landscape. Red pine is a typical natural plant of the Mediterranean zone of Turkey also it is called as Turkish pine too. This tree can be used as afforestation tree in huge open areas to establish big recreational places near the city. Irrigated grasslands shouldn’t be preferred too much in urban landscape to provide cooling effect. Additionally, it needs water regularly in hot summer times and this is not good for water economy. Some alternative plant materials can be preferred instead of grasslands like perennial shrubs or little trees to cover the surface efficiently against UHI.

An Integrated Approach for Sustainable Supplier Selection in Fuzzy Environment

Ahmet Alp Şenocak*, Hacer Güner Gören*

*Pamukkale University, Department of Industrial Engineering, 20070, Denizli, Turkey
{asenocak, hgoren}@pau.edu.tr

Abstract—The term sustainability, which means maintaining a balance or acting responsibly for the future, has come into prominence in many fields. One of the most crucial practices is cooperating with convenient collaborators and composing effective supply chains in terms of social, economic and environmental considerations. Therefore, sustainable supplier selection is getting more and more important to compete in rapidly changing environment. To deal with sustainable supplier selection problem, this study aims to determine the selection of appropriate suppliers and allocation of orders to them. The proposed approach operates in three stages. In the first stage, Fuzzy Decision Making Trial and Evaluation Laboratory is used to obtain the weights of the criteria considering sustainability perspective. In the second stage, by using Fuzzy Grey Relational Analysis, a set of suppliers are ranked and their suitability scores are calculated. In the last stage, optimal order quantities to be provided by the suppliers are obtained via fuzzy linear programming including imprecise data of demand, error rate and capacity.

Keywords—Sustainable supplier selection, fuzzy logic, DEMATEL, grey relational analysis, fuzzy linear programming

I. INTRODUCTION

Nowadays, it has been obligatory to analyze customers' requirements precisely and meet the demand in short time. While meeting the demand, the production technology should also be considered and improved to gain flexibility in production process. Moreover, the limited resources of the world should be utilized effectively considering the future. Companies should make the decisions taking into account economic dimension of sustainability as well as social and environmental dimensions. Sustainable supplier selection problem, the main topic of our study, means to select the suppliers in an effective way to provide sustainability with all dimensions.

This study which proposes an integrated approach for sustainable supplier selection is organized as follows. In section two, a literature review on the relevant subject is presented. In section three, the problem and the proposed approach are explained. The implementation of the proposed methodology is illustrated in section four. In the last section, the paper is concluded with some future research directions.

II. LITERATURE REVIEW

In today’s highly competitive business life, profitability of the company has direct relation with its own source consumption and internal productivity, as well as the effectivity of the overall supply chain. Therefore, supplier selection and supplier performance evaluation are the key elements for composing effective supply chains. In the literature, numerous studies exist on supplier selection problem. The problem includes more than one criterion and with this aspect it is an example of multi criteria decision making (MCDM) problems. For addressing the solution of the problem, different MCDM methods have been applied.

Sustainable supplier selection has been a prominent topic since the middle of 1990s. Brandenburg et al. [1] and Zimmer et al. [2] reviewed the literature of the mathematical models for sustainable supplier management in detail. They also summarized the sustainable supplier management approaches into two groups such as integrated models and single models which consist of qualitative, mathematical programming, mathematical analytical, artificial intelligence [2]. Azadi et al. [3] and Yousefi et al.[4] applied robust dynamic and fuzzy data envelopment analysis method for sustainable supplier selection problem. Trapp and Sarkis [5] proposed an optimization model using binary integer programming for simultaneous supplier selection and development. Orji and Wei [6] added the time dimension to decision making process and suggested a dynamic framework consisting of system dynamics and simulation for selecting appropriate suppliers considering sustainability factors. The results of the proposed approach were compared to the results derived from TOPSIS method. Su et al. [7] assumed that there can be incomplete information throughout the decision making process and proposed an approach to compensate incomplete information using grey theory and applied DEMATEL. Amindoust et al. [8] and Ghadimi and Heavey [9] implemented fuzzy inference system to determine the suitable suppliers. Azadnia et al. [10] proposed an integrated approach based on fuzzy AHP, neural networks, clustering and TOPSIS. Shaw et al. [11] proposed an integrated approach using fuzzy AHP to calculate the weights of the criteria and fuzzy multi-objective linear programming model to allocate the orders. Büyükozkkan and Çifçi [12] developed an integrated methodology using fuzzy ANP, DEMATEL and TOPSIS for sustainable supplier evaluation and selection. Bai and Sarkis [13] suggested a supplier evaluation model based on rough set theory and grey system theory to deal with the information vagueness.

The literature review has stated that the importance of sustainable supplier selection problem has increased recently. To find a solution to this problem, most studies have focused on integrated approaches instead of single models. Another assessment from the review is that fuzziness and vagueness in decision making process is substantially taken into consideration. Motivated from these inferences, we propose an
integrated fuzzy approach for this problem. The proposed approach first determines the appropriate sustainable suppliers and then allocates the orders to these suppliers. The details are given in the following section.

III. THE PROPOSED INTEGRATED METHODOLOGY

This study integrates fuzzy DEMATEL, fuzzy grey relational analysis and fuzzy linear programming to solve sustainable supplier selection problem and operates in three stages. In the first stage, we used fuzzy DEMATEL to calculate the weights of the criteria. In the second stage, fuzzy grey relational analysis was used to rank suppliers according to sustainability dimensions. In the third stage, the weights of the suppliers which were calculated in the previous stages, were incorporated into the fuzzy linear programming model to obtain the optimum order sizes of the appropriate suppliers. The main steps of the proposed integrated approach are shown in Fig.1.

IV. A CASE STUDY

In this section, the illustration of the proposed model is shown. This study particularly focuses on the sustainable supplier selection problem of an online retailer store located in Canada that works with different travertine-marble suppliers located in Turkey. Recently, it needs to search for sustainable, reliable and constant suppliers due to the problems about orders faced with the previous suppliers. Within this scope, three most demanded products and four possible suppliers are determined. Before the application of the proposed approach, the criteria which are used for supplier selection considering sustainability factors are determined. Therefore, the criteria are determined based on triple bottom line [14] and explained in Table 1.

A. Fuzzy Decision Making Trial and Evaluation Laboratory (DEMATEL) Implementation

DEMATEL method is mainly based on graph theory and was conducted by Geneva Research Centre of the Battelle Memorial Institute [17]. DEMATEL is a comprehensive method for building and analysing a structural model involving causal relationships between complex factors [7]. This aspect helps the decision maker to reveal and visualize the interdependence relationships between criteria and sub-criteria. Furthermore, it lets the decision process come to a conclusion relatively easily and reliably. The basic steps and application of fuzzy DEMATEL method is described as follows.

Each criterion which is determined based on sustainability dimensions is written throughout columns and rows. Elements of the matrix show the pairwise comparison values of the criteria and are determined by means of linguistic variables. In this part we used the linguistic scale shown in Table 2.

The direct relation matrix (A) is established according to the expert’s remarks and shown as follows.

The normalized direct relations matrix is obtained [19] and shown partly in Eq. (2).

Once the normalized direct relation matrix is obtained, the total relation matrix is established [19]. Total relation matrix can be separated into separate sub matrices i.e., $X_l$, $X_m$, $X_s$ to overcome the following defuzzification process easily. To illustrate this step, Eq. (3) is given which includes $X_l$ and $T_l$ matrices.

Several methods can be used for defuzzification process but we adopted an extensive defuzzification method of converting fuzzy data into crisp scores (CFCS) which was introduced by Opricovic and Tzeng [20]. The steps of defuzzification process consist of normalization, right and left hand side normalized values, total normalized value and crisp values. The application of defuzzification illustrated partly in Table 3.

The next step includes calculating the sum of rows and the sum of columns separately denotes as vectors D and R within the total relation matrix. The weights of the criteria are obtained via D and R values [19] and shown in Table 4.

B. Fuzzy Grey Relational Analysis (GRA) Implementation

Grey relational analysis method is mainly based on grey system theory which was introduced by Deng and used to show the correlations between the references and alternatives of a system [21]. The basic steps and application of fuzzy GRA method is described as follows.

The method starts with generating the decision matrix which shows the evaluation of the suppliers according to decision maker. The linguistic scale which is used in this part is shown in Table 5.

<table>
<thead>

</tbody>
</table>

The normalized decision matrix is obtained [22] and shown partly in Eq. (4).

\[
x = \begin{pmatrix}
(0.571429, 0.785714, 1) & (0.222222, 0.308889, 0.555556) & \cdots & (0.222222, 0.488889, 0.555556) \\
(0.571429, 0.785714, 1) & (0.488889, 0.555556, 1) & \cdots & (0.488889, 0.656565, 1) \\
(0.571429, 0.785714, 1) & (0.444444, 0.611111, 0.777778) & \cdots & (0.444444, 0.666667, 0.833333) \\
(0.571429, 0.785714, 1) & (0.444444, 0.666667, 0.833333, 1) & \cdots & (0.444444, 0.666667, 0.833333, 1)
\end{pmatrix}
\] (4)

The reference series are obtained [22] and shown partly in Eq. (5).

\[
\tilde{r} = \begin{pmatrix}
(0.571429, 0.785714, 1), (0.666667, 0.833333, 1), \cdots , (0.666667, 0.833333, 1)
\end{pmatrix}
\] (5)

The distance between the reference value and each comparison value is computed [22]. The grey relational coefficient is calculated [22] via the distance matrix and grey relational coefficient matrix shown partly in Eq. (6).

\[
\gamma = \begin{pmatrix}
1 & 0.466666 & 0.520038 & 1 & 0.486638 & \cdots & 0.486638 \\
1 & 1 & 1 & 0.685101 & 1 & \cdots & 1 \\
1 & 0.654602 & 0.685101 & 0.520038 & 0.654602 & \cdots & 0.654602 \\
1 & 0.654602 & 0.520038 & 0.520038 & 0.654602 & \cdots & 0.654602
\end{pmatrix}
\] (6)

In the last step of fuzzy GRA, the elements of grey relational coefficient matrix are multiplied by the weights of the criteria which was obtained from DEMATEL method. The grey relational grades which shows the importance values of the suppliers are shown in Table 7.

C. Fuzzy Linear Programming Implementation

Each element of classical linear mathematical models has certain values and these models consist of parameters, decision variables, objective function and constraints. Fuzzy linear programming mathematical models consist of the same components but they have fuzziness and vagueness in it. As a result of that, they have different ways to solve the models [23]. In our study, we have vagueness in capacities, error rates and demands which compose the right hand side values of constraints. Therefore, the most suitable fuzzy linear model for our problem is the approach which was introduced by Verdegay [24]. This method is a non-symmetric model and needs to conversion to parametric programming decision model [25].

1) Index:
- \( i \): Supplier
- \( j \): Product

2) Decision Variable:
- \( A_{ij} \): Amount of product \( j \) provided by supplier \( i \)

3) Parameters:
- \( N \): Number of suppliers \((N=4)\)
- \( M \): Number of products \((M=3)\)
- \( w_i \): The grey relational grade of supplier \( i \) \((w_1=0.190, w_2=0.307, w_3=0.268, w_4=0.235)\)
- \( D_j \): The demand of product \( j \) \((D_3=300, D_3=400, D_3=600)\)
\( C_i \): The capacity of supplier \( i \) for the company \( (C_1=400, C_2=500, C_3=200, C_4=450) \)

\( q_i \): The error rate of supplier \( i \) \( (q_1=0.12, q_2=0.06, q_3=0.08, q_4=0.09) \)

\( Q_j \): The desired error rate for product \( j \) \( (Q_1=0.10, Q_2=0.08, Q_3=0.09) \)

4) Objective Function:

The objective function of the model aims to maximize the value of purchasing (TVP) and shown by Eq. (7).

\[
\text{Max} Z = \sum_{i=1}^{N} \sum_{j=1}^{M} (A_j \times w_j)
\]

5) Constraints:

Eq. (8) illustrates the demand of each product is satisfied. Eq. (9) shows the equality of the sum of products provided by supplier and the capacity of related supplier. Eq. (10) guarantees to maintain supplier’s error rate below than desired error rate for the product. Eq. (11) shows that the decision variables are positive integers.

\[
\sum_{j=1}^{M} A_j \geq D_j \quad \forall j \in M
\]

\[
\sum_{j=1}^{M} A_j \leq C_i \quad \forall i \in N
\]

\[
\sum_{j=1}^{M} (q_j \times A_j) \leq (Q_j \times D_j) \quad \forall j \in M
\]

\[ A_j \geq 0 \]

After the construction of the model, tolerances for demand, capacity and error rate are determined via decision maker’s remarks. The tolerances are respectively 100 units, 100 units and 0.5. Ten membership functions for the right hand side values are obtained from the tolerances. The first membership function is shown in Eq. (12).

\[
\mu(z) = \begin{cases} 
1 & A_1 + A_2 + A_3 + A_4 < 300, \\
\frac{1 - (A_1 + A_2 + A_3 + A_4) - 300}{100} & 300 \leq A_1 + A_2 + A_3 + A_4 \leq 400, \\
0 & A_1 + A_2 + A_3 + A_4 > 400, 
\end{cases}
\]

\( \lambda \) cuts are determined for the right hand side values. Then mathematical model is converted to parametric linear model via \( \theta=(1-\lambda) \) transformation. The final mathematical model is shown in Eq. (13).

\[
Z = \sum_{i=1}^{N} \sum_{j=1}^{M} (A_j \times w_j) \rightarrow \text{Maximum}
\]

\[
\begin{align*}
A_1 + A_2 + A_3 + A_4 &= 300 + 100\theta \\
A_1 + A_2 + A_3 + A_4 &= 400 + 100\theta \\
A_1 + A_2 + A_3 + A_4 &= 500 + 100\theta \\
A_1 + A_2 + A_3 + A_4 &= 600 + 100\theta \\
A_1 + A_2 + A_3 + A_4 &\leq 30 + 300 \times 0.05\theta \\
A_1 + A_2 + A_3 + A_4 &\leq 32 + 400 \times 0.05\theta \\
A_1 + A_2 + A_3 + A_4 &\leq 54 + 600 \times 0.05\theta 
\end{align*}
\]

Parametric linear programming model was solved in LINDO 6.1 for different \( \theta \) values and the order quantities which are shown in Table 8 are obtained.

The decision maker has different alternatives for the selection of suppliers within tolerances. According to different levels of demand, capacity and error rate, the quantities of products to be provided by the suppliers can be determined from Table 8.

V. CONCLUSIONS

In this paper, an integrated approach is proposed for sustainable supplier selection problem using fuzzy DEMATEL, fuzzy GRA and fuzzy linear programming. The weights of the criteria based on sustainability dimensions are determined via DEMATEL. The importance values of suppliers are calculated using GRA. These outputs are used as inputs for fuzzy linear programming model and the quantities of products to be provided by the suppliers were obtained. For future research, a multi-objective mathematical model considering the minimization of total costs can be built to obtain a more realistic outcome. Another interesting research direction can be to add more realistic constrains such as carbon gas emissions into the models.

Abstract—In this study, we realized a controller design which can reduce torque ripple of 10/8 Switched Reluctance Motor (SRM). To perform the study, a Switched Reluctance Motor with 5 phase, U type segmental rotor was used. The control of the SRM was actualized by bipolar converter used H-bridge topology. The control signals of converter are obtained by control circuit designed by using dsPIC33E (PS12MU810). One of the reasons of the current ripples in the SRM is the ON-OFF times in a period of the control signals. When the ripples of the current reduced, the ripple of torque of the SRM also reduced. Therefore, in this study, the ON-OFF times in a period of phase control signals were determined by an algorithm used particle swarm optimization. When SRM was controlled by this algorithm developed, the decreasing of its torque ripples was determined.

Keywords—Segmental Type Switched Reluctance Motor, H-Bridge Converter, dsPIC33, Torque Ripple, PSO

I. INTRODUCTION

Switched Reluctance Motors (SRM) are the electrical machines which have been used widely in recent years. They have a simple and enduring structure, low-cost, low inertia, high speed, high efficiency and a high performance [1]. Whereas the place of the use of SRMs is increasing, their torque ripples and the acoustic noise are the most important disadvantages for them [2]. In most of the works performed so far, this problem has been tried to be solved through the physical structure of the motor, drive circuit or control circuit. In the works that were carried out, a new 5-phase and U shape SRM with a segmental rotor was designed and it was stated that this new designed SRM produced more torque than the classical SRM [3, 4].

Many studies have been performed to reduce the torque ripple that is the most important problem of SRMs. The ripples in the torque were minimized by using a method called Torque Sharing Function (TSF). In this method, the reference torque value was directly turned into reference analytical wave by analytical method. It is a study performed using this method and arranging triggering angles. Linear and sinusoidal TSF method was used and compared, and the torque ripples were minimized [5]. In the control of 8/6 SRM, the starting and ending angles of the triggering angles of power switches were determined and a new approach was brought [6]. For SRM a direct torque control was recommended with Lyapunov function stability based. The magnetic properties of SRM have an indirect structure (because torque, phase current and rotor positions have complicated positions). Torque ripples were minimized through the method recommended in this study [7]. The effects of the stator pole shape over moment ripples were searched in SRMs. As a result of the studies, a motor design with a high average moment production and with low moment ripples was fulfilled [8]. It is stated that the converter structure that is used in the control of SRM affects the overall performance of the system and the loss of the motor and torque ripples are the factors to be taken into account while evaluating the motor [9]. Besides, another study was also carried out to determine proportion between rotor and stator thread width inside SRM for a high torque and proper output power [10]. By using B-spline neural network (BSNN), torque ripples of the SRM were reduced. Closed loop torque control was performed using an online torque estimator. Because of local weight updating algorithm used for BSNN, a proper phase current profile was obtained as real-time so as to reduce torque ripples and it was expressed that it had a good dynamic performance according to the changes in the desired torque. It was explained that the suggested schema did not require a current controller with high bandwidth and the validity of the schema was shown by simulations and experimental results [11]. Speed regulation was carried out by using Adjustable Fuzzy Cerebellar Model Articulation Controller [12]. ANN model was used to determine the rotor position of SRM. Three methods were compared to each other: Traditional ANN, Developed ANN and the method where developed ANN and curve fitting were used together [13]. Sudden torque control was performed by using linear magnetic model. Torque control was performed by determining commutation angle. It was seen in the results of the simulation and experiment that torque ripple decreased [14]. The speed of SRM was checked by using the method of Takagi-Sugeno-Kang (TSK) Fuzzy Controller [15]. A new stable technique was developed for the speed control applications of Switched Reluctance Motor and the mathematical model of SRM was used in this technique. In this study, Second Order Sliding Mode Control (SOSMC) and a super twisting algorithm schema were used [16]. The speed control of on grid Switched Reluctance Generator that was...
driven by wind turbine was checked by using Adaptive ANN controller [17]. A 5-phase segmental type SRM was designed to increase the torque in SRMs. Also, a bipolar driving strategy was used to increase the torque even more. A traditional full bridge converter was used. A higher torque output was obtained as a result of bipolar driving method [18].

A new SRM was designed by placing auxiliary winding and permanent magnet in the stator yoke of Switched Reluctance Motor. The traditional SRM and newly designed SRM were tested by asymmetrical half-bridge [19]. 50 kW- SRM was designed for hybrid electrical vehicles (Toyota Prius 2003). Designed SRM and stable magnetic synchronous motor were compared. It was seen that the performance of the newly designed SRM was 95% and it reached the targeted torque at the rate of 85% [20]. The vibration and the noise of the motor could be reduced by the changes in the design and control system of the motor and it was also stated that triggering angles affected the torque ripple of the motor [21].

In this study, optimum triggering angle values were determined so as to reduce the torque ripples of the 5-phase 10/8 segmental type SRM (ST-SRM). Particle Swarm Optimization (PSO) was used to determine optimum triggering angles. Triggering angle values which were determined by PSO were applied to H-bridge driving circuit by SnadPIC PIC Microchip Development Board with dsPIC33EP512MU810 on it and ST-SRM was checked as a bipolar. As a result of the experimental study, the effects of triggering style of SRM motor on motor torque was also determined.

II. SEGMENTAL TYPE SWITCHED RELUCTANCE MOTOR

In this study, 10/8 segmental type SRM (ST-SRM) that has a different rotor type from a classical SRM was used. The rotor of the ST-SRM motor consists of both the parcels formed by laminated silicon steel and an aluminium block in which these parcels are placed. The aluminium block that is used in rotor structure functions as a flux barrier and this speciality isolates the motor from classical SRMs. It can be called as U shape segmental type motor because the rotor type of segmental type SRM is U shape. The sectional view of Segmental Type Switched Reluctance Motor is seen in Figure 1 [22].

The features of Segmental Type Switched Reluctance Motor are given at Table 1.

III. INDIRECT MATHEMATICAL MODEL OF SEGMENTAL TYPE SWITCHED RELUCTANCE MOTOR

When magnetic hysteresis loss, Eddy current loss and phase winding are omitted, the mathematical expressions of SRM are given in Equation (1) [23].

\[ V_i = R_k j_k + \left( L_k + j_k \frac{\partial L_k}{\partial \theta} \right) \frac{dj_k}{dt} + j_k \frac{\partial L_k}{\partial \theta} \frac{d\theta}{dt} \] (1)

When phase winding mutual inductance is omitted in Equation (1), \( \theta \) refers to rotor position, \( j_k \) refers to current, \( L_k \) refers to winding inductance for each phase, \( R_k \) refers to phase winding resistance.

The rotor position of the motor can be converted to angular speed as in Equation (2).

\[ \omega = \frac{d\theta}{dt} \] (2)

In this case, when the expression in Equation (1) is written in its place in Equation (2), it is also described as in Equation (3) that is mathematical model of equivalent circuit of SRM.

\[ V_i = R_k j_k + \left( L_k + j_k \frac{\partial L_k}{\partial \theta} \right) \frac{dj_k}{dt} + \omega j_k \frac{\partial L_k}{\partial \theta} \] (3)

In Equation (3), it is seen that the source voltage equals the total of 3 voltages. To show k phase circuit, the first voltage is the voltage drop in the resistance; the second voltage is the transformer electromotive force caused by the changed flux because the current was charged; the third one is about electromechanical energy of SRM caused by the changed flux because the position of the rotor was changed [24].

Torque statement of one phase of SRM is given in Equation (4).

\[ T_e = \frac{1}{2} j_k \frac{dL_k}{d\theta} \frac{d\theta}{dt} \] (4)

In SRMs, m is the phase number and total electrical torque produced in the motor can be calculated as in Equation (5).

\[ T_e = \sum_{k=1}^{m} T_e \] (5)
Mechanical modelling of SRM can be calculated as in Equation (6).

$$T = T_r - T_L = J \frac{d\omega}{dt} + B\omega$$  \hspace{1cm} (6)

In Equation (6), $\omega$ is angular speed, $T_L$ is load torque, $B$ is friction coefficient and $J$ is inertia.

Torque ripple of SRM is calculated as in Equation (7).

$$\%T_{\text{ripple}} = \frac{T_{\text{max}} - T_{\text{min}}}{T_{\text{avg}}} \times 100$$  \hspace{1cm} (7)

IV. ACCURACY OF THE MODELLING

Accuracy is a value that shows how close the calculated value is the measured value. Equation (8) is used for every data value to determine the error value between the value measured and the value that is calculated or estimated.

$$\delta_i = \frac{|R_i - R_{i0}|}{R_i} \times 100$$  \hspace{1cm} (8)

Here $\delta_i$ is the error of each data, $R_i$ is estimated results, $R_{i0}$ is experimental results and $i$ is data index.

Equation (9) is used to determine total errors of whole model.

$$\Delta = \frac{1}{n} \sum\delta_i$$  \hspace{1cm} (9)

Here $\Delta$ is the estimated accuracy of the model, $n$ is number of data.

Error ratio of the torque ripple was determined by using Equation (8) and (9).

V. PARTICLE SWARM OPTIMIZATION

PSO is a heuristic algorithm that was developed by James Kennedy and Russell Eberhart in 1995 [25]. This is a heuristic algorithm that exists in all living creatures in the nature and based on social intelligence. Human beings share the knowledge by talking, the birds make use of each other to find their directions and a school of fish decides their behavior through a mutual decision and all these attitudes are the evidence of a social being. PSO was developed being inspired of the birds’ making use of each other for directions and the mutual behaviors of the fish [26]. PSO shows similarities with evolutionary optimization techniques like GA but it does not have evolutionary operators (crossbreeding and mutation). The solutions called as particles in PSO travel in the problem space by following the best results within the solutions.

PSOs are easier to carry out when compared to GA and the number of the parameters to be arranged is lower. For this reason, PSOs are used in many fields today as an application. [26]. Flow chart of PSO is seen in Figure 2.

Figure 2. PSO flow chart

General steps of PSO algorithm can be listed as follows [27]:

1. Population is created. Initial value and the speed of each particle are casually assigned.
2. Suitability value of each particle is calculated according to the objective function.
3. The best value of the particle is found. The suitability value found out in the previous step is compared to the best personal value (pbest) that is in the memory of the particle. If the result found out in the previous step is better than the current “pbest” value, the new value is changed as “pbest.”
4. The best global particle is found. The suitability value that is calculated for each particle in the second step is compared to the best global value “gbest” that is kept in the memory of the program. If there is a better result, this result is changed with “gbest.”
5. The speed and speed factor of the particle are arranged according to Equation (10) and the position of the particle is arranged according to Equation (11). $r_1$ ve $r_2$ are the numbers produced between [0,1].

$$v_{i+1} = w \cdot v_i + c_1(p_{\text{best}i} - x_i) + c_2(p_{\text{gbest}i} - x_i)$$  \hspace{1cm} (10)

$$x_{i+1} = x_i + v_{i+1}$$  \hspace{1cm} (11)

6. The processes between the steps of 2-5 are repeated until the ending condition or conditions are fulfilled.

VI. TEST FUNCTIONS

To determine the accuracy of the PSO algorithm software, algorithm was worked on the functions that were known before and their performances were evaluated. For this reason, PSO algorithm was tried by using some functions that were known in the literature and the accuracy of the unit software was determined. A test function group that consists of the Benchmark functions seen in the Table 2 was created so as to inspect the accuracy of the unit software prepared in MATLAB. The mathematical expressions in the test functions at Table 2 were tried in PSO [28-30]. The particle number in PSO whose unit software was performed was approached as 100 and learning coefficient was approached as 2. Ending criteria was accepted as 1000 for iteration number or 0 for error value.
### Table 2. Test Functions

</tbody>
</table>

Instead of working PSO algorithm once and getting a result from it, the average of the results that are received after working it many times are accepted. For this reason, PSO algorithm was worked 20 times and the averages were accepted as results, then they were given in Table 3.

For the test functions, global minimum solutions that were carried out in the previous studies were given in Table 4.

### VII. MATERIAL AND METHOD

In this study, the reduction of the ripple values in the torque was aimed to reduce by arranging the ON and OFF time of the signal when the phase windings are energized. Here, the PSO algorithm determines signals to be used angularly. As seen in Figure 3, it was thought that one triggering signal was applied to one phase. 3 different position values seen in the figure were optimized. This means that the number of the factors in the algorithm is 3. The number of the factors was determined as 3 because increasing this number would make it difficult for the current to reach the desired value. Phase limit in the Figure 3 was determined as the ending position of the each phase. The limits of the factors in the PSO algorithm were determined as $4 \leq \theta_1 \leq 8$, $8 \leq \theta_2 \leq 13$, $13 \leq \theta_3 \leq 17$ by taking into account the increasing and decreasing times of the current.

### VIII. EXPERIMENT SETUP AND THE RESULTS

In this study, H-Bridge converter structure, with the control of dsPIC33EP512MU810, was used for the segmental type SRM.

A phase circuit of the H-Bridge that was designed in Proteus program is given in Fig. 4.

![Fig. 4. A driving circuit and H-Bridge of a phase](image)

In this study, the motor was run as bipolar. The sequence of trigger signals of 5 phase segmental type SRM is given in Table 5 [3]. In the performed studies, the sequence of the triggering was performed as in Table 5.

The experiments were performed using the testing apparatus set up in Fig 5.

![Fig. 5. The picture of the testing apparatus](image)
In this study RD300 model of FUTTEK brand, with 0-10 Nm measuring range, was used to measure motor torque. The signal received from the torque sensor was increased to 0-5 V voltage level using FUTTEK brand CSG110 amplifier. The motor speed was measured by 3600 pulse Autonics brand encoder. Motor current was measured using ACS712 current sensor. The signals received from current and torque sensors and the encoder were transferred to the computer, to the interface designed at Visual C# by SnadPIC PIC Microchip Development Board. In the designed interface, torque and current interface were both displayed in the screen and saved in the data base.

7.2°, 11°, 16.4° triggering angles that were determined by PSO algorithm and the torque ripple of the ST-SRM that was controlled as bipolar were calculated as 31.9 % as seen in the interface screen in Figure 6.

Torque ripple values of PSO obtained as a result of the algorithm and the torque ripple values obtained experimentally are seen at Table 6.

Table 6. PSO algorithm and experimental results

<table>
<thead>

<th>Torque Ripple</th>
</tr>
</thead>
<tbody>
<tr>
<td>Torque Ripple (PSO)</td>
</tr>
<tr>
<td>Torque Ripple (Experimental)</td>
</tr>
<tr>
<td>Error Value (%)</td>
</tr>
</tbody>
</table>

As seen at Table 6, there is a 5.83% error value between the torque ripple values obtained by PSO algorithm and obtained experimentally. This value shows that PSO gave a successful performance for a system with a quite difficult modeling. Besides, in the previous studies performed on ST-SRM which was used in this study, the motor had a 56% torque ripple [3, 4]. For this reason, the control signal of the motor was changed in this study and a 40.35% reduction was obtained in the torque ripple.

IX. CONCLUSIONS

In this study, the controlling of the 5-phase 10/8 Segmental Type SRM was carried out by H-bridge converter topology that was controlled by dsPIC33EP512MU810. The angle values of the triggering signal recommended for the control of ST-SRM were determined by means of PSO algorithm. When compared to the previous studies, there was a 40.35% reduction in the torque ripple of the ST-SRM that worked with the values obtained from PSO algorithm. This shows that heuristic algorithm could produce a successful result about torque ripple that is the most important disadvantage of the SRMs. In the next studies, by using different heuristic algorithm or changing the parameter values of the PSO, their effects on the torque ripple of the motor can be searched.

Abstract— For surveillance system, the background subtraction plays an important role for moving object detection with an algorithm embedded in the camera. Since the existence of algorithms cannot satisfy the good accuracy on complex background including illumination change and dynamic objects, we have put forward the concept of Common Vector Approach (CVA) as a new idea for background modelling. Effectiveness of proposed method is presented based on the experiments on popular Wallflower dataset. The obtained visual outputs are compared with well-known methods based on the subjective and objective criteria. From the overall evaluation, we can note the proposed method is not only exhibit successful foreground detection results, but also promises an effective and efficient system for background modelling.

Keywords— Common Vector Approach, Background Modelling, Foreground Detection, Moving Object Detection, Change Detection.

I. INTRODUCTION

Background subtraction, determining changes in the sequence of images, is an important and painful task in computer vision. One key problem in background detection is coping with dynamic backgrounds, which involve shadows, highlights, waving trees, camera jitter, camouflage, fountains and similar movements. The key idea is deriving a model that comprises the rich information about processed scene and taking difference between the model and current image in order to yield the foreground, which is usually called as change detection. Although utilizing this idea is convenient for static background, but for dynamic backgrounds, it is not easy applicable and promising.

Until now, various methodologies are applied to alleviate problems encountered from dynamic backgrounds. The proposed methods can grouped in two ways; pixel or block based approaches. While in pixel approaches, a model is constructed for each pixel by taking the history of them, in other side, in block based approaches, the contribution of neighbour pixels are taking into account in case of modelling the background.

A crowded set of algorithms have been utilized to demonstrate satisfactory results for non-stationary background. A survey is presented by Bouwman for revealing the performance of subspace based background learning methods [1]. The impact of Principal Component Analysis (PCA) for background learning is firstly investigated in the work of Oliver et. al [2]. They applied the concept of PCA on a model of the probability distribution function of the background. Since the PCA works based on the least square estimation as sensitive to outlier, an alternative approach was developed by Torre and Block. It is called as Robust Principal Component Analysis (RPCA) [3]. Comparing with PCA and RPCA, it should be noted that effects of outliers are suppressed in case of linear based optimization when compared with nonlinear based optimization as utilized in PCA. Inspiring from the theory of work performed by Torre and Block, some variants of RPCA [4] have been developed and utilized for subspace based background learning. With a different idea, the Independent Component Analysis has been attempted with a purpose of background modelling [5]. The aim is obtaining the background model \(Y = WX_\tau\), where \(W\) and \(X_\tau\) denote the de-mixing and mixing matrices, respectively. \(X_\tau\) contains background and foreground images. The size of \(X_\tau\) is \(2xK\) as \(K\) are stored in vector format. Yet another method is Gaussian model based background modelling, which was proposed by Wren et. al in order to tracking person body, named as Pfiffer [6]. In referred work, a 2-D model based on the Maximum Posteriori Probability (MAP) was introduced for detecting and tracking human body. By focusing the changes in the region of interest (ROI) a blob model is proceeded to reveal the person body. Moreover, a comprehensive survey is available in study performed by Bouwman [7].
The capacity of each method is limited when utilized to overcome challenges caused from dynamic backgrounds. For this reason, we have proposed a new nonparametric and subspace based background modelling technique, which relies on the concept of common vector approach. The ability of Common Vector Approach (CVA) [8] for background subtraction is firstly analysed in this work. The proposed background subtraction system involves two stages; (i) the background modelling by using training images and (ii) detecting foreground objects in test image sequence. To evaluate the system performance, an experiment is conducted on well-known Microsoft’s Wallflower dataset [9, 10]. The obtained good visual and statistical results implies that the CVA can be applied for background modelling and change detection.

The rest of the paper is arranged as follows. In section 2, the CVA and its application to background modelling is presented. In section 3, the experimental results and performance comparison with well-known methods is carried out. Finally, a conclusion is touched.

II. CVA WITH APPLICATION TO BACKGROUND SUBTRACTION

CVA is a popular subspace based classification algorithm as applied for face recognition [11], spam classification [12], image denoising [13] and edge detection [14] tasks. The motivation of CVA is inspired from theory behind the PCA. While in PCA, the data is recovered by using eigenvectors corresponding to largest eigenvalues, but it has been emphasized that using null space of data gives more impressive accuracy in case of classification [8]. Based on the this fact, CVA algorithm has been put forward by authors of study in [8, 15, 16]. Specifically, by using CVA algorithm, a frame is represented with two components, which are common and difference as shown in Eq. (1). There are two cases in CVA algorithm as sufficient and insufficient data cases. If the number of vectors is less than dimension vectors, then it is called as insufficient data case, otherwise, it is sufficient data case. In case of insufficient data case, common and difference frames can be calculated by using the Gram Schmidt procedure.

In this study, the motivation under the CVA algorithm is adopted for background modelling. The key point of algorithm is encapsulating background information of different frames in order to obtain a single and meaningful background frame. Likewise to PCA, each frame is converted in to vector format.

Assuming that we have given \( n \) samples \((a_1, a_2, \ldots, a_n)\) and each frame in 1-D. With CVA algorithm, it is accepted that a given frame \( a_i \) can be separated into two parts as common and difference frame, which is denoted in Eq. (1).

\[
a_k = a_{\text{com}} + a_{\text{diff}}
\]  

(1) Where the \( a_{\text{com}} \) and \( a_{\text{diff}} \) refers to common and difference frames, respectively. In order to obtain orthogonal and orthonormal basis, the concept of Gram Schmidt is carried out on given vector set \((a_1, a_2, \ldots, a_n)\). As a first stage, the selected reference frame is subtracted from remain vectors as shown in Eq. (2). In this study, the first frame \((k = 1)\) is considered as reference frame for the sake of simplicity.

\[
d_i = a_i - a_1
\]

\[
d_2 = a_i - a_2
\]

\[
\vdots
\]

\[
d_{n-1} = a_i - a_{n-1}
\]

(2) From the combination of difference vectors, a matrix \( M = \{d_1, d_2, \ldots, d_{n-1}\} \) is obtained. The next stage is computing the orthonormal and orthogonal vectors with the idea of Gram-Schmidt procedure which is shown in Eq. (3) and Eq. (4).

\[
v_i = d_i \quad \text{and} \quad u_i = \frac{v_i}{|v_i|}
\]

(3)

\[
v_i = d_i \sum_{j=1}^{i-1} \langle d_j, u_j \rangle u_j \quad \text{and} \quad u_i = \frac{v_i}{|v_i|} \quad i = 1, \ldots, n-1
\]

(4)

Where, \( \langle d_i, u_j \rangle \) refers to dot product of two vectors and \(|v_i|\) denotes the \( l_2 \) norm of each vector. Each vector is normalized by dividing with their \( l_2 \) norm. At the end of Gram-Schmidt orthogonalization procedure the \((u_1, u_2, \ldots, u_{n-1})\) orthonormal and orthogonal \((v_1, v_2, \ldots, v_{n-1})\) sets are obtained to yield difference frame.

(3) Once the orthonormal sets are obtained, the difference frame is determined as given in the below formula. Specifically, the selected reference frame is projected on orthonormal vectors and summed up to obtain the difference frame. In this study, the first frame is taken as reference, and \( k = 1 \).

\[
a_{k, \text{diff}} = \langle a_1, u_1 \rangle u_1 + \langle a_1, u_2 \rangle u_2 + \ldots + \langle a_1, u_{n-1} \rangle u_{n-1}
\]

(4) As a result, the common vector \( a_{\text{com}} \) is derived by subtracting the \( a_{k, \text{diff}} \) from \( a_k \).

\[
a_{\text{com}} = a_k - a_{k, \text{diff}}
\]

(5)
As an improvement on CVA, a low noise value between 0-1 is injected to each difference subspace in Eq. 2 in terms of making high correlated data as low correlated form. The reason of making data low correlated is explained with idea that if the data is highly correlated then the rank becomes smaller than 2. As a result of small rank value, the obtained common vector does not become meaningful to eye. With this way, a background model with training data set is constructed as common frame refers to background and difference frame indicates foreground.

The motivation behind the CVA based background modelling is exhibited in Fig. 1. As we can observe from the Fig. 1, there are two components of a frame as:

1. first component provided the common frame of training set, which refers to obtained background model.
2. other component denotes the difference frame that exhibits details including moving objects and changes of training set.

From the Fig. 1, the ability of CVA for change detection can be observed clearly. Inspired from this fact, we have utilized the CVA algorithm for background modelling and change detection.

In case of foreground extraction, the common vector of processed test frame is computed as projecting the test frame onto the orthonormal basis generated by Gram-Schmit procedure [15]. As a first stage, the difference vectors corresponding to the test frame is obtained with Eq. 6.

\[ t_{\text{diff}} = \{t_{u_1}u_1 + t_{u_2}u_2 + \ldots + t_{u_n}u_n\} \]  

Once the difference vector is subtracted from the test vector, the common vector of processed test frame is determined as shown in Eq. 7.

\[ t_{\text{com}} = t - t_{\text{diff}} \]  

The difference between the two common vectors is considered in terms of observing the foreground regions.

\[ \forall (i, j), I(i, j) = \begin{cases} 1 & \text{abs}(t_{\text{com}} - t_{\text{diff}}) > \text{threshold} \\ 0 & \text{otherwise} \end{cases} \]  

As indicated in Eq. 7, for each pixel location \( \forall (i, j) \), if the absolute difference is greater than a fixed threshold value, then foreground mask is marked as 1, otherwise marked as 0. However, taking the absolute difference for Moved Object, Light Switch, Camouflage videos, produce a lot of erroneous pixels in foreground mask. To overcome this, only difference of two common vectors is put into the thresholding procedure. The utilized threshold value for each video are predetermined as follows; 0.1 for Camouflage, Bootstrap, Light Switch, Waving Trees, 0.2 for Foreground Aperture and 0.3 for Time Of Day and Moved Object video, respectively.

After thresholding procedure, it has been observed that some morphological procedure is greatly required to obtain best results. For this purpose, firstly, a 5x5 median filter is applied on the binary foreground mask. Then, the connected components having size of less than 20, are considered as ghosts and ignored by applying the area open morphological operator. To close the holes in binary region, the morphological closing procedure is performed with disk structural element having size of 5 and binary holes are filled with morphological filling operator. As a last step, morphological opening with disk structural element having size of 5 is performed to mitigate the effect of closing operator.

III. PERFORMANCE EVALUATION

A. Dataset

To judge the performance proposed method, some experimental are conducted on popular Wallflower Dataset. Technically Wallflower dataset [8] provides different classes of about dynamic backgrounds which are Moved Object, Time of Day, Light Switch, Waving Trees, Camouflage, Bootstrapping and Foreground Aperture. Until now, various methods have been made experimental on this dataset. The priory specified training and test images with their ground truth [10] are utilized to obtain subjective and objective results.

B. Subjective Results

In order to comment the obtained results, we have compared the produced results with other ones. For this purpose, the subjective outputs are presented on Table 2. Specifically, the visual results that are presented in the study of Bouwman [1] are considered as reference in case of performance comparison. For a benchmark comparison, the obtained visual results are compared with state of popular subspace and other methods, which are given as Single Gaussian (SG) [6], Mixture of Gaussian (MOG) [17], Kernel Density Estimation (KDE) [18], Subspace Learning PCA (SL-PCA) [19], Subspace Learning ICA (SL-PCA), Subspace Learning ICA (SL-PCA) [20], Subspace Learning via Incremental Non Negative Matrix Factorization (SL-INMF) [21] and Subspace Learning via Incremental Rank-(R1, R2, R3) Tensor (SL-IRT) [22].

The all of visual results are exhibited in Table 1. The first column indicates the method’s name, the rest of columns

</table>
show the performance of each aforementioned methods. Also, the first row denotes the processed image, second row indicates the ground truth related to given image and other rows show visual result generated by each method.

At a first glance, we can observe that similar outputs are obtained from each method. Upon inspecting results, one can emphasize that probabilistic based methods including MOG and KDE produce similar results in terms of foreground region detection. The results of KDE and MOG are superior than SG, since background modelling with single Gaussian is a short-side in term of complex background. Again, we can emphasize that SG, MOG and KDE are sensitive illumination changes because of working on historical probability of each pixel.

On the other side, the subspace based methods are more robust to illumination and complex background changes. By examining results of PCA, ICA, INMF and IRT, it can be seen that the visuals result of IRT are not converged to ground truth as some objects are disappeared in foreground mask. Moreover, although the PCA method exhibits good results in case of Time of Day, Light Switch, Waving Trees, Camouflage, Foreground Aperture, but some erroneous pixels are obtained for Moved Objects and Bootstrap videos. Furthermore, visual outputs of ICA and INMF are similar to each other, however, the performance of ICA is more dominant for Camouflage and Bootstrap videos.

Finally, we can observe that CVA and PCA generate closest results, however, the PCA method fails in case of indoor crowded scene (bootstrap). Also, one can note that the proposed method can perfectly model the clean background in case of illumination changes, crowded scenes and other complex backgrounds. As a result, good foreground mask are determined for all videos.

C. Objective Results

In addition to subjective evaluation, the objective results for each method is determined with respect to statistical metrics, called false positive (FP) and false negative (FN). While the FP indicates the pixel marked as foreground in processed image but it is background in ground truth image, conversely the FN refers to the pixel marked as background in processed image but it is foreground in ground truth image. If a pixel is marked as 1 in processed image, but it is 0 in ground truth image, then the count of FP is incremented by 1. Similarly, If a pixel is marked as 0 in processed image, but it is 1 in ground truth image, then the count of FN is incremented by 1. By combining these error values, the Total Error (TE) metric is computed as a sum of FP and FN. The lower value of error value denotes the best performance in the concept of foreground segmentation. Also, the Total Errors without light switch (TE without LS) and Total Errors without Camouflage switch (TE without Camouflage) are presented on the last columns of Table 2.

The Table 2 summarizes all of the objective results for aforementioned background modelling methods. As we can see that the performance MOG and KDE are close to each other and show better performance than SG method. The performance of MOG and KDE are better when the light switch video excluded, but worse in case of TE metric. Comparing the PCA, ICA, INMF and IRT, one can observe that the performance of ICA is dominant in case of all metrics. On the other side, we can find that the CMA method combining with the basic post processing procedure show favourable results in terms of all metrics.

IV. Conclusions

In the present, a new idea is introduced for background modelling and foreground detection in a given video. Through experiments on real and complex videos, we have observed that the proposed method can efficiently detect the changes in a given set of images. The performance of proposed are compared with state of algorithms including SG, MOG, KDE, PCA, ICA, IRT and INMF and commented with respect to the some objective and subjective measures. The obtained superior results indicate that it is appropriate to use the CVA method for background modelling. Also, we can emphasize that an intelligent post processing procedure is vitally needed in order to accurate foreground detection and segmentation.

Abstract—With the developing technology of electrical energy use is increasing, and this increase in the search for new sources of electrical energy generation brings. Fossil-based increasingly depletion of resources and environmental pollution lead to these fuels from renewable energy resources become more important with each passing day brings. Today, wind energy, electricity generation of approximately 70 countries around the world in an area that has become a benefit. There are different prediction techniques useful to estimate the uncertainty of the wind. These prediction techniques are used to estimate wind power generation capacity for the system. This study supplies grip on the first estimation methods, incorporated with wind speed and power, established on numeric weather prediction (NWP), statistical approaches, ARIMA models, artificial neural network (ANN) and hybrid techniques over different time-periods. This study will be helpful for the new surveyors who are going to work in this area. This study will be useful to the wind generations attendants to understand about the present wind forecasting model capacities and will give an opinion to forecast the wind speed at their exclusive wind energy systems.

Keywords—neural networks, fuzzy logic, wind speed prediction, auto-regressive moving average, auto-regressive integrated moving average

I. INTRODUCTION

Determine the level of development of the country of primary importance criteria is the use of electrical energy. With the developing technology of electrical energy use is increasing, and this increase in the search for new sources of electrical energy generation brings. Fossil-based increasingly depletion of resources and environmental pollution lead to these fuels from renewable energy resources become more important with each passing day brings. Today, wind energy, electricity generation of approximately 70 countries around the world in an area that has become a benefit. In recent years, instead of fossil fuels in Turkey preferred wind energy, most investment in electricity generation is among the areas. In order to generate electricity from the wind, The potential of that region must be determined. To establish the potential of the wind energy, The wind speed per hour and direction information in the area, should be measured for at least one year. The resulting analysis of these records gives important ideas about whether to establish a wind farm in the region. Even in the planning large and powerful wind power plants, established in a long period it is necessary to comprehensive retrospective analysis coverly long years. In this study, by researching the publication of the researchers, tried different speed estimation techniques, the nearest wind speed estimation methods will be determined.

A. Statistical Techniques

Short-term wind speed forecasting experimental stages, Statistical techniques are preferred because of low cost and can be easily modeled. but due to the increase in the estimated error rate with increasing duration of medium and long-term wind speed prediction it is not preferred. Statistical methods contain the auto-regressive moving average (ARMA), auto-regressive integrated moving average (ARIMA), curve fitting, Bayesian model, time series models.

ARIMA techniques can effectively be used to forecast attitude, of a time series from past data exclusively ARMA models are a integrated of Auto-Regression (AR) and Moving Average (MA) models and a particular state of Auto-regressive Integrated Moving Average (ARIMA) models. Auto-Regression Moving Average (ARMA) models are the most preferred type in the time-series situated approach to forecast futurity data of wind speed.

Auto-Regression Integrated Moving-Average (ARIMA) techniques are the generalized forms of ARMA models. This model generally includes three components, which are autoregressive, integrated and moving average. ARIMA model is data independent.

The statistical time series techniques are mostly preferred at short-term estimations. Typical time series models are advanced established on historical data. They are easy to model and able to provide timely forecasting. Time series is a set of successive data points of a parameter that are generally spaced at same time periods. A time-series forecasting sample usages the previous cases of the parameter to establish its forward data. One of the basic characteristics of Bayesian statistics rests on the fact that, opposite to the frequentist approach, the possibilities associated to a variable in a given results are not taken as how many times, or how frequently (their frequency) they are observed.

Maatallah et al. [8] in 2015 for a three year data obtained from two different sites from 1 to 24 hours wind speed forecasting developed approach hammerstein model adapted for multilayer neural network and comparing it with ARIMA. Kulkarni et al. [10] The curve fitting, artificial neural networks, export the periodic function estimation and Autoregressive Integrated moving average wind speed estimation methods were compared in 2008.
Liu et al. [31] wind speed forecasting EMD-ANN hybrid method compared with the model of auto-regressive moving integrated average (ARIMA) in 2012. Palomares-Salas et al. [29] used estimating wind speed ann and arima methods compared detailed in 2014.

Kavasseri and Seetharaman [38] in 2009 North Dakota wind speed obtained from the four regions according to the records of the fractional ARIMA, or f-ARIMA models using the 24-hour and 48-hour wind speed forecasting of before. S. Salcedo-Sanz et al. [48] meteorological prediction of physical model in 2014 by using variables, a Coral Reef Optimization algorithm (SAK) and Extreme learning machine (ELM) based on a newer approach to short-term wind speed estimation. Kiplangat et al. [49] in 2016 wind speed variation and to predict time series modeling, the auto-regressive (AR) and f-ARIMA models were compared. S. Salcedo-Sanz et al. [45] prediction of meteorological physical model by using variables, a Coral Reef Optimization algorithm (SAK) and Extreme learning machine (ELM) based on a newer touch to very short periods wind speed prediction in 2014.

Miranda and Dunn [55] to characterize the wind resource in 2006 one hour before using a Bayesian approach it focuses on wind speed forecast. Liu et al. [58] spectral clustering (SC) in their study in 2015 and echo state Networks resilient were studied based on a wind speed estimation methods. Jiang et al. [65] studied the work they did short time periods wind speed for Bayes estimated based on modeling of time series analysis and structural breaksin 2013. Wang et al. [66] using wind data of the four sites in China in their study in 2016, and the wind speed probability distribution and methods of estimation parameters for these models (commonly used methods and stochastic heuristic optimization algorithm) to popular parametric and non-they compared parametric models. Skittides and Früher [67] In a study conducted in 2014 in Edinburgh due to a site from the Meteorological Office from 2008 to 2009 wind speed and direction data to Principal Component Analysis (PCA), based on tested new statistics for the data from the applied wind estimator 2010. D'Amico et al. [70] used the semi-Markov model to estimate wind speed and power to be generated by the wind turbine in 2014.

Koivistio et al. [77] in a study conducted in 2016 wind speed forecast is bound to the intervention Vector-Autoregressive-To-Anything (VARTA) and montecarlo simulation. Cassola and Burlando [77] in 2012 to fall and the wind speed estimated wind farm for numerical weather prediction (NWP) method of kalman filter (KF) applied with.

B. Fuzzy System Based Models

Fuzzy logic is an ambiguous world's gray, discreet help to computers to produce pictures of machine intelligence. Fuzzy logic modeling of human thinking concept in general format. Fuzzy logic is different from classical mathematical method, is that it allows the qualitative lack of deterministic and identifications. Uncertainties can be expressed as mathematical modeling of complex systems fuzzy logic is considered the biggest convenience. Fuzzy logic in the concept of a member of a cluster is determined by whether or not a member of the membership functions. Used fuzzy logic inference methods with this concept by using the events as an attempt is made to make comment. Onat and Ersoz [5] in 2010 using five-layered adaptive neuro-fuzzy inference system (ANFIS) for the three regions of Turkey's were able to identify the relationship between wind speed and other climatic variables. Petković [21] was used to Adaptive neuro-fuzzy inference system (ANFIS) estimate wind speed the probability density distribution in 2015. Damousis et al. [24] in 2004 made an estimated wind speed for wind parks with fuzzy method. Monfareda et al. [30] compared with a different strategy wind speed prediction methods artificial neural networks (ANN) with fuzzy logic in 2009. Shammari et al. [57] a study conducted in 2014 used adaptive neuro-fuzzy inference system (ANFIS) wind speed prediction for wind energy production systems. Shammari et al. [61] in 2014 to predict the wind speed probability density distribution, adaptive neuro-fuzzy inference frame (ANFIS) was used. Shammari et al. [62] In a study conducted in 2015, wind speed and annual probability density distributions to estimate adaptive neuro-fuzzy inference system (ANFIS) were used. Nikolić et al. [68] their study in 2015 on the strength and to predict the wind speed on ANFIS (adaptive neuro-fuzzy inference system) were involved in the implementation. to provide statistical analysis of the RMS (root mean square error), determination (R2) and Pearson's correlation coefficient (r) coefficients were used. Shuang An et al. [40] fuzzy partition fuzzy regression based on fuzzy rough sets consisting of forecast values a regression algorithm explained in 2014. Mohandes et al. [43] used to estimate wind velocities at different heights by adaptive neuro-fuzzy inference system (ANFIS) in 2011. Al-Shammari et al. [44] used adaptive neuro-fuzzy inference system (ANFIS) to estimate the wind speed to design wind turbines for wind farms in 2015. Sun et al. [46] used a fuzzy copula model for wind speed forecasting in 2016. Petković et al. [47] in a study conducted in 2015 were used adaptive neuro-fuzzy inference system (ANFIS) to estimate the annual wind speed probability density distribution function.

C. Artificial Neural Networks

Artificial neural networks (ANN) is to derive new information and learning ways in which the characteristics of the human brain-like capabilities to create new knowledge and the possibility of discovering the computerized system developed with the aim to automatically perform without any help. Artificial neural networks; Inspired by the human brain, the mathematical modeling has emerged as a result of the learning process pursuit. Abdel-Aal et al. [1] Average hourly wind speed estimates for 1 hour abductive various models next year in May during 1994-2005 over Dhahran, Saudi Arabia has been developed using wind speed data in 2009. Amjadi and Theocharis in 2006 [4] using locally recurrent neural networks (LNN) estimation long time periods wind power and speed for a wind farm. Li and Shi [11] North Dakota gained two observation House hour average wind speeds of 3 different neural networks (typical neural networks, Adaptive Linear
According to previously established analytical method to vector regression (SVR) Weibull distribution function 2014 polynomial and wind speed forecast model with neural networks and support and D. (NN) models decomposit to compare wind forecasting using the empirical mode used data included from a wind farm in Inner spatial dimensions using.

Zheng et al. [34] photovoltaic and wind power generation for the last 10 years and the estimate the methods of statistical and artificial intelligence were examined in 2011. Charhate et al. [48] in the Arabian Sea and the Western Indian coast around wind data obtained from the measurements five nautical point made from, genetic programming (GP) to assess the wind-wave affair and artificial neural network (ANN) have used two pure non-linear approach in 2008. Agrawal and Sandhu [51] in their study 2016 Artificial neural networks-based Annual Auto Regressive (ANNYAR) model that extends from 6 to 96 hours effects of wind forecast most effective parameter and time horizon (TH) annual data set needed to figure out a series in and around fields 'VABB airport Mumbai is included for the purpose of Data Modeling and analysis. Chen and Yu [51] In a study conducted in 2014, unscented Kalman filter (UKF) full wind speed short-term forecast on the SVR-UKF method with artificial neural networks (ANN) method was compared to Noorollahi et al. [64] 2016 In this study, three wind monitoring stations in Iran (Woss) neural networks of the one-hour time interval obtained by wind speed data artificial neural networks (ANN) have made wind speed estimated in both temporal and spatial dimensions using. Shouxiang Wang et al. [51] in 2016 used data included from a wind farm in Inner Mongolia China to compare wind forecasting using the empirical mode decomposition and GE-BP neural network based on wind speed estimation method and wavelet wind speed of neural Networks (NN) models

D. Support Vector Machine

Support vector machines (SVM) are a series of related supervised learning methods used for classification and regression. Sreelakshmi and Kumar [12] in 2008 short term wind speed forecast model with neural networks and support vector machine models were compared. Petković et al. [23] in 2014 polynomial and Radial basis function (RBF) support vector regression (SVR) Weibull distribution function according to previously established analytical method to estimate the two parameters) have imposed as a kernel function. Mohammadi et al. [56] in China 2015 based on a newer model is presented to estimate the wind energy density. The validity of the ELM (extreme learning machine) model SVM (Support Vector Machine), ANN (Artificial Neural Networks) and GP (Genetic Programming) is validated by comparing predictions with techniques. All approaches compared with the results estimated by the wind forces calculated using measured data. Chen and Yu [59] In a study conducted in 2014, unscented Kalman filter (UKF) full wind speed short-term forecast on the SVR-UKF method with artificial neural networks (ANN) method was compared to. Yuan et al. [60] to predict the wind power briefly in a study conducted in 2015, based on least squares a hybrid model (LSSVM-GSA Back Propagation (BP) neural network and support vector machine (SVM) they compared the model, Jian-Zhou et al. [63] in 2015 Wavelet Packet Transform (WPT) series with several different frequencies are used to parse the wind speed range. Simulated annealing (PSOS A) based on a Least Squares Support Vector Machines (LSSVM), which was set up by a particle swarm optimization parameters, this series is built to model. Suitably the model, the input phase area again (PSR) was determined. To support the influence of the propounded model, Gansu Province, Northwest China, four wind farms was used as a condition research the fresh average wind speed set. Tagliaferri, et al. [63] artificial neural networks (ANN) and support vector machines (SVM) based wind speed estimation techniques were compared in 2015. Kong et al. [63] using the reduced support vector machine (RSVM) for the Real time wind power plant data wind speed prediction in 2015.

E. Hybrid Techniques

Hybrid techniques integration of different approaches is referred to as a hybrid approach, usually produce good wind speed prediction results compared to singular techniques. The object of hybrid techniques is utilizing from the superiors of each method and acquires a globally optimum prediction accomplishment. Since the data included in the separate forecasting method is constricted, hybrid technique can maximize the valid information, integrate separate model instructions and make the best use of the advantages of multiple forecasting techniques thus improving the estimation accuracy. There are the hybrid techniques integration different approaches such as mixing physical and statistical approaches or combine short-term and medium-term models. Many types of hybrid techniques were utilized to estimate wind speed. The types of combinations can be:

- Integration of physical and artificial intelligence approaches
- Integration of statistical and artificial intelligence approaches
- Integration of alternative artificial intelligence models

short time periods and medium time periods wind speed for 5 hours up to 1 hour intervals in 2016. Wei Sun and MLP (multi Layer Perceptron) neural networks were recommended for accurate predictions, GA (Genetic Algorithm) and Ensemble Empirical Mode Decomposition (FEEMD), MEA (Mind and the Kalman Filter (KF) compared single and hybrid forms in 2012. Shukur and Lee [39] obtained wind speed data from Iraq and Malaysia, used based on the ARIMA model a hybrid of MF-ANN model to wind speed estimation in 2015. Wang, [50] Support vector regression (SVR), machine learning technique (MLT), seasonal index adjustment (SIA) and Elman recurrent networks, support vector machine and hybrid techniques are employed by researchers about the publications. As a result of the publications, while short term forecasting fuzzy logic and statistical techniques were successfully. Long-term wind speed estimation in support vector machines (SVM), neural networks (NN) and hybrid techniques predictions were more successfully. It is expected to give more reliable results by developing wind speed estimation methods in future

II. CONCLUSIONS

At the present time the electric energy with renewable energy sources for the production of electricity from wind power has increased. The share in total electricity supply is increasing. Wind speed estimation methods have been developed to determine the potential of wind. First of all wind prediction systems have been developed in order to determine efficient wind energy potential. In this article we have searched wind speed prediction of statistical techniques, fuzzy logic, neural networks, support vector machine and hybrid techniques are explored by researchers about the publications. As a result of the publications, while short term forecasting fuzzy logic and statistical techniques were successfully. Long-term wind speed estimation in support vector machines (SVM), neural networks (NN) and hybrid techniques predictions were more successfully. It is expected to give more reliable results by developing wind speed estimation methods in future.

Abstract— This study deals with determining the foreground region by background subtraction based on a new tensor decomposition method. With this aim, the concept of Common Matrix Approach (CMA) is utilized with a purpose of background modelling. The performance of proposed method is validated by making experiments on real videos provided by Wallflower dataset. The obtained results are compared with well-known methods based on subjective on objective evaluation measures. The obtained good results indicate that using the CMA algorithm for background modelling is a simple and effective technique in terms computational cost and implementation. As an eventual result, we have observed that the superior results are determined on complex backgrounds including dynamic objects and illumination variation in image sets.

Keywords— Common Matrix Approach, Background Modelling, Foreground Detection, Moving Object Detection, Change Detection.

I. INTRODUCTION

Foreground detection is the principal interest topic of computer vision based applications such as intelligent visual surveillance, intelligent visual observation of animals and insects, optical motion capture, human-machine interaction, content based video coding, etc. The most extensively utilized areas can be given as road surveillance airplane surveillance, maritime surveillance, boats and store surveillance systems, in where “people” is the main point of interest [1].

Major challenges associated with background subtraction can be noted as shadow, waving trees, foundations, intensity changes and camera jitter, which are called as dynamic backgrounds. Although a perfect solution has not been proposed to cope with these problems, but an affirmed method should be capable to alleviate all dynamic problems. The general idea is actuating a mathematical model to represent all image sequences of the processed background scene with a rich information one. Once the background model obtained, the difference between the test frame and model is considered as foreground.

Numerous algorithms are proposed for background subtraction with a statistical or mathematical theory. By taking the handling strategy of images, the categorization of them can be grouped in two ways as 2-D based methods or tensor based methods. Technically, in the concept of 2-D based methods, each MxN frame is converted into vector format and a 2-D matrix is constructed with (M.N)xK size as K denotes number of frames in training set. Conversely, in tensor based one (3-D), a set of 2-D frames are combined and background is modelled through the tensor without converting frame into vector format. The 2-D based methods have disadvantages when compared with the tensor one. Specifically, in vector based methods the spatial information behind the neighbourhood pixels are neglected as all columns in a frame are connected as back to back in case of converting frame into vector format.

Various tensor decomposition based methods have been illustrated in research area of background subtraction. The Diffusion Bases (DB) [2] methodology has been adopted by decomposing 3-D data into 2-D plane, which denotes the learnt background model. The capability of incremental tensor based background modelling [3] has been investigated with application for foreground segmentation and tracking. Another alternative method versus Principal Component Analysis (PCA) has been utilized by applying the concept of Locality Preserving Projections (LPP) [4], which is called as LPPP. An optimal rank-(R1, R2, ..., Rn) tensor decomposition [5] model has been proposed in order to the high-dimensional tensor to low dimensional as sparse irregular patterns. Also, the Tensor Singular Value Decomposition on Fourier Domain has been analyzed for multilinear data completion and denoising, which is named as t-SVD [6].

Because of different challenges in the concept of background dataset, proposed methods do not meet all expectations. With this aim, a new tensor based background learning and change detection algorithm is presented in order to successful discrimination of foreground and background. Specifically, the theory of Common Matrix Approach (CMA)
is applied to decompose 3D dimensional data (tensor) [7]. In case of orthogonal decomposition, the motivation of Gram-
Schmidt orthogonalization is adopted. After projection stage, a common matrix that refers to obtained background model is
determined. To report the statistical and visual results, the test
stage is conducted on Wallflower dataset [8, 9]. By comparing the statistical results with some of other tensor
based approaches, one can observe that the proposed method
provides impressive and dominant results.

The remain part of paper is designed as follows. In section 2
the CMA and its application to foreground extraction is
presented. In section 3, the obtained objective and subjective results are compared with other tensor based approaches.
Finally, a conclusion is touched.

II. CMA WITH APPLICATION TO BACKGROUND SUBTRACTION

The CMA algorithm is an extended form of Common
Vector Approach, which is a subspace based method and
utilized for face recognition [10], spam classification [11],
image denoising [12] and edge detection [13] tasks. However
the ability of CMA for background modelling has not been
realized in literature of computer vision. In case of CVA the
data is handled in vector format as a 2-D matrix is constituted
from training set and matrix decomposition strategy is applied,
whereas for CMA, a tensor is generated from 2-D frames.

The main idea behind the CMA is combining background
information from different frames and obtaining a single
frame, in which summarizes cues about background locations.
Assuming that we have given n sample frames 
\(S_1, S_2, \ldots, S_n\) and each frame in 2-D. In the context of CMA
a frame can be represented with common and difference frame
as shown in Eq. (1).

\[
S_k = S_{com} + S_{diff_k} \quad (1)
\]

(1) Where the \(S_{com}\) and \(S_{diff_k}\) refers to common and
difference frames, respectively. To calculate, Common
frame a tensor with 3-D size is constructed and the concept of Gram
Schmidt is applied to derive orthogonal and orthonormal basis. First of all,
difference matrices are calculated by taking a first
frame as reference. Instead of first frame, a different
frame can be chosen as reference.

\[
D_k = \begin{cases} 
S_k - S_1 \\
S_k - S_2 \\
\vdots \\
S_k - S_{n-1}
\end{cases} \quad (2)
\]

(2) Once a tensor \(T = \{ D_1, D_2, \ldots, D_{n-1} \} \) is obtained, the
Gram-Schmidt procedure is activated on elements of \( T \),
which is shown in Eq. (3) and Eq. (4).

\[
V_i = D_i \text{ and } U_i = \frac{V_i}{|V_i|} \quad (3)
\]

\[
V_i = D_i - \sum_{j=1}^{i-1} \langle D_j, U_j \rangle U_j \text{ and } U_i = \frac{V_i}{|V_i|} \quad (4)
\]

Where, \( \langle D_i, U_j \rangle \) indicates dot product of two vectors
and \( |V_i| \) denotes the Frobenious norm of each vector
Each of the orthogonal matrices \( V_i \) is divided by their
Frobenious norm to make them normalized. After Gram-
Schmidt orthogonalization procedure the orthogonal 
\( (V_1, V_2, \ldots, V_{n-1}) \) and \( (U_1, U_2, \ldots, U_{n-1}) \)
orthonormal sets are extracted to compute difference matrix.

(3) The next stage of CMA based background modelling
algorithm is computing the difference and common
matrices based upon orthonormal basis as given in the
below equation.

\[
S_{diff_k} = \{ S_k, U_1 \} + \{ S_k, U_2 \} + \ldots + \{ S_k, U_{n-1} \} U_{n-1} \quad (5)
\]

(4) Finally, subtracting the \( S_{diff_k} \) from \( S_k \) gives common
matrix for class, where \( k = 1 \)

\[
S_{com} = S_k - S_{diff_k} \quad (5)
\]

With this way, the training of set background can be
represented by a unique 2-D frame, which is named as,
common matrix. In other side, all details including noises
and outliers of training set are stored in difference matrix
\( S_{diff_k} \).

![CMA Algorithm](image)

Fig. 1. Demonstration of proposed method

To obtain meaningful common matrix a low value of random
noise is added to each difference subspaces obtained in Eq. 2.
Since the rank of data becomes smaller than 2 in case of
highly correlated data and results in not meaningful common
matrix that is undistinguishable with human eye. To overcome
this problem, a low noise value between 0-1 is injected to each
difference subspace in Eq. 2 in terms of reducing the correlation ratio among the processed images.

From the Fig. 1, we can observe that the decomposed tensor generates two components:
1. The first component reserves the common matrix of training set, which is the obtained background model.
2. The other component involves the difference matrix that refers to detail features of training set.

By using the CMA, we can see that foreground and changes are observed in difference matrix. Therefore, the strategy behind CMA provides a new way to detect moving and stable objects in a given dataset. In order to reveal the foreground objects, the common matrix of test frame (F) is determined from the projection of incoming test frame onto the orthonormal basis returned by Gram-Schmit procedure [14]. First of all, the difference matrix related to the test frame is calculated as shown in below equation.

\[ F_{\text{diff}} = \{F, U_1\} U_1 + \{F, U_2\} U_2 + \ldots + \{F, U_{(n-1)}\} U_{(n-1)} \]  

Again, the common matrix corresponding to the test frame is computed by subtracting from the difference matrix.

\[ F_{\text{con}} = F - F_{\text{diff}} \]  

In case of revealing the foreground objects the difference between the common matrix of processed video and common matrix of processed frame is taken into account.

\[ \forall (i, j), I(i, j) = \begin{cases} 1 & \text{abs}(F_{\text{con}} - S_{\text{con}}) > \text{threshold} \\ 0 & \text{otherwise} \end{cases} \]  

As shown in equation above, the difference of two common matrix presents foreground objects. In case of Moved Object and Camouflage videos, the difference of two common matrices are considered to find the foreground regions for other ones the absolute difference taken into account. The threshold value for each video are determined as follows: 0.1 for Camouflage, Bootstrap and Waving Trees, 0.2 for Foreground Aperture, Light Switch and Moved Object, and 0.3 for Time Of Day video, respectively.

To obtain the pleasing visual results, some fixed morphological operations are applied on the foreground mask. Firstly, 5x5 median filter are utilized on the binary image. The connected components with the size of less than 20, are considered as ghost are removed by area open morphological operator. Then, the morphological closing procedure is utilized with disk structural element having size of 5 and binary holes are filled with morphological filling operator. Finally, morphological opening with disk structural element having size of 5 is performed to mitigate the effect of closing operator.

III. PERFORMANCE EVALUATION

A. Dataset

The experimental stages are conducted on well-known Wallflower Dataset. Numerous methods have been utilized this dataset in order to objective and subjective performance comparison. Wallflower dataset [9] includes real-world background datasets as associated with dynamic events including Moved Object, Time of Day, Light Switch, Waving Trees, Camouflage, Bootstrapping and Foreground Aperture. In case of background modelling (obtaining Common Matrix), we have utilized prior determined train images, which are specified by authors of dataset [8]. For each video, the first 199 images are taken to learn the background frame in case of training stage.

B. Subjective Results

In the present work, a simple thresholding methodology is realized in case of revealing the binary skeleton of objects. Since the difference of two common matrix gives changes, a fixed thresholding is carried over the absolute difference. The obtained visual results are demonstrated on Table 2. To subjectively judge performance of both methods, the obtained visual results are compared with state of popular subspace and other methods, which are given as Single Gaussian (SG) [15], Mixture of Gaussian (MOG) [16], Kernel Density Estimation (KDE) [17], Subspace Learning PCA (SL-PCA) [18], Subspace Learning ICA (SL-ICA) [19], Subspace Learning via Incremental Non Negative Matrix Factorization (SL-INMF) [20] and Subspace Learning via Incremental Rank-(R1, R2, R3) Tensor (SL-IRT) [21]. For this purpose, the visual results determined in the work of Bouwman [22] are taken as ground on in case of performance comparison.

In Table 2, the first column denotes method’s name, the other columns show video’s name, respectively. Again, the first row and second row exhibit test image and related ground truth, and other rows demonstrates visual results returned from each method. From the exhibited results, we can observe that each method presents similar foreground objects in the meaning of obtained foreground skeleton. By analysing results, one can note that results of MOG and KDE are closes to each other and are dominant than SG method. The performance of SG, MOG and KDE are weakness to illumination changes due to work on historical probability of pixels. To continue, we can see that subspace based method are more robust to light changes. By comparing the PCA, ICA, INMF and IRT, we can emphasize that the result of IRT is the worst one in terms of preserving foreground skeleton. While the INMF shows good results in case of bootstrap video, but the same performance has not maintained in case of camouflage video. Moreover, the results of PCA are similar to CVA method, however, the PCA method fails in case of indoor crowded scene (bootstrap). Furthermore, the proposed method not only robust to dynamic structures but also resistance to illumination change in case of foreground detection.

C. Objective Results

In addition to subjective results, the statistical results are obtained by considering the false positive (FP) and false

negative (FN) pixels. With this aim, the ground truth images and acquired foreground object are compared to find the number of erroneous pixels by counting the number of FP and FN. If a pixel marked as foreground in processed image, but marked as background in ground truth, then it is considered as FP. For opposite case, if a pixel marked as foreground by ground truth, but marked as background in processed image, then it is considered as FN. The sum of FP and FN denotes the error measure in terms of comparing the objective results. Specifically, the Total Errors, Total Errors without light switch (TE without LS) and Total Errors without Camouflage switch (TE without Camouflage) are demonstrated on the last columns of Table 2. The less error value indicates the best performance in terms of foreground segmentation.

The obtained statistical results are presented in Table 2. From the Table, one can derive that a superior performance is obtained by the proposed method, called CMA. In conjunction with visual results, the performance SG, MOG and KDE similar to each other. However, when the light switch video is excluded in case of performance evaluation, we can observe that the MOG and KDE generate better results than almost of all algorithms except CMA. These results are attributed to characteristic of probability based foreground and change detection property. Moreover, when the camouflage video is used and considered, the worst performance is produced by probabilistic based background subtraction methods. Also, comparing the subspace based methods including SL-PCA, SL-ICA and SL-INMF, one can note that the performance of SL-ICA is favourable against SL-PCA and SL-INMF. The performance of SL-PCA and SL-IRT are closed to each other, but difference bears in case of removing the light switch.

IV. CONCLUSIONS

In this study, the impact of CMA is evaluated for background modeling based foreground detection. The performance of the proposed method is compared with other well-known methods for dynamic backgrounds including Moved Objects, Time of Day, Light Switch Waving Trees, Camouflage, Bootstrap, Foreground Aperture. From the objective and subjective evaluation, it has observed that the proposed method exhibit eye pleasing results. The obtained experimental results present significant performance difference between PCA, ICA, INMF and probabilistic based methods (SG, MOG and KDE) in terms of accuracy and robustness to dynamic changes among the images for a given video. From the overall evaluation, one can emphasize that a smart post processing procedure is greatly needed to both accurately reveal the region of foreground object meanwhile perturbing the noisy pixels caused by uncontrolled changes, which are waving trees and illumination changes. As a future work, a comprehensive and universal background subtraction method is aimed to develop by using the concept of CMA.
